Preface

Modern Automotive Technology is an easy-to-understand, up-to-date textbook detailing the operation, diagnosis, service, and repair of automobiles and light trucks. It has been designed to help prepare aspiring technicians for exciting and productive careers in automobile technology. It also provides the information needed to prepare for ASE automobile certification tests.

No longer can the untrained person effectively diagnose and repair modern vehicles. As technology has evolved, even the most basic automotive systems have become dauntingly complex. Multiple onboard computers are now used to monitor and control the engine, transmission, suspension, brakes, emission controls, and other vital vehicle systems. As the demand has grown for technicians who can diagnose and repair these increasingly sophisticated automotive systems, so has the need for a learning solution that prepares students for entry-level employment in this exciting field. ***Modern Automotive Technology*** will give you the tools you need to succeed in the challenging and ever-changing world of automotive technology.

The 2017 edition of ***Modern Automotive Technology*** is organized around the ASE automobile test areas and correlated to the NATEF Task List. It has been thoroughly revised by the author and carefully vetted by a panel of experts in the field of automotive education, as well as a team of technical editors, to make sure the material is technically accurate, up-to-date, and presented in the most logical and effective manner.

Modern Automotive Technology has been painstakingly designed to provide a student-focused approach to learning. Short sentences, concise definitions, and thousands of color illustrations will help you learn quickly and easily.

Information is presented using a building-block approach that starts with simple principles and general rules, and progresses gradually to more complex subjects. Each major automotive system is covered in two or more chapters. The first chapter explains the construction and operation of a specific system. The second chapter expands on this by discussing diagnosis, service, and repair of the same system.

As society transitions from printed textbooks to digital learning tools, we know it is important to provide the content you need in the format you need it in. The ***Modern Automotive Technology*** textbook and the accompanying workbook and shop manual are available in both print and digital formats, and are supported with professionally developed, user-friendly online resources. These resources include electronic study tools, videos, animations, simulations, and interactive activities designed to prepare you for success in your studies and career.

We congratulate you on your study of automotive technology and encourage you to take advantage of all the resources available as part of the ***Modern Automotive Technology*** learning solution.

About the Author

James E. Duffy has devoted much of his professional life to developing educational materials that help people understand vocational and technical subjects. Mr. Duffy earned a Bachelor of Science degree in Industrial Technology from Indiana State University. After college, Mr. Duffy worked as an automotive instructor at Brandon High School in Brandon, Florida, and at Hillsborough Adult Education Center in Tampa, Florida. After teaching for several years, Mr. Duffy joined Goodheart-Willcox Publisher as a technical editor and eventually began writing textbooks. In addition to ***Modern Automotive Technology***, Mr. Duffy's books include ***Auto Electricity and Electronics***, ***Auto Engine Repair***, ***Automatic Transmissions and Transaxles***, and ***Manual Drive Trains and Axles***.

Acknowledgments

The author and publisher would like to thank the following companies, organizations, and individuals for their contribution of resource material, images, or other support in the development of ***Modern Automotive Technology***.

Together, We Build Careers

At Goodheart-Willcox, we take our mission seriously. Since 1921, G-W has been serving the career and technical education (CTE) community. Our employee-owners are driven to deliver exceptional learning solutions to CTE students to help prepare them for careers. Our authors and subject matter experts have years of experience in the classroom and industry. We combine their wisdom with our expertise to create content and tools to help students achieve success. Our products start with theory and applied content based on a strong foundation of accepted standards and curriculum. To that base, we add student-focused learning features and tools designed to help students make connections between knowledge and skills. G-W recognizes the crucial role instructors play in preparing students for careers. We support educators' efforts by providing time-saving tools that help them plan, present, assess, and engage students with traditional and digital activities and assets. We provide an entire program of learning in a variety of print, digital, and online formats, including economic bundles, allowing educators to select the right mix for their classroom.

Student-Focused Curated Content

Goodheart-Willcox believes that student-focused content should be built from standards and/or accepted curriculum coverage. Standards from NATEF, ASE, and Precision Exams were used as a foundation in this text. ***Modern Automotive Technology*** also uses a building block approach with attention devoted to a logical teaching progression that helps students build on their learning. We call on industry experts and teachers from across the country to review and comment on our content, presentation, and pedagogy. Finally, in our refinement of curated content, our editors are immersed in content checking, securing and creating figures that convey key information, and revising language and pedagogy.

ASE and NATEF Connections

Modern Automotive Technology is correlated to standards established by the National Institute for Automotive Service Excellence (ASE) and the National Automotive Technicians Education Foundation (NATEF). These standards were developed with input from industry experts to ensure they reflect the skills students and technicians must master to succeed in the automobile service and repair industry.

ASE certification is becoming the benchmark for automobile repair technicians. It is recommended that you seek ASE certification once you have sufficient knowledge and meet the work experience requirements. Visit the ASE website for more information on ASE certification.

NATEF has established a training program accreditation process designed to improve the quality of training offered at both secondary and postsecondary levels. NATEF grants accreditation to programs that comply with their evaluation procedure, meet established standards, and adhere to the policies set forth by the organization. To learn more about the NATEF accreditation process, visit the NATEF website.

Precision Exams Certification

Goodheart-Willcox is pleased to partner with Precision Exams by correlating ***Modern Automotive Technology*** to their Automotive Service Introduction Standards. Precision Exams Standards and Career Skills Exams™ were created in concert with industry and subject matter experts to match real-world job skills and marketplace demands. Students who pass the exam and performance portion of the exam can earn a Career Skills Certification™. Precision Exams provides:

- Access to over 150 Career Skills Exams™ with pre- and post-exams for all 16 Career Clusters.
- Instant reporting suite access to measure student academic growth.
- Easy-to-use, 100% online exam delivery system.

To see how ***Modern Automotive Technology*** correlates to the Precision Exams Standards, please visit www.g-w.com/modern-automotive-technology-2017 and click on the Correlations tab. For more information on Precision Exams, including a complete listing of their 150+ Career Skills Exams™ and Certificates, please visit www.precisionexams.com.

Features of the Textbook

Features are student-focused learning tools designed to help you get the most out of your studies. This visual guide highlights the features designed for the textbook.

Illustrations have been designed to clearly and simply communicate the specific topic.

Learning Objectives clearly identify the knowledge and skills to be obtained when the chapter is completed.

Cautions identify situations that may cause damage to a vehicle, equipment, or tools if proper procedures are not followed.

Service Procedures are highlighted throughout the textbook to provide clear instructions for hands-on service activities. You can refer back to these procedures easily.

Tech Tips provide supplemental technical information and service hints related to the procedure or system being explained.

Warnings identify repair operations that can result in personal injury if proper procedures or safety measures are not followed.

Troubleshooting Charts help you develop critical-thinking, diagnostic, and troubleshooting skills needed in the workplace today.

Workplace Skills, Customer Relations, Green Tech, In the Rearview Mirror, Industry Trend, Safety First, and **Hybrid Tip** features help you develop the professional skills, behaviors, and traits employers look for in their employees.

Review Questions allow you to demonstrate knowledge, identification, and comprehension of chapter material.

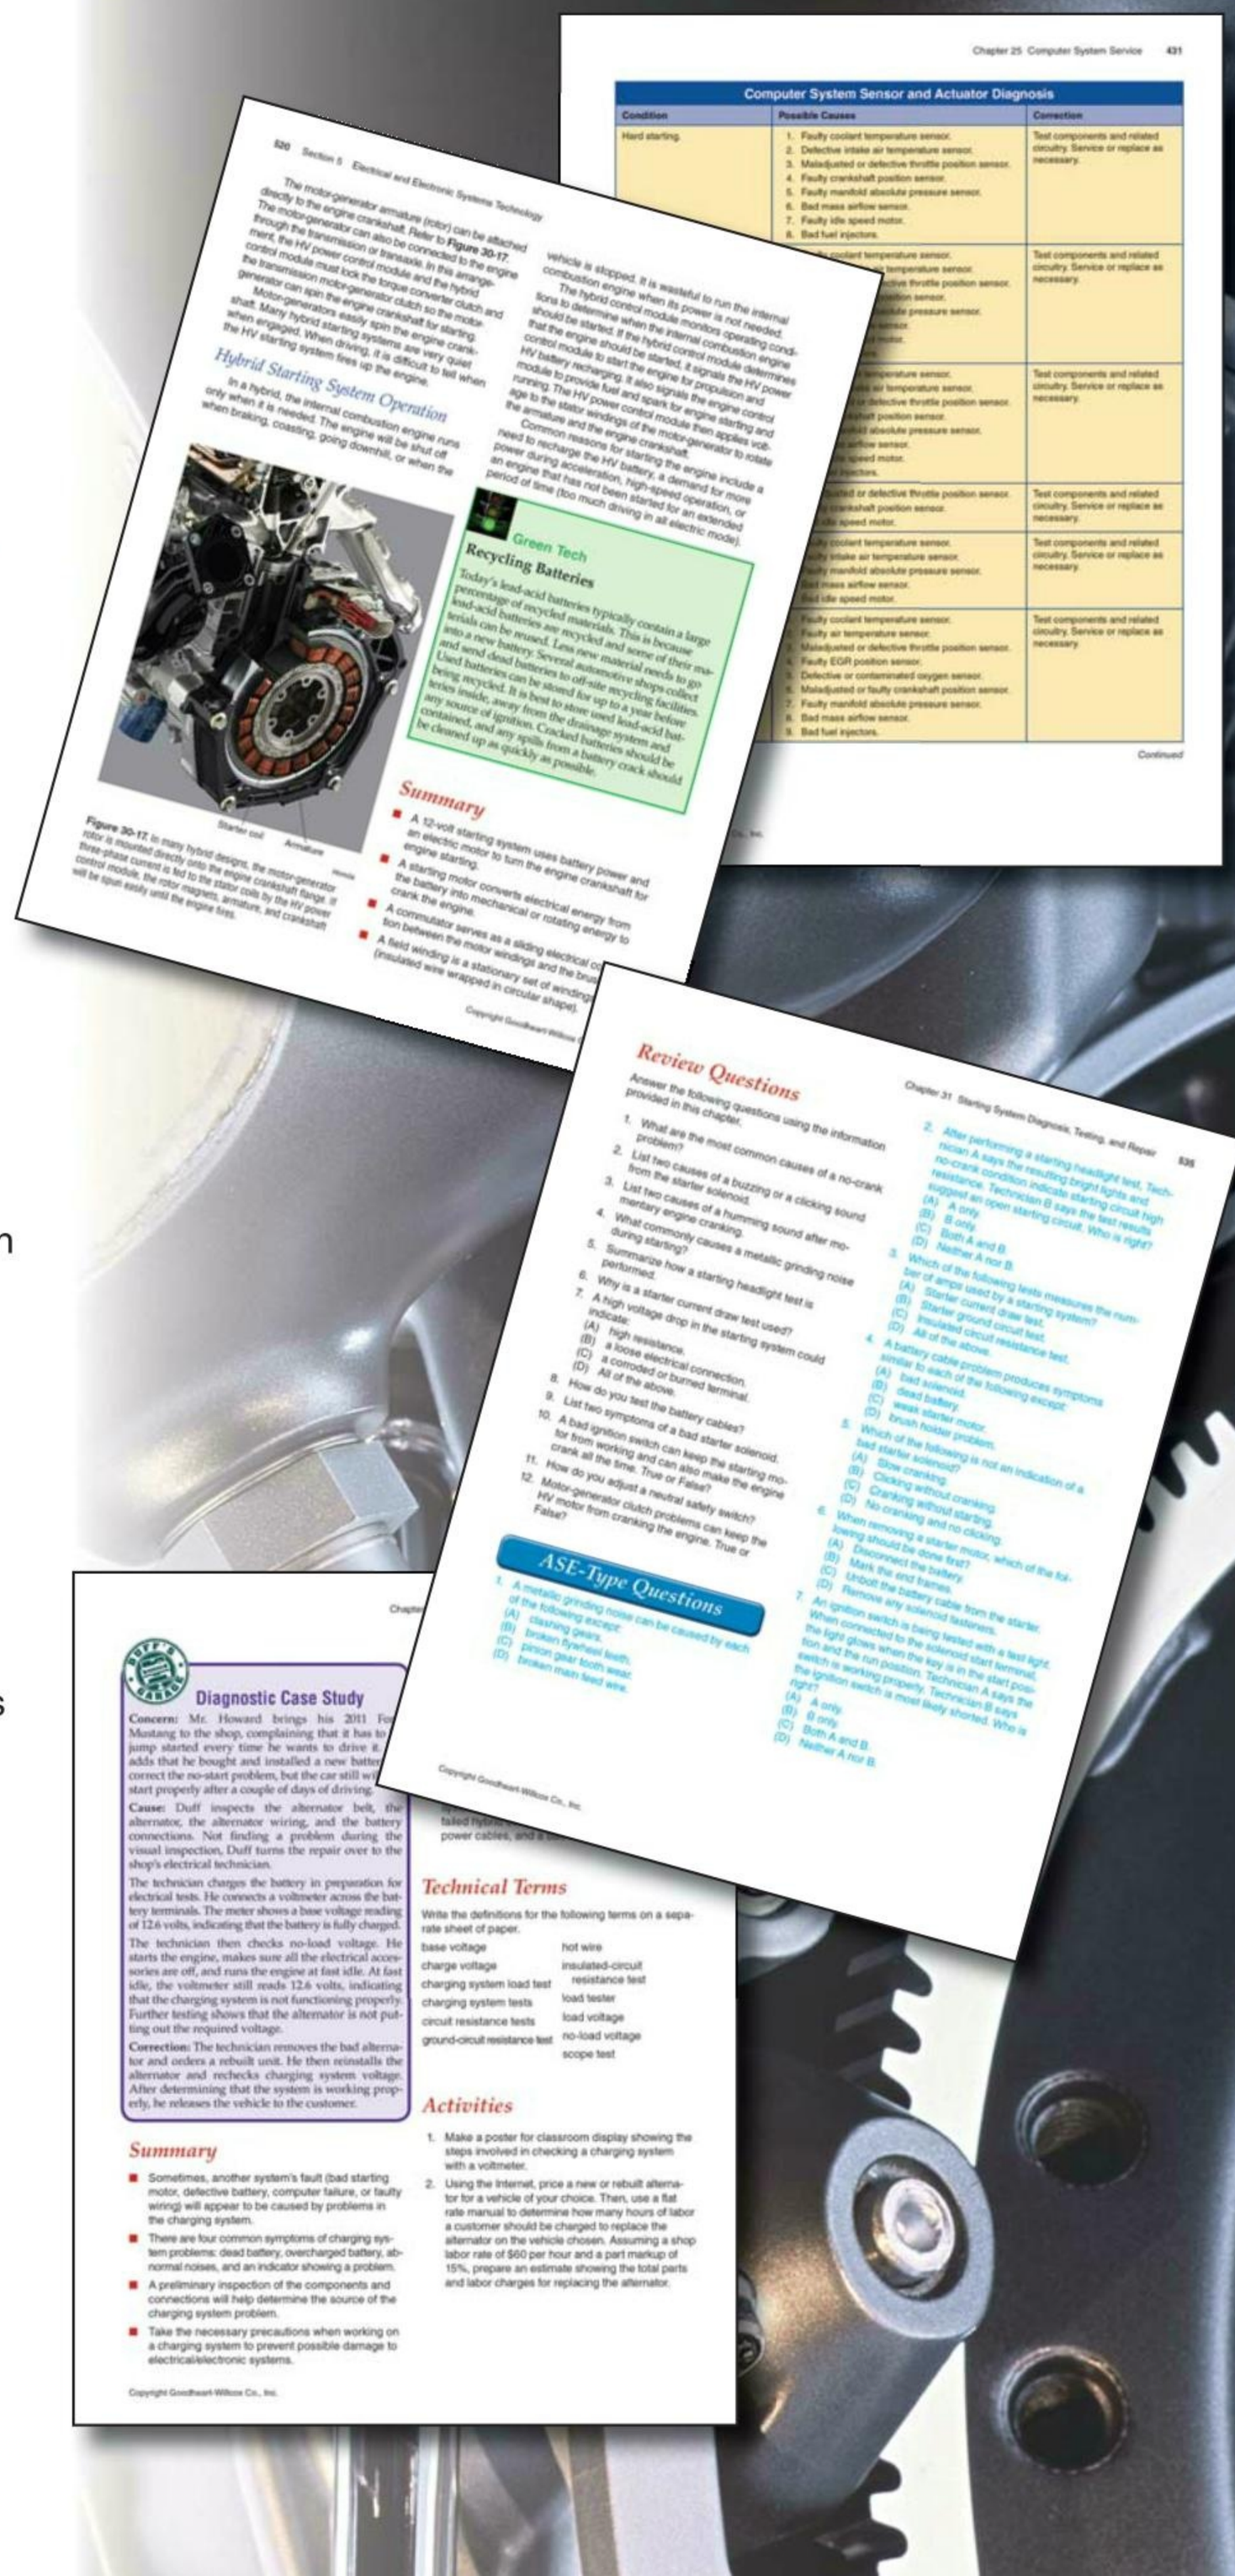
ASE-Type Questions help you prepare for the types of questions encountered on the ASE certification tests.

Diagnostic Case Studies help you develop logical troubleshooting techniques and reinforce the 3Cs approach to vehicle diagnosis and repair.

Technical Terms list the key terms that were presented in the chapter.

Activities extend your learning and help you analyze and apply knowledge.

Summary feature provides an additional review tool for you and reinforces key learning objectives.



Student Resources

Textbook

The ***Modern Automotive Technology*** textbook provides an exciting, full-color, and highly illustrated learning resource. The textbook is available in print or online versions.

Workbook

The student workbook includes a variety of questions, in various formats, to help reinforce textbook content. Each chapter corresponds to the text and reinforces key concepts and applied knowledge. Step-by-step jobs in the workbook guide students through important service and repair procedures.

Shop Manual

The shop manual provides hands-on practice of 100% of the tasks in all three sections of the NATEF Task List (MLR, AST, and MAST). Each job in this manual is a hands-on activity that corresponds to one or more NATEF Tasks. The jobs help students develop the hands-on skills needed to succeed in the field and are intended to be completed in a shop setting under the guidance of an instructor.

MLR Shop Manual

The MLR Shop Manual provides hands-on practice of 100% of the tasks in the NATEF Maintenance and Light Repair Task List. It is designed specifically for use in MLR-accredited training programs, as well as in programs seeking MLR accreditation. Each of the jobs in this manual is designed to be accomplished in a single lab session.

Online Learning Suite

Available as a classroom subscription, the Online Learning Suite provides the foundation of instruction and learning for digital and blended classrooms. An easy-to-manage shared classroom subscription makes it a hassle-free solution for both students and instructors. An online student text and workbook, along with rich supplemental content, brings digital learning to the classroom. All instructional materials are found on a convenient online bookshelf and are accessible at home, at school, or on the go.

Online Learning Suite/Student Textbook Bundle

Looking for a blended solution? Goodheart-Willcox offers the Online Learning Suite bundled with the printed text in one easy-to-access package. Students have the flexibility to use the print version, the Online Learning Suite, or a combination of both components to meet their individual learning style. The convenient packaging makes managing and accessing content easy and efficient.

Instructor Resources

Instructor resources provide information and tools to support teaching, grading, and planning; course administration; class presentations; and assessment.

Instructor's Presentations for PowerPoint®

Help teach and visually reinforce key concepts with prepared lectures. These presentations are designed to allow for customization to meet daily teaching needs. They include objectives, outlines, and images from the textbook.

ExamView® Assessment Suite

Quickly and easily prepare, print, and administer tests with the ExamView® Assessment Suite. With hundreds of questions in the test bank corresponding to each chapter, you can choose which questions to include in each test, create multiple versions of a single test, and automatically generate answer keys. Existing questions may be modified and new questions may be added. You can prepare pretests, formative tests, and summative tests easily with the ExamView® Assessment Suite.

Instructor's Resource CD

One resource provides instructors with time-saving preparation tools such as answer keys; lesson plans; correlation charts to NATEF, ASE, and Precision Exam standards; and other teaching aids.

Online Instructor Resources

Online Instructor Resources provide all the support needed to make preparation and classroom instruction easier than ever. Available in one accessible location, support materials include Answer Keys, Lesson Plans, Instructor Presentations for PowerPoint®, ExamView® Assessment Suite, and more! Online Instructor Resources are available as a subscription and can be accessed at school or at home.

Video Clip and Animations Library

Live-action videos and animations provide students the opportunity to watch hands-on demonstrations of essential skills.

G-W Online

This exciting new learning product brings the text and learning alive for your students! The textbook's interactive learning activities engage your students, providing them with dynamic visuals and immediate feedback. It enhances your course with course management and assessment tools that accurately monitor and track student learning. The ultimate in convenient and quick grading, G-W Online allows you to spend more time teaching and less on administration. This G-W Online also contains DVOM Simulations with activities that allow students to practice using this important electrical testing tool.

Computer Locations 386
Computer Types 386
Computer Operation 387
Output Drivers 390
Actuators 390
Actuator Locations 390
Actuator Classifications 390
Actuator Operation 390
Specific Actuators 391
Computer Networks 392

Chapter 24
On-Board Diagnostics and Scan Tools 399

On-Board Diagnostic Systems 400
Early On-Board Diagnostic Systems 400
OBD II Systems 400
Malfunction Indicator Light (MIL) 400
Diagnostic Trouble Codes 401
Computer System Problems 401
Scanning Computer Problems 403
Data Link Connector (Diagnostic Connector) . . 404
Connecting the Scan Tool 404
Using Scan Tools 404
Diagnostic Trouble Code Identification 406
Failure Types 407
Datastream Values 408
Key-On/Engine-Off Diagnostics 408
Wiggle Test 408
Key-On/Engine-On Diagnostics 409
Switch Diagnostic Test 409
Actuator Diagnostic Test 409
Scanning during a Test-Drive 410
Erasing Trouble Codes 410

Chapter 25
Computer System Service 415

Preliminary Visual Inspection 415
Electrical Component Damage 416
Computer System Circuit Problems 416
Locating Computer Problems 417
Sensor and Actuator Problems 417
Poor Electrical Connections 417
Vacuum Leaks 418
Sensor Service 419
Testing Passive Sensors 419
Testing Active Sensors 420
Replacing Sensors 422
Actuator Service 422
Testing Actuators 422
Replacing Actuators 423
Computer Service 424
Measuring Computer Output 425
Saving Memory 425
Computer Replacement 425
EEPROM Programming Using Computerized Equipment 426
Computer Relearn Procedures 428

Section 5
Electrical and Electronic Systems Technology

Chapter 26
Hybrid Drive Technology 435

Hybrid Vehicles 435
Hybrid Vehicle History 436
Hybrid Drive Construction 437
Types of Hybrid Vehicles 438
Full and Mild Hybrids 438
Series Hybrid 439
Parallel Hybrid 439
Series-Parallel Hybrid 439
Plug-In Hybrid Electric Vehicles (PHEVs) 439
Full-Electric Vehicles 440
Flywheel Generator Hybrids 440
Hybrid Vehicle Operation 440
All-Electric Drive Mode 440
Motor-Assist Mode 442
Idle Stop Mode 442
Regenerative Braking Mode 442
Engine Starting Mode 442
Battery Charging Mode 442
Hybrid Drive Assemblies 443
HV Battery 443
Motor-Generator 443
Power Splitter 446
HV Power Control Module 447
Hybrid Control Module 448
Hybrid Rotor Sensor 448
HV Power Cables 448
Hybrid Ground Fault Interrupter 448
Impact Sensors 448
Hybrid Dash Display 449

Chapter 27
Hybrid Drive Systems Diagnosis and Repair 453

Hybrid Problem Diagnosis 453
Hybrid Service Safety 454
Remove Jewelry 454
Wear Eye Protection 454
Wear Insulating Gloves 454
Wear Rubber-Soled Shoes 454
Keep a Fire Extinguisher Nearby 455
Follow Towing Safety Procedures 456
Disable the Hybrid Drive when Working 456
Set Up a High-Voltage Buffer Zone 456
Remove the High-Voltage Disconnect 456
HV Battery Service 458
Diagnosing HV Battery Problems 458
Checking HV Battery Relays and Contactors 458
HV Power Cable Service 459
HV Power Control Module Service 460
HV Power Control Module Replacement 461
Hybrid Cooling System Service 462
Motor-Generator Service 463
Testing a Motor-Generator 464
Removing and Installing a Motor-Generator . . . 465
Hybrid Wiring Problems 467

Chapter 28
12-Volt and HV Battery Technology . . 471

Battery Principles 471
Basic Battery Cell 472
Battery Functions 472
12-Volt Batteries 473
12-Volt Battery Construction 474
12-Volt Battery Cables 475
Battery Tray and Retainer 476
12-Volt Battery Types 476
12-Volt Battery Ratings 477
Battery Temperature and Efficiency 477
HV Batteries 477
HV Battery Construction 478
HV Battery ECM 480
HV Power Cables 481
HV Battery Ratings 481
HV Capacitor Banks 482
Fuel Cells 482
Flywheel Generator 483

Chapter 29
12-Volt and HV Battery Service 487

12-Volt Battery Maintenance 487
12-Volt Battery Service 488
12-Volt Battery Leakage Test 488
12-Volt Battery Terminal Test 488
Checking 12-Volt Battery Electrolyte Level 490
Checking 12-Volt Battery Charge 491
Discharged 12-Volt Battery 493
Battery Drain Test 494
12-Volt Battery Chargers 494
Charging a 12-Volt Battery 495
12-Volt Jump Starting 496
12-Volt Battery Load Test 497
Activating Dry-Charged 12-Volt Batteries 498
Removing and Installing a 12-Volt Battery 499
HV Battery Service 499
Hybrid Jump Starting 500
Checking HV Battery Condition 501
Testing HV Battery Voltage 501
Charging an HV Battery 502
HV Battery Load Test Drive 502
In-Shop HV Battery Load Test 503
HV Battery Removal and Replacement 504
HV Cable Connections Service 506
HV Battery Control Module Service 507

Chapter 30
Engine Starting Systems 511

12-Volt Starting System Principles 512
Starting System Action 512
Starting Motor Fundamentals 512
Simple Electric Motor 512
Changing Electricity into Motion 513
Increasing Motor Power 513
12-Volt Starting Motor Construction 513
Armature 514
Field Windings 514
Field Magnets 514
Frames 515
Pinion Gear 515
Starter Solenoid 516
Reduction Gearing 517

12-Volt Neutral Safety Switch 517
Neutral Safety Switch Operation 517
12-Volt Starter Relay 518
Starter Relay Operation 519

ECM-Controlled 12-Volt Starting Circuit 519
Hybrid Starting Systems 519
Hybrid Starting System Operation 520

Chapter 31
Starting System Diagnosis, Testing, and Repair 523

Starting System Diagnosis 523
Common 12-Volt Starting System Problems . . . 524
12-Volt Starting Headlight Test 524
Checking the 12-Volt Battery 525
12-Volt Starting System Voltage Drop Tests . . . 526
12-Volt Battery Cable Service 527
Testing Battery Cables 527
Replacing Battery Cables 528
Starter Solenoid Service 528
Testing the Starter Solenoid 528
Replacing the Starter Solenoid 528
Ignition Switch Service 529
Testing the Ignition Switch 529
12-Volt Starter Relay Service 529
Neutral Safety Switch Service 529
Testing the Neutral Safety Switch 529
Adjusting the Neutral Safety Switch 530
12-Volt Starter Service 530
12-Volt Starting Motor Removal 530
12-Volt Starting Motor Rebuild 531
Hybrid Starting System Diagnosis 532
Motor-Generator Problems 533

Chapter 32
Charging System Technology 537

12-Volt Charging System Functions 537
12-Volt Charging System 538
Alternator 538
Voltage Regulator 544
ECM Charging System Monitoring and Control . . 545
Battery Thermistor 545
Fail-Safe Circuit 545
Alternator Drive Belt 545
Charge Indicators 545
Hybrid Charging Systems 547

Chapter 33
Charging System Diagnosis, Testing, and Repair 551

12-Volt Charging System Diagnosis 551
Preliminary Inspection 552
Scanning 12-Volt Charging Systems 553
12-Volt Charging System Precautions 553
12-Volt Charging System Tests 553
Scan Tool Test 554
Load Test 554
Scope Tests 555
Voltmeter Test 555
Circuit Resistance Tests 557
Alternator Service 558
Alternator Removal 558
Alternator Rebuild 559
Alternator Installation 559
Hybrid Charging System Service 559
Scanning Hybrid Charging Systems 559

Chapter 34
Ignition System Technology 565

Ignition System Fundamentals 565
Ignition System Operation 566
Primary and Secondary Circuits 567
Ignition System Supply Voltage 567
Secondary Wires 567
Spark Plugs 567
Ignition Coils 569
Ignition Coil Operation 570
Ignition Coil Designs 570
Coil Pack Ignition System 571

ECM Scan Tool Data 767
Idle Speed Motor Testing 767
Idle Air Control Valve Service 767
Multiport Throttle Body Service 768

Chapter 43
Diesel Injection Fundamentals 773

Diesel and Gasoline Engine Differences 773
Basic Mechanical Injection 774
Diesel Injection Pumps 775
Diesel Injection Lines 776
Diesel Injector Nozzles 776
Glow Plugs 779
Diesel Injection Timing 779
Diesel Injection System Accessories 780
Water Detector 780
Fuel Heater 780
Block Heater 780
Vacuum Pump 781
Computer-Controlled Diesel System 781

Chapter 44
Diesel Injection Diagnosis, Service, and Repair 785

Diesel Injection Maintenance 785
Diesel Injection Diagnosis 785
Engine Scanning 786
Abnormal Exhaust Smoke 786
Excessive Knock 787
Engine Miss 787
Engine No-Start Condition 787
Lack of Power 787
Poor Fuel Economy 787
Injection Cleanliness 787
Testing Diesel Injection Operation 788
Diesel Injection Service 789
Injector Nozzle Service 789
Glow Plug Service 793
Injection Pump Service 793
Computerized Diesel Injection Service 794
Diesel Injection Service Rules 794

Chapter 45
Exhaust System Technology and Repair 797

Exhaust System Operation 797
Exhaust System Parts 797
Exhaust Back Pressure 798
Single and Dual Exhaust Systems 799
Exhaust Manifold 799
Exhaust Pipes 800
Heat Shields 800
Catalytic Converter 800
Muffler 801
Exhaust System Service 801
Exhaust System Inspection 801
Catalytic Converter Temperature Check 802
Exhaust System Back Pressure Test 802
Engine Vacuum Test 802
Exhaust System Repairs 803
Stainless Steel Exhaust System Repairs 805

Chapter 46
Turbochargers and Superchargers—Construction, Operation, and Repair 809

Engine Aspiration 809
Turbochargers 810
Turbocharger Operation 811
Turbo Lag 811
Variable Vane Turbochargers 811
Turbocharger Locations 811
Turbocharger Lubrication 813
Waste Gate 813
Turbo Blow Off Valve 814
Turbocharger Intercooler 815
Sequential Turbocharger Systems 815
Turbocharged Engine Modifications 816
Turbo Computer Control 816
Turbocharging System Service 817
Scanning a Turbocharging System 817
Inspecting Turbocharger System 817
Turbocharger Service 818
Installing a Turbocharger 820
Waste Gate Service 820
Superchargers 820
Supercharger Bypass Valve 822
Supercharger Operation 823
Supercharger Intercooler 823
Supercharger System Service 824
Scanning a Supercharging System 825
Supercharger System Diagnosis 825
Measuring Supercharger Boost Pressure 826
Supercharger Belt Replacement 827
Supercharger Clutch Service 827
Supercharger Replacement 828
Intercooler Service 829
Intercooler Replacement 829
Supercharger Oil Service 830

Section 7
Cooling and Lubrication Systems Technology

Chapter 47
Cooling System Technology 835

Vehicle Cooling Systems 835
Specific Cooling Systems 835
Cooling System Functions 836
Removing Engine Heat 837
Maintaining Operating Temperature 837
Reaching Operating Temperature Quickly 838
Heater Operation 838
Cooling System Types 838
Air Cooling Systems 838
Liquid Cooling Systems 838
Cooling System Parts 839
Water Pump 840
Radiator and Heater Hoses 841
Radiator 841
Cooling System Fans 844
Thermostat 847
Cooling System Instrumentation 848
Temperature Warning Light 849
Engine Temperature Gauge 849
Antifreeze 849
Prevents Winter Freeze Up 849
Prevents Rust and Corrosion 849
Lubricates the Water Pump 849
Cools the Engine 849
Antifreeze/Water Mixture 849
Block Heater 850
Supercharger Cooling Systems 850
Hybrid Cooling Systems 850
HV Battery Cooling Systems 851
Motor-Generator Cooling Systems 852
HV PCM Cooling Systems 852

Chapter 48
Cooling System Testing, Maintenance, and Repair 859

Cooling System Troubleshooting 860
Cooling System On-Board Diagnostics 861
Diagnosis Charts 861
Cooling System Inspection 861
Cooling System Problems 862
Coolant Leaks 862
Engine Overheating 865
Engine Overcooling 867
Water Pump Service 867
Checking a Water Pump 867
Removing a Water Pump 868
Installing a Water Pump 868
Thermostat Service 870
Thermostat Testing 870
Thermostat Replacement 870
Bleeding the Cooling System 873
Cooling System Hose Service 873

Checking Cooling System Hoses 874
Coolant Hose Replacement 874
Freeze Plug Service 875
Radiator Service 876
Radiator Removal and Installation 876
Radiator Repair 876
Engine Fan Service 877
Electric Fan Service 878
Testing an Electric Fan 878
Belt-Driven Fan Service 878
Coolant Service 879
Visual Coolant Inspection 879
Coolant Voltage Testing 879
Changing Coolant 880
Testing Coolant Strength 880
Coolant Test Strips 881
Corrosion of Aluminum 881
Flushing a Cooling System 882
Temperature Gauge Service 882
Supercharger Coolant Service 883
Hybrid Cooling System Service 884

Chapter 49
Lubrication System Fundamentals . . 891

Lubrication System Functions 891
Lubrication System Operation 892
Engine Oil 892
Oil Pan and Sump 896
Dry Sump Lubrication System 898
Oil Pickup and Screen 898
Oil Pumps 898
Oil Pump Drives 899
Multi-Stage Oil Pumps 900
Pressure Relief Valve 900
Oil Filters 901
Oil Cooler 903
Oil Galleries 903
Oil Spray Nozzles 904
Positive Crankcase Ventilation System 904
Oil Pressure Indicator 905
Oil Pressure Gauge Circuit 905
Oil Level Sensor 906
Low Oil Pressure Safety Circuit 906
Variable Camshaft Timing 906
Variable Camshaft Lift and Duration 907

Chapter 50
Lubrication System Diagnosis, Testing, and Repair 911

Lubrication System Diagnosis and Repair . . . 912
Lubrication System Problems 912
Engine Sludge 912
Oil Contamination from Water 912
High Oil Consumption 912
Low Oil Pressure 914
High Oil Pressure 914
Defective Indicator or Gauge 915
Oil Pressure Test 915
Engine Oil and Filter Service 917
Oil and Filter Change Intervals 917
Changing Engine Oil and Filter 917
Oil Pan Service 919
Installing an Engine Oil Pan 921
Oil Pump Service 922
Oil Pump Removal 922
Oil Pump Rebuild 922
Oil Pump Installation 922
Pressure Relief Valve Service 924
Oil Pressure Indicator and Gauge Service . . . 925
PCV Valve Service 926
Camshaft Phaser Service 926

Section 8
Emission Control System Technology

Chapter 51
Emission Control System Technology 931

Air Pollution 931
Smog 931
Motor Vehicle Emissions 932
Hydrocarbons (HC) 932
Carbon Monoxide (CO) 932
Oxides of Nitrogen (NO_X) 933
Particulates 933
Sources of Vehicle Emissions 933
Engine Modifications Related to Emission Control 934
Vehicle Emission Control Systems 934
Positive Crankcase Ventilation (PCV) 935
PCV System Operation 935
PCV Valve 935
Electric PCV Valve 936
Oil/Air Separators 937
Evaporative Emissions Control Systems 937

Evaporative Emissions System Components . . 937
Evaporative Emissions Control System Operation 938
Enhanced Evaporative Emissions Control System 939
Enhanced Evaporative Emissions Control System Operation 939
Air Cleaner Carbon Element 940
Exhaust Gas Recirculation (EGR) 940
Vacuum-Controlled EGR 940
Electronic-Vacuum EGR Valves 941
EGR System Variations 941
Electronic EGR System 942
Air Injection System 944
Air Injection System Components 944
Air Injection System Operation 944
Pulse Air System 945
Pulse Air System Operation 945
Catalytic Converter 945
Types of Catalytic Converters 946
Dual-Bed Catalytic Converter Operation 947
Computerized Emission Control Systems . . . 948
Oxygen Sensors 948
OBD II Emission System Monitoring 952
Diesel Particulate Filter 954

Chapter 52
Emission Control System Testing, Service, and Repair 957

Computer-Controlled Emission System Service 957
Scanning Emission Systems 958
Emission Maintenance Reminder 958
Inspecting Emission Control Systems 959
Engine Exhaust Gases 959
Exhaust Gas Analyzer 959
Types of Exhaust Gas Analyzers 960
Using an Exhaust Gas Analyzer 960
Exhaust Gas Analyzer Readings 961
State Emissions Testing Programs 964
IM 240 964
Vehicle Inspection Reports 965
Drive Trace Report 967
Vacuum Solenoid Service 968
PCV System Service 968
PCV System Testing 968
Evaporative Emissions System Service 972
EGR System Service 972
EGR System Testing (Vacuum Type) 973
EGR System Testing (Electronic Type) 973
Air Injection System Service 973
Testing Air Injection Systems 973
Pulse Air System Service 975
Catalytic Converter Service 975
Testing Catalytic Converter Efficiency 976
Catalyst Replacement 976
Catalytic Converter Replacement 976
Oxygen Sensor Service 976
Testing Oxygen Sensors 977
Oxygen Sensor Replacement 977
OBD II Drive Cycle 978
Emission Control Information Sticker 980

Section 9
Engine Troubleshooting and Performance

Chapter 53
Engine Performance and Driveability 987

Locating Engine Performance Problems 988
Performance Problem Troubleshooting Charts . . . 989
Technical Service Bulletins 989
Other Sources of Service Information 990
Typical Performance Problems 991
No-Crank Problem 991
No-Start Problem 991
Hard Starting 992
Stalling 992
Misfiring 993
Engine Load 994
Rough Idle 994
Hesitation 995
Stumbling 996
Surging 996
Backfiring 996
Dieseling (After-Running, Run-On) 996
Pinging (Spark Knock) 996
Vapor Lock 996
Fuel Line Freeze 996
Poor Fuel Economy 997
Lack of Engine Power 997
Scanning Diesel Engine Problems 997
Vacuum and Pressure Gauge Tests 997
Vacuum Pump Tests 997
Other Engine Performance Problems 999

Chapter 54
Advanced Diagnostics. 1003

Advanced Diagnostics 1003
- Advanced Scan Tool Tests 1004
- Checking ECM Terminal Values 1004
- Using a Breakout Box. 1006
- Isolating Electromagnetic Interference 1006
- Digital Thermometer Tests 1006
- Dynamometer Testing. 1007
- Using an Oscilloscope 1008
- Diagnostic Laptop Computers and Tablets . . . 1018

Section 10
Engine Service and Repair

Chapter 55
Engine Mechanical Problems 1025

Why Is Diagnosis Important? 1025
Common Engine Mechanical Problems 1026
- Engine Smoke 1026
- Engine Pre-Teardown Inspection 1027
- Abnormal Engine Noises 1028

Testing Engine Mechanical Conditions 1029
- Cranking Balance Test 1029
- Compression Test. 1030
- Wet Compression Test 1032
- Dynamic Engine Compression Test 1033
- Cylinder Leakage Test 1034
- Vacuum Test. 1034
- Cylinder Balance Test. 1034

Deciding What Type of Engine Repair Is Needed. 1035
Evaluating Engine Mechanical Problems. . . 1035
Engine Gasket Problems 1035
Cylinder Head Problems 1035
Valve Train Problems 1036
- Valve Problems. 1036
- Camshaft Problems 1039
- Hydraulic Lifter or Tappet Problems 1040
- Rocker Arm Problems. 1040
- Valve Spring Problems 1042
- Push Rod Problems 1042

Timing Mechanism Problems 1043
Cylinder Block Problems 1043
Connecting Rod Problems. 1045
Piston Problems 1045
- Burned Piston. 1046
- Worn Piston Rings and Cylinders. 1046
- Piston Breakage 1046
- Piston Knock. 1047
- Piston Pin Knock 1047

Crankshaft and Bearing Problems 1048
- Rod Bearing Knock 1048
- Spun Rod Bearing 1049
- Main Bearing Knock 1049
- Worn Main Bearings. 1050
- Excess Crankshaft Endplay 1050
- Flywheel Problems 1050
- Crankshaft Vibration Damper Problems 1050

Engine Mount Problems. 1050
- Checking Engine Mounts 1050

Intake and Exhaust Manifold Problems 1051

Chapter 56
Engine Removal, Disassembly, and Cleaning. 1057

Engine Identification 1057
- Identify Engine Type 1057
- Vehicle Identification Number. 1058
- Casting Numbers 1059
- Part Measurement 1059

Is Engine Removal Necessary?. 1059
Engine Overhaul 1061
- Parts Replaced or Reconditioned. 1061
- In-Vehicle Engine Overhaul 1061

Preparing for Engine Removal 1062
Removing Transmission with Engine 1064
Engine Removal 1065
- Installing Lifting Fixture or Chain 1065
- Lifting Engine from Vehicle 1066
- Lowering Engine from Vehicle 1068
- Separating Engine and Transmission/Transaxle 1068
- Placing Engine on Engine Stand 1070

Engine Disassembly. 1070
- Engine Top End Disassembly 1071
- Engine Front End Disassembly 1073
- Cylinder Head Disassembly 1073
- Engine Bottom End Disassembly 1075

Cleaning Engine Parts 1078
- Scrape off Old Gaskets and Hard Deposits. . . . 1078
- Cleaning Threads 1078
- Power Cleaning Tools 1078
- Cleaning Solvents. 1080
- Media Blasting 1082
- Air Blowgun 1082

Chapter 57
Short Block Rebuilding and Machining 1087

Cylinder Block Service. 1087
- Inspecting the Cylinder Block 1088
- Finding Cracks in the Block 1088
- Repairing Block Cracks 1090
- Checking Main Bearing Bores 1090
- Line Boring the Block 1091
- Measuring Cylinder Block Deck Warpage . . . 1091
- Measuring Cylinder Diameter 1093
- Cylinder Wear 1093

Cylinder Honing and Deglazing 1096
- Hone Grit Selection 1096
- Using a Power Hone 1096
- Using a Flex Hone 1098

Block Boring 1099
- Overbore Sizes 1100
- Overbore Limit 1101
- Oversize Pistons and Rings 1101
- Cylinder Sleeving 1101
- Cleaning Cylinder Walls 1101

Camshaft and Balancer Bearing Installation . . . 1102

Core Plug Installation. 1104

Crankshaft Service 1104
- Measuring Journal Taper, Out-of-Round, and Cheek Width 1105
- Checking for a Cracked Crankshaft 1106
- Checking Crankshaft Straightness 1106
- Crankshaft Turning 1106
- Undersize Bearing Markings 1108
- Cleaning the Crankshaft 1108

Installing the Rear Main Oil Seal 1109
- Two-Piece Seal 1109
- One-Piece Seal 1110

Main Bearing and Crankshaft Installation . . 1111
- Installing the Main Bearings 1111
- Installing the Crankshaft 1111
- Checking Main Bearing Clearance 1112
- Torquing the Main Caps 1113
- Torque-to-Yield 1114
- Checking Crankshaft Endplay 1114
- Replacing the Pilot Bearing 1116

Piston Service. 1117
- Cleaning Piston Ring Grooves 1117
- Measuring Piston Wear 1117
- Measuring Piston Clearance 1118
- Measuring Piston Ring Gap 1118
- Checking Ring Groove Depth 1118

Piston Pin Service 1119
- Piston Pin Clearance 1119
- Free-Floating Pin Service 1119
- Pressed-In Pin Service 1120
- Measuring Piston Pin Wear and Clearance . . 1121

Connecting Rod Service 1122
- Rod Small End Service 1122
- Rod Big End Service 1122
- Checking Rod Straightness 1122
- Rebuilding Connecting Rods 1122

Installing Piston Rings. 1124
- Installing Oil Rings 1124
- Installing Compression Rings 1124
- Piston Ring Gap Spacing 1125
- Measuring Piston Ring Side Clearance 1125

Installing the Piston and Rod Assembly . . . 1126
- Protecting the Crankshaft 1127
- Installing Piston and Rod in Block 1127
- Checking Rod Bearing Clearance 1128
- Torquing Connecting Rods 1128
- Checking Rod Side Clearance 1130

Engine Balancing 1131

Balancer Shaft Service. 1132

Chapter 58
Engine Top End Rebuilding. 1137

Cylinder Head Problems 1137
- Cylinder Head Warpage 1137
- Cylinder Head Milling 1139
- Cracked Cylinder Head 1140
- Repairing Cracked Heads 1141

Head Disassembly 1141

Valve Guide Service 1143
- Measuring Valve Guide and Stem Wear 1143
- Repairing Valve Guide Wear 1144

Valve Seat Reconditioning. 1145

Valve Seat Resurfacing 1145
- Selecting Stone and Pilot 1146
- Dressing Stone 1147
- Grinding Valve Seats 1147
- Cutting Valve Seats. 1149
- Checking Seat Concentricity and Width 1149
- Narrowing Valve Seats 1150
- Moving the Seat Contact Point 1150
- Valve Retrusion 1150
- Valve Seat Replacement 1151

Valve Seat Machine 1152

Grinding Engine Valves 1153
- Valve Grinding Machine 1153

Valve Grinder Setup 1153
Grinding Valve Faces 1154
Grinding Valve Stem Tips 1156
Checking Valve-to-Seat Contact 1156
Valve Spring Service 1159
Inspecting Valve Springs 1159
Shimming Valve Springs 1160
Cylinder Head Reassembly 1162
Installing Valve Seals 1162
Installing Valve Springs 1163
Checking for Valve Leakage 1164
In-Vehicle Valve Seal Service 1165
Camshaft Service 1165
Measuring Camshaft Wear 1165
Camshaft Grinding 1166
Installing an Overhead Valve Camshaft 1167
Camshaft Endplay 1168
OHC Bearing Service 1168
Rocker Assembly Service 1168
Rocker Arm Stud Service 1169
Push Rod Service 1169
Lifter (Tappet) and Follower Service 1170
Inspecting Lifters 1170
Testing Lifter Leak-Down Rate 1170
Rebuilding Hydraulic Lifters and Followers . . . 1170
Bleeding Cam Followers 1170

Chapter 59
Engine Front End Service 1175

Timing Chain Service 1176
Timing Chain Problems 1176
Inspecting a Timing Chain 1176
Installing a Timing Chain 1177
Installing a Chain Tensioner 1179
Installing an Oil Slinger 1179
Engine Front Cover Service 1179
Front Seal Service 1179
Installing a Front Cover 1180
Vibration Damper Installation 1182
Timing Gear Service 1183
Measuring Timing Gear Backlash 1183
Replacing Timing Gears 1184
Measuring Timing Gear Runout 1184
Timing Belt Service 1185
Inspecting the Timing Belt Mechanism 1185
Installing the Timing Belt Sprockets 1186
Installing the Timing Belt 1187
Adjusting Timing Belt Tension 1188
Installing the Timing Belt Cover 1188

Chapter 60
Engine Reassembly, Installation, and Break-In 1193

General Engine Assembly Rules 1193
Engine Reassembly 1194
Installing the Oil Pump 1194
Installing the Oil Pan 1195
Installing Accessory Units 1197
Cylinder Head Installation 1197
Installing the Head Gasket 1197
Installing the Cylinder Head 1198
Installing and Torquing Head Bolts 1198
Lifter Installation 1200
Intake Manifold Installation 1200
Inspecting the Intake Manifold 1200
Installing the Intake Manifold Gasket 1201
Torquing the Intake Manifold Bolts 1203
Checking the Engine Thermostat 1203
Exhaust Manifold Installation 1203
Camshaft Housing Installation 1205
Overhead Camshaft Installation 1206
Installing a Camshaft with One-Piece Bearings 1206
Installing a Camshaft with Two-Piece Bearings 1207
Assembling Valve Train 1207
Installing Push Rods 1207
Installing Rocker Arms 1208
Adjusting Valve Train Clearance 1208
Valve Cover Installation 1211
Camshaft Cover Installation 1211
Valve Cover Installation 1212
Final Engine Assembly 1213
Installing External Engine Parts 1214
Installing the Engine Flywheel 1214
Installing a Clutch 1214
Installing a Torque Converter 1215
Servicing Hybrid Motor-Generators 1215
Installing the Transmission or Transaxle 1216
Installing the Engine 1216
Engine Installation Rules 1216
Installing the Engine without the Transmission or Transaxle 1217
Installing the Engine with the Transmission or Transaxle 1218
Installing the Engine from under the Vehicle . . . 1220
Engine Startup 1222
Engine Break-In 1222
Customer Delivery 1222

Section 11
Drive Train and Axle Technology

Chapter 61
Clutch Technology 1227

Clutch Principles 1227
- Basic Clutch Parts 1229
- Clutch Action 1229

Clutch Construction 1229
- Pilot Bearing 1229
- Flywheel 1231
- Clutch Disc 1231
- Release Bearing 1233
- Clutch Housing 1234
- Clutch Fork 1234
- Clutch Release Mechanisms 1235
- Clutch Start Switch 1237

Automatic Manual Clutch 1237

Hybrid Vehicle Clutch 1238
- Hybrid Vehicle Wet Clutch 1239
- Hybrid Power Splitter 1239

Chapter 62
Clutch Diagnosis, Service, and Repair 1245

Diagnosing Clutch Problems 1245
- Verify the Clutch Problem 1245
- Common Clutch Part Failures 1246

Servicing a Clutch 1251
- Adjusting the Clutch 1252
- Removing the Clutch 1253
- Inspecting and Cleaning Clutch Parts 1254
- Installing the Clutch 1257

Engine/Motor-Generator Clutch Service . . . 1257

Engine/Motor-Generator Wet Clutch Service . . . 1259

Automated Manual Clutch Service 1259

Chapter 63
Manual Transmission Technology . . 1265

Basic Transmission Parts 1265

Purpose of a Manual Transmission 1266

Gear Fundamentals 1267
- Gear Ratios 1267
- Gear Reduction and Overdrive 1268
- Gear Types 1268
- Manual Transmission Lubrication 1268
- Transmission Bearings 1268

Manual Transmission Construction 1268
- Transmission Case 1269
- Extension Housing and Front Bearing Hub . . 1269
- Transmission Shafts 1270
- Transmission Gears 1270
- Transmission Synchronizers 1273
- Shift Forks 1275
- Shift Linkage and Shift Lever 1275

Manual Transmission Types 1276

Manual Transmission Power Flow 1277
- First Gear 1277
- Second Gear 1278
- Third Gear 1278
- Reverse 1278
- Neutral 1278
- Overdrive Gear 1278

Speedometer Drive 1279

Manual Transmission Actuators 1280

Manual Transmission Sensors and Switches 1280

Chapter 64
Manual Transmission Diagnosis, Service, and Repair . . . 1287

Manual Transmission Problem Diagnosis . . 1287

Manual Transmission Problems 1288
- Gears Grind When Shifting 1288
- Transmission Noise 1288
- Transmission Difficult to Shift 1289
- Transmission Jumps out of Gear 1289
- Transmission Leaks Lubricant 1289
- Transmission Locked in Gear 1289
- Diagnosis Chart 1289

Transmission Identification 1289

Manual Transmission Service 1289
- Manual Transmission Removal 1289
- Manual Transmission Disassembly 1290
- Cleaning and Inspecting Parts 1291
- Replace Worn or Damaged Parts 1292
- Transmission Reassembly 1293
- Transmission Installation 1294

Chapter 65
Automatic Transmission Technology 1301

Basic Automatic Transmission 1301
- Transmitting Power 1302
- Transmission Housings and Case 1302
- Torque Converter 1303

Automatic Transmission Shafts 1306
Planetary Gears 1307
Clutches and Bands 1309
Overrunning Clutches 1312
Hydraulic System 1312
Automatic Transmission Fluid 1314
Transmission Oil Pump 1315
Pressure Regulator 1316
Manual Valve 1316
Shift Valves (Balanced Valves) 1316
Valve Body 1316
Parking Pawl 1316
Automatic Transmission Power Flow 1317
Electronic Transmission Control 1317
Automatic Transmission Solenoids 1318
Automatic Transmission Designs 1321

Chapter 66
Automatic Transmission Diagnosis, Service, and Repair . . . 1325

Automatic Transmission Diagnosis 1325
Preliminary Checks 1327
Road Testing 1328
Shop Testing 1329
Automatic Transmission Maintenance 1331
Changing Transmission Fluid 1332
Fluid Leaks 1333
Automatic Transmission Adjustments 1333
Electronic Control System Service 1335
Major Transmission Service 1335
Automatic Transmission Removal 1335
Automatic Transmission Rebuild 1338
Automatic Transmission Installation 1338

Chapter 67
Drive Shaft and Transfer Case Technology 1343

Drive Shaft Assembly 1343
Functions of Drive Shaft Assembly 1344
Drive Shaft Operation 1344
Slip Yoke 1345
Rear Yoke 1345
Drive Shaft 1345
Universal Joints 1346
Center Support Bearing 1348
Driveline Types 1349
Hotchkiss Driveline 1350
Torque Tube Driveline 1350
Transfer Cases 1350
Transfer Case Ranges 1352
All-Wheel Drive 1353

Chapter 68
Drive Shaft and Transfer Case Diagnosis, Service, and Repair . . . 1357

Drive Shaft Problems 1357
Drive Shaft Noise 1357
Drive Shaft Vibration 1358
Drive Shaft Inspection 1358
Measuring Drive Shaft Runout 1359
Drive Shaft Balancing 1359
Measuring Driveline Angle 1359
Drive Shaft Maintenance 1360
Drive Shaft Service 1360
Drive Shaft Removal 1360
Universal Joint Service 1360
Drive Shaft Installation 1362
Transfer Case Service 1363

Chapter 69
Differential and Rear Drive Axle Technology 1369

Basic Rear Drive Axle Assembly 1369
Rear Axle Power Flow 1370
Functions of a Rear Drive Axle 1370
Differential Construction 1370
Pinion Gear and Ring Gear 1370
Differential Carrier 1373
Differential Case 1373
Spider Gears 1373
Differential Lubricant 1373
Differential Action 1373
Limited-Slip Differentials 1375
Clutch Pack Differential 1375
Cone Clutch Differential 1375
Ratchet Differential 1375
Torsen Differential 1375
Rear Drive Axles 1376
Swing Axles 1376
Differential Breather Tube 1379
Front Drive Axle—Four-Wheel-Drive Vehicles 1379
Electro-Hydraulic Differential 1379
All-Wheel-Drive Differential 1382

Chapter 70
Differential and Rear Drive Axle Diagnosis, Service, and Repair . . . 1387

Rear Axle Problem Diagnosis 1387
- Eliminate other Problem Sources 1388

Chapter 10
Career Success

We are truly living in a "world of wheels." Every day, millions of people depend on their cars, trucks, vans, and sport-utility vehicles as their primary means of transportation. As a result, economic experts predict a strong demand for skilled automobile technicians and related professionals for the foreseeable future. You have chosen to study an area of employment that pays well and will require thousands of new graduates yearly.

Section 1 will introduce you to the basics of automotive technology, including information on automobile construction and operation, ASE certification, safety, tools and equipment, fasteners, service information, careers, and vehicle maintenance. This section will give you the knowledge needed to secure an entry-level job. It will also lay the groundwork for later chapters, which provide in-depth coverage of automotive service and repair.

Copyright Goodheart-Willcox Co., Inc.

Chapter 1
The Automobile

After studying this chapter, you will be able to:

- Identify and describe primary automotive assemblies and major automotive systems.
- Explain the frequent electronic interaction of major automotive systems or circuits.
- Describe and compare major automobile design variations.
- Identify and locate the most important systems used to operate conventional and hybrid passenger vehicles.
- Comprehend later textbook chapters with a minimum amount of difficulty.
- Correctly answer ASE certification test questions that require a general understanding of the major parts and systems of a vehicle.

The term ***automobile*** is derived from the Greek word *autos*, which means self, and the French word *mobile*, which means moving. Today's "self-moving" vehicles are engineering marvels of safety and dependability. Over the last century, engineers and skilled workers the world over have used all facets of ***technology*** (application of math, science, physics, engineering, and other subjects) to steadily give us a more efficient means of transportation.

You are about to begin your study of the design, construction, service, maintenance, and repair of modern passenger vehicles. This chapter provides a "quick look" at different makes and models of cars and how they operate. By knowing a little about all major systems, you will be better prepared to learn the more detailed information presented later in this textbook.

Today, a vehicle is as much electronic as it is mechanical. Failure of one computer-controlled system can affect the operation of a seemingly unrelated system. This makes a thorough understanding of the whole automobile and its major systems critical.

Tech Tip

Try to learn something new about the automotive industry every day. In addition to studying this book and doing all the hands-on activities, read automotive magazines, browse the Internet, and watch "motor-sport" television programs. Increasing your knowledge daily will help you become a better technician with little effort!

Parts, Assemblies, and Systems

A ***part,*** sometimes called a ***component***, is the smallest removable item on a car. A part is not normally disassembled. It is often a one-piece casting or forging made of metal or plastic. An electrical component is a part in an electrical circuit or system.

An ***assembly*** is a set of fitted parts designed to complete a specific function. For example, the engine is an assembly that converts fuel into useable power to move the vehicle. Technicians must often take assemblies apart and put them back together during maintenance, service, and repair operations. See **Figure 1-1.**

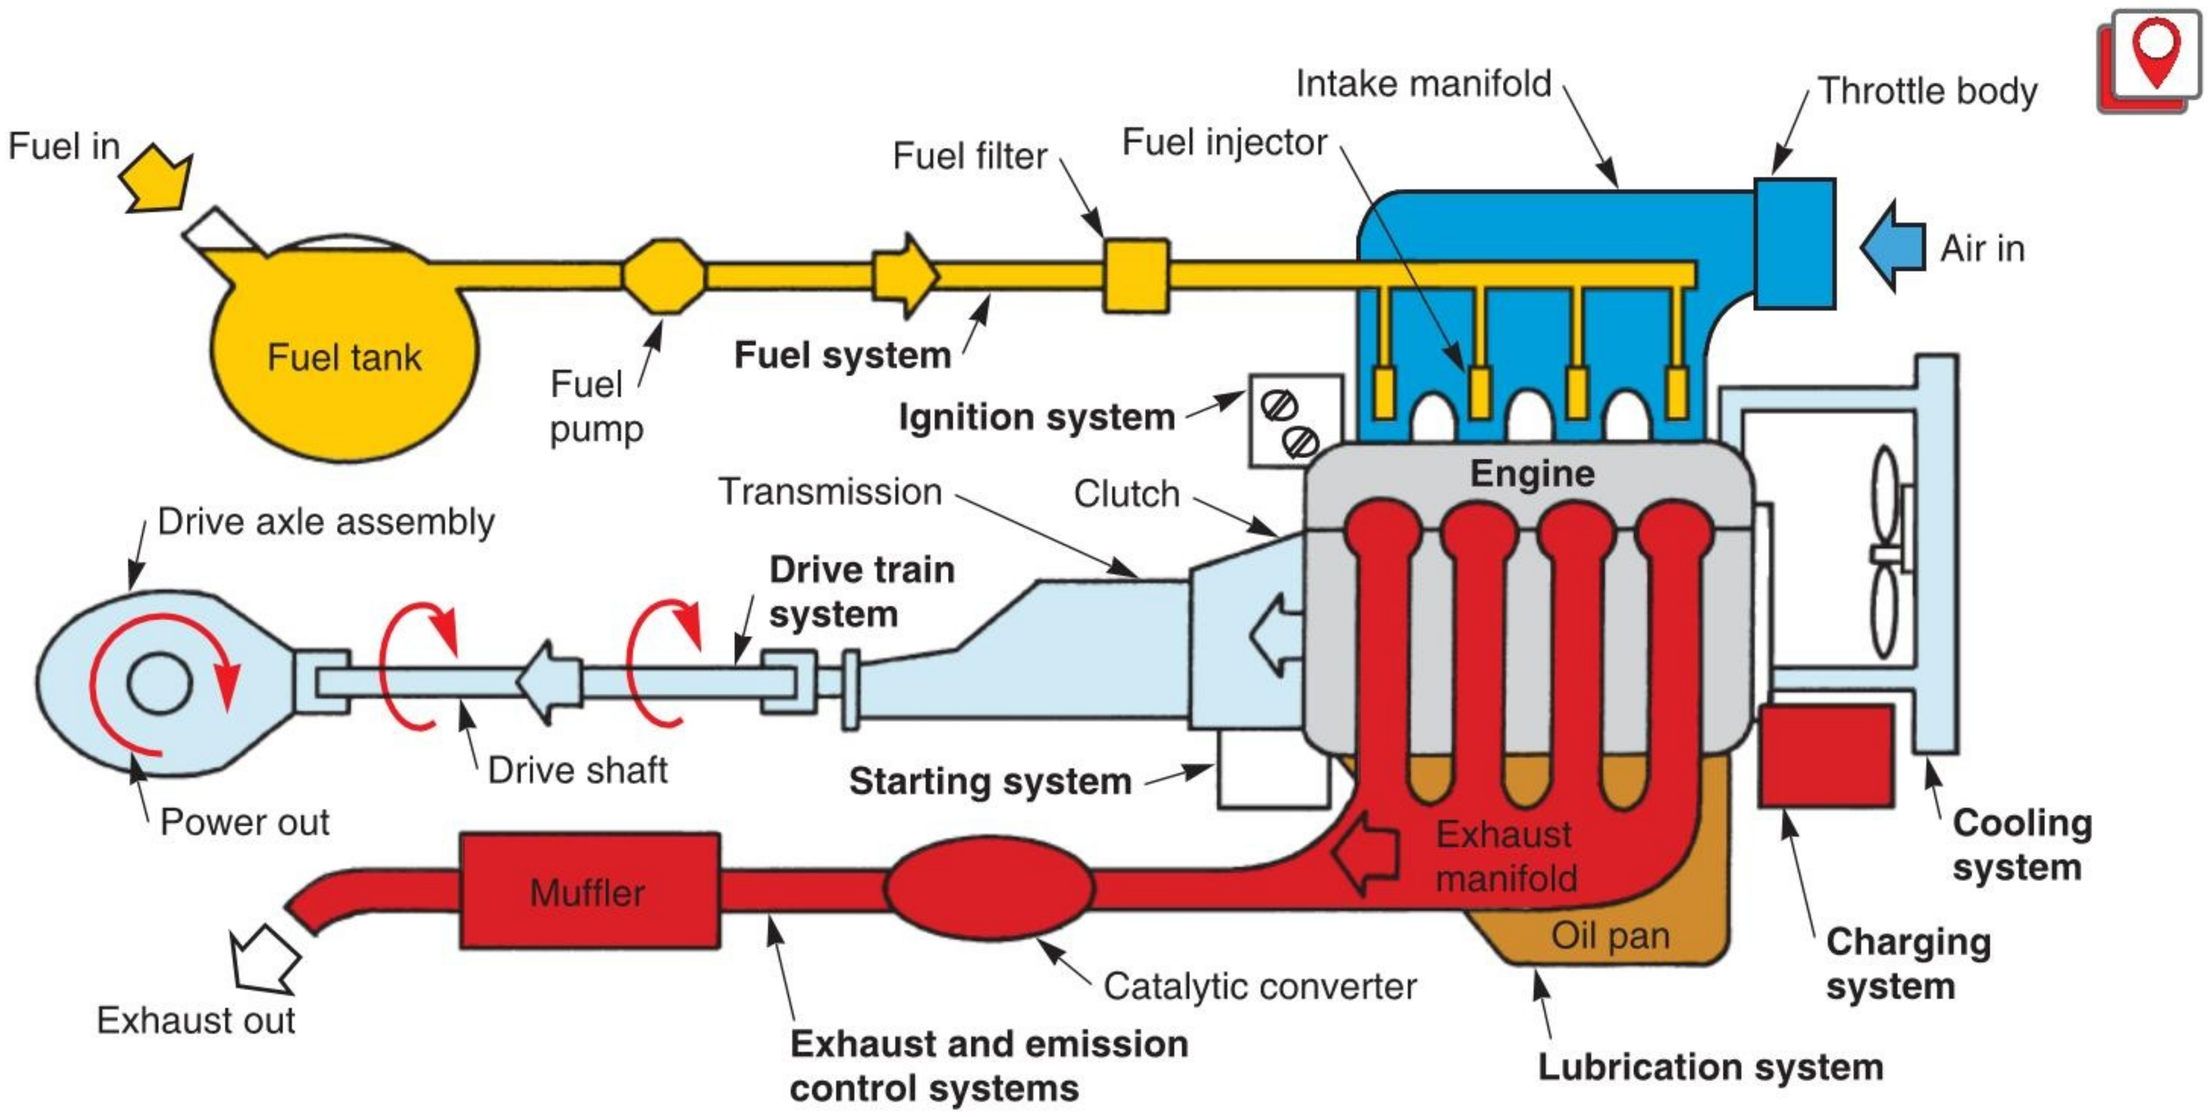
An automotive ***system*** is a group of related parts and assemblies that performs a specific function (job or task). For example, your vehicle's steering system contains the steering wheel, steering shaft, steering gears, linkage rods, and other parts. These parts allow you to control the direction of the wheels and tires for maneuvering (turning) your vehicle. **Figure 1-2** shows the major systems of a vehicle. Memorize the name and general location of each system. The following sections will provide you with an overview of the parts and systems found on late-model vehicles.

Audi

Figure 1-1. An assembly is a group of parts that work together to perform a function. For example, an engine is an assembly that contains pistons, which convert the fuel's heat energy into useable kinetic energy (motion). As you will learn, an engine has many other parts.

Frame, Body, and Chassis

The frame and body are the two largest sections, or parts, of a motor vehicle. The ***frame*** is the strong metal structure that provides a mounting place for all the other



Goodheart-Willcox Publisher

Figure 1-2. Note the general location of the major vehicle systems. Study the fuel, air, exhaust, and power.

Copyright Goodheart-Willcox Co., Inc.

parts. The frame holds the engine, transmission, suspension, steering, and other assemblies in position.

The ***body*** is a steel, aluminum, fiberglass, plastic, or composite (carbon fiber) skin forming the outside of the vehicle. The body is painted to give the vehicle an attractive appearance.

The term ***chassis*** is often used when referring to a vehicle's frame and everything mounted to it except the body—tires, wheels, engine, transmission, and drive axle assembly.

In ***body-over-frame construction***, or full-frame construction, the frame consists of thick steel members. The chassis parts and the body bolt to this frame. This heavy, strong design is used on some cars, vans, pickup trucks, and sport-utility vehicles (SUVs). Full size trucks always use body-over-frame construction. Refer to **Figure 1-3**.

With ***unibody construction***, sheet metal body panels are welded together to form the body and frame. Also called unit-body construction or unitized construction, this is the most common design used to build small and medium passenger cars. Unibody vehicles are generally lighter and more fuel efficient than body-over-frame vehicles and have a high strength-to-weight ratio. See **Figure 1-4**.

General Vehicle Specifications

The following section describes common vehicle specifications. Manufacturers generally publish these specifications for each model they produce.

Vehicle curb weight is the total weight of the vehicle with a full tank of gas and no driver. Vehicle curb weights vary. Generally, pickup trucks and SUVs

Ford

Figure 1-3. With body-over-frame construction, the chassis parts bolt to a strong frame.

Mazda

Figure 1-4. Unibody vehicles do not have a separate frame. Steel or aluminum panels are normally welded together at the factory to produce a unibody vehicle. A—Unibody with the chassis removed. B—Chassis components attach directly to the sheet metal body structure through large steel crossmembers.

Copyright Goodheart-Willcox Co., Inc.

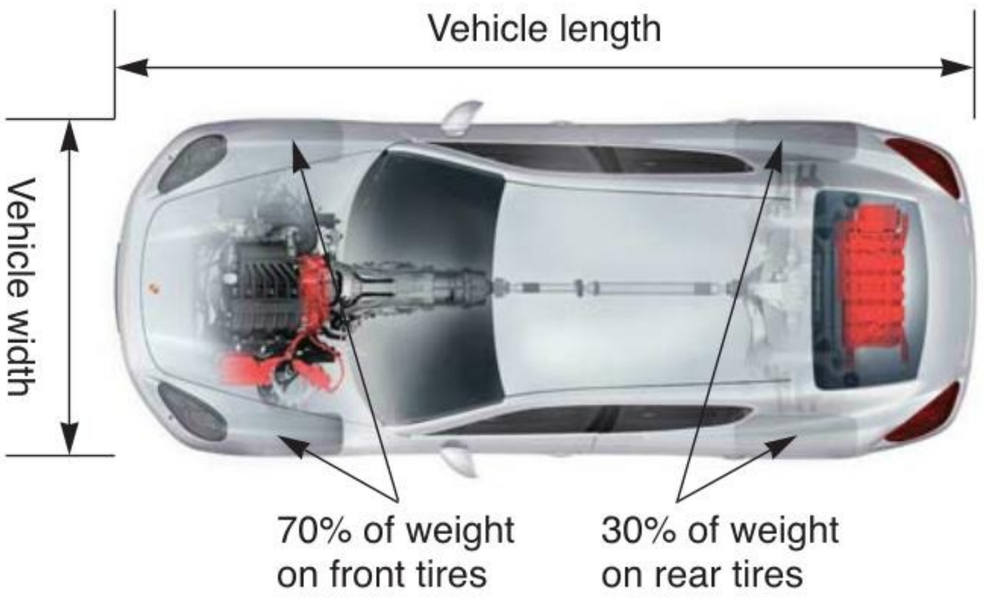
are the heaviest vehicles and weigh two and a half tons. Full-size cars, station wagons, and full-size vans weigh about two tons. Compact cars have a low curb weight of about 3000 lb (1360 kg). Small sports cars and micro cars are the lightest passenger vehicles, weighing in at about 2000 lb (907 kg).

Vehicle weight distribution is a measurement of how much force is pushing down on the front and rear tires of the vehicle. An ideal weight distribution for economy and cornering ability (ability to turn a corner while maintaining directional stability) is 50/50, or 50% front and 50% rear. A 50/50 weight distribution can be found on many high-performance sports cars. Front-wheel drive vehicles have about a 70% front and 30% rear weight distribution for good tire traction with the road surface.

Vehicle wheelbase is the distance from the centerline of the front wheels to the centerline of the rear wheels. A typical wheelbase for a full-size car might be 100″ (254 cm) for a small, compact car and up to 150″ (381 cm) for a full-size pickup truck.

Track width is the distance between the centerlines of the two wheels on the same axle (right and left front wheels or left and right rear wheels). The trend is to make vehicles wider so they can corner more quickly without a rollover accident. A typical track width might be 62″ (157 cm) at the front axle and 64″ (163 cm) at the rear axle.

Vehicle length is a measurement from the outermost point on the front bumper to the outermost point on the rear bumper. ***Vehicle width*** is the distance between the two widest points from the right to left sides of the body measured perpendicular to the vehicle's centerline. Refer to **Figure 1-5**. ***Vehicle height*** is measured from the ground to the highest point on the roofline.



www.thenewsmarket.com

Figure 1-5. Note how the vehicle dimensions and weight distribution are given for a passenger vehicle.

Vehicle Size

A full-size car is capable of carrying four or five adults. It usually has four doors and is rear- or all-wheel drive with a relatively large engine. Full-size cars are the heaviest passenger cars, but they still get slightly better gas mileage than most trucks and SUVs.

A midsize car is shorter and lighter than a full-size car, but it can still carry up to four adults comfortably. It often has a smaller engine and gets better fuel economy than full-size cars because of its reduced curb weight and frontal cross section.

A compact car usually has front-wheel drive with a small 4- or 6-cylinder engine. Compact cars are generally very fuel efficient because they are smaller and lighter than full-size and midsize cars.

The minicompact car is the smallest car allowed on public roads. It often only seats two people. Its wheelbase is very short, and the diameter of its wheels and tires is normally smaller than that of other vehicles. Their low weight and tiny engine make the minicompact car one of the most fuel-efficient vehicles on the market. See **Figure 1-6**.

Vehicle Aerodynamics

Aerodynamics is the study of the motion of air as it interacts with a moving object. In automotive engineering, aerodynamics is the study of the resistance to airflow over and under the car body at highway speeds. Aerodynamic drag is the "worst enemy" of good gas mileage.

The goal of auto manufacturers is to design a vehicle with a very low drag, or resistance to movement through the air. This is done by designing cars

Figure 1-6. This micro car is an example of a minicompact car.

Copyright Goodheart-Willcox Co., Inc.

with very small frontal cross-sectional areas. The height and width of the car body should be very small. A vehicle with a small cross-sectional area produces less resistance to airflow than a vehicle with a large cross-sectional area. Refer to **Figure 1-7**.

Coefficient of drag (Cd) is a number that represents the force required to move a passenger vehicle through air. A good Cd for a small sports car is 0.26. The Cd for a larger vehicle, such as a truck or van, might be as high as 0.40. Fuel economy is reduced by an increase in Cd, as the vehicle has to push more air out of its way when moving.

Vehicle Body Types

Automobiles are available in several models, or body types, including the sedan, convertible, hatchback, station wagon. In addition, the minivan, crossover vehicle, sport-utility vehicle (SUV), pickup truck, and micro car have become increasingly popular.

A sedan is a car that has front and back seats and will carry four to six people. Both two-door and four-door sedans are available. They have center body pillars, or "B" pillars, between the front door and rear quarter panel, **Figure 1-8A**.

A convertible has a roof panel that can be raised and lowered into a well located behind the back seat. The convertible roof can be made of metal, a composite, or a synthetic fabric. Metal roofs fold into the trunk area. A convertible has no door pillars, and its strength is designed into the center area of the frame or floor pan. Convertibles are normally two-door models, **Figure 1-8B.**

A hatchback, or liftback, has a large rear door for easy access when hauling items. This style car is available in three- and five-door models, **Figure 1-8C.**

A station wagon has a long, straight roof that extends all the way to the rear of the vehicle. Station wagons have large rear interior compartments and come in two- and four-door models. See **Figure 1-8D**.

A full-size van has a large body for large families or commercial service. The minivan is midsize and similar to the station wagon, but it has a higher roofline for more headroom and cargo space. Most minivans are designed to carry seven passengers. They are usually front-wheel drive. See **Figure 1-8E**.

A pickup truck is a front-engine, cab-forward vehicle with a large, open cargo area in the rear. Full-size pickups use a frame made of heavy gauge steel. The cab, bed, fenders, and other body panels are bolted to the frame. Rubber bushings fit between body panels and the frame to prevent noise and vibration from entering the passenger area.

Sport-utility vehicles are often equipped with four-wheel drive systems and have a high roofline and floor pan. Because of the high floor pan, SUVs have ample

Mazda

Figure 1-7. A low-slung car body with smooth shapes and a small frontal cross section decreases aerodynamic drag and amount of power needed to keep the vehicle moving at any speed. The trend is moving away from heavy SUVs and trucks to smaller vehicles that get better gas mileage.

Copyright Goodheart-Willcox Co., Inc.

ground clearance for off-road driving. They provide the comfort of a passenger car, the interior space of a station wagon, and the durability of a truck. Since an SUV is very heavy, with a complex heavy-duty four-wheel drive system, it is not as fuel efficient as other types of vehicles, **Figure 1-8F**.

The crossover vehicle is a design mix. It is an SUV built on a passenger car or station wagon chassis. The crossover is about half as tall as a minivan, which lowers its center of gravity for more rollover stability when cornering rapidly. The crossover also has a smaller cross section for improved aerodynamics.

Common names for various automobile body parts are shown in **Figure 1-9**. Note that a vehicle's right and left sides are denoted as if you were sitting in the car looking forward.

Fuel Efficiency

Fuel efficiency, or fuel economy, is a rating of how far a vehicle can travel on only one gallon of fuel

A—Sedan

B—Convertible

C—Hatchback

D—Station Wagon

E—Minivan

F—Sport-Utility Vehicle

Chrysler, Porsche, Ford, Subaru, Honda

Figure 1-8. Note the various vehicle body styles.

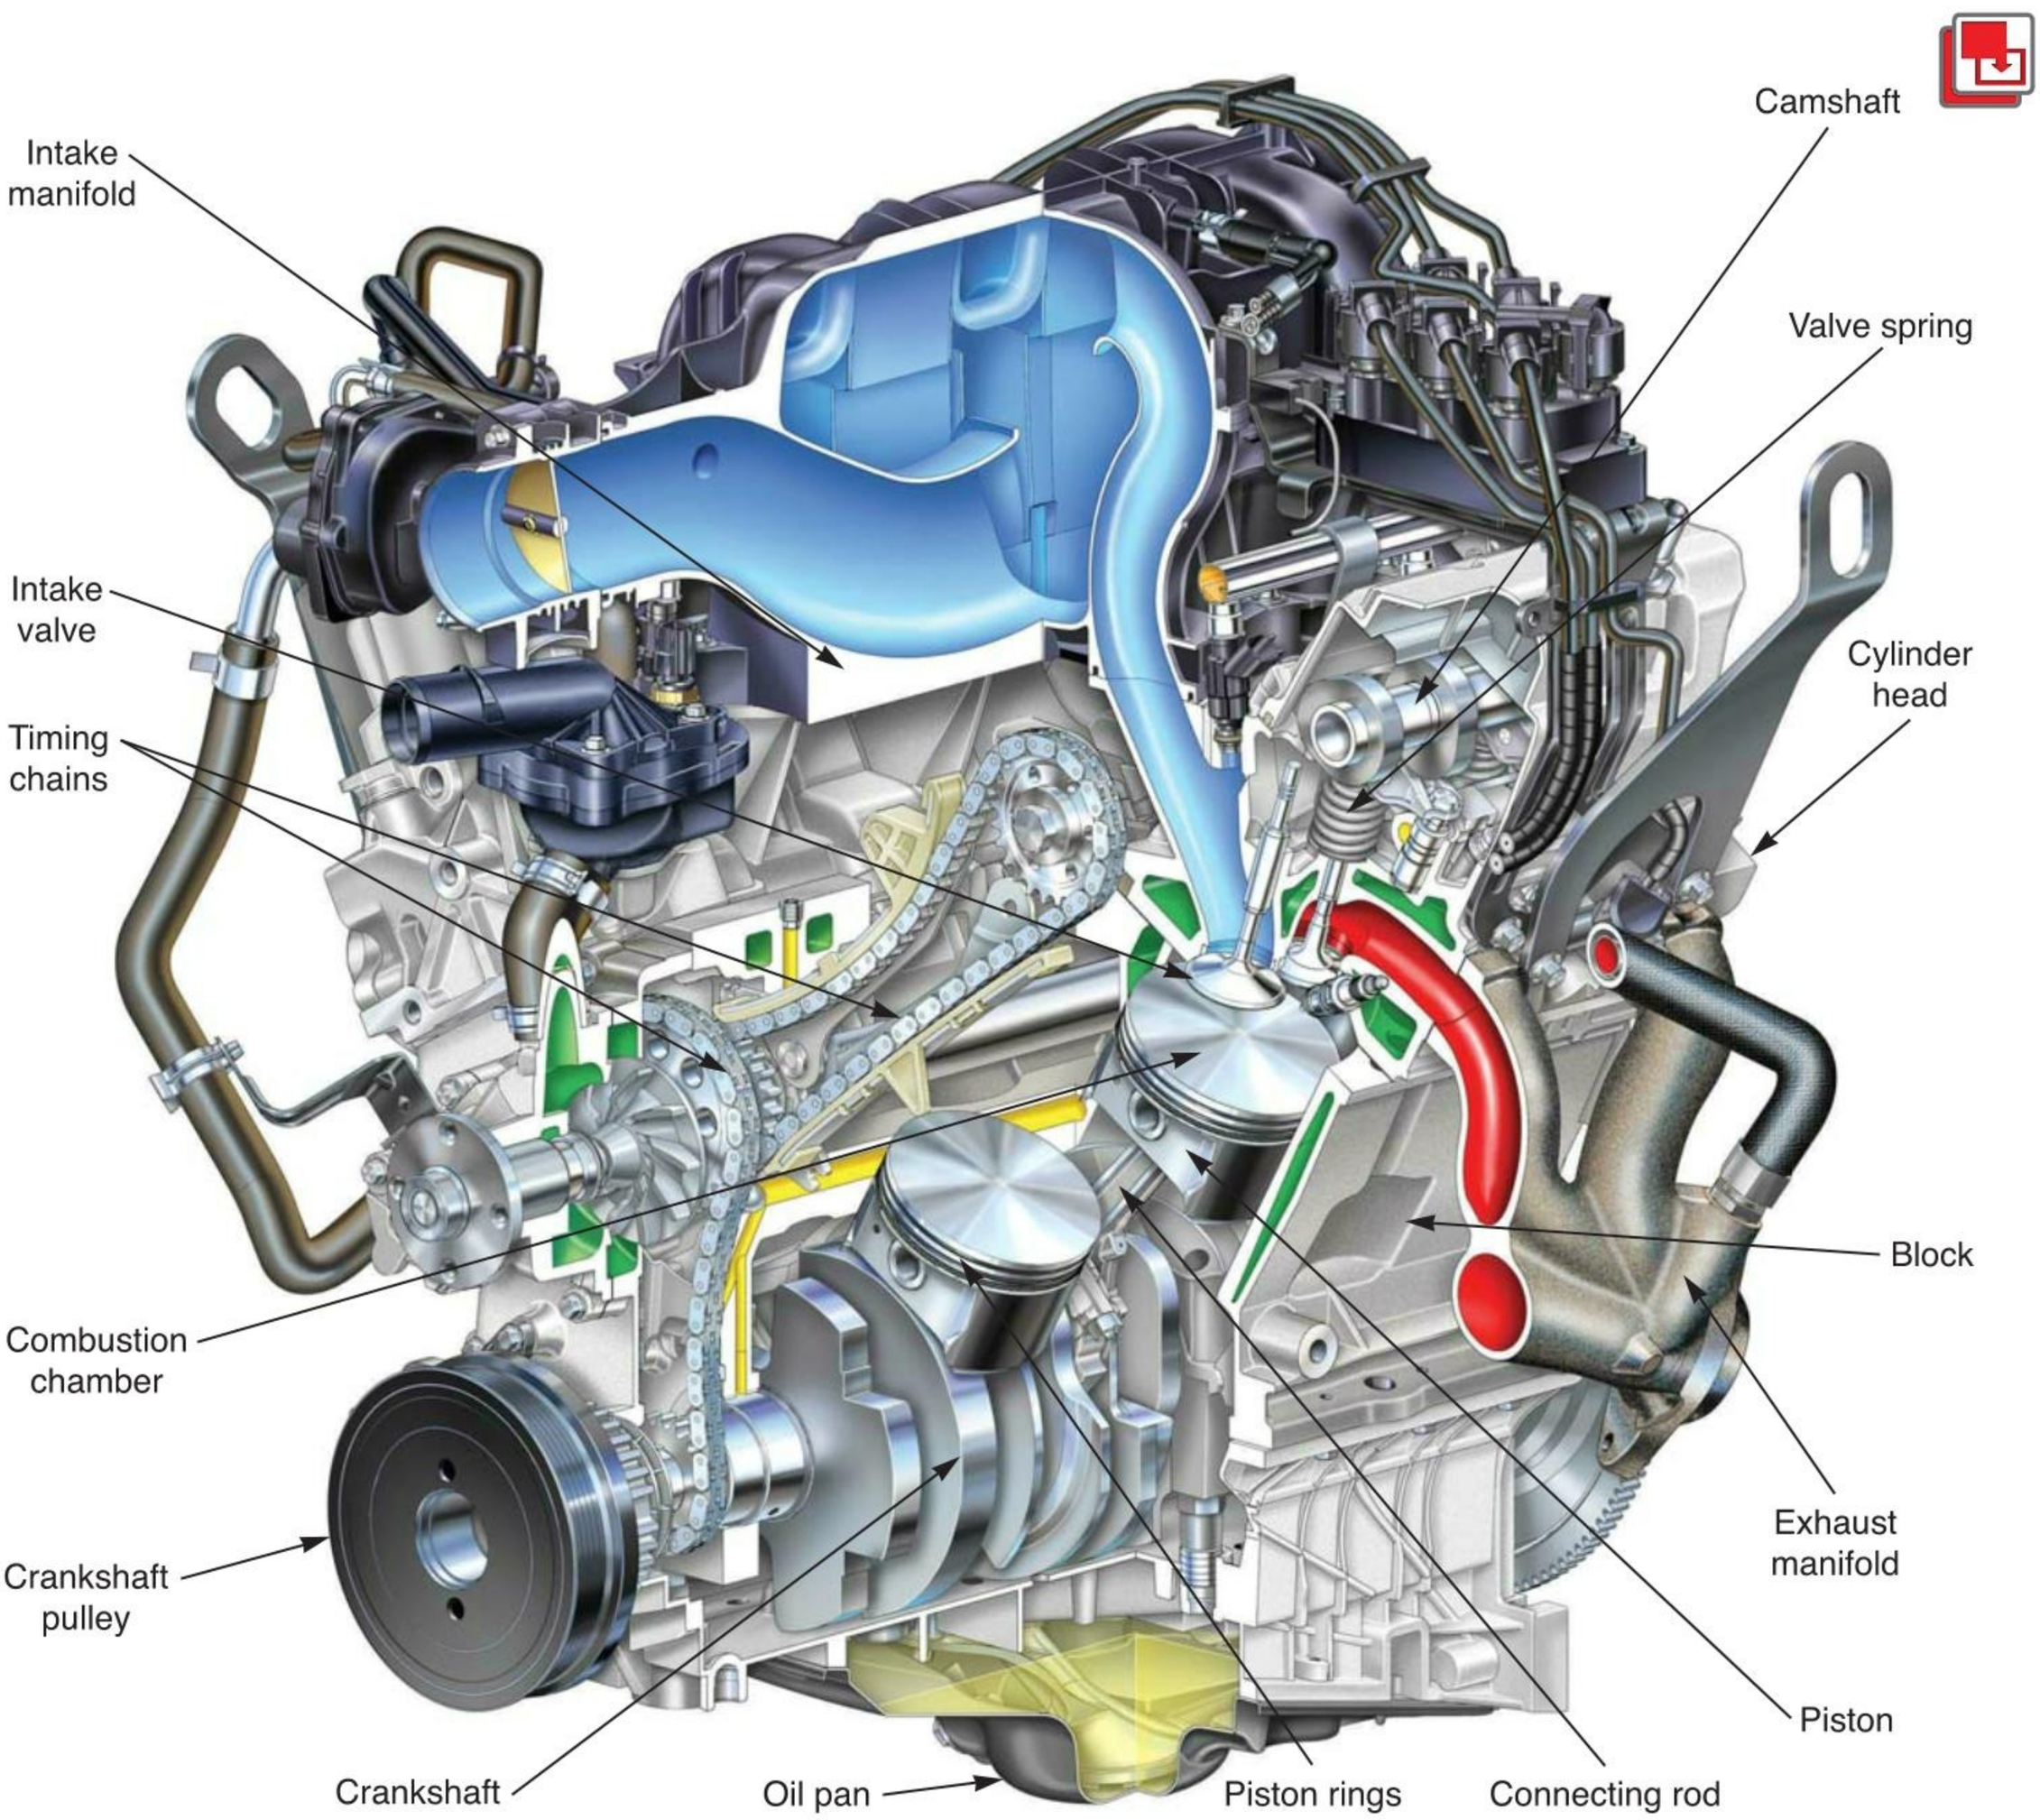
(gasoline or diesel fuel). The EPA tests and rates cars to give them an average city and highway fuel economy rating. A typical fuel economy rating for a small economy car might be 40 miles per gallon (mpg) city and 43 mpg highway.

Estimated city EPA fuel economy testing is done with a preset number of stops so the car has to accelerate to cruising speeds. Estimated highway EPA fuel economy ratings are for steady state interstate cruising speeds.

Engine

The ***engine*** provides the energy to propel (move) the vehicle and operate other vehicle systems. Most engines consume gasoline or diesel fuel. The fuel burns inside the engine to produce heat. This heat causes hot gas expansion, creating high pressure inside the engine to move its parts to produce power. See **Figure 1-10**.



Ford

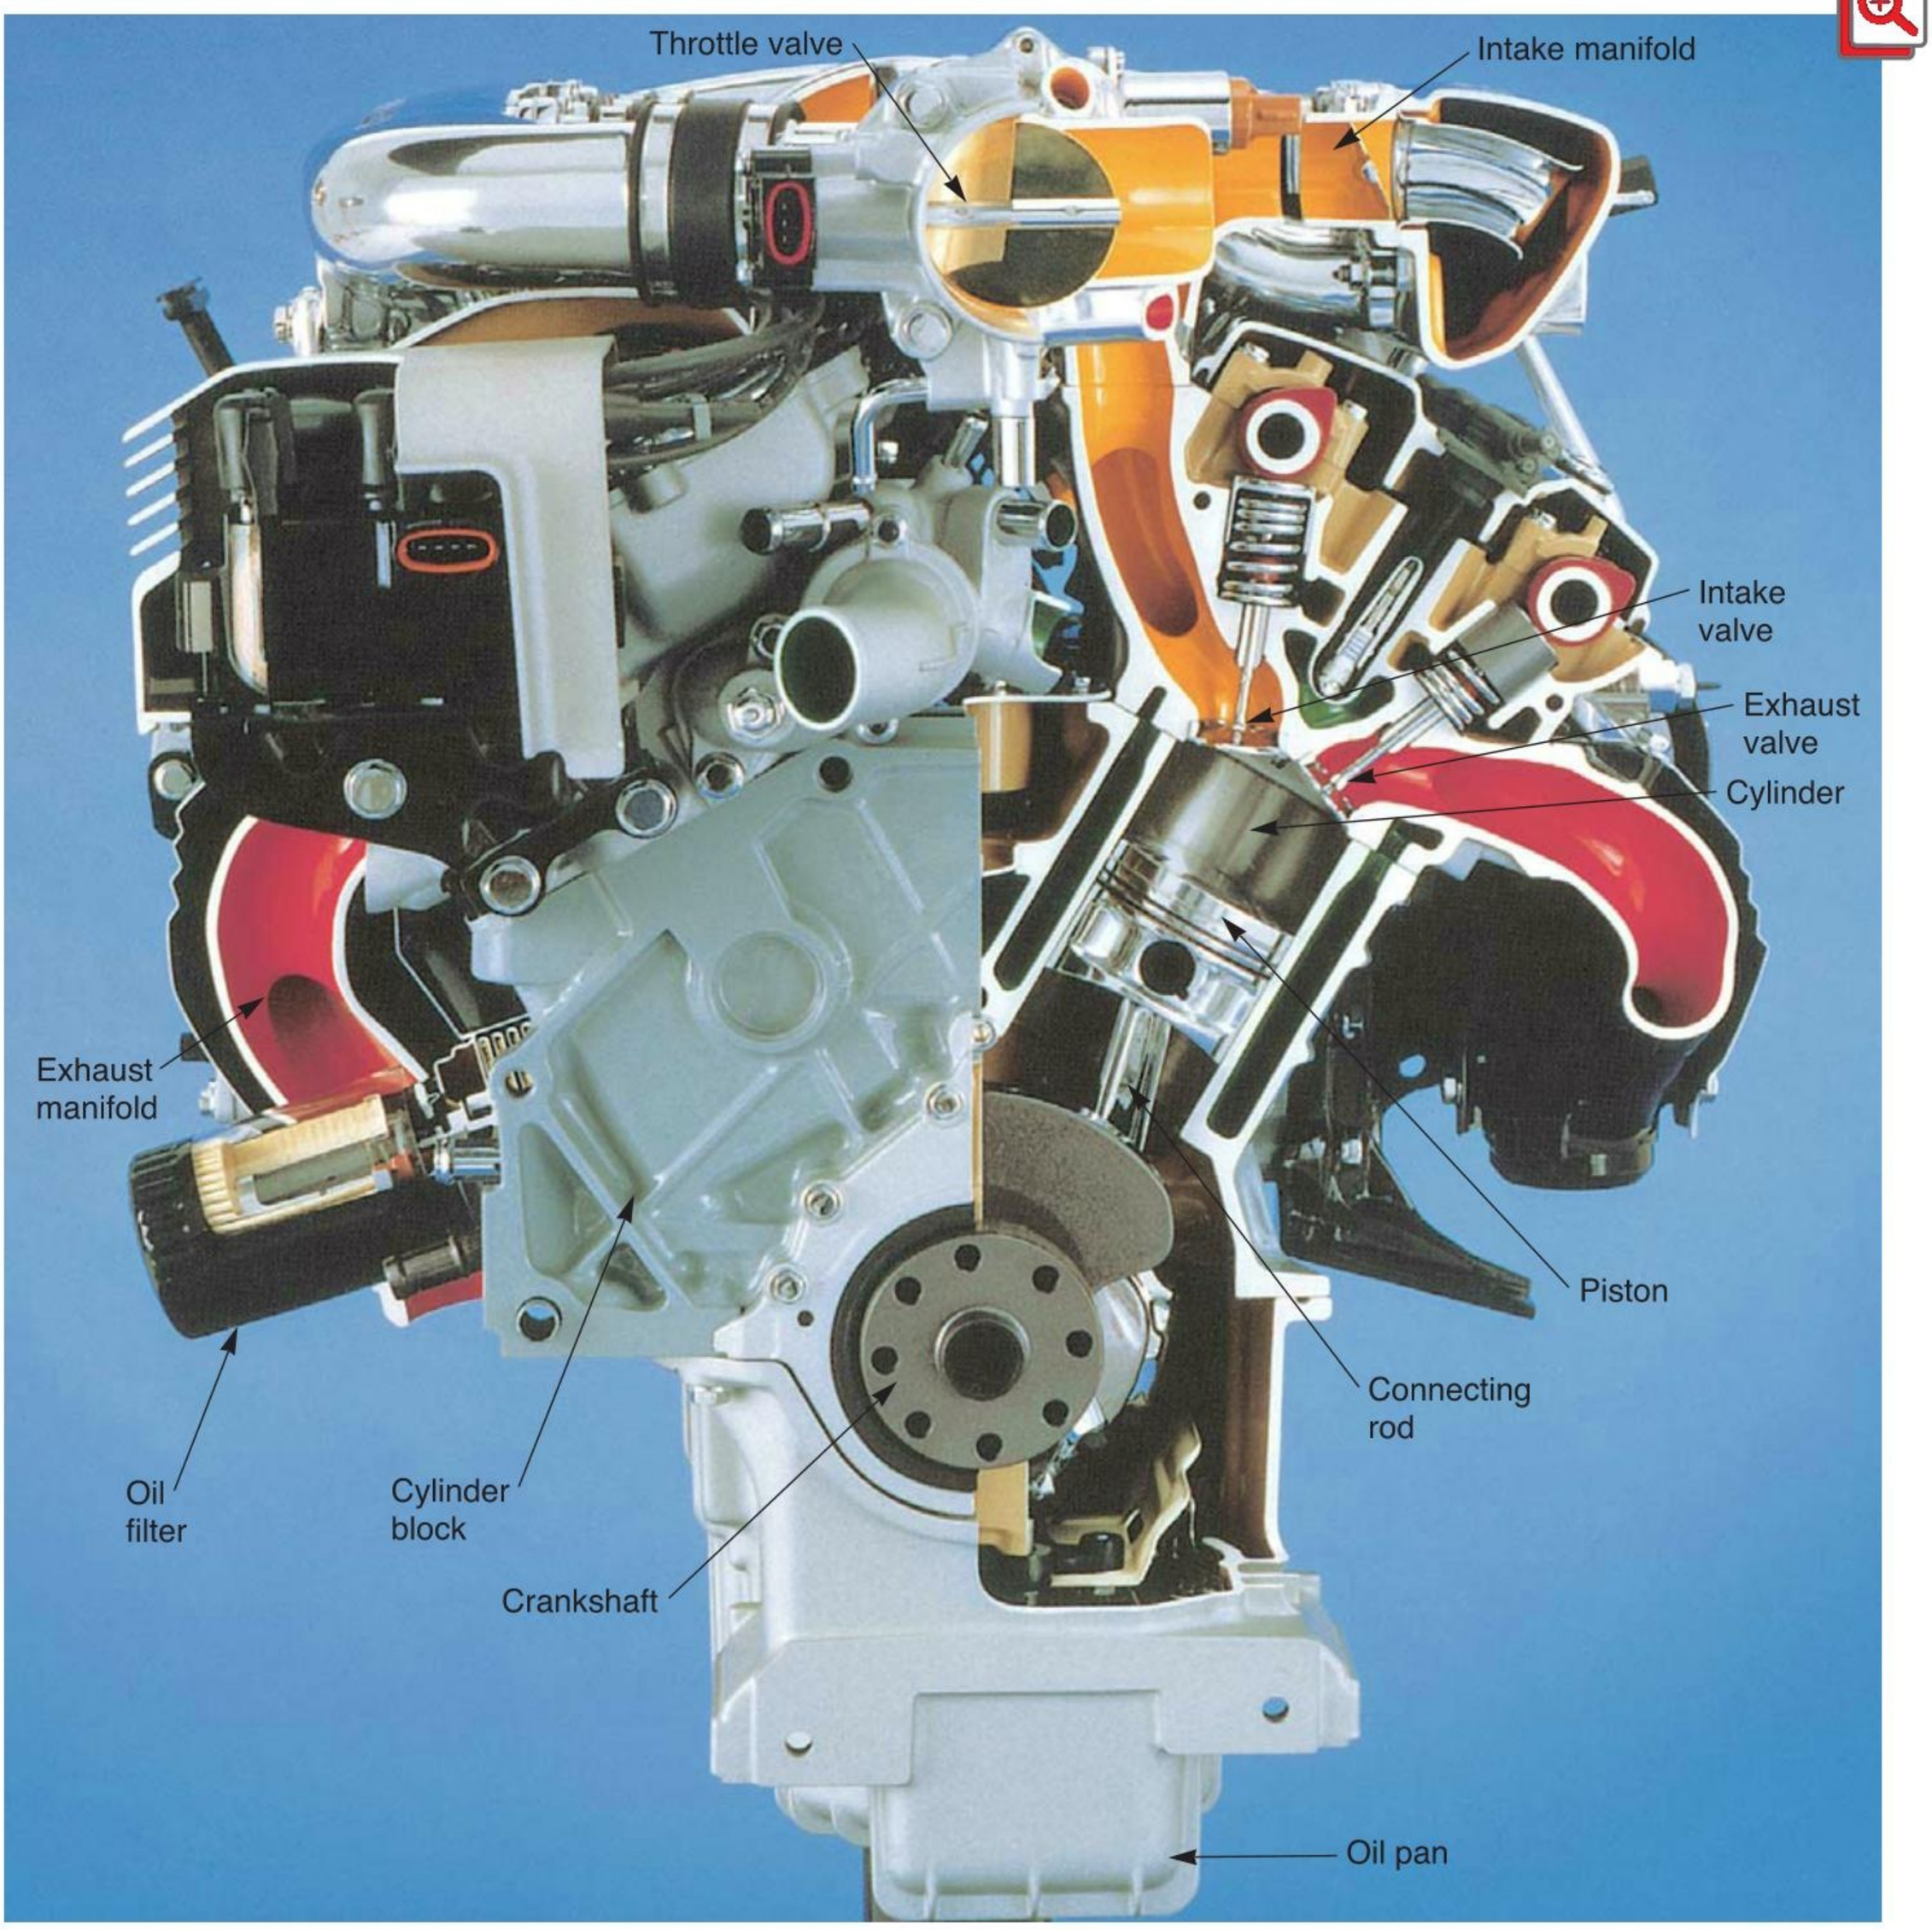
Figure 1-10. Study the major parts from the front view of a modern engine.

Copyright Goodheart-Willcox Co., Inc.

Basic Engine Parts

The basic parts of an engine are shown in **Figures 1-10** and **1-11**. Refer to these illustrations as each part is introduced.

- Block—The metal casting that holds all the other engine parts in place is the block.
- Cylinder—The cylinder is a round hole that is bored (machined) in the block. It guides piston movement.
- Piston—The piston is a cylindrical component that transfers the energy of combustion (burning of air-fuel mixture) to the connecting rod.



Ford

Figure 1-11. Locate the major parts with the rear view of the engine. The clutch and transmission often bolt to the steel crankshaft flange to harness the engine's high power output.

Copyright Goodheart-Willcox Co., Inc.

- Rings—The small gap around the sides of the piston are sealed by rings. They keep combustion pressure and oil from leaking between the piston and the cylinder wall (cylinder surface).
- Connecting rod—The connecting rod links the piston to the crankshaft.
- Crankshaft—The crankshaft changes the reciprocating (up-and-down) motion of the piston and rod into useful rotary (spinning) motion.
- Cylinder head—The top of the cylinder is covered and sealed by the cylinder head. It also holds the valves, rocker arms, and often, the camshaft.
- Combustion chamber—The combustion chamber is a small cavity (hollow area) between the top of the piston and the bottom of the cylinder head. The burning, or combustion, of the air-fuel mixture occurs in the combustion chamber.
- Valves—The valves open and close to control the flow of air or an air-fuel mixture into the combustion chamber and exhaust gases out of the combustion chamber.
- Camshaft—The opening of the valves is controlled by the camshaft.
- Valve springs—The valve springs keep the valves closed when they do not need to be open.
- Rocker arms—The rocker arms transfer camshaft action to the valves.
- Lifters—The lifters, or cam followers, ride on the camshaft and transfer motion to the other parts of the valve train.
- Flywheel—The flywheel helps keep the crankshaft turning smoothly. It also provides a large gear that is engaged by the starting motor during engine starting.

Automotive Engines

Automobile engines normally use a four-stroke cycle. Four separate piston strokes (up or down movements) are needed to produce one cycle (complete series of events). The piston must slide down, up, down, and up again to convert heat energy (burning fuel) into kinetic energy (spinning crankshaft).

Automotive engines are ***multi-cylinder engines***, which means they have more than one piston and cylinder. Today's vehicles can have 2-, 3-, 4-, 5-, 6-, 8-, 10-, or 12-cylinder engines. Additional cylinders generally increase engine size and power output, but they lower fuel economy. The industry trend is to smaller engines with 2, 3, and 4 cylinders. More power is needed for speeding up, or accelerating, as well as towing and traveling uphill. The additional cylinders smooth engine operation because there is less time (degrees of crankshaft rotation) between power (energy producing) strokes.

Computer System

The ***computer system*** uses electronic and electrical devices to monitor and operate various mechanical systems. Electronic controls are provided for the engine, drive train, suspension, instrumentation, restraint, and other systems. The use of computer systems has improved vehicle efficiency and dependability. Additionally, all on-board computers now have a powerful self-diagnostic capability. Today's vehicle computers can troubleshoot every major assembly, circuit, component, and system almost instantly.

There are three major parts of an automotive computer system:

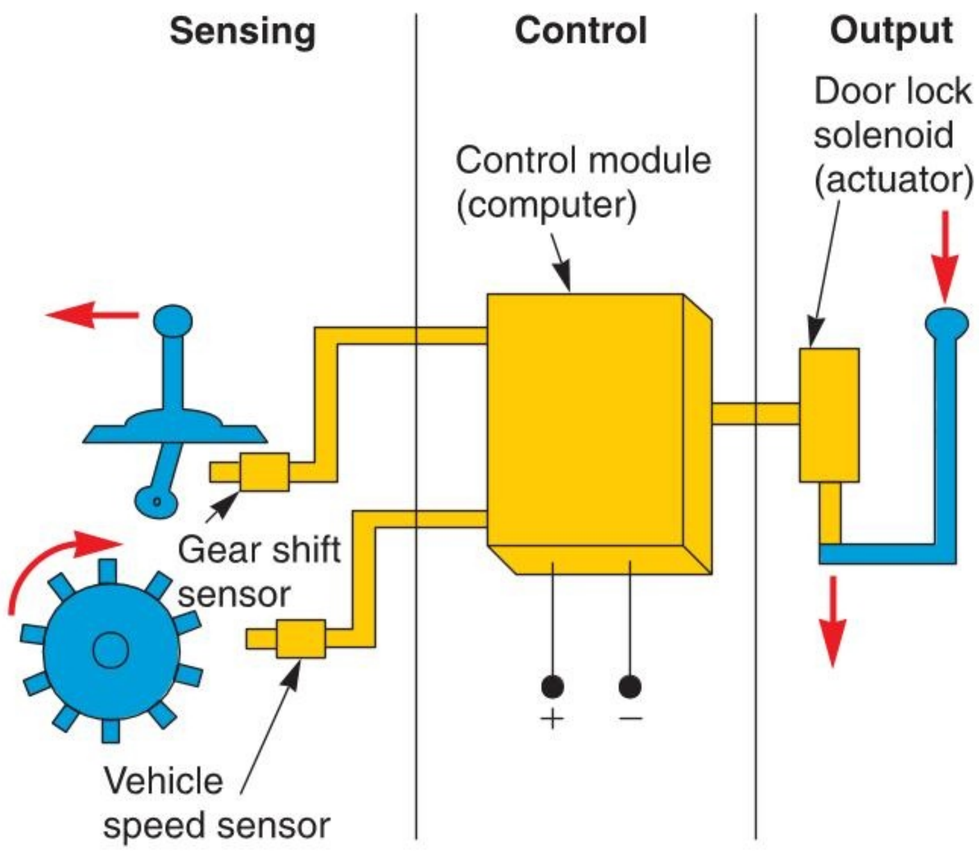
- Sensors—Sensors are input devices that can produce or modify electrical signals with a change in a condition, such as motion, temperature, pressure, speed, location, etc. The sensors are the "eyes, ears, and nose" of the computer control system.
- Electronic control module—The electronic control module is a computer (complex electronic circuits) that uses signals from input devices (sensors) to control various output devices (actuators). The control module is the "brain" of the computer control system.
- Actuators—Actuators are output devices, such as small electric motors or electromagnets, that can move parts when energized by the control module. The actuators serve as the "hands and arms" of the computer control system.

A modern car can have several control modules and dozens of sensors and actuators, all "talking" (transferring data) with a main computer processor. See **Figure 1-12**. A main computer processor is a larger, more complex control module with more memory than the other control modules wired into the vehicle's network. All system control modules are wired to this main computer processor to exchange data on vehicle operation. If any other sensor or system control module detects a problem, it will signal the main computer processor so it can turn on a dash warning light.

Tech Tip

Learn all you can about electricity and electronics. Now that an electronic network operates every major vehicle system, it is almost impossible to service anything on a car without handling some type of electric or electronic component. This book covers electronics in almost every chapter.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 1-12. This computer can operate the fuel injectors, fire the spark plug, and lock the car doors. When the sensors send the correct signals to their control modules, the electronic circuit energizes one or more of its circuit actuators. Solenoids and small electric motors can then convert the electrical signal into motion. This basic type of electronic control module is used in most major vehicle systems.

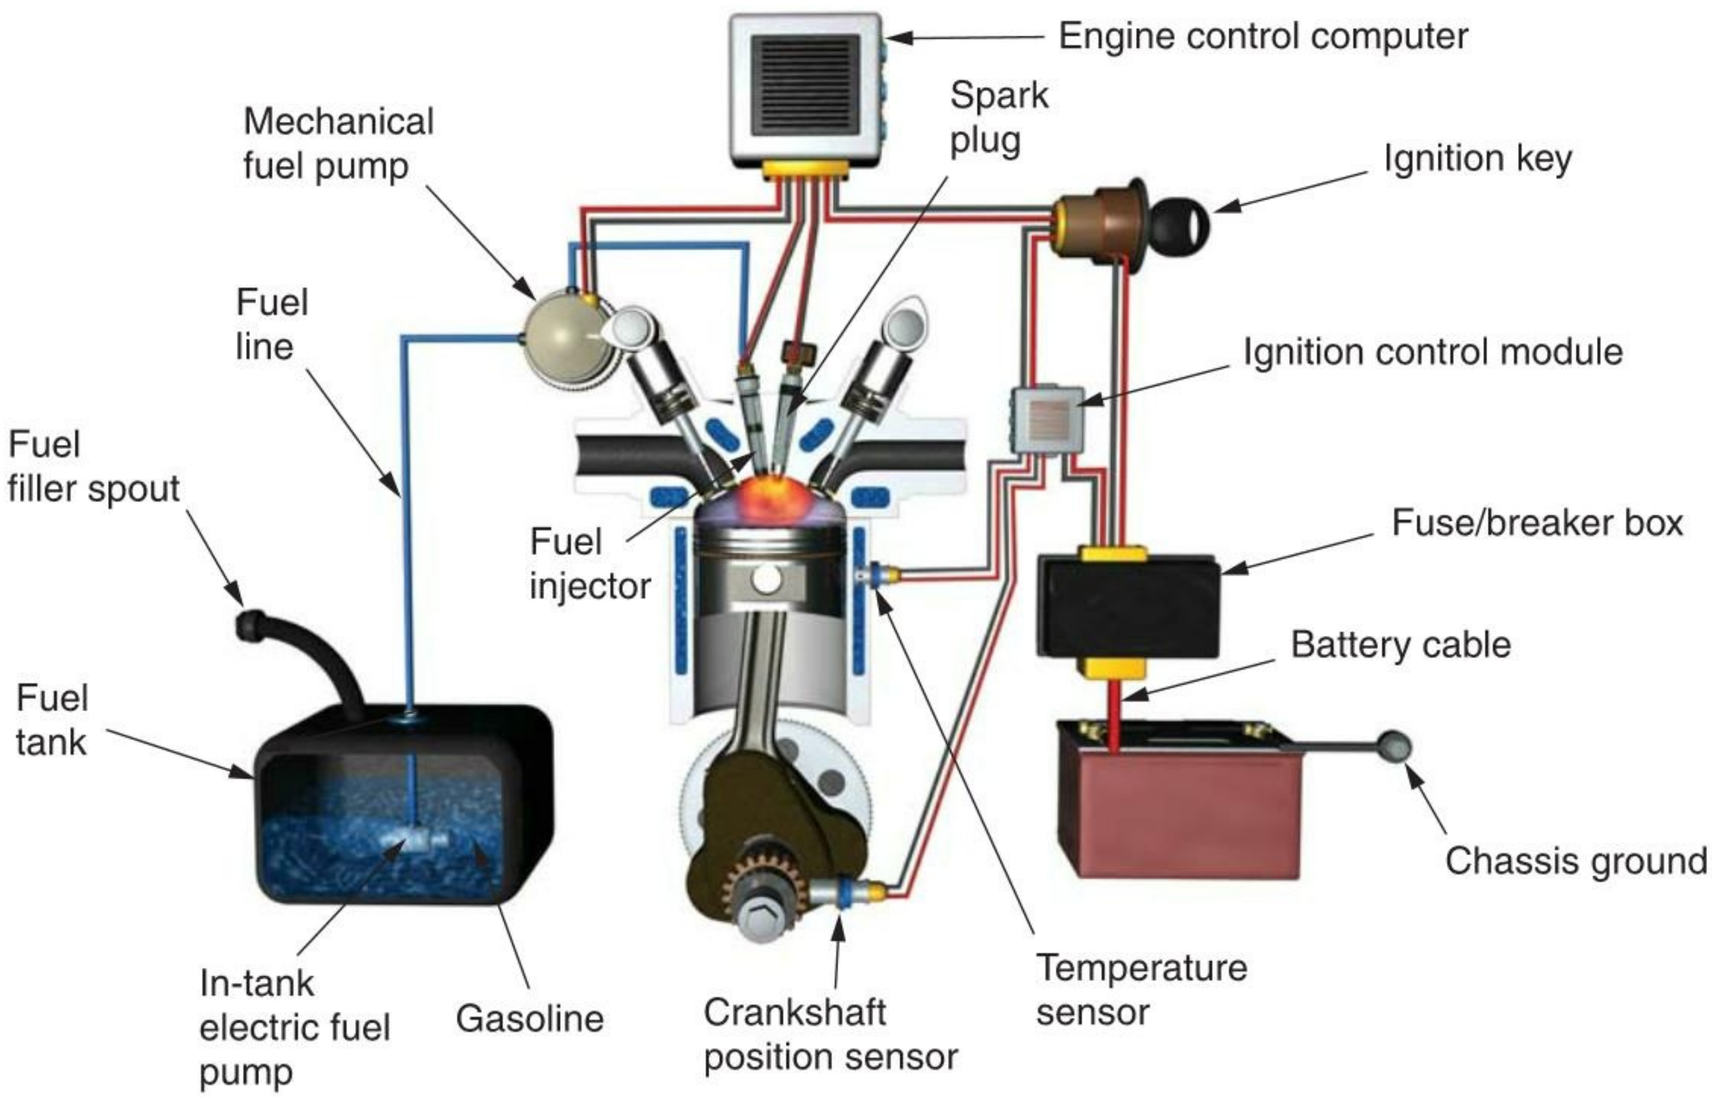
Fuel System

The ***fuel system*** must introduce the correct amount of fuel into the cylinders for efficient combustion (burning) inside the engine. This ensures that a very volatile (flammable) mixture exists inside the combustion chambers when the electric arc lights the mixture at a spark plug during the compression stroke. A spark plug provides an air gap between two large electrodes so a high-voltage electrical arc can ignite the air-fuel mixture in the combustion chamber of a gasoline engine cylinder. The ignition system spark plugs screw into the cylinder heads so electrodes and air gaps extend inside the combustion chambers of the gasoline engine.

The fuel system must also alter the ***air-fuel ratio*** (percentage of air and fuel) with changes in engine operating conditions (temperature, altitude, engine speed, load, and other variables). Refer to **Figure 1-13**.

Gasoline Injection System

Almost all late-model engines use ***direct gasoline injection systems***, which spray gasoline right into the combustion chambers above the pistons. In this type of system, an in-tank electric fuel pump forces



Basic Engine Ignition and Fuel Systems

Goodheart-Willcox Publisher

Figure 1-13. Note the basic parts and operation of an engine's fuel and ignition systems. The fuel tank usually stores gasoline. The in-tank electric fuel pump forces gasoline to an engine-mounted fuel pump. This pump increases fuel pressure to about 3000 psi and delivers this fuel to the injectors. The ignition system is used to start combustion. The spark plug must fire at the correct time during the compression stroke.

Copyright Goodheart-Willcox Co., Inc.

fuel from the fuel tank to the engine. Another engine-mounted mechanical fuel pump highly pressurizes this fuel and forces it to the electrically operated fuel injectors (fuel valves). The engine control module, reacting to electrical data it receives from the engine sensors, energizes the fuel injectors. When the computer energizes an injector, an electromagnet inside the injector pulls the injector nozzle open to allow a fine mist of fuel to spray into the combustion chamber, mixing with the air already inside the cylinder.

A throttle valve controls airflow, engine speed, and engine power. When the throttle valve is open for more engine power output, the computer holds the injectors open longer, allowing more fuel to spray out into the combustion chambers. When the throttle valve is closed, the computer opens the injectors for only a small amount of time, reducing engine power output. The throttle valve (air valve) is mechanically or electrically connected to the accelerator pedal. When the floor-mounted pedal is pressed, the throttle valve opens. This increases the amount of air and fuel entering the engine for more power and speed.

Electrical System

The vehicle's electrical system consists of several subsystems (smaller circuits), including the ignition, starting, charging, and lighting systems. Each subsystem is designed to perform a specific task, such as "fire" the spark plugs to ignite the engine's air-fuel mixture, electrically rotate the crankshaft to start the engine, illuminate the highway for safe night driving, etc.

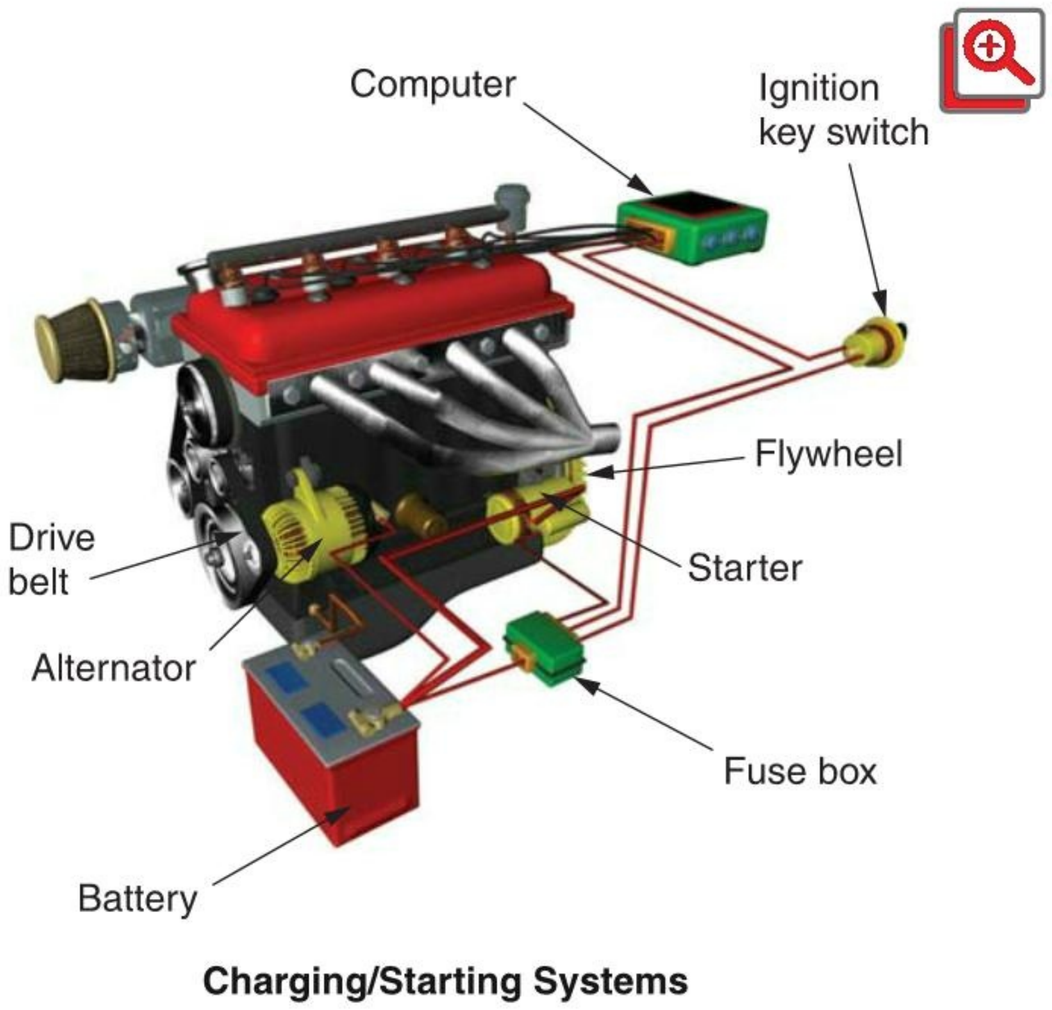
Ignition System

An ***ignition system*** is needed on gasoline engines to ignite the air-fuel mixture. It produces a high-voltage surge that jumps, or arcs, across the air gap at the spark plug tip at the correct time. This causes the air-fuel mixture to start to burn and expand in the combustion chamber.

Starting System

The ***starting system*** has a powerful electric starting motor, which rotates the engine's crankshaft until the engine "fires" and runs on its own power. The major parts of the starting system are shown in **Figure 1-14**.

A battery provides the electricity for the starting system. The driver turns the ignition key to the start position or presses an engine start button. The current then flows through the starting circuit to energize the starting motor. The starting motor then spins the crankshaft. As soon as the engine starts, the driver releases the key or button so the engine keeps running. With late-model cars, the computer de-energizes and disengages the starting motor as soon as the engine starts and its speed increases.



Charging/Starting Systems

Goodheart-Willcox Publisher

Figure 1-14. Note the location of basic parts of conventional starting and charging systems. These parts are eliminated in hybrid vehicles with the motor-generator.

Charging System

The ***charging system*** is needed to replace electrical energy drawn from the battery. With a 12-volt battery, a belt-driven alternator forces electric current back into the battery.

When the engine is running, a drive belt spins the alternator pulley. The alternator can then produce electricity to recharge the battery and operate other electrical needs of the vehicle. A voltage regulator, usually built into the alternator, controls the voltage and current output of the alternator.

Tech Tip

Most late-model hybrid vehicles do not need conventional starting and charging systems with a separate alternator and starting motor. Instead, hybrids use a motor-generator to recharge the batteries and "crank the engine" for start-up. This reduces vehicle weight and complexity for added fuel economy and dependability.

Copyright Goodheart-Willcox Co., Inc.

Lighting System

The ***lighting system*** consists of a vehicle's interior and exterior lights and all the components that operate them (fuses, wires, switches, relays, etc.). The exact circuit and part configurations will vary from one model to another.

The exterior lights typically include the headlights, turn signals, brake lights, parking lights, backup lights, and side marker lights. The interior lights include the dome light, trunk light, instrument panel lights, and other courtesy lights.

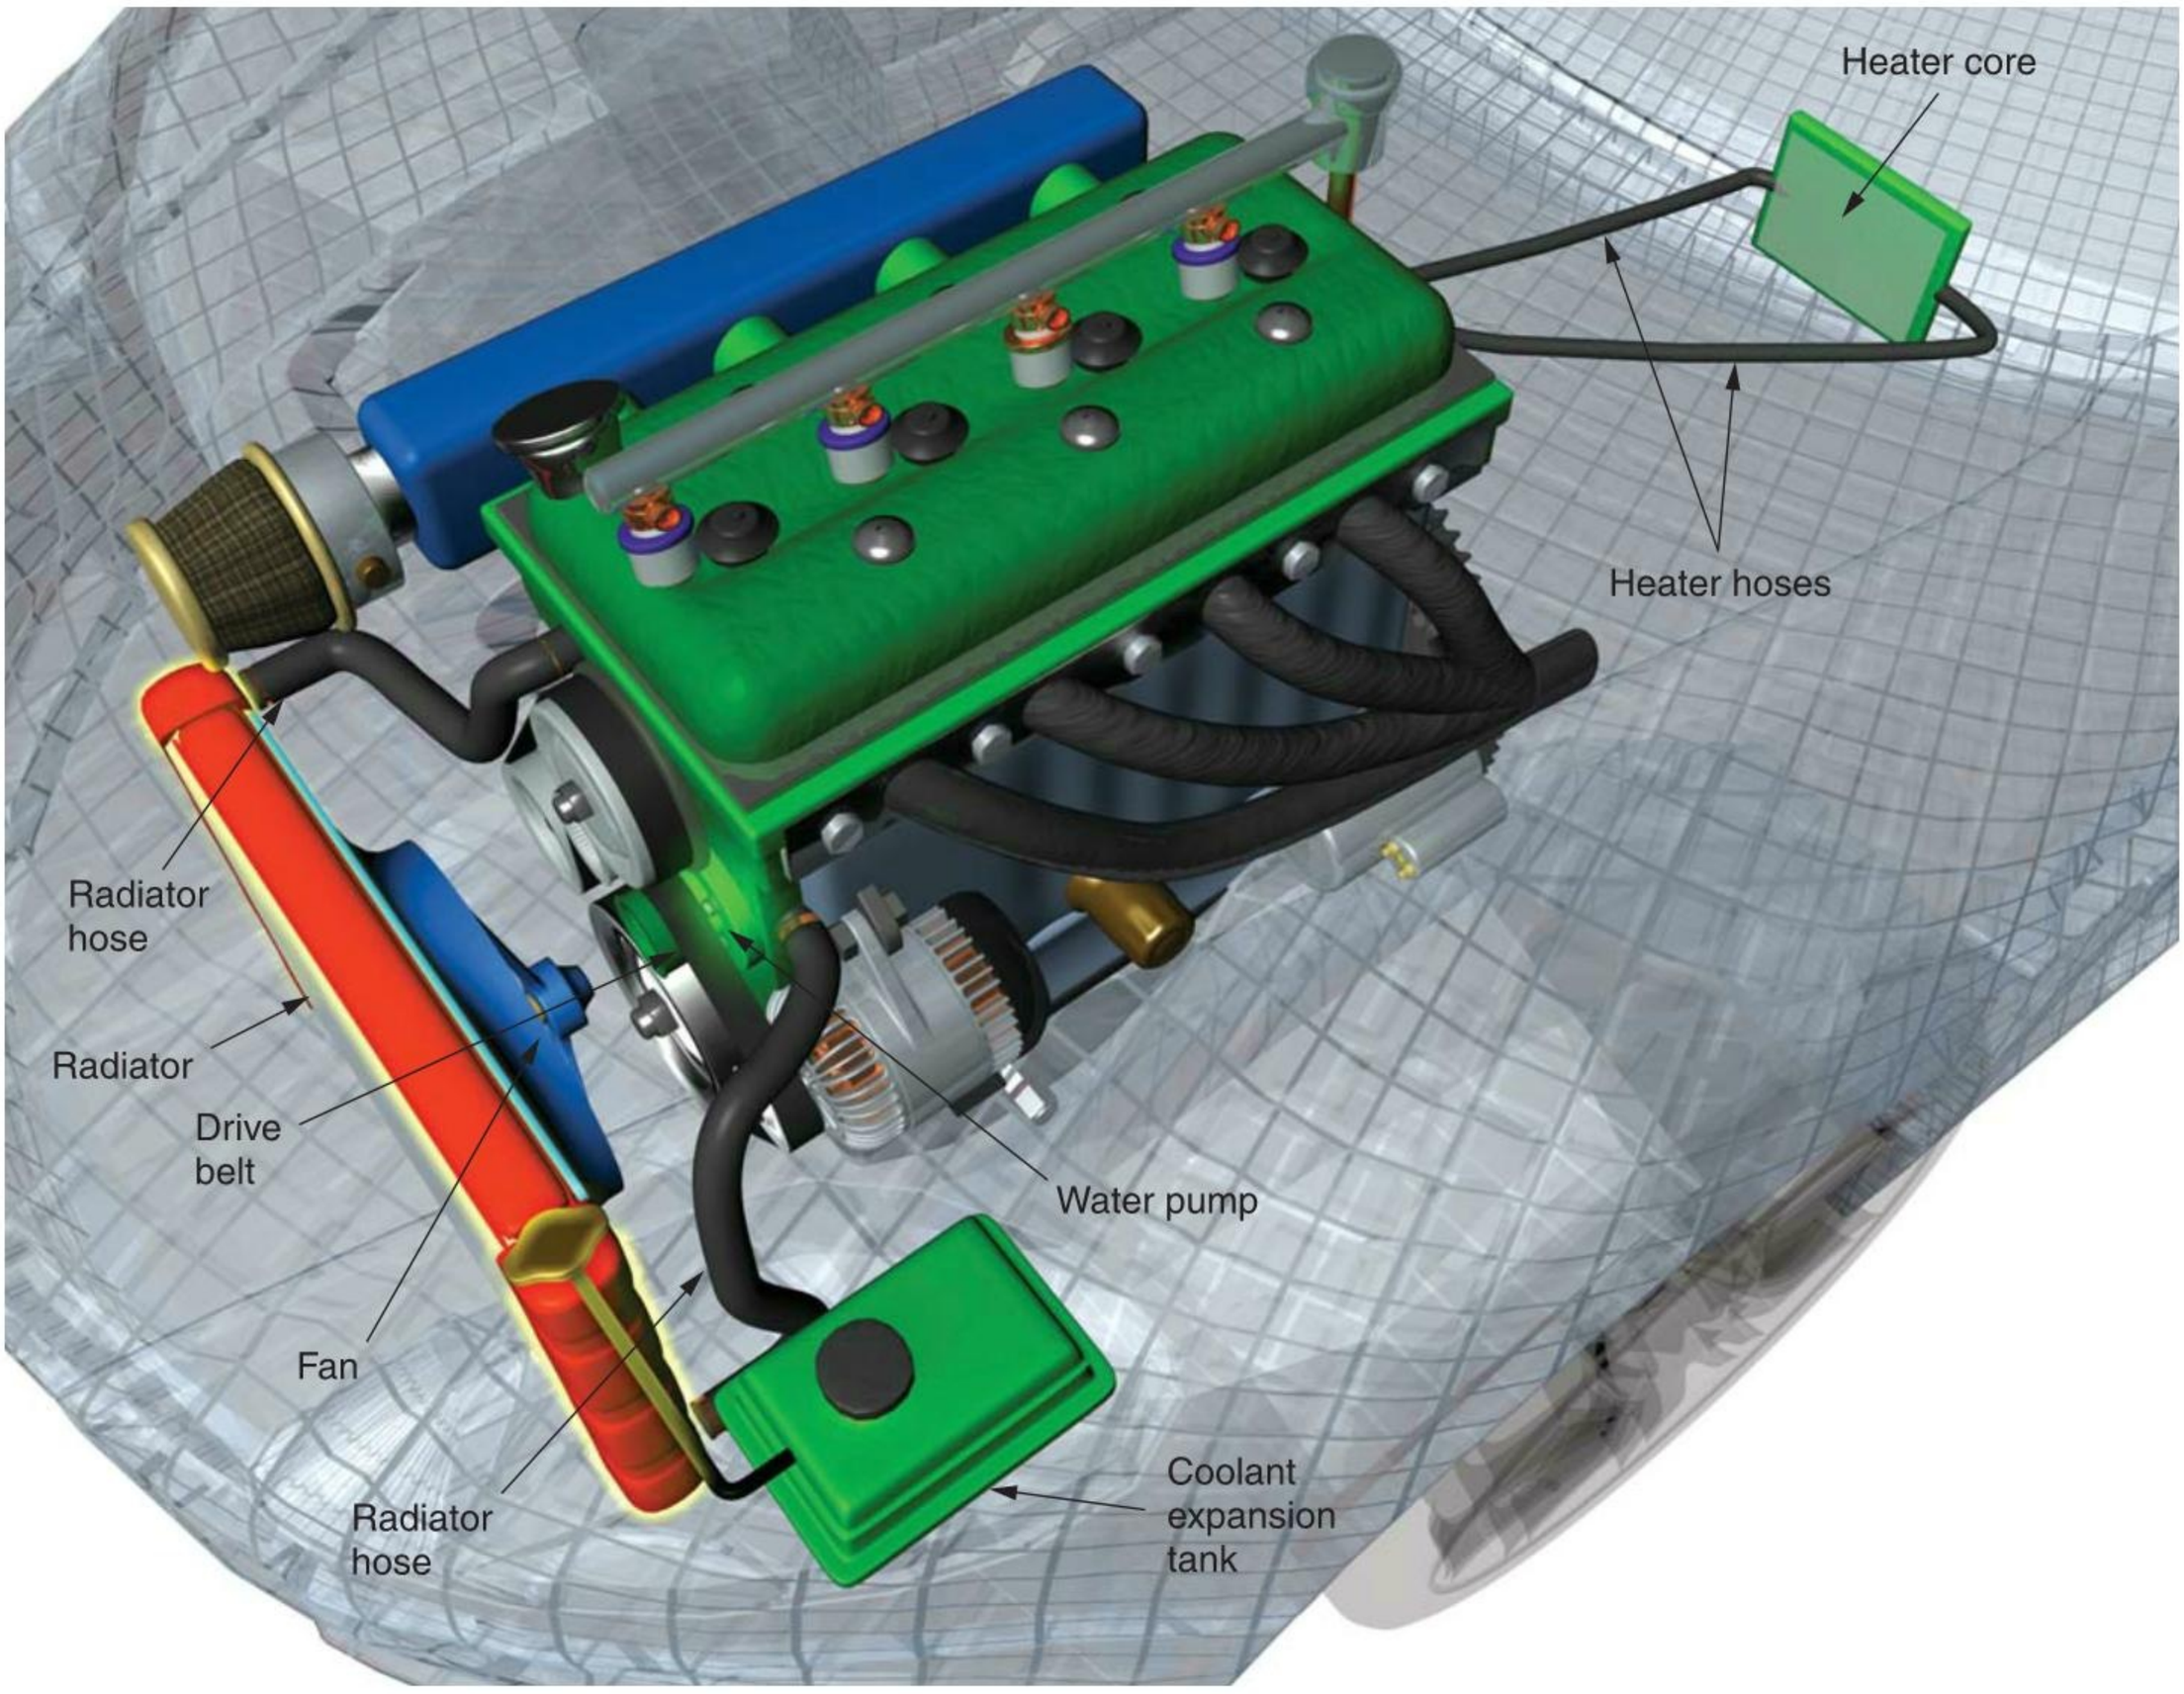
Cooling and Lubrication Systems

The cooling and lubrication systems are designed to prevent engine damage and wear. They are vital systems that prevent the engine from self-destructing.

The ***cooling system*** maintains a constant engine operating temperature. It removes excess combustion heat to prevent engine damage and also speeds engine warm-up. Look at **Figure 1-15**.

The water pump forces coolant (water and antifreeze solution) through the inside of the engine, hoses, and radiator.

The coolant collects heat from the hot engine parts and carries it back to the radiator. The radiator



Cooling System

Goodheart-Willcox Publisher

Figure 1-15. The cooling system must protect the engine from the heat of combustion. Combustion heat could quickly and easily melt and ruin many aluminum engine parts. For exhaust cleanliness, the cooling system must also speed engine warm-up and maintain a constant operating temperature.

Copyright Goodheart-Willcox Co., Inc.

allows the coolant heat to transfer into the outside air. An engine fan draws cool air through the radiator.

The thermostat controls coolant flow and engine temperature. It is usually located where the top radiator hose connects to the engine.

The ***lubrication system*** reduces friction and wear between internal engine parts. It circulates clean, filtered oil to high-friction points in the engine, such as bearings, camshaft, crankshaft, and pistons. The lubrication system also helps cool the engine by carrying heat away from high-friction points in the engine.

Exhaust and Emission Control Systems

The ***exhaust system*** quiets the noise produced during engine operation and routes engine exhaust gases to the rear of the vehicle body. **Figure 1-16** illustrates the basic parts of an exhaust system. Trace the flow of exhaust gases from the engine exhaust manifold to the tailpipe. Learn the names of the parts.

Various ***emission control systems*** are used to reduce the amount of toxic (poisonous) substances produced by an engine and fuel system. Some systems prevent fuel vapors from entering the atmosphere (air surrounding the earth). Other emission control systems remove unburned and partially burned fuel from the engine exhaust. Later chapters cover these systems in detail.

Drive Train Systems

The ***drive train*** transfers turning force from the engine crankshaft to the drive wheels. Drive train configurations vary, depending on vehicle design. The most common drive-train configurations are front-wheel drive, rear-wheel drive, and all-wheel drive.

Front-wheel drive is commonly found on passenger cars. A front-wheel drive vehicle has superior traction because the weight of the engine and transaxle is directly above the drive wheels. Note the lightweight "dead axle" in the rear of the car. See **Figure 1-17A**.

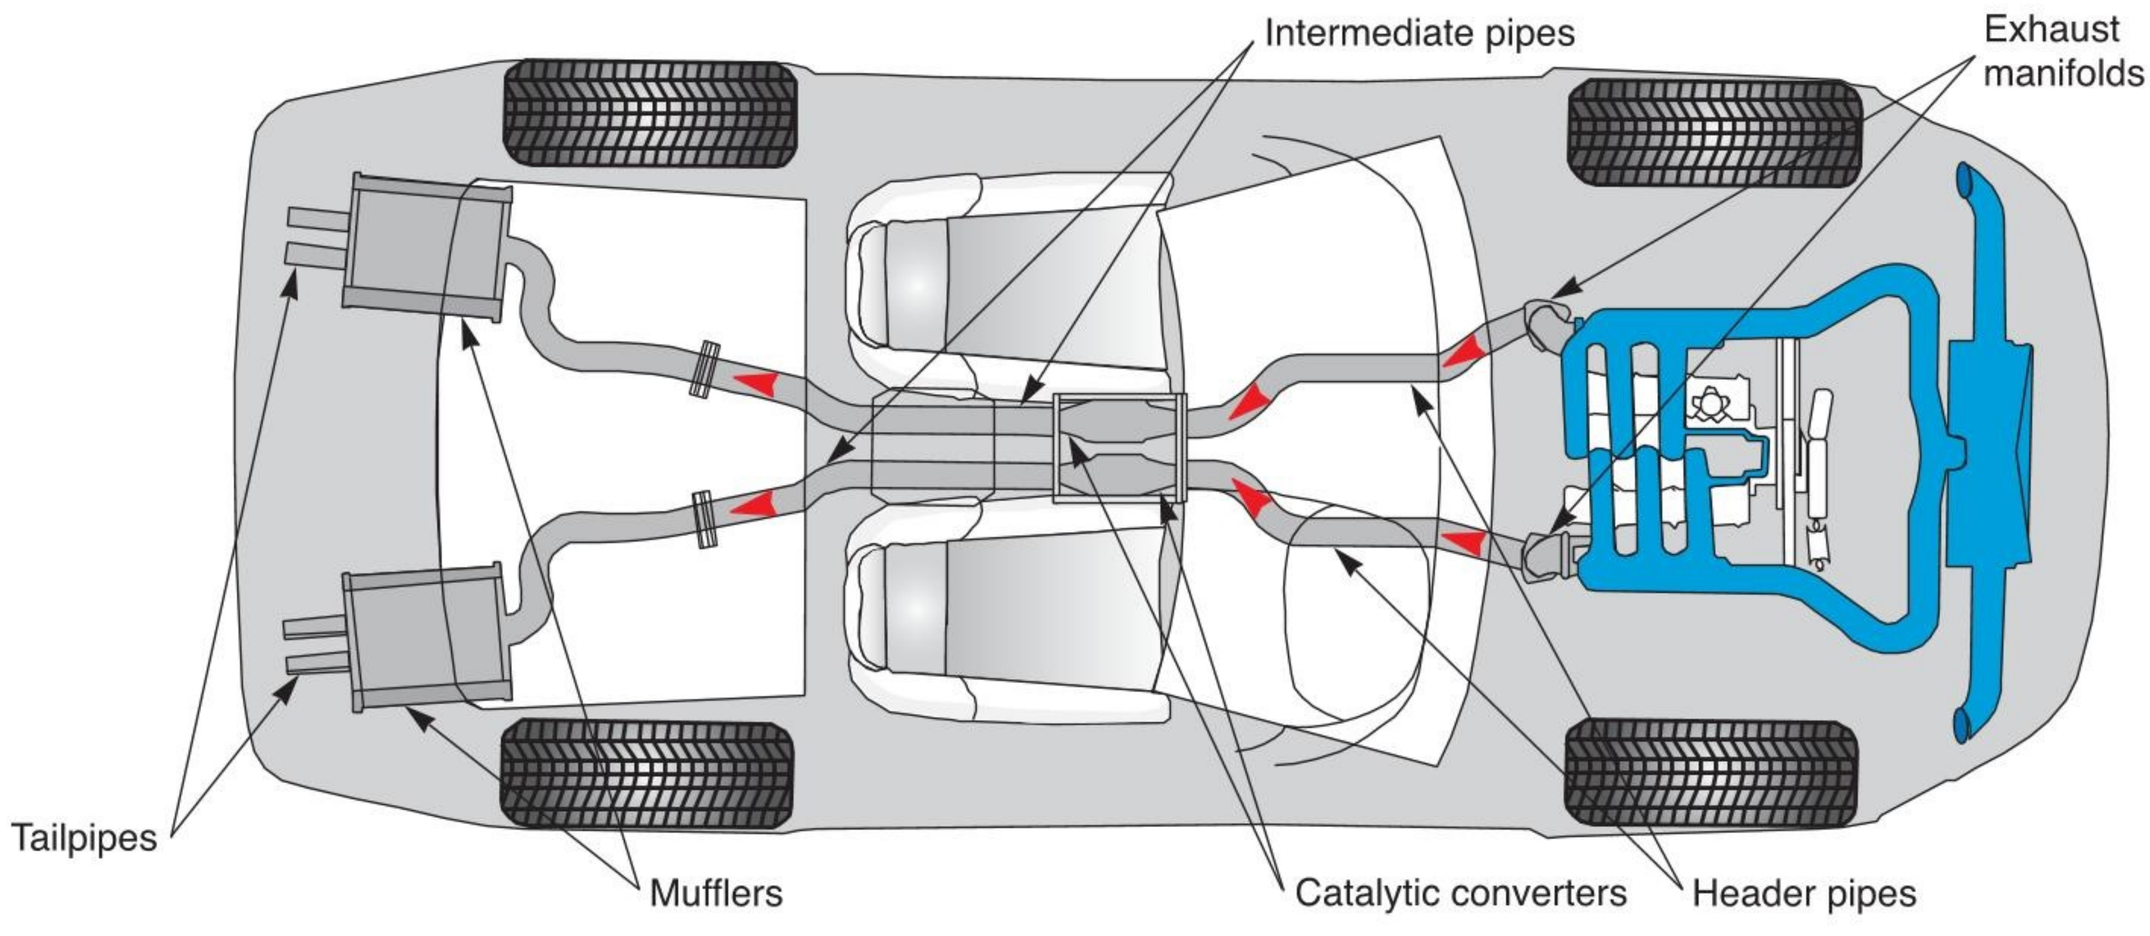
The front-engine, ***rear-wheel drive*** configuration shown in **Figure 1-17B** is popular because the heavy engine is still in the front for safety. Because of the weight distribution, vehicles with this drive train configuration have more precise steering than front-engine, front-wheel drive vehicles. However, they have less traction on slippery surfaces than front-wheel drive vehicles because less of the vehicle's weight is over the drive wheels.

Some rear-wheel drive vehicles have a ***mid-engine drive train***. In this configuration, the engine is located right behind the driver's seat with a transaxle mounted behind it. This provides for almost equal weight distribution to each tire for high cornering capabilities. See **Figure 1-17C**.

A vehicle with ***all-wheel drive*** often has the engine in the front and twin differentials to distribute engine/electric power to all four wheels and tires. It has the excellent traction on wet or snow-covered roads. See **Figure 1-17D**.

Drive Train Parts

The drive train parts commonly found on a front-engine, rear-wheel-drive vehicle include the clutch,



Nissan

Figure 1-16. The exhaust system carries burned gases to the rear of the vehicle. It also reduces engine noise.

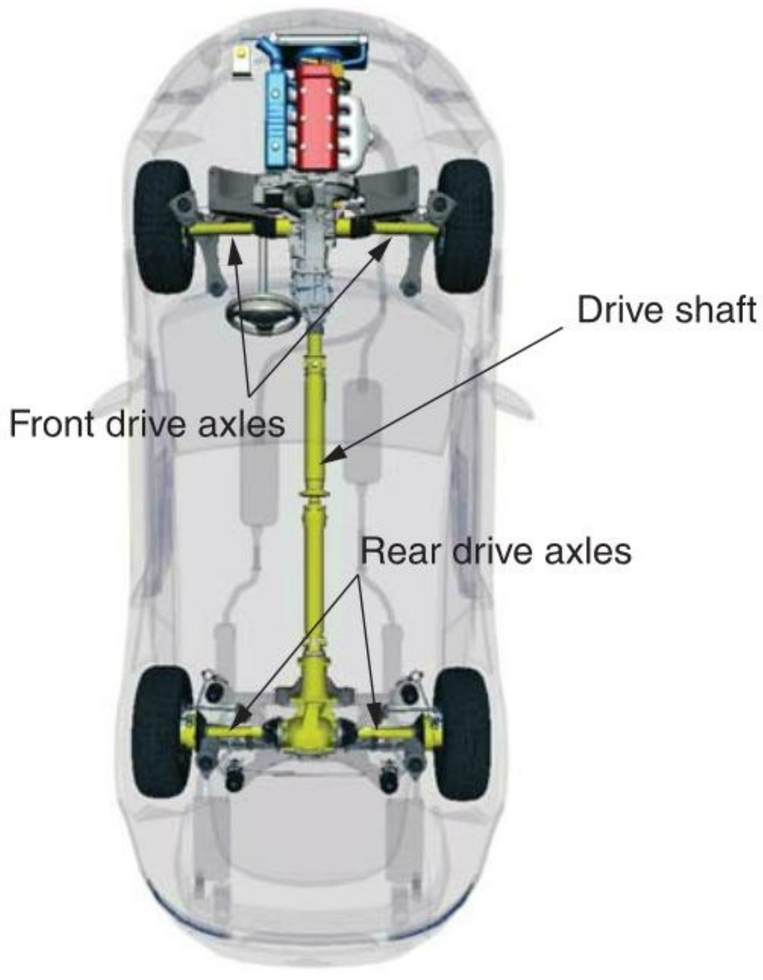
C—Mid-Engine, Rear-Wheel Drive



D—All-Wheel Drive

Figure 1-17. Note the location of the engine in different drive train designs. A—Front-engine, front-wheel drive is the most common type of drive train found on modern passenger vehicles. B—Front-engine, rear-wheel drive is often used on large luxury cars and pickup trucks. C—Mid-engine, rear-wheel drive is found on a few high performance sports cars. D—All-wheel drive is superior to front- or rear-wheel drive on wet or snow-covered roads.

Copyright Goodheart-Willcox Co., Inc.

transmission, drive shaft, and rear axle assembly. The drive train parts used on most front-engine, front-wheel-drive vehicles include the clutch, transaxle, and drive axles. Refer to **Figure 1-17** as these components and assemblies are discussed.

Discussed briefly, the parts included in the drive train can vary with vehicle design and whether the vehicle is front-wheel drive or rear-wheel drive.

Clutch

The clutch allows the driver to engage or disengage the engine and manual transmission or transaxle. When the clutch pedal is in the released position, the clutch locks the engine flywheel and the transmission input shaft together. This causes engine power to rotate the transmission gears and other parts of the drive train to propel the vehicle. When the driver presses the clutch pedal, the clutch disengages power flow and the engine no longer turns the transmission input shaft and gears. Refer to **Figure 1-17**.

Transmission

The transmission uses various gear combinations, or ratios, to multiply engine speed and torque to accommodate driving conditions. Low gear ratios allow the vehicle to accelerate quickly. High gear ratios permit lower engine speed, providing good gas mileage.

A manual transmission lets the driver change gear ratios to better accommodate driving conditions, **Figure 1-18A**. A clutch is used to engage and disengage the gearsets when changing gear ratios and vehicle speeds.

A ***semi-automatic transmission*** often uses paddle shift buttons on the steering wheel instead of a console shift lever. The computer control system reacts to signals from the paddle shifter switches to change gear engagement semi-automatically using electric actuators.

An automatic transmission, on the other hand, does not have to be shifted by the driver. It uses an internal hydraulic system and electronic controls to shift gears. The input shaft of an automatic transmission is connected to the engine crankshaft through an oil-filled torque converter (fluid coupling) instead of a dry friction clutch. The elementary parts of an automatic transmission are pictured in **Figure 1-18B**.

Drive Shaft

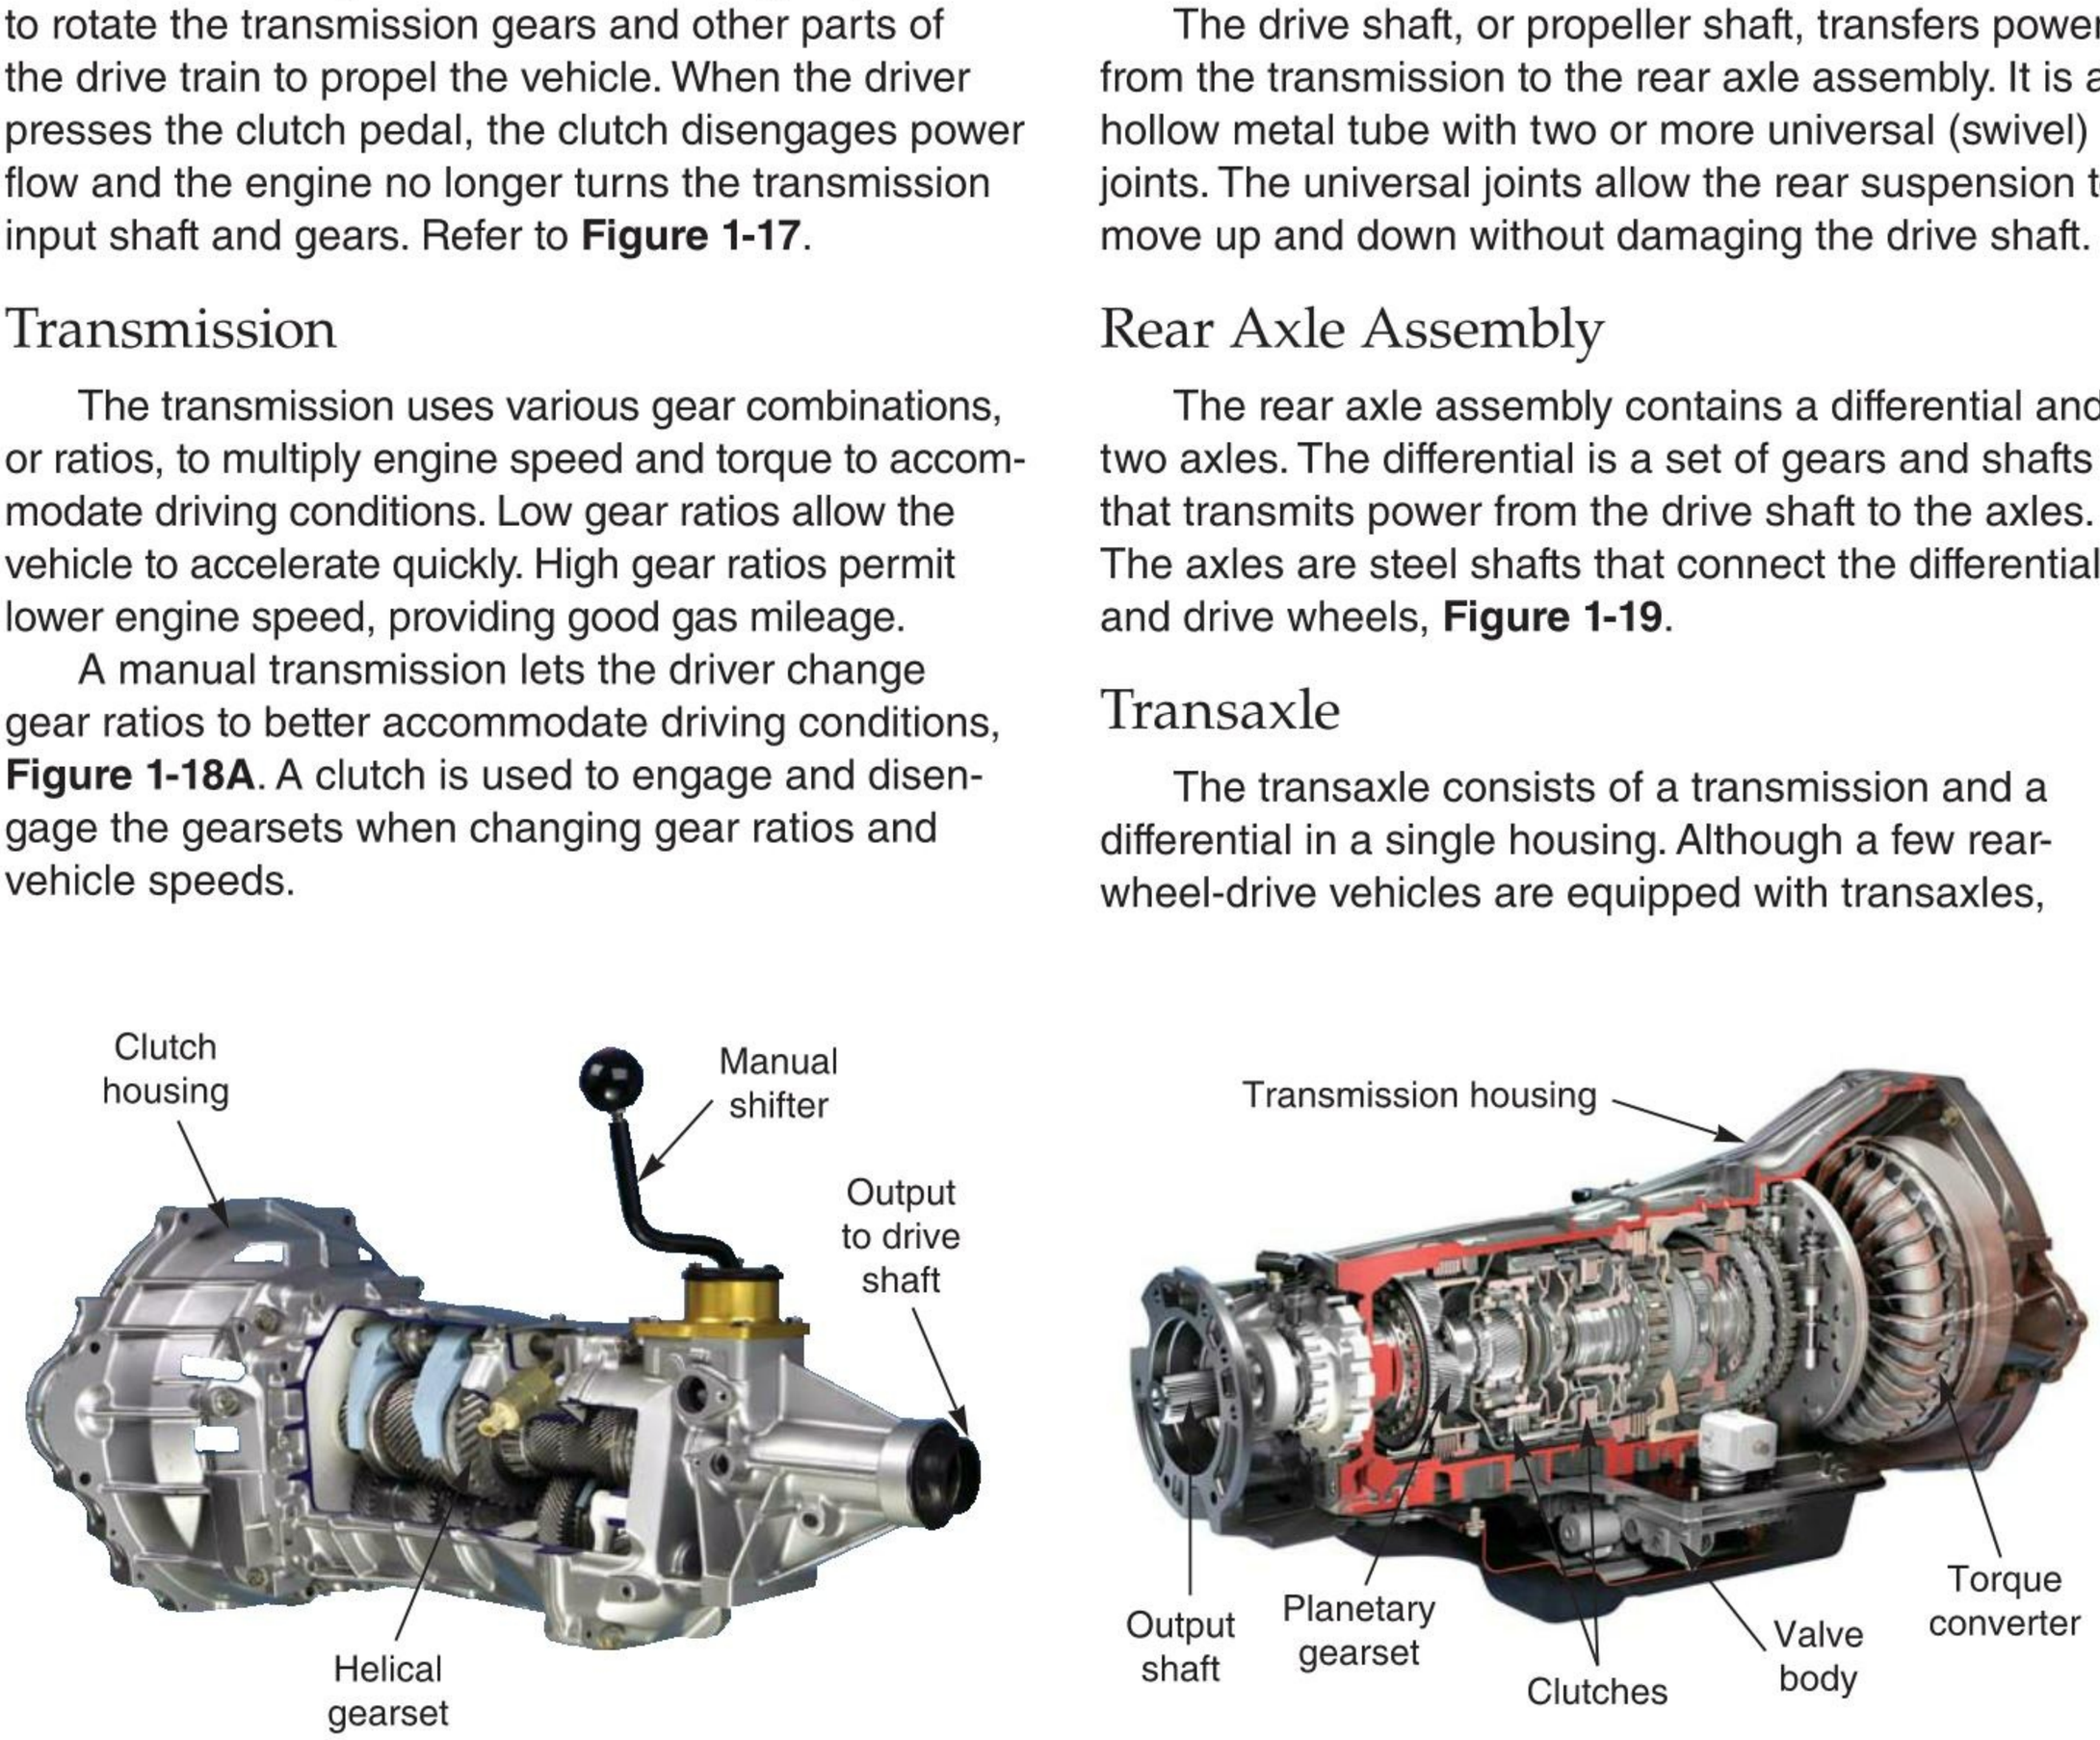
The drive shaft, or propeller shaft, transfers power from the transmission to the rear axle assembly. It is a hollow metal tube with two or more universal (swivel) joints. The universal joints allow the rear suspension to move up and down without damaging the drive shaft.

Rear Axle Assembly

The rear axle assembly contains a differential and two axles. The differential is a set of gears and shafts that transmits power from the drive shaft to the axles. The axles are steel shafts that connect the differential and drive wheels, **Figure 1-19**.

Transaxle

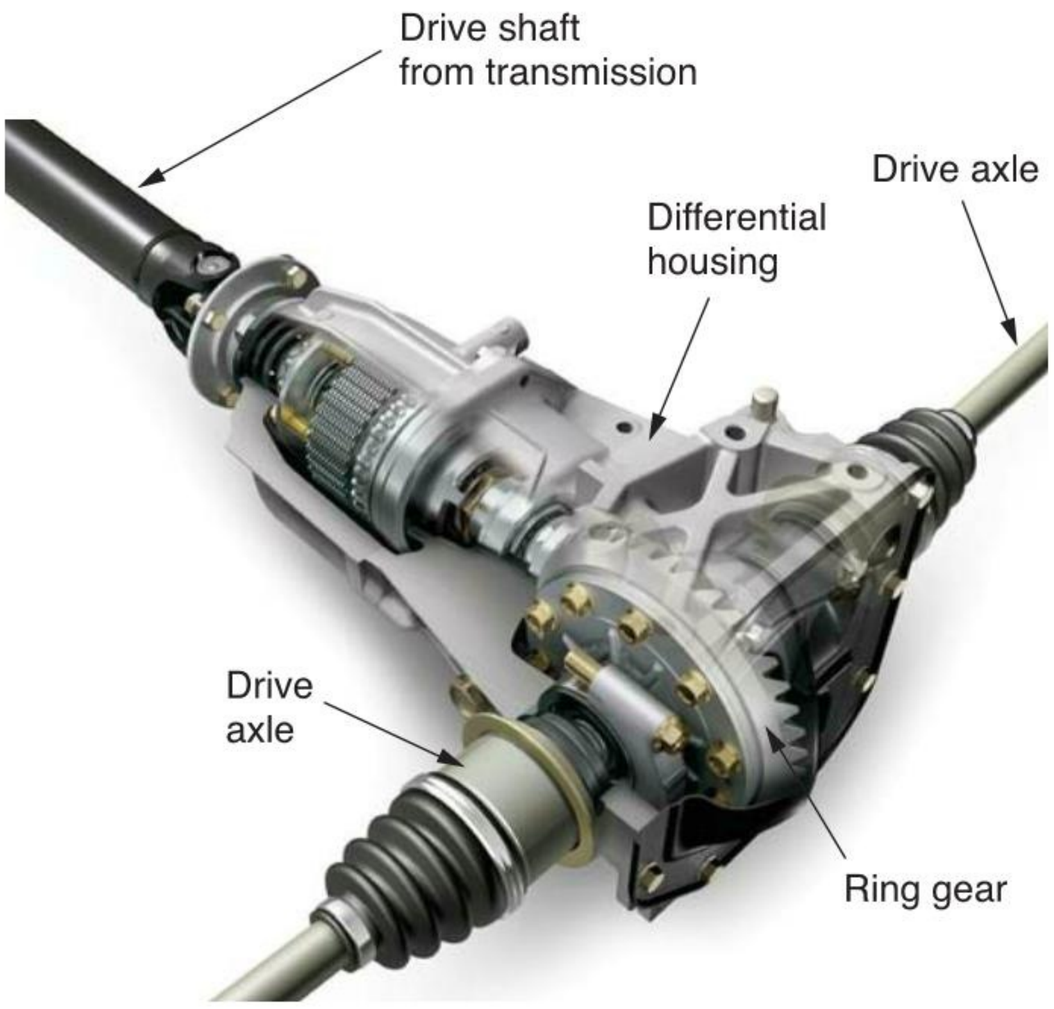
The transaxle consists of a transmission and a differential in a single housing. Although a few rear-wheel-drive vehicles are equipped with transaxles,



Chrysler, Ford

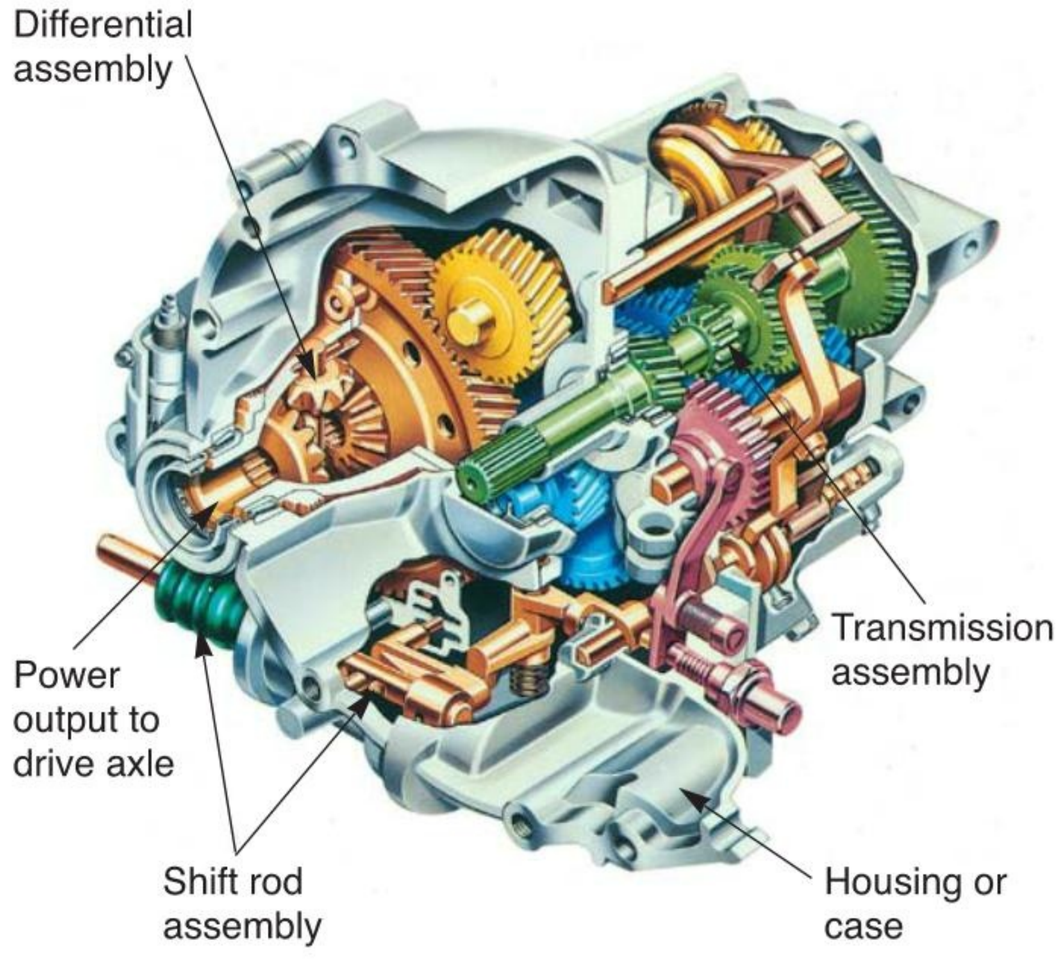
Figure 1-18. Study the two major types of automobile transmissions.

Copyright Goodheart-Willcox Co., Inc.



Mazda

Figure 1-19. The rear axle assembly contains the differential and two axles that turn the rear drive wheels. The drive shaft sends power to the rear axle assembly.



Ford

Figure 1-20. A transaxle contains a transmission and a differential in one housing.

they are most commonly used with front-wheel-drive vehicles. Both manual and automatic transaxles are available. The internal parts of a modern transaxle assembly are illustrated in **Figure 1-20**.

Front Drive Axles

The front drive axles connect the transaxle differential to the hubs and wheels of the vehicle. These axles are equipped with constant-velocity joints, which allow the front wheels to be turned to the left or right and to move up and down.

Suspension, Steering, and Brake Systems

The suspension, steering, and brake systems are the movable parts of the chassis. They bolt or anchor to the frame and provide directional stability when maneuvering. Directional stability is the ability of a vehicle to corner, brake, and accelerate with minimal body roll and body dive. Poor directional stability will cause a car to skid off the road in a high-speed turn or to skid out of control during high-speed braking.

Suspension System

The ***suspension system*** allows the vehicle's wheels and tires to move up and down with little effect on body movement. This makes the vehicle's ride smooth and safe. The suspension system also prevents excessive body lean when turning corners quickly. As you can see in **Figure 1-21**, various springs, bars, swivel joints, and arms make up the suspension system.

Steering System

The ***steering system*** allows the driver to control vehicle direction by turning the wheels right or left. It uses a series of gears, swivel joints, and rods to do this. Study the names of the parts in **Figure 1-21**.

Brake System

The ***brake system*** produces friction to slow or stop the vehicle. When the driver presses the brake pedal, fluid pressure actuates a brake mechanism at each wheel, forcing friction material (brake pads or shoes) against metal discs or drums to slow wheel rotation. **Figure 1-22** shows the fundamental parts of a brake system.

Accessory and Safety Systems

Common ***accessory systems*** include the air conditioner, sound system, power seats, power windows, and rear window defogger. Common ***safety systems*** include seat belts, air bags, and security systems. See **Figures 1-23** and **1-24**.

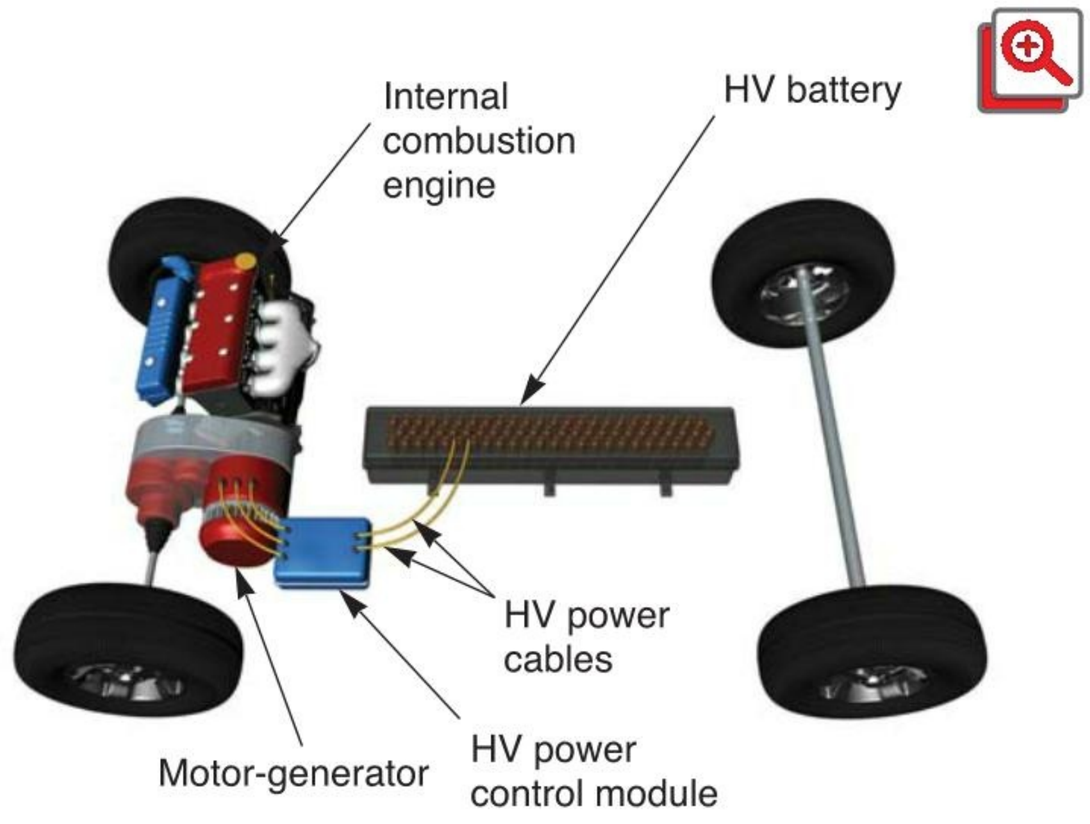
Goodheart-Willcox Publisher

Figure 1-24. The lighting and instrumentation systems are now controlled and connected with the body computer separate from the engine or drive train control computers. Wheel speed sensors tell when to re-aim the headlights, sound an alarm through the stereo speakers, energize the turn signals, put a hot engine warning display up in the dash, or tell you the car's present location on a detailed map. These complete electronic networks are fully explained in later chapters.

Hybrid Vehicles

A ***hybrid electric vehicle (HEV)*** uses two methods of propulsion: an internal combustion engine and an electric drive train, which consists of a high voltage (HV) battery and at least one motor-generator assembly. All major auto manufacturers now build and sell hybrid vehicles. Study **Figure 1-25**.

When the HV battery has an adequate charge, the hybrid vehicle will operate in the all-electric mode, without the internal combustion engine ever starting or running. In the all-electric mode, the motor-generator, powered by electricity from the HV battery, propels the vehicle. After the energy stored in the HV battery has been depleted, the motor-generator "fires up" the internal combustion engine, which in turn spins the motor-generator's armature. This causes the motor-generator to produce enough electricity to recharge the HV battery. By linking the running engine's crankshaft to the transmission input shaft, the vehicle is propelled by the engine while the motor-generator is spun by the engine to recharge the HV battery.



Goodheart-Willcox Publisher

Figure 1-25. A basic hybrid power train contains an internal combustion engine, a motor-generator, large HV power cables, HV battery, and an HV power control module. If the HV battery is fully charged, the vehicle will drive in full electric mode for about 50 miles. When the battery becomes discharged, the engine starts up to operate the motor-generator, which begins to recharge the HV battery.

Copyright Goodheart-Willcox Co., Inc.

All hybrids use ***regenerative braking*** to convert the kinetic energy of the moving vehicle into large amounts of stored electrical energy. When the driver presses the brake pedal, the vehicle's drive axles rotate the motor-generator. Since the large permanent magnet armature shaft is difficult to turn, the "electrical/mechanical friction" inside the motor-generator helps slow the car while also recharging the batteries. The conventional hydraulic brake system has to do little or no work, unless the brake pedal is suddenly pressed down hard.

In the Rearview Mirror

Early automobile manufacturers originated in various ways. In many instances, they evolved from bicycle makers, carriage and wagon makers, and other types of industry. Early motorcars were similar to horse-drawn carriages, but they were equipped with noisy gasoline-powered engines, steam engines, or electric motors and batteries. A single lever called a tiller was used to steer the vehicle. Another hand lever would apply "rawhide brake shoes" to rub on the wagon wheels to slow the loud, self-propelled buggy! Imagine driving one of these contraptions.

Summary

- The body and frame support, stop, and enclose the vehicle.
- The engine provides dependable, efficient power for propulsion and electrical systems.
- The computer system uses electronic and electrical devices to monitor and control various auto assemblies.
- The fuel system provides the correct mixture of air and fuel for efficient and complete combustion.
- Electrical systems operate the electrical-electronic circuits, components, and devices, as well as propulsion in hybrid vehicles.
- The cooling system maintains a constant operating temperature for improved combustion efficiency.
- The lubrication system reduces friction between moving parts inside the engine.
- Emission control systems reduce air pollution produced by the vehicle.
- Drive train systems transfer turning force from the engine crankshaft and/or the motor-generator to the drive wheels.
- Suspension, steering, and brake systems support and control vehicle handling, maneuvering, and deceleration.
- Accessory and safety systems increase passenger comfort, safety, security and convenience.
- A hybrid electric vehicle uses two methods of propulsion—an internal combustion engine and an electric drive train.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

accessory system
aerodynamics
air-fuel ratio
all-wheel drive

Activities

1. Draw an automotive engine and drive train and label the parts. Then describe how the power is transferred from the engine to the drive wheels.
2. Using information from the text, write a report discussing any major vehicular system.
3. Arrange a field trip to tour an automobile assembly plant or to an auto shop.
4. Measure and record all four tire air pressure values on a car. Compare actual pressure to recommended tire pressure. Use the internet to research the effects low tire pressure has on fuel economy, vehicle handling, and tire wear. Write a report summarizing your findings.
5. Use the Internet to theoretically "build" a new car. Go to any major automobile manufacturer's website, select the vehicle model you would like to build, and choose the *Build and Price* option. Then, equip the vehicle as you wish. Write a paragraph describing the vehicle you selected. Be sure to included information on the make, model, engine, drive train configuration, fuel economy, interior and exterior colors, options, and price.

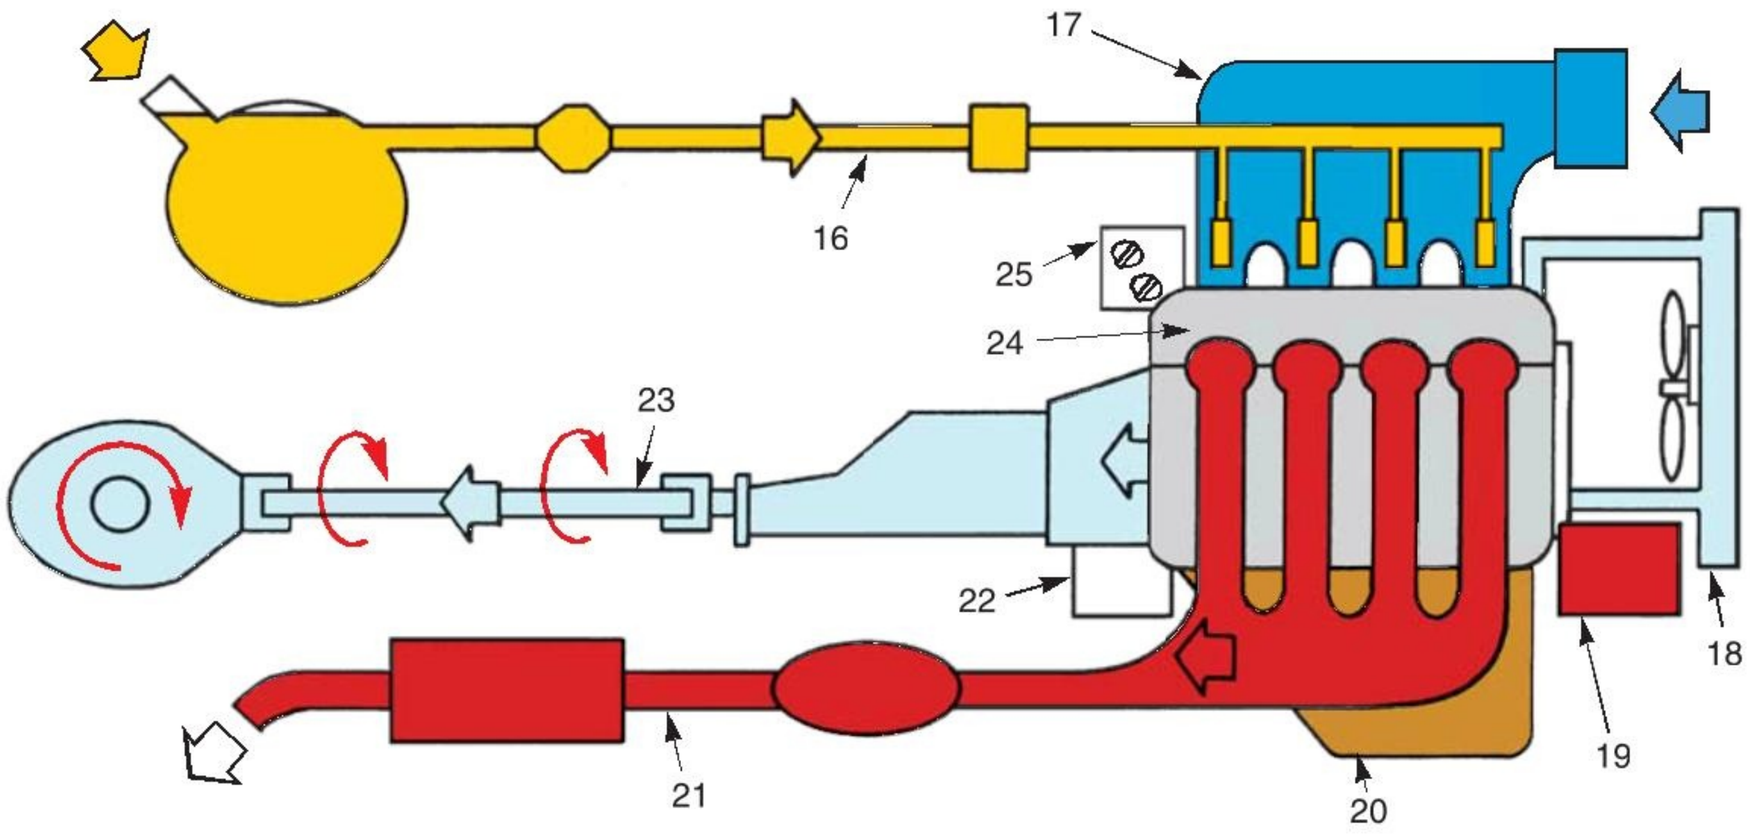
Review Questions

Answer the following questions using the information provided in this chapter.

1. What is an automotive system?
2. In _____ construction, sheet metal body panels are welded together to form the vehicle's body and frame.
3. Explain how an engine turns fuel into power to move the car.
4. Which of the following is *not* part of an engine?
   (A) Block.
   (B) Piston.
   (C) Muffler.
   (D) Crankshaft.
5. Most car engines are multi-cylinder engines. True or False?
6. There are three major part of an automotive computer system. Name them.
7. A direct gasoline injection system sprays fuel into the _____ chambers above the pistons.
8. The car's electrical system consists of the:
   (A) ignition, starting, lubrication, and lighting systems.
   (B) ignition, charging, lighting, and hydraulic systems.
   (C) lighting, charging, starting, and ignition systems.
   (D) None of the above.
9. The _____ system reduces the amount of toxic substances released by the vehicle.
10. Summarize the major differences between manual transmissions, hybrid drive transmissions, and automatic transmissions.
11. A one-piece drive shaft rotates the drive wheels on most front-wheel-drive cars. True or False?
12. A rear axle assembly contains two _____ and a(n) _____.
13. Explain the term *transaxle*.
14. The suspension system mounts the car's wheels solidly on the frame. True or False?
15. List four `accessory systems.

16–25. Identify the parts and systems in the following illustration. Write the numbers 16–25 on your paper. Then write the correct letter and words next to each number.

Copyright Goodheart-Willcox Co., Inc.



Can you identify the following parts and systems? (A) Starting system. (B) Charging system. (C) Drive train. (D) Fuel system. (E) Cooling System. (F) Engine. (G) Ignition system. (H) Lubrication system. (I) Exhaust system. (J) Intake manifold.

ASE-Type Questions

1. Technician A says that unibody vehicles are generally lighter and more fuel efficient than body-over-frame vehicles. Technician B says that full-size trucks always use body-over-frame construction. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. The _____ controls the opening of engine's valves.
   (A) camshaft
   (B) crankshaft
   (C) valve springs
   (D) combustion chamber
3. All of the following are major components in the computer system *except:*
   (A) calipers.
   (B) sensors.
   (C) actuators.
   (D) computer.
4. In modern gasoline injection systems, where does the fuel injector spray gasoline?
   (A) Top of the intake manifold.
   (B) On the intake manifold.
   (C) Into the intake port.
   (D) Into the combustion chamber.
5. The ignition system produces a high-voltage surge that jumps across the air gap at the tip of the _____.
6. The _____ system uses a powerful electric motor to rotate the engine's crankshaft until the engine fires and runs on its own power.
7. A car with a dead 12-volt battery is brought into the shop. Technician A says to check the output of the alternator. Technician B says to check the condition of the spark plugs. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. A vehicle is brought into the shop with a slipping clutch. Technician A says that the clutch is part of the drive train. Technician B says that the clutch is part of the suspension system. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Gear ratios are being discussed. Technician A says that low gear ratios allow a vehicle to accelerate quickly. Technician B says that high gear ratios permit lower engine speeds, providing good gas mileage. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. A transaxle case contains both the:
    (A) injector and drive shaft.
    (B) transmission and differential.
    (C) torque converter and clutch.
    (D) electric motor and brakes.

Copyright Goodheart-Willcox Co., Inc.

Chapter 2
Automotive Careers and ASE Certification

After studying this chapter, you will be able to:

- List the most common automotive careers and related fields of employment.
- Describe the types of skills needed to be a qualified automotive technician.
- Explain the specialized tasks completed by each type of auto technician.
- Summarize the ASE certification program.

Economists predict a continued demand for skilled automotive technicians and other automotive-related professionals for many years into the future. Because many technicians will be needed to fill job openings, you are in an ideal situation.

Today, there are well over 250 million registered passenger vehicles on the road in the U.S. alone. Americans spend approximately eight-hundred billion dollars to own and operate their vehicles every year. There are about thirty million people employed in the automotive field. About one in every seven working Americans is employed in an automotive-related field. All of these people are needed to build, sell, insure, and service passenger vehicles.

Globally, auto production has increased tremendously. Look in almost any newspaper or browse online job sites and you will find job openings for qualified, technicians in all areas of expertise.

The Automotive Technician

An ***automotive technician***, or technician, makes a living diagnosing, servicing, and repairing cars, vans, and light trucks. The technician must be highly skilled and well trained.

He or she must be a "jack-of-all-trades," being able to perform a wide variety of tasks. For example, an experienced master automobile technician is usually capable of performing operations common to the following occupations:

- Machinist—Machinists perform precision measurements and repairs on various high-tolerance parts suffering from wear.
- Plumber—Plumbers work with high-pressure fuel lines, vacuum hoses, power steering tubing, and air suspension lines.

Copyright Goodheart-Willcox Co., Inc.

- Computer technician—Computer technicians test, replace, and reprogram modern on-board computers.
- Residential/commercial electrician—These electricians work on charging, starting, and high-voltage electric drive train circuits.
- Electronic technician—This type of technician tests and repairs low-voltage analog and digital circuits common in passenger vehicles.
- TV-radio technician—TV-radio technicians install and repair vehicle sound and entertainment systems.
- Air conditioning technician—Air conditioning technicians diagnose, repair, and recharge auto air conditioning systems.
- Welder—Welders must safely weld exhaust system parts and make repairs.
- Bookkeeper—Bookkeepers are needed to fill out repair orders, calculate hours on a job, order parts, total work order costs, and figure out weekly paychecks.
- Automotive engineer—Automotive engineers understand the construction and operation of complete vehicle systems and know how to diagnose vehicle problems efficiently.

As this list demonstrates, an automobile technician's job can be very challenging. Today's technician is called on to perform a variety of repair tasks, which prevents boredom on the job. If you like to use your mind and your hands, the field of passenger vehicle repair can be a rewarding and interesting profession.

General Job Classifications

A wide variety of jobs are available in the automotive field. Many of these jobs involve troubleshooting, service, and repair. Others involve getting parts, dealing with customers, and shop management.

Apprentice

One way to get started in automotive service is to become an apprentice. The ***apprentice***, or helper mechanic, works under the direction of an experienced technician. This is a good way to get paid for an education. As an apprentice, you learn about automotive technology by running for parts, cleaning parts, maintaining tools, and helping with repairs. See **Figure 2-1**.

Many schools partner with local service facilities and dealerships to offer ***cooperative training programs***. These programs combine classroom instruction with real-world experience. The employer helps the student technician learn the trade while receiving relatively low-cost labor and the opportunity to identify future technicians for hire. Ask your program advisor or automotive instructor about a possible cooperative training program in your school.

Goodluz/Shutterstock.com

Figure 2-1. An apprentice works under the direction of an experienced automotive technician. This is an excellent way to learn the trade.

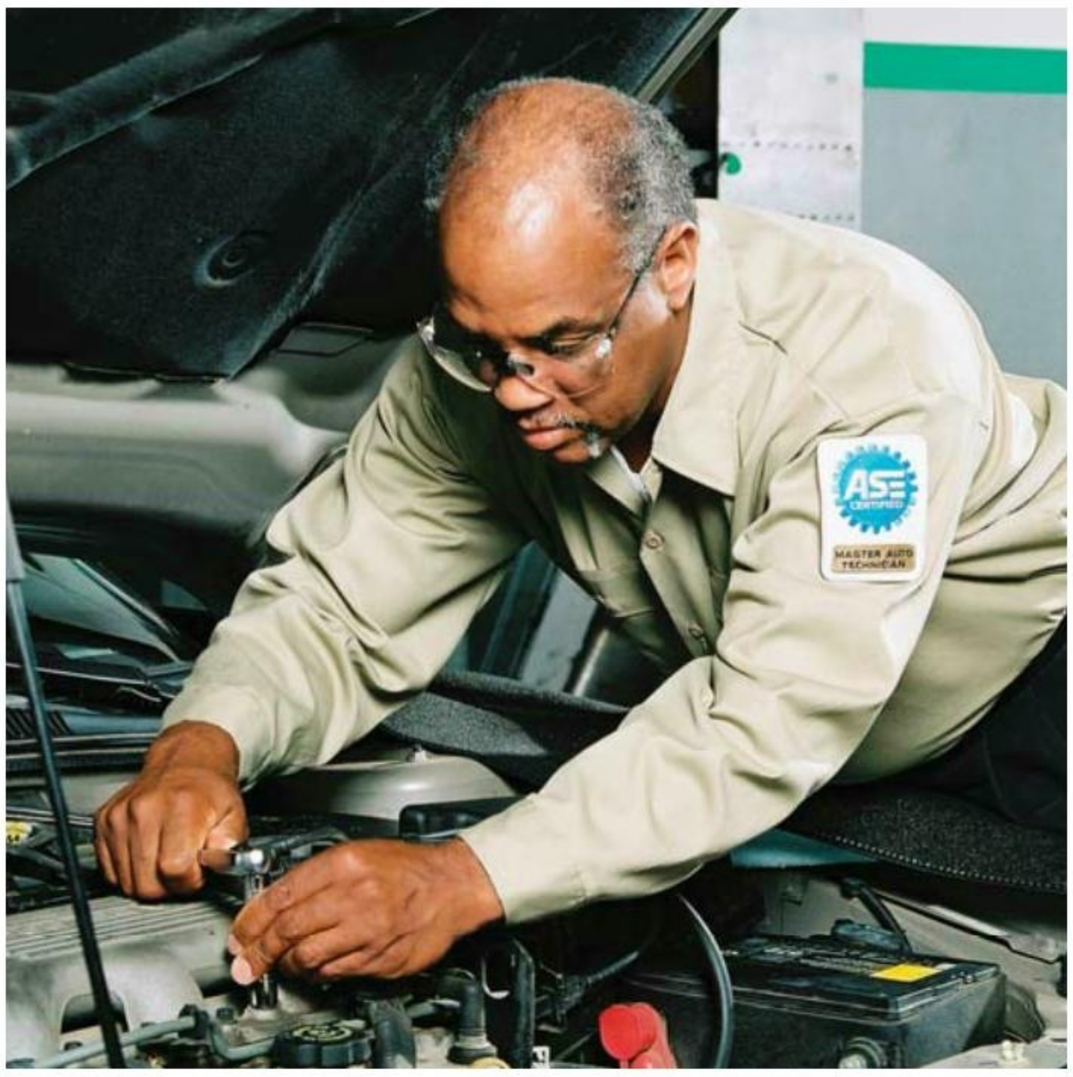
Specialized Technician

A ***specialized technician*** is an expert in one area of automotive repair, such as engines, brakes, electrical, or other areas. Because of the increasingly complex nature of today's vehicles, the trend is toward specialization. It is much easier to learn to repair one system than all systems. After specializing in one area, you can expand your abilities to include other areas of repair. Common areas of specialization include engines, transmissions, steering and suspension, brakes, electrical, heating and cooling, driveability and performance, exhaust systems, tires, and lubrication.

An engine technician troubleshoots, services, and repairs automobile engines. This requires a knowledge of all types of engines, such as gasoline, diesel, 4-cylinder, 6-cylinder, and 10-cylinder. The engine technician has one of the most physically demanding automotive jobs. It requires a fairly strong individual who can lift heavy assemblies and easily torque large fasteners. Refer to **Figure 2-2**.

A transmission technician works on automatic, manual, and hybrid transmissions; transaxles; clutches; and sometimes, rear axle assemblies. Because transmissions are so complex, the transmission technician must receive very specialized training

Copyright Goodheart-Willcox Co., Inc.



ASE

Figure 2-2. The engine technician must be highly skilled. Late-model engines are very complex. One mistake during assembly can cause major engine damage.

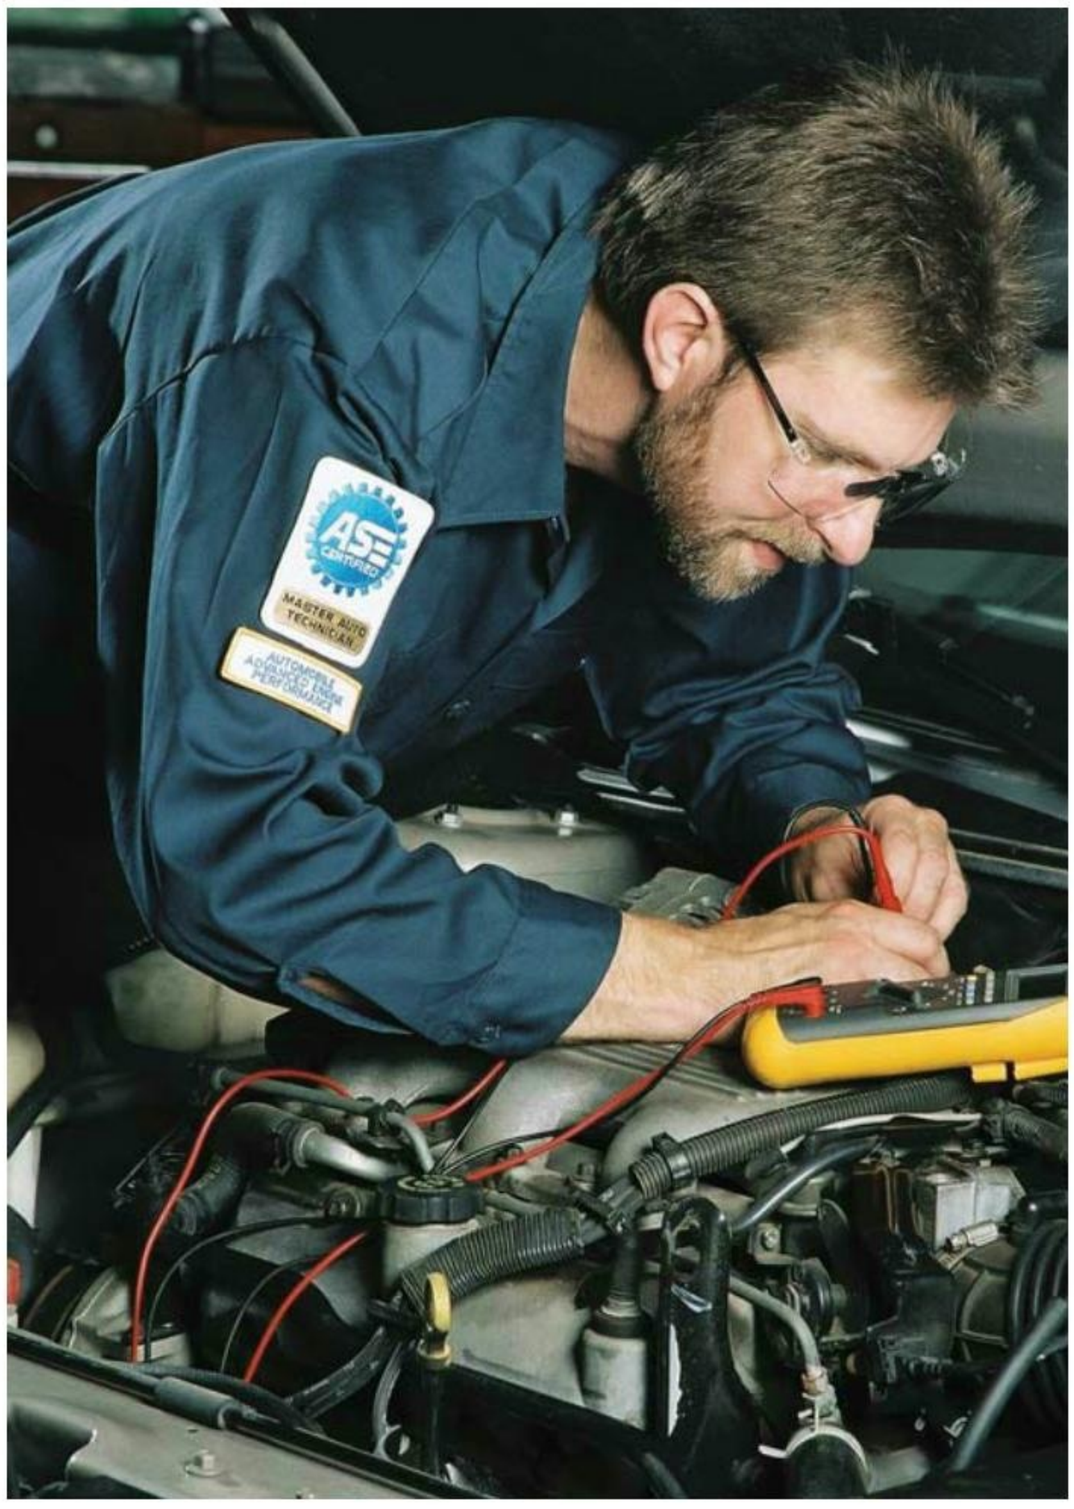
and must frequently retrain. Some large service facilities have a rear axle specialist, who works on nothing but differentials, axle shafts, and drive shafts.

A steering and suspension technician is responsible for checking, replacing, and adjusting steering and suspension components. This technician must use specialized equipment, such as the wheel alignment rack, to line up the wheels. A steering and suspension technician may also take care of tire and wheel problems.

A brake technician specializes in brake system service and repair. This individual must be capable of rapidly diagnosing problems and making adjustments or repairs. A brake technician's job is one of the easiest to master. Jobs are available in both small and large shops, service stations, and tire outlets.

The electrical system technician must be able to test and repair lighting systems, charging systems, computer control systems, starting systems, hybrid electric drives, and other electrical systems. Compared to other specialties, this area of repair might be desirable because it requires less physical strength than other areas. See **Figure 2-3**.

A heating and air conditioning technician must troubleshoot, service, and repair heaters, vents,



ASE

Figure 2-3. This electrical system technician is using a digital voltmeter to measure battery voltage.

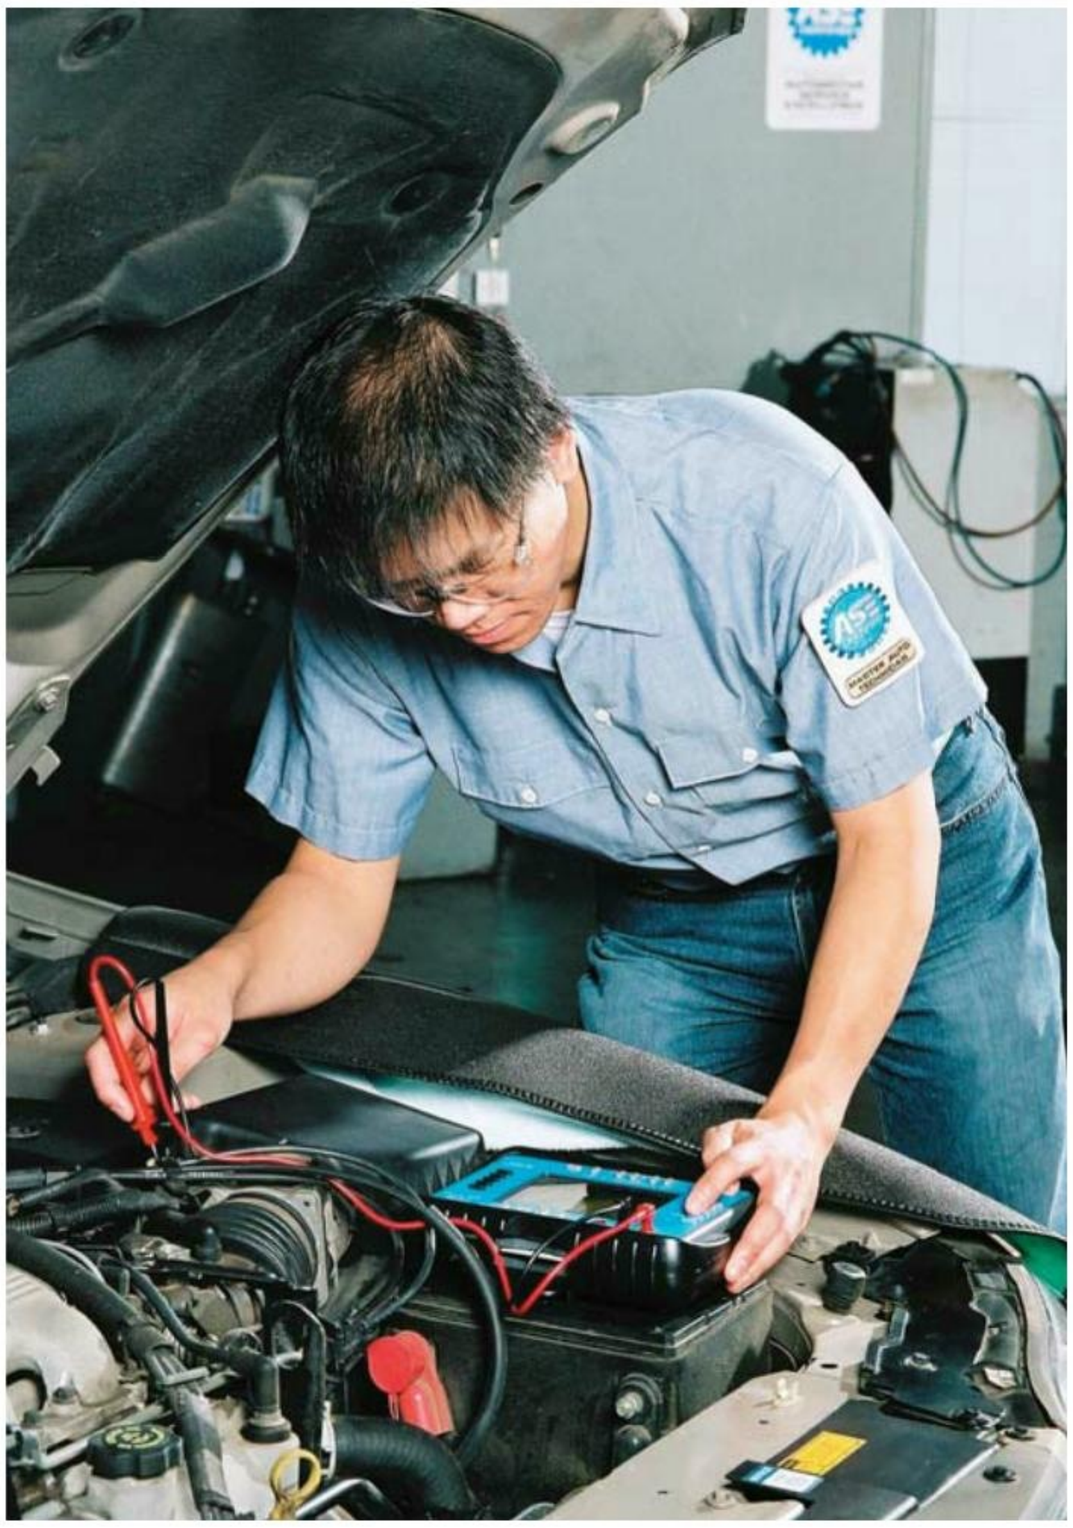
and air conditioning systems. He or she must use a charging station to capture and store the old refrigerant so it is not released into the atmosphere. The charging station is also used to fill the air conditioning system with oil and refrigerant.

The driveability and performance technician must test and service engine fuel, ignition, computer, and emission systems. This involves the use of special test equipment to keep engines in top running condition. See **Figure 2-4**.

The lubrication specialist changes engine oil, filters, and transmission fluid. He or she checks various fluid levels and performs "grease jobs" (lubricates pivot points on suspension and steering systems).

A hybrid specialist has special training in the diagnosis and repair of very dangerous high-voltage electric drive systems. They must be competent at

Copyright Goodheart-Willcox Co., Inc.



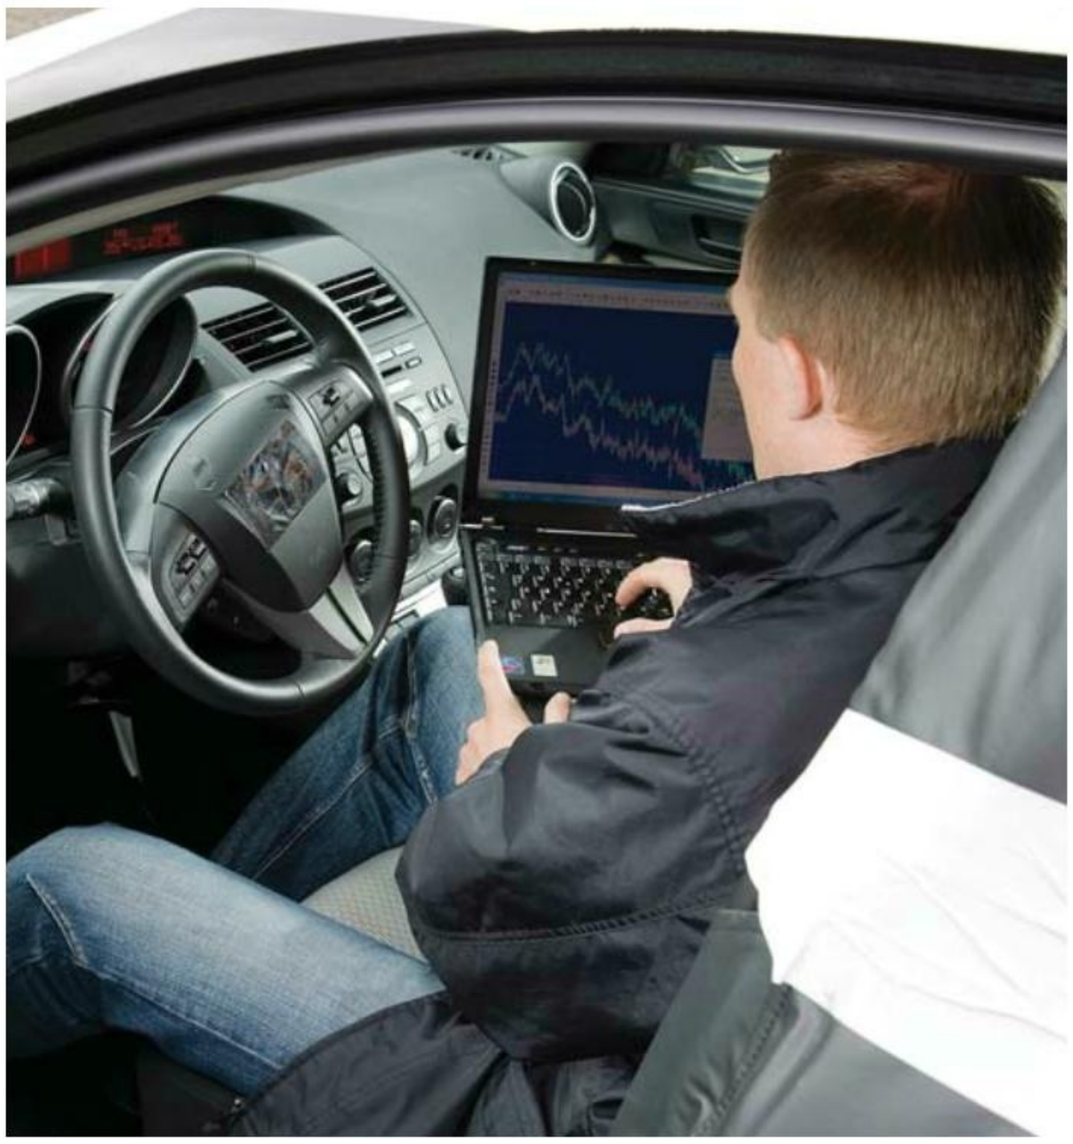
ASE

Figure 2-4. The driveability and performance technician must use state-of-the-art equipment, such as this diagnostic analyzer, to find the source of engine performance problems.

following all safety measures that must be taken to safely work on the high-voltage battery pack, motor-generator, and other high-voltage components. A hybrid specialist is usually sent to special training classes conducted by the vehicle manufacturer. Refer to **Figure 2-5**.

Master Technician

A ***master technician***, or general technician, is an experienced professional who has mastered all the specialized areas of automotive technology and is capable of working on almost any part of a vehicle. This person can service and repair engines, brakes, transmissions, axles, heaters, air conditioners, and electrical systems. A master technician generally has enough experience to advance to a position as a shop supervisor, a service manager, or an instructor.



Goodheart-Willcox Publisher

Figure 2-5. This hybrid specialist is using a laptop computer to analyze trouble codes with the electric drive system. Special training is needed to safely service hybrid vehicles.

Shop Supervisor

The ***shop supervisor*** is in charge of all the other technicians in the service facility. The supervisor must be able to help others troubleshoot problems in all automotive areas. The shop supervisor must also communicate with the service manager, parts manager, and technicians.

Service Manager

The ***service manager*** is responsible for the complete service and repair operation of a large repair facility. This person must use a wide range of abilities to coordinate the efforts of the shop supervisor, parts specialist, service writer, service dispatcher, and other shop personnel. The service manager must also handle customer complaints, answer questions, and ensure that the technicians are providing quality service for their customers.

Other Automotive Careers

There are numerous other automotive careers that do not require extensive mechanical ability. They do, however, require a sound knowledge of automotive technology. A few of these careers are discussed next.

Copyright Goodheart-Willcox Co., Inc.

An ***auto parts specialist*** must have a general knowledge of the components and systems of a vehicle. This person must be able to use customer requests, parts catalogs, price lists, and parts interchange sheets to quickly and accurately find needed parts.

A ***service writer***, or service consultant, prepares work orders for vehicles entering the shop for repair or service. This person greets customers and listens to descriptions of their problems. The service writer must then fill out the repair order, describing what might be wrong.

A ***service dispatcher*** must select, organize, and assign technicians to perform each auto repair. The dispatcher must also keep track of all the repairs taking place in the shop.

An ***auto salesperson*** informs potential buyers of the features and equipment on a vehicle while trying to make a sale. By understanding how a vehicle works, the salesperson will be better prepared to answer questions. Positions are also available selling automotive-related parts and equipment, **Figure 2-6**.

An ***automotive designer*** has art training and can make sketches or models of new body and part designs. This person is employed by automobile or automotive part manufacturers, **Figure 2-7**.

An ***automotive engineer*** designs new and improved automotive systems and parts. This person must use math, physics, and other advanced technologies to improve automotive designs. An engineer is a

Mitsubishi

Figure 2-7. Automotive designers must have extensive engineering knowledge and a strong art background to design buildable yet aesthetically pleasing vehicles.

Kobby Dagan/Shutterstock.com

Figure 2-6. A convention allows manufacturers of parts, tools, and equipment to display new and established products. People well versed in automotive technology and sales are needed to work at these events.

Copyright Goodheart-Willcox Co., Inc.

highly paid, college-trained individual with a working knowledge of the entire automobile, **Figure 2-8**.

Automotive instructors are experienced technicians capable of sharing their knowledge effectively. In addition to on-the-job experience, most instructors are required to have a college degree, **Figure 2-9**.

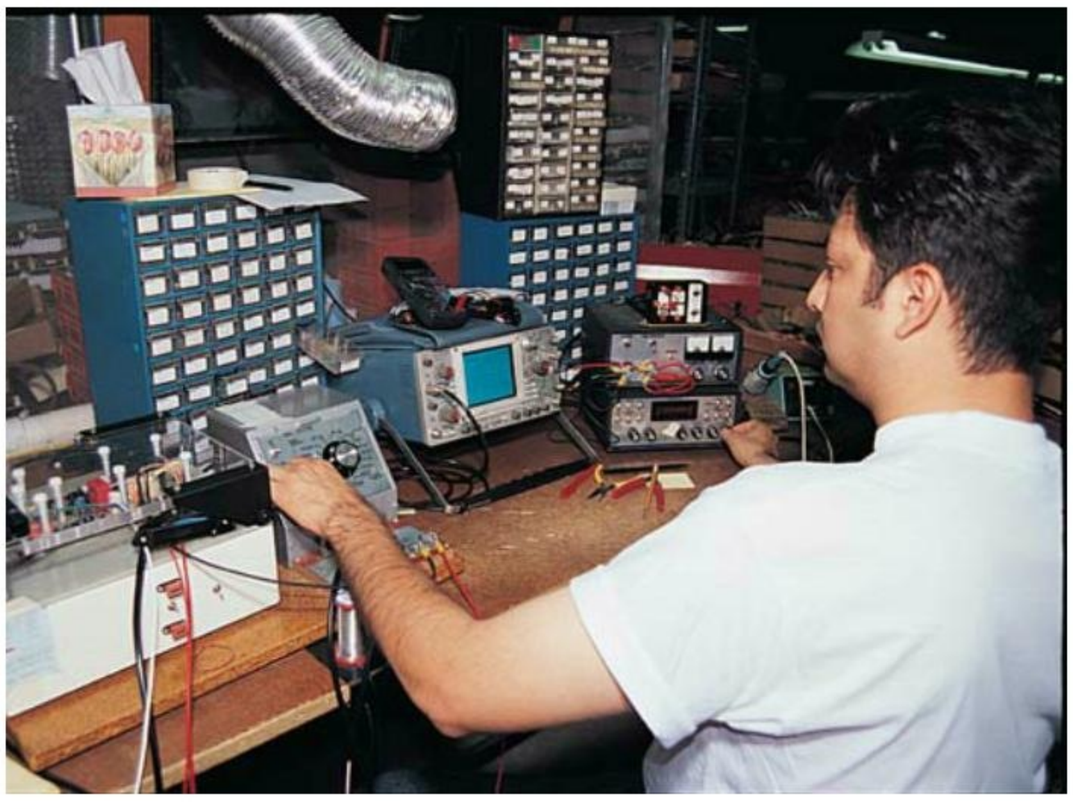
There are dozens of other job titles in the automotive field. Check with your school guidance counselor for more information.

Tech Tip

Many people start their careers as automotive technicians and then move to other related job areas or into management of auto repair facilities. Never limit your sights on the future. Always try to improve your skills and potential for a new and better job.

Entrepreneurship

An ***entrepreneur*** is someone who starts a business, such as a muffler shop, tune-up shop, parts house, or similar facility. To be a good entrepreneur, you must be able to organize all aspects of the business: bookkeeping, payroll, facility planning, hiring, etc. After gaining several years of on-the-job experience, you might want to consider starting your own business.



MSD Ignitions

Figure 2-8. Automotive engineers normally have a bachelor's degree in a related engineering discipline. A working knowledge of automotive technology is a must for the engineer.

Monkey Business Images/Shutterstock.com

Figure 2-9. An automotive instructor must have a strong background in automotive technology and must also be able to communicate well.

Most successful entrepreneurs have a quality known as leadership. Effective leaders have the courage to set a course of action and get the cooperation of others in meeting goals. Leaders are willing to accept responsibility for their actions. If their decisions show signs of failure, they take action to correct mistakes. If their decisions are good, they are willing to share the "glory." Good leaders readily credit the work of others who have contributed to the success of the business venture.

Preparing for a Career in Automotive Technology

A career as an automobile technician can be quite challenging. Late-model cars and light trucks are very complex. They are constantly being updated and redesigned. This makes it difficult to keep up with the latest technology.

Copyright Goodheart-Willcox Co., Inc.

Many of the basic skills needed to succeed in automotive technology are learned in the classroom. Automobile technicians must have above-average math and English skills. They must be proficient at working with numbers to calculate part clearances and fill out work orders. They must also have good verbal skills to effectively communicate with customers and other technicians. After graduation from high school, many automotive students seek further training at trade schools or in colleges.

ASE Certification

The ***National Institute for Automotive Service Excellence***, or ***ASE***, is a nonprofit, nonaffiliated (no ties to industry) organization formed to help ensure the highest standards in automotive service.

ASE directs an organized testing and certification program under the guidance of a 40-member board of directors. The members of this board represent all aspects of the automotive industry—educators, shop owners, consumer groups, government agencies, aftermarket parts distributors, auto manufacturers, etc. This broad group of experts guides the ASE certification program and helps ASE stay in touch with the needs of the industry.

ASE certification is a program in which persons take written tests to prove their knowledge of automotive technology. ASE certification tests are voluntary. They do not have to be taken, and they do not license technicians.

Some countries have made technician certification a requirement. In the United States, however, technicians take the tests for personal benefit and to show their employers and customers they are fully qualified to work on a system of a car or an engine.

Over 500,000 technicians have passed ASE certification tests. Thousands of these technicians have been retested and recertified after five years to maintain their credentials.

Test Categories

In the automobile and light truck category, there are nine certification tests: Engine Repair, Automatic Transmission/ Transaxle, Manual Drive Train and Axles, Suspension and Steering, Brakes, Electrical Systems, Heating and Air Conditioning, Engine Performance, and Light Vehicle Diesel Engines. You can take any one or all of these tests. However, ASE suggests that you attempt no more than 250 questions per testing session. There are also eight medium/heavy truck tests, four collision repair and refinish tests, and one advanced engine performance test. ASE automobile and light truck certification categories are shown in **Figure 2-10**. ASE test categories include:

- Auto Maintenance and Light Repair Certification Test (G1)
- Automobile & Light Truck Certification Tests (A1–A9 Series)
- Collision Repair & Refinish Certification Tests (B2–B5 Series)
- Damage Analysis & Estimating Certification Test (B6)
- Automobile Service Consultant Certification Test (C1)
- Truck Equipment Certification Tests (E1–E3)
- Alternate Fuels Certification Test (F1)
- Transit Bus Certification Tests (H1–H8)
- Advanced Engine Performance Specialist Certification Test (L1)
- Electronic Diesel Engine Diagnosis Specialist Certification Test (L2)
- Light Duty Hybrid/Electric Vehicle Specialist Test (L3)
- Parts Specialist Certification Tests (P1 and P2)
- School Bus Certification Tests (S1–S7)
- Medium-Heavy Truck Certification Tests (T1–T8)
- Undercar Specialist Exhaust Systems Test (X1)

Tech Tip

Visit the ***National Institute for Automotive Service Excellence*** at www.ase.com. You can learn more about their testing/certification programs, take sample tests, and find other information that will help you in your career.

Tech Tip

Become a certified automobile technician! If you master the material in this textbook, you should have no trouble passing all the ASE automobile certification tests. As an ASE-certified technician, you will gain added respect from your employer and your customers.

General diagnosis	9 questions
Cylinder head and valve train diagnosis/repair	5 questions
Engine block diagnosis/repair	5 questions
Lubrication and cooling systems diagnosis/repair	6 questions
Air induction and exhaust systems diagnosis/repair	12 questions
Fuel system diagnosis/repair	13 questions

ASE

Figure 2-10. These are the test categories for ASE automobile certification. If you pass a test in a given area and have two years of applicable work experience, you will be certified as an ASE Automobile Technician. If you pass A1–A8 tests and have the required work experience, you will be certified as an ASE Master Automobile Technician.

Copyright Goodheart-Willcox Co., Inc.

Applying for ASE Tests

Anyone may take the ASE tests; however, a passing grade does not lead to automatic certification. To receive certification, the applicant must also have at least two years of experience as an automobile or truck technician. This experience does not have to be in any specific area of automotive service. In some cases, training programs, apprenticeship programs, or time spent performing similar work can be substituted for all or part of the work experience.

In some cases, formal training can be substituted for all or part of the experience requirement:

- High school training for two full years in automotive technology can be substituted for one year of work experience.
- Post-high school training for two years in a public or private facility can be substituted for one year of work experience.
- Two months of short training courses can be substituted for one month of work experience.
- Three years in an apprenticeship program can be substituted for two years of work experience.
- Two years in a post-secondary, factory-sponsored training program that results in an associate degree or equivalent, such as an ASEP, ASSET, or T-Ten.

To have schooling substituted for work experience, you must include a copy of your transcript (list of courses taken) or a certificate verifying your training or apprenticeship, as well as your completed Work Experience Reporting Form, your registration form, and fee payment. Each should give your length of training and subject area.

To apply to take ASE tests, find the registration information online at www.ase.com. The ASE website contains the proper registration form, as well as instructions for completing the form. You can fill in the form online or print it out and mail it in to the address given on the ASE website. Fill out the form carefully.

ASE tests are given year round. The tests are given at designated test centers at over 300 locations in the United States.

Consult the ASE website for test locations. Be sure to determine the closest test center and record its number in the appropriate space on the application form. Most test centers are located at local colleges, high schools, or vocational schools.

When submitting the application, you can pay online with a credit card or send a check, money order, or credit card information with your mailed registration form to cover all necessary fees. You can also register by phone. A fee is charged to register for the test series, and a separate fee is charged for each test taken. Refer to the ASE website for the current fee structure. In some cases, employers pay the registration and test fees. Check with your employer before submitting your application.

After receiving your application and fees, ASE will send you a confirmation e-mail or fax. You should receive the ticket by mail about two weeks after submitting your application.

Test-Taking Techniques

Follow all instructions given by the test administrators. During the test, read each question carefully before deciding on a proper answer. You must select the *most correct* response. Sometimes more than one response is correct. However, one answer will always be more correct than the others.

You will not be required to recall exact specifications unless they are general and apply to most makes and models of cars. For example, compression test pressure readings and engine clearances are typically about the same for all gasoline engines. This type of general information might be needed to answer some questions.

After completing all the questions in a particular test, recheck your answers to ensure that you did not make a careless error. In most cases, rechecking your answers more than once is unnecessary and may lead you to change correct answers to incorrect ones. The time allowed for each testing session is usually about four hours. However, you may leave after completing your last scheduled test and handing in all test material.

A few tips that might help you pass ASE certification tests include:

- Read the statements or questions slowly. You might want to read through them twice to make sure you fully understand the questions.
- Analyze the statement or question. Look for hints that make some of the possible answers wrong.
- Try to answer the question as if you were the technician trying to fix the car. Think of all possible situations and use common sense to pick the most correct response.
- When two technicians give statements concerning a problem, try to decide if either is incorrect. If both are valid statements about a situation,

Copyright Goodheart-Willcox Co., Inc.

choose the answer stating that both technicians are correct. If only one is correct or neither is correct, mark the answer accordingly. This is one of the most difficult types of questions.

- If the question gives only limited information, make sure you do not pick one answer as correct because it describes a more common condition. If the question does not let you conclude that one answer is better than another, both answers are correct.
- Your first thought about which answer is correct is usually the correct response. If you think about a question too much, you may read something into the question that is not there. Read the question carefully and make a decision.
- Do not waste time on any one question. Make sure you have enough time to answer all the questions on the test.
- Visualize yourself performing a test or repair when trying to answer a question. This will help you solve the problem more accurately.

Types of ASE Test Questions

ASE tests are designed to measure your knowledge of three things:

- The operation of various automotive systems and components.
- The diagnosis and testing of various automotive systems and components.
- The repair of automotive systems and components.

All test questions are multiple choice and contain four possible answers. Sample questions are given below. The answer to each question is explained in detail.

One-Part Questions

In a one-part question, you must choose the best answer out of all the possibilities.

1. Which of the following components ignites the fuel in a gasoline engine?
   (A) Injector.
   (B) Valve.
   (C) Spark plug.
   (D) Glow plug.

The spark plug produces the electric arc to start the fuel burning. Therefore, the correct answer is *(C) Spark plug*. The injector simply sprays fuel into the engine. The valve allows the air-fuel mixture to flow into the engine. The glow plug is only used in a diesel engine to warm the combustion chamber to aid combustion.

Two-Part Questions

Two-part questions require you to read two statements and decide if they are true. Both statements can be true or both can be false. In some cases, only one of the statements is true.

1. Technician A says a locking rear differential assembly can be refilled with regular gear oil. Technician B says the differential assembly allows the vehicle to turn corners without wheel hop. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

In this question, the statement made by Technician A is wrong. A locking rear wheel differential assembly must be refilled with special nonslip oil. Technician B's statement is correct, since the purpose of the differential assembly is to allow the vehicle to turn corners without wheel hop. Therefore, the correct answer is *(B) B only*. Note that Technician A and Technician B appear in many ASE test questions. You must carefully evaluate the statements of each technician before deciding which answer is correct.

Negative Questions

Some questions are called negative questions. These questions require you to identify the *incorrect* answer. Negative questions will usually contain the word "*except.*"

1. An engine contains all of the following bearings *except:*
   (A) connecting rod bearings.
   (B) crankshaft main bearings.
   (C) camshaft bearings.
   (D) reverse idler bearings.

Since reverse idler bearings are used in transmissions and there is no bearing with that name used in the engine, the correct answer is *(D) reverse idler bearings*.

A variation of the negative question contains the word "*least.*"

1. An automatic transmission installed in a late-model vehicle slips during acceleration. Which of these defects is *least* likely to be the cause?

Copyright Goodheart-Willcox Co., Inc.

(A) Clogged transmission oil filter.
(B) Defective transmission oil pump.
(C) Bad shift solenoid.
(D) Low fluid level.

In this case, the least likely cause of transmission slippage is a bad shift solenoid, which is much more likely to cause shifting problems than slippage. Therefore, the correct answer is *(C) Bad shift solenoid*.

Completion Questions

Some test questions are simply sentences that must be completed. One of the four possible answers correctly completes the sentence.

1. A torque wrench is used to measure:
   (A) twisting force on fasteners.
   (B) shear applied to fasteners.
   (C) horsepower applied to fasteners.
   (D) transmission slip yoke angles.

Once again, the question calls for the best answer. The torque wrench is used to measure twisting force, or torque, so *(A) twisting force on fasteners* is correct.

Test Results

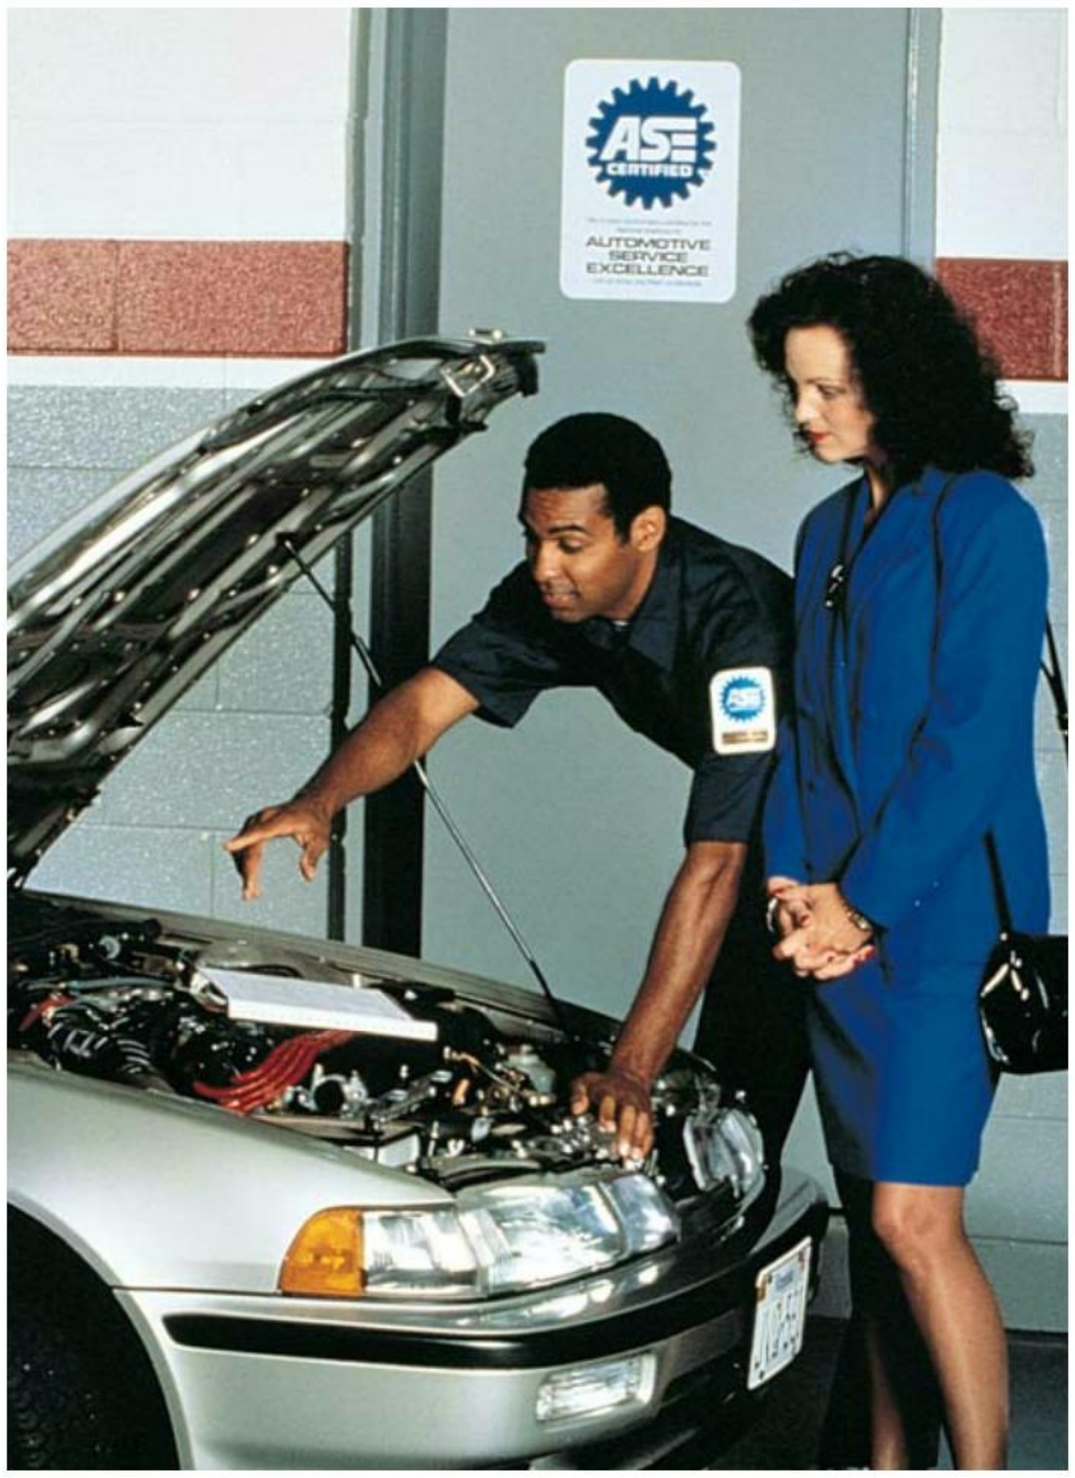
The results of your test will be available before you leave the test center. Only you will find out how you did on the tests. You can then inform your employer if you like.

If you pass a test, you should consider taking more tests. If you fail, you will know that more study is needed before retaking the test.

Certification Status

Assuming the work experience requirements have been met, ***ASE-certified automobile technician*** status is granted for each ASE automobile test passed. ***ASE-certified master automobile technician*** status, previously called certified general technician status, is granted when eight automobile tests have been passed and the experience requirements have been met. Test A9 is not required for master technician status.

Certificates and wallet cards are awarded for each test passed. You also have the option to buy sleeve or shirt patches for each test passed. This will let your customers know that you are fully capable of repairing their vehicles. See **Figure 2-11**.



ASE

Figure 2-11. If you become certified, your customers and your employer will know that you are prepared to properly repair cars and light trucks.

Recertification Tests

Once you are certified in any area, you must take a recertification test every five years to maintain your certification. Recertification test questions concentrate on recent developments. This ensures that certified technicians will keep up with changes in technology.

Applying to take recertification tests is similar to applying for original certification tests. If you allow your certification to lapse, you must take the regular certification test(s) to regain your certification.

Text Organization and ASE Certification

This textbook will help you prepare for ASE certification. The content, scope, and organization were developed with the ASE certification tests in mind. Each chapter contains a section of ASE-type questions, which will help you pass the ASE certification tests.

Copyright Goodheart-Willcox Co., Inc.

Workplace Skills

The automotive industry is one of the largest industries in the United States. A wide variety of jobs and career fields are available within the automotive industry. As you study automotive technology, keep other automotive-related professions in mind. For example, you might enjoy selling cars more than working on them. Nevertheless, your knowledge of automotive technology will make you a better employee in any field within the automotive industry. Try to learn something new every day to become a better-qualified automotive worker.

Summary

- Economists are predicting a continued demand for automotive technicians for many years.
- An automotive technician makes a living by diagnosing, servicing, and repairing cars and light trucks.
- One way to get started in automotive service is to become an apprentice or helper mechanic, working under an experienced technician.
- A specialized technician is an expert on one system of a car. This type of specialist may work only on brakes, transmissions, engines, tune-ups, electrical systems, or air conditioning.
- An engine technician must be able to troubleshoot, service, and repair automobile engines.
- A transmission technician usually works on automatic and manual transmissions, transaxles, clutches, and sometimes, rear axle assemblies.
- A steering and suspension technician is responsible for checking, replacing, and adjusting steering and suspension components.
- A brake technician specializes in brake system service and repair.
- The electrical system technician must be able to test and repair lighting systems, charging systems, computer control systems, and starting systems.
- The driveability and performance technician must test and adjust engine fuel, ignition, and emission systems.
- The hybrid specialist has had special training working with dangerous high-voltage electric drive systems.
- A master technician is an experienced professional who has mastered all specialized areas and is capable of working on almost any part of a vehicle.
- A shop supervisor is in charge of other technicians in a large garage.
- An entrepreneur is someone who starts a business. This might be a muffler shop, tune-up shop, parts house, or similar facility.
- Auto technician certification is a program where persons voluntarily take written tests to prove their knowledge as an auto technician.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

apprentice
ASE-certified automobile technician
ASE-certified master automobile technician
auto parts specialist
auto salesperson
automotive designer
automotive engineer
automotive instructor
automotive technician
cooperative training program
entrepreneur
master technician
National Institute for Automotive Service Excellence (ASE)
service dispatcher
service manager
service writer
shop supervisor
specialized technician

Activities

1. Research an automotive career of your choice. Using word processing software, prepare a written report covering such topics as duties, working conditions, pay range, and opportunities for advancement.
2. Interview a manager of a parts department for a local garage. Report on the duties performed.

Copyright Goodheart-Willcox Co., Inc.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List four skills that may be needed when working as an automotive technician.
2. What is a cooperative training program?
3. Which of the following is *not* a typical specialized technician?
   (A) Engine technician.
   (B) Steering and suspension technician.
   (C) Brake technician.
   (D) Drive shaft technician.
4. Describe some of the responsibilities of a drive-ability and performance technician.
5. A(n) _____ specialist may have to do grease jobs.
6. What is a master technician?
7. Explain the job of a service manager.
8. A(n) _____ is an individual who starts a business.
9. List the eight test categories of ASE certification.
10. You will receive a(n) _____ and a(n) _____ for each ASE certification exam passed.

ASE-Type Questions

1. Technician A says that an automotive technician must be a "jack-of-all-trades." Technician B says that the technician's job is seldom boring. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. A used car needs a wheel alignment. Which technician would usually complete this operation?
   (A) Engine technician.
   (B) Steering and suspension technician.
   (C) Wheel technician.
   (D) Brake technician.
3. A vehicle comes into the shop for repairs. Technician A says to check with the service writer for the details of the customer complaint. Technician B says to check with the shop supervisor to get information on the complaint. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says some ASE questions cover the operation of various automotive systems and components. Technician B says some ASE questions cover the repair of various automotive systems and components. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. All the following are automatic benefits of ASE certification, *except:*
   (A) recognition.
   (B) the option to purchase a sleeve patch.
   (C) a pay raise.
   (D) a wall certificate.

A speed handle is an often-underutilized hand tool. It can be used to start and quickly tighten small nuts and bolts.

Copyright Goodheart-Willcox Co., Inc.

Chapter3
Basic Hand Tools

After studying this chapter, you will be able to:

- Identify common automotive hand tools.
- List safety rules for hand tools.
- Select the right tool for a given job.
- Maintain and store tools properly.
- Use hand tools safely.
- Explain why insulated tools must be used when servicing electric drive trains.
- Correctly answer ASE certification test questions referring to hand tools.

Professional auto technicians invest thousands of dollars on their tools, and for good reason. It is almost impossible to do even the simplest auto repair without using some type of tool.

Tools serve as extensions to parts of the human body. Tools increase the physical abilities of fingers, hands, arms, legs, eyes, ears, and back. A well-selected set of tools speeds up repairs, improves work quality, increases profits, and makes mechanical repair work easier and more enjoyable.

Tech Tip

It is very frustrating trying to fix a vehicle without the right tools. It can be like trying to "fight a forest fire with a squirt gun"—impossible! Invest in a complete set of quality tools.

Tool Rules

There are several basic tool rules that should be remembered. These are as follows.

- Purchase quality tools—With tools, you usually get what you pay for. Quality tools are lighter, stronger, easier to use, and more dependable than off-brand, bargain tools. Many manufacturers of quality tools provide guarantees. Some are for the lifetime of the tool. If the tool fails, the manufacturer will replace it free of charge. This can save money in the long run.
- Keep tools organized—A technician has hundreds of different tools. For the tools to be located quickly, they should be neatly arranged. There should be a place for every tool, and every tool should be in its place. If tools are just thrown into

Copyright Goodheart-Willcox Co., Inc.

the toolbox, time and effort are wasted "digging and searching" instead of fixing the vehicle.

- Keep tools clean—Wipe tools clean and dry after each use. A greasy or oily tool can be dangerous! It is very easy to lose a grip on a dirty tool, cutting or breaking a finger or hand.
- Use the right tool for the job—Even though several different tools may be used to loosen a bolt, usually one will do a better job. It may be faster, grip the bolt better, be less likely to break, or require less physical effort. A good technician knows when, where, and why a particular tool will work better than another. Keep this in mind as you study automotive tools.

Tech Tip

The time spent maintaining your tools and toolbox is time well spent. Well-organized tools will save time on each job and help you get more work done. Unorganized or poorly maintained tools will hurt your on-the-job performance and your appearance as a professional technician.

Tool Storage

A ***toolbox*** stores and protects a technician's tools when not in use. There are three basic parts to a typical toolbox, **Figure 3-1**. These include:

- A large lower roll-around cabinet.
- An upper tool chest that sits on the roll-around cabinet.
- A small carrying tray. This is usually placed in the upper tool chest.

The lower roll-around cabinet holds bulky, heavy tools. Large power tools are normally kept in this part of the box. Extra storage compartments can be attached to the sides of the roll-around cabinet.

Commonly used tools are normally placed in the upper tool chest. Being near eye level, tools can be easily seen and reached without bending. This saves time and energy, and increases production.

Toolbox Organization

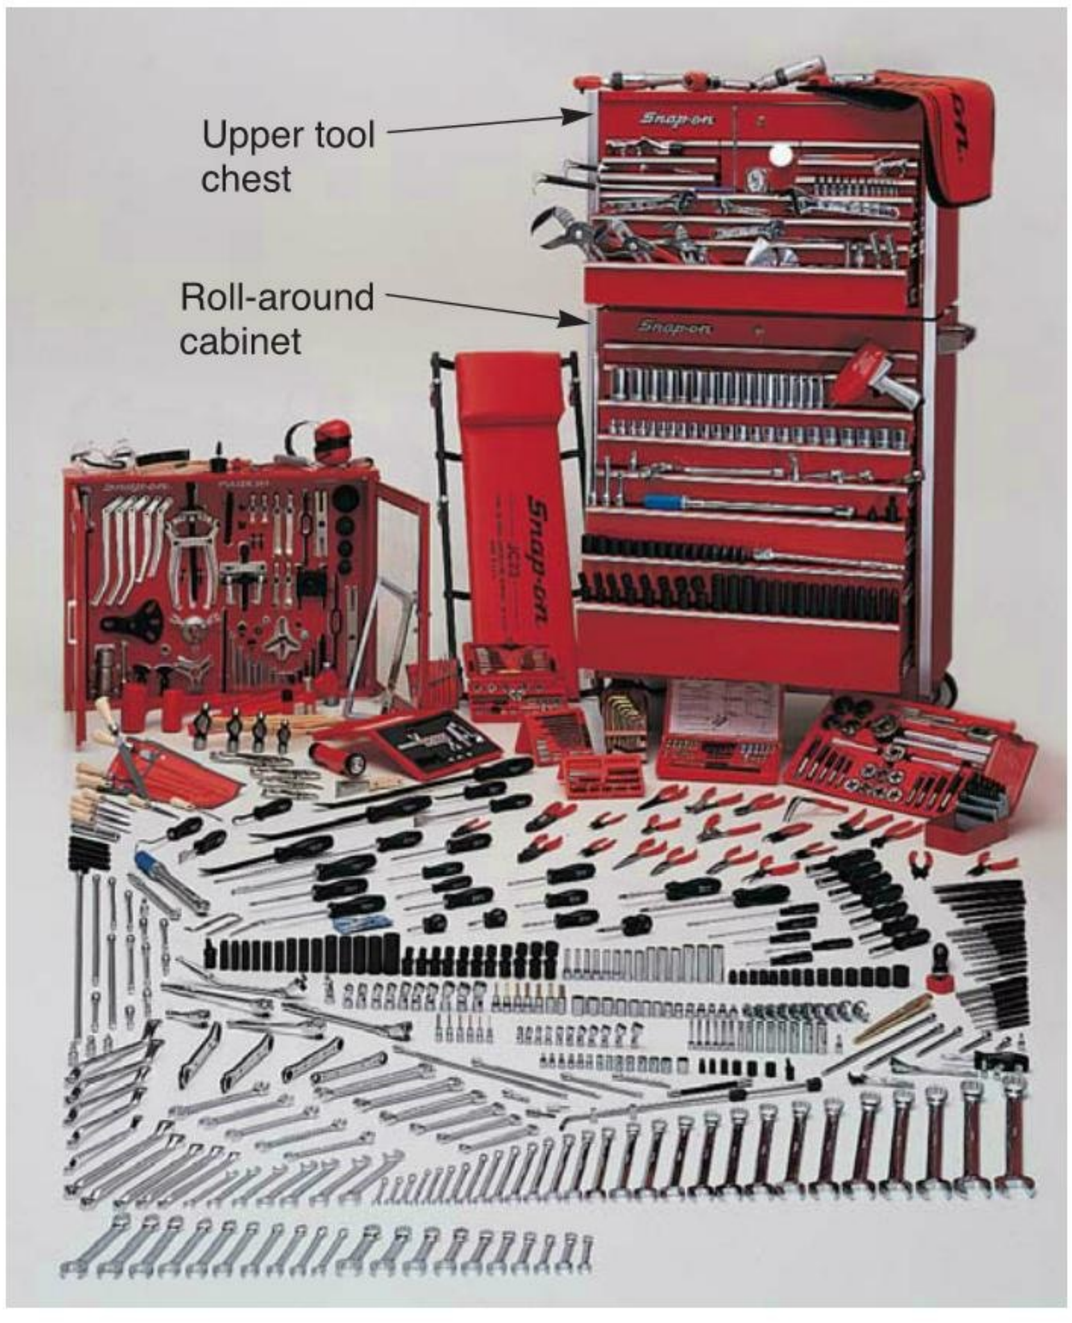
Related tools are normally kept in the same toolbox drawer. For example, various types of hammers may be stored in one drawer and all screwdrivers in another. Small or delicate tools should not be kept with large, heavy tools to prevent damage. ***Tool holders*** help organize small tools. These include small clips, magnetic racks, cloth or plastic pouches, and socket trays. They are often used to protect tools and to keep them organized by size. Holders also allow a full set of tools to be taken to the job.

Warning

Never open several toolbox drawers at one time. If you do, the heavy toolbox might flip over. Serious injury or death can result since a full toolbox can weigh up to 2000 pounds (907 kg). Close each drawer before opening the next.

Wrenches

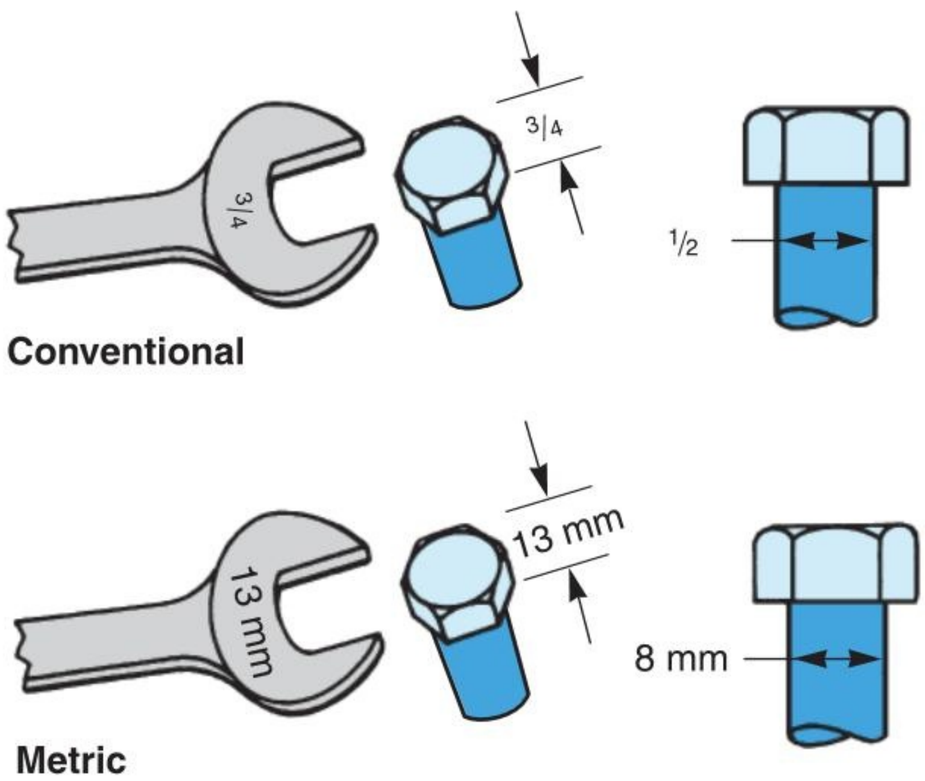
Wrenches are commonly used to install and remove nuts and bolts. ***Wrench size*** is determined by measuring across the wrench jaws. Refer to



Snap-on Tool Corp.

Figure 3-1. A toolbox is used to organize the wide variety of tools a technician needs.

Copyright Goodheart-Willcox Co., Inc.



Deere & Co.

Figure 3-2. Look at conventional and metric wrenches. A—Conventional tool sizes are given in fractions of an inch. The measurement is the width of the jaw opening. As shown here, these sizes are not the same as bolt sizes. B—Metric wrench sizes are given in millimeters. The measurement is the width of the jaw opening. The wrench size is not the same as the bolt size (bolt diameter).

Figure 3-2. Wrenches come in both conventional (inch) and metric (millimeter) sizes. The size is stamped on the side of the wrench. Here are a few wrench rules to follow.

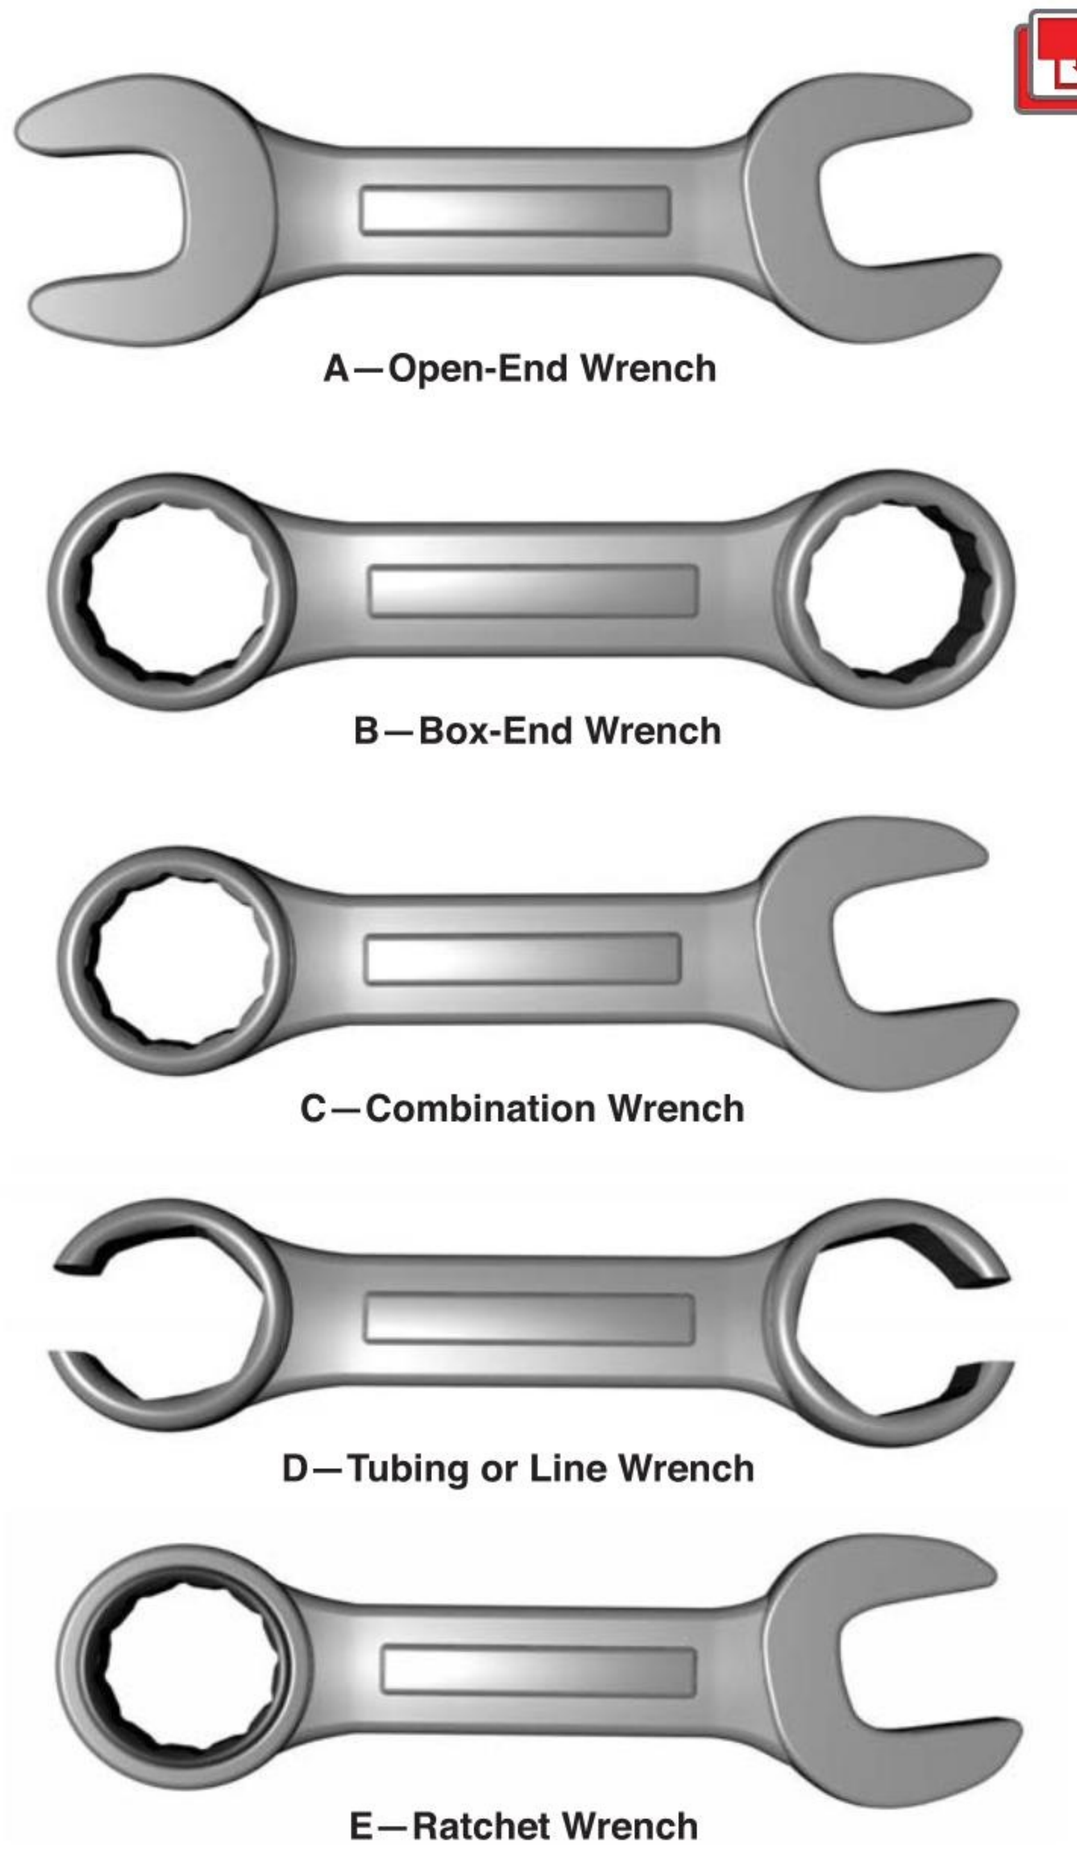
- Always select the right size wrench. It must fit the bolt head snugly. A loose-fitting wrench will round off the corners of the bolt head.
- Never hammer on a standard wrench to break loose a bolt or large nut. Use a longer wrench or a special slug wrench. A longer wrench will provide more leverage. A slug wrench is designed to be hit with a hammer.
- When possible, pull on the wrench. Then, if the wrench slips, you are less likely to hurt your hand. When you must push, use the palm of your hand and keep your fingers open.
- Never use a steel bar or pipe to increase the length of a wrench for leverage. Excess force can bend or break the wrench.

Open-End Wrenches

An open-end wrench has an open, or split, jaw on both ends. Each end is a different size and set at an angle, **Figure 3-3A**. This angle allows the open-end wrench to turn bolts and nuts with little wrench swing space. The wrench can be turned over after each swing to get a new "bite" on the bolt head. An open-end wrench has weak jaws. It should not be used on extremely tight nuts or bolts. Its jaws will flex outward and round off the bolt head if too much torque is applied.

Box-End Wrenches

Box-end wrenches are completely closed on both ends. They fully surround and grip the head of a bolt or nut, **Figure 3-3B**. A box-end wrench will not round off bolt heads as easily as an open-end wrench. Box-end wrenches are available with either 6- or 12-point openings. A 6-point opening is the strongest configuration. It should be used on extremely tight, rusted, or partially rounded bolt or nut heads.



Goodheart-Willcox Publisher

Figure 3-3. Study the basic types of hand wrenches.

Copyright Goodheart-Willcox Co., Inc.

Combination Wrenches

A combination wrench has a box-end on one end and an open-end on the other, **Figure 3-3C**. Both ends are usually the same size. A combination wrench provides the advantage of two types of wrenches for the price of one.

Line Wrenches

A line wrench, also called a tubing wrench or flare nut wrench, is a box-end wrench with a small opening, or split, in the jaw, **Figure 3-3D**. The opening allows the wrench to be slipped over fuel lines, brake lines, or power steering lines and onto the fitting nut. A line wrench prevents damage to soft fittings.

Ratcheting Wrenches

A ratcheting wrench has a gear and lever mechanism so the wrench can be moved back and forth for rapid fastener installation or removal. Most ratcheting wrenches come with ends that are the same size, with one open-end and one closed-end. See **Figure 3-3E**.

Socket Wrenches

A socket wrench consists of a socket and a socket handle. A ***socket*** is a cylinder-shaped, box-end tool for removing or installing bolts and nuts. See **Figure 3-4**. One end fits over the fastener. The other end has a square opening that fits on a socket handle. The socket handle provides leverage to turn the socket and fastener.

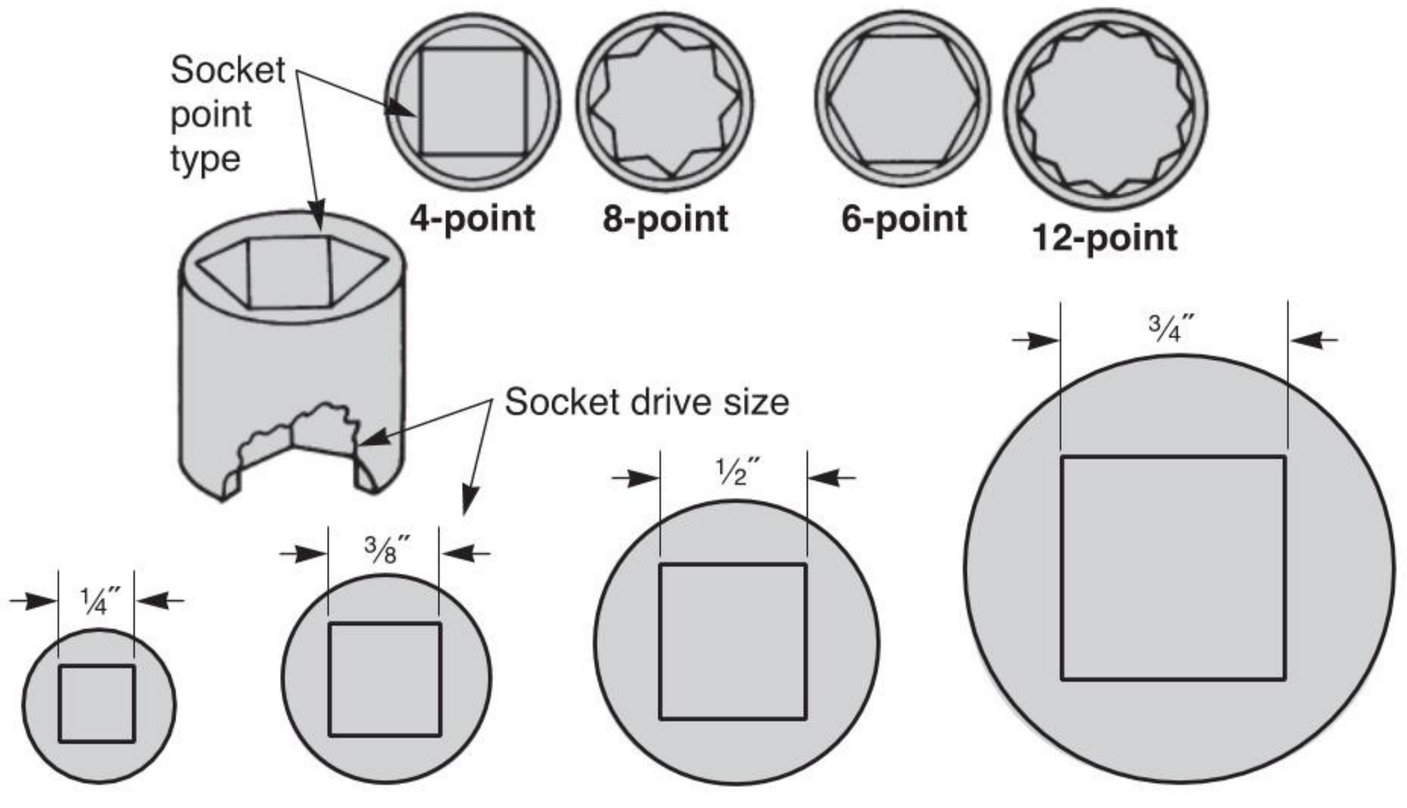
A socket's drive size is the size of the square opening for the ratchet or tool handle. As pictured in **Figure 3-5**, sockets come in four drive sizes: 1/4″, 3/8″, 1/2″, and 3/4″.

If a small drive size is used on large or tight fasteners, the socket or handle can be broken. A large drive may be too awkward for small nuts and bolt heads. Generally, a 1/4″ drive should be used on bolt and nut heads 1/4″ and smaller. A 3/8″ drive is adequate on bolt head and nut sizes between 1/4″ and 5/8″. A 1/2″ drive is strong enough to handle bolt or nut heads from 5/8″ to 1″. A 3/4″ drive is for bolts and nuts with a head size larger than 1″.

They also come in four different points: 4-point, 6-point, 8-point, and 12-point. A 6-point socket is required when a bolt is very tight and you do not want to "round off" and strip the bolt head flats. A 12-point socket is handy on bolts that are not rusted or bound up and will rotate with little torque.

Goodheart-Willcox Publisher

Figure 3-4. Study the different socket types.



Goodheart-Willcox Publisher

Figure 3-5. Sockets come in four drive sizes and four point types. The most commonly used drives are 3/8″ and 1/2″. The most common point types are 6-point and 12-point.

Copyright Goodheart-Willcox Co., Inc.

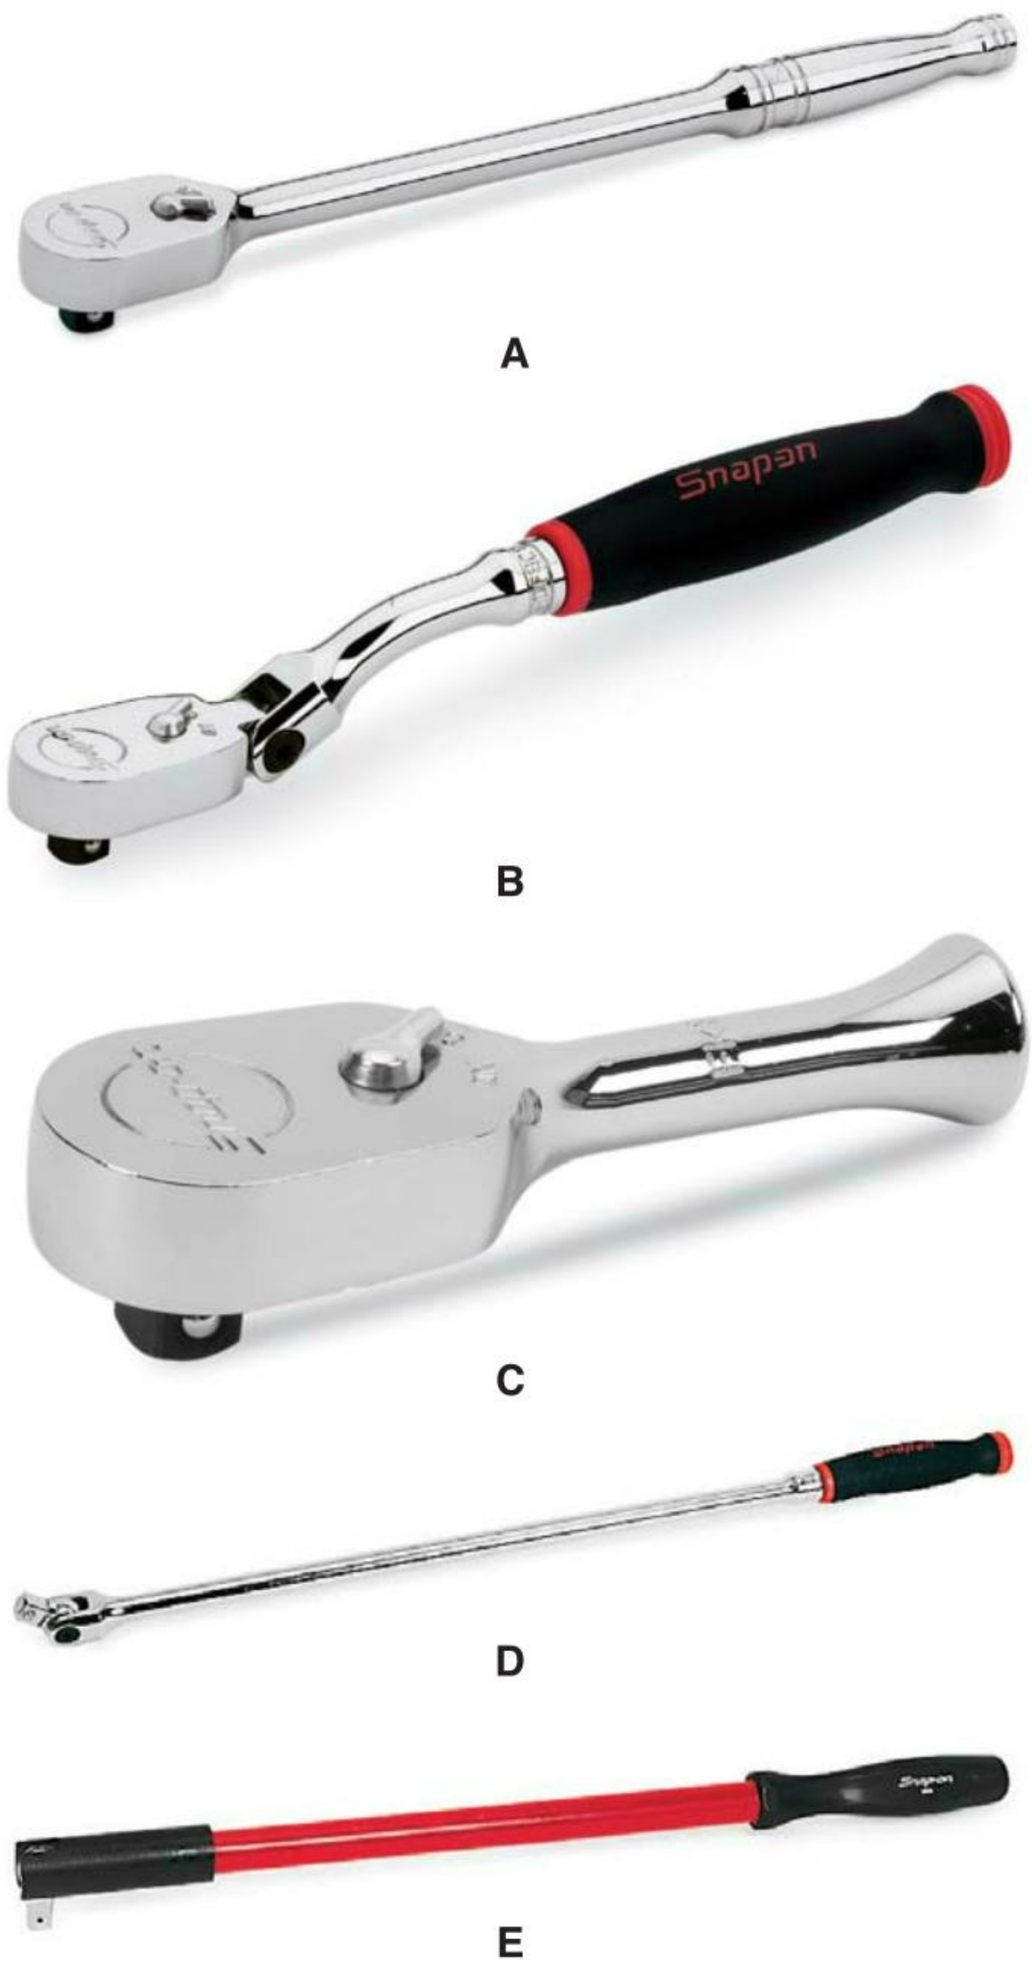
Socket Handles

Socket handles fit into the square opening in the top of the socket. Several types are shown in **Figure 3-6**.

Like a ratcheting wrench, a ratchet handle has a gear and lever mechanism so the wrench can be moved back and forth for rapid fastener installation or removal. The ratchet handle can often be used to remove fasteners in obstructed areas without having to reposition the handle. Ratchet handles can be short for tight quarters or long to apply more torque to stubborn nuts and bolts.

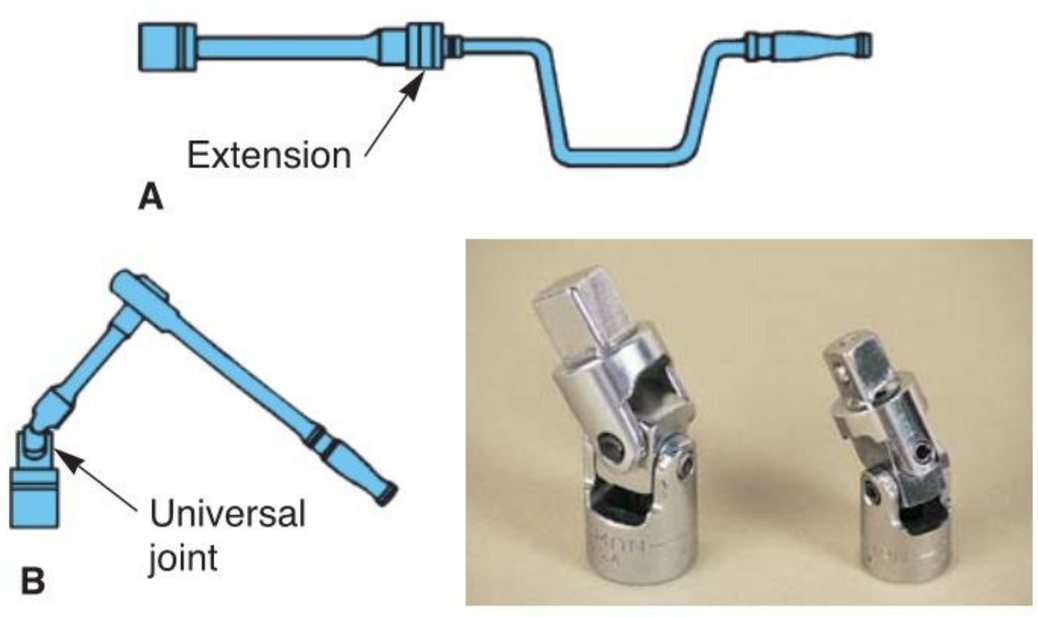
A flex bar, or breaker bar, is the strongest socket handle and provides the most leverage. It should be used when breaking loose large or extremely tight bolts and nuts.

Extensions are used between a socket and its handle. See **Figure 3-7A**. They allow access to difficult-to-reach fasteners.



Snap-on Tool Corp.

Figure 3-6. Study the various socket handles. A—Standard ratchet has straight handle with reversing lever. B—Offset ratchet will reach over parts to reach fastener. C—Stubby ratchet is for tight places. D—Breaker bars or flex handles are required for loosening stubborn nuts and bolts. E—Insulated breaker bars are used for hybrid vehicles.



Goodheart-Willcox Publisher

Figure 3-7. Extensions and universal joints are needed to reach hidden fasteners. A—An extension moves the socket away from the handle for more ratchet clearance. B—A universal joint allows the socket to be turned from an angle to the fastener.

Copyright Goodheart-Willcox Co., Inc.

A ***universal joint*** is a swivel that lets the socket wrench reach around obstructions, **Figure 3-7B**. It is used between the socket and handle, with or without an extension. Avoid putting too much bend into a universal joint, or it may bind and break.

Other Wrench Types

An ***adjustable wrench***, or Crescent wrench, has jaws that can be adjusted to fit different size bolt and nut heads. It should be used only when other type wrenches will *not* fit. Adjustable wrenches can loosen and round off fasteners during use. An adjustable wrench is a handy tool to carry for emergencies. It is like having a full set of open-end wrenches.

A ***pipe wrench*** is an adjustable wrench used to grasp cylindrical objects. The toothed jaws actually dig into the object. For this reason, never use it on parts that will be ruined by marks or nicks.

An ***Allen wrench*** is a hexagonal (six-sided) shaft-type wrench. It is used to turn setscrews on pulleys, gears, and knobs. To prevent damage, make sure the Allen wrench is fully inserted into the fastener before turning. These and other types of wrenches are shown in **Figure 3-8**

Snap-on Tool Corp.

Figure 3-8. Study wrench types. A—Adjustable, or Crescent, wrenches can be set to various sizes. B—Pipe wrenches will turn with great force, but can mar the surface of a part. C—Allen, or hex, wrenches have six sides and come in many sizes. D—Insulated ratcheting wrenches will help prevent electrocution. E—Reversing ratcheting wrenches are handy and narrow. F—Flex combination wrench. G—Half-moon, 12-point wrenches will work in tight quarters. H—Chain wrenches will grasp oil filters for removal.

Copyright Goodheart-Willcox Co., Inc.

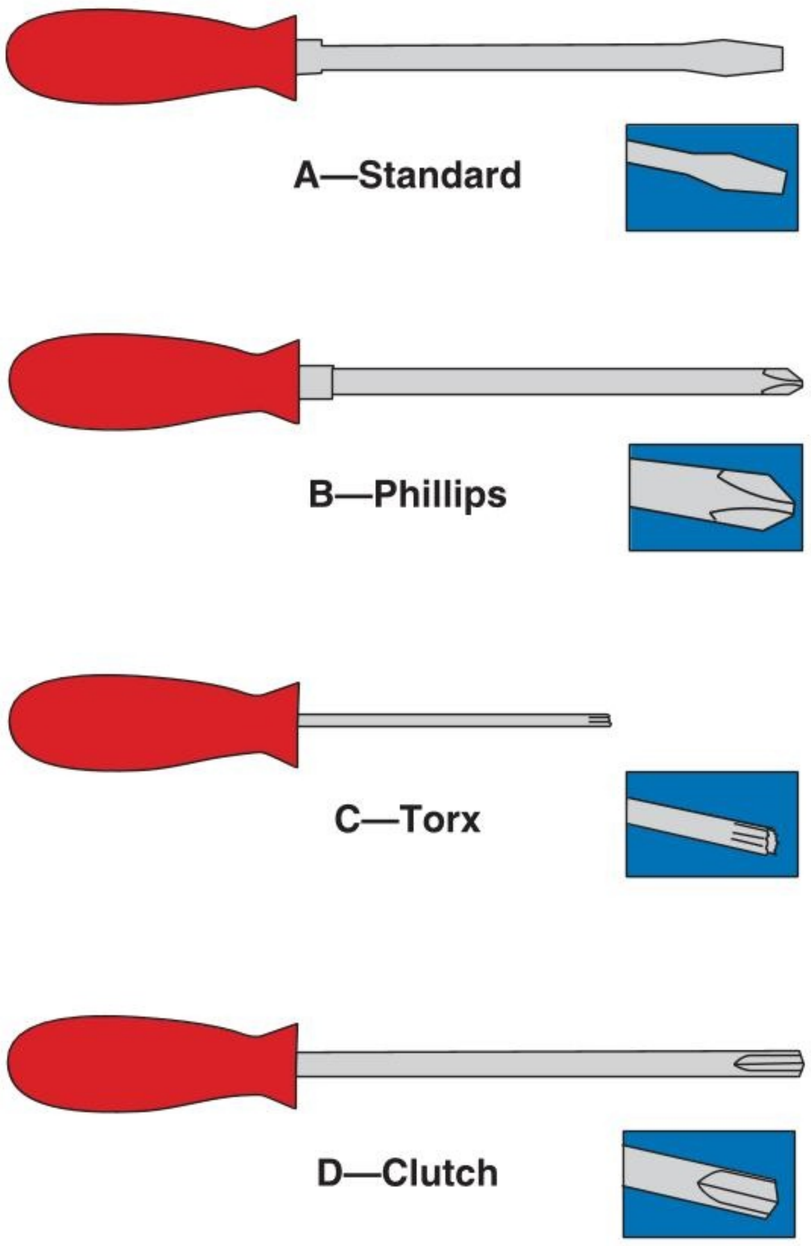
Screwdrivers

Screwdrivers are used to remove or install screws. They come in many shapes and sizes. A standard screwdriver has a single blade that fits into a slot in the screw head. A Phillips screwdriver has two crossing blades that fit into a star-shaped screw slot.

Torx and clutch-type screwdrivers are used to remove and install special types of screws. Torx screwdriver is used to tighten or loosen Torx screws. This type of screw has a 6-point, star-shaped indentation formed into its head. The shape of the indentation allows Torx screws to be rotated with a great deal of force, or torque, without damaging the head.

A clutch-type screwdriver is used for clutch-head fasteners. A clutch-head fastener has a bow-tie shaped opening in its head. Clutch-head fasteners are sometimes found on small parts, allowing for quick removal during repairs. Study the types of screwdrivers shown in **Figure 3-9**.

Offset and stubby screwdrivers are good in tight places, **Figures 3-10A** and **B**. For example, a stubby screwdriver is needed for loosening screws inside a glove box. Starting screwdrivers hold the screw securely until started in its hole. They prevent the screw from being dropped and lost, **Figure 3-10C**.



Snap-on Tool Corp.

Figure 3-9. Memorize screwdriver types.

A ***scratch awl*** looks like a screwdriver, but it has a sharp, pointed tip, **Figure 3-10D**. It is used for marking sheet metal and other parts. An ***impact driver*** can be used to loosen extremely tight screws. When struck with a hammer, the driver exerts powerful turning and downward forces. This is shown in **Figure 3-11**.

A—Offset Screwdriver

B—Stubby Screwdriver

C—Starting Screwdriver

D—Scratch Awl

Lisle

Figure 3-10. Compare different types of specialty screwdrivers.

A

B

Warren Price Photography/Shutterstock.com

Figure 3-11. A—An impact driver can be used to loosen stubborn fasteners. B—Hit the impact driver squarely with a hammer to free and turn stubborn or stripped out fasteners.

When selecting a screwdriver, pick one that is wide and thick enough to completely fill the screw head. If the screwdriver is too large or too small, damage to the screwdriver or screw may occur. Most screwdrivers are not designed to be hammered on or pried with. Only heavy-duty screwdrivers with a full shank can withstand light hammering and prying.

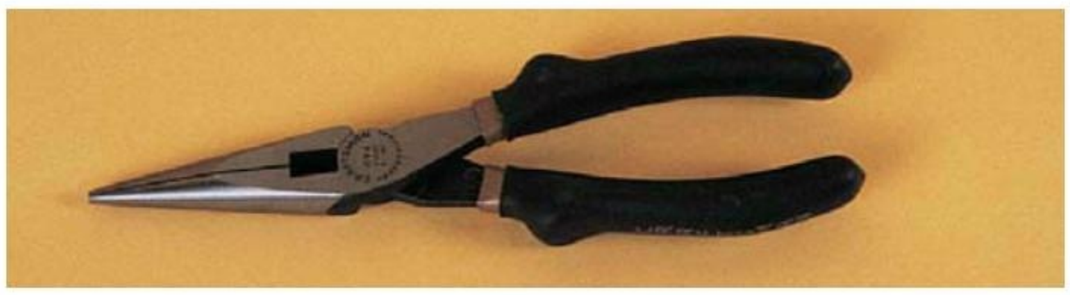
Pliers

Pliers are used to grip, cut, crimp, hold, and bend various parts. Different pliers are helpful for different situations. Never use pliers when another type of tool will work. Pliers can nick and scar a part. Several types of pliers are pictured in **Figure 3-12**.

Combination pliers, or slip-joint pliers, are the most common pliers used by an automotive technician. The slip joint allows the jaws to be adjusted to

A—Slip-Joint Pliers

B—Rib Joint Pliers



C—Needle Nose Pliers

D—Diagonal Cutting Pliers

E—Vise Grip Pliers

F—Snap Ring Pliers

Goodheart-Willcox Publisher

Figure 3-12. Study different types of pliers.

Copyright Goodheart-Willcox Co., Inc.

grasp different size parts, **Figure 3-12A**. Rib joint pliers, also called channel lock pliers, open extra wide for holding very large objects, **Figure 3-12B**.

Needle nose pliers are excellent for handling extremely small parts or reaching into highly restricted areas, **Figure 3-12C**. Do not twist too hard on needle nose pliers, or the long thin jaws can be bent.

Diagonal cutting pliers are the most commonly used cutting pliers, **Figure 3-12D**. Their jaw shape allows them to cut items flush with an adjacent surface. Diagonal cutting pliers are often used to cut off cotter pins, wires, and plastic ties.

Locking pliers, or vise grips, clamp onto and hold a part, **Figure 3-12E**. This frees both hands to do other tasks. Because of their clamping power, vise grips can sometimes be used to unscrew fasteners with stripped or rounded heads. However, never use them on undamaged nuts or bolts because the jaws can distort the surfaces they are clamped onto.

Snap ring pliers have sharp, pointed tips for installing and removing special clips called snap rings. A pair of snap ring pliers is shown in **Figure 3-12F**.

Wire stripping pliers are designed to easily remove plastic insulation from different sized wires. Battery pliers have jaws for grasping corroded fasteners on battery cables.

Hammers

Various types of hammers are used for operations that involve striking a tool or part. Several hammers are shown in **Figure 3-13**. The following are some general rules governing hammers.

- Select the right size hammer. If a large part is struck by a small hammer, the hammer can fly backwards dangerously. If the hammer is too large, however, it may damage the part.
- Always check that the hammer head is tight on the handle. If not, the head may fly off and cause injury or damage.
- Use a brass, plastic, or dead blow hammer on parts and tools that can be damaged by a steel hammer. Use a steel hammer only when maximum driving force is required.
- Grasp the hammer near the end of the handle and strike the part or tool squarely.

A ***ball peen hammer*** is the most common type of hammer used in automotive work, **Figure 3-13A**. It has a flat face for general striking. It also has a round end for shaping metal parts, such as sheet metal or rivet heads.

A—Ball Peen Hammer

B—Sledgehammer

C—Plastic Hammer

D—Rubber Mallet

E—Dead Blow Hammer

Goodheart-Willcox Publisher

Figure 3-13. Note different hammer types.

Copyright Goodheart-Willcox Co., Inc.

A ***sledgehammer*** has a very large head, **Figure 3-13B**. It is usually the heaviest hammer and produces powerful blows. A sledgehammer is sometimes used to free frozen parts.

The brass hammer has a soft, heavy head and is useful when scarring the surface of a part must be avoided. The relatively soft head deforms to protect the part surface from damage.

A ***plastic hammer*** is light and has a soft head, **Figure 3-13C**. It is used where light blows are needed to prevent part breakage or damage to surfaces on small and delicate parts.

A ***rubber mallet*** has a head made of solid rubber, **Figure 3-13D**. It will rebound, or bounce, upon striking and is not effective on solid metal parts. It is recommended on many sheet metal or plastic parts, such as garnish molding and plastic or sheet metal wheel covers.

The head of a ***dead blow hammer*** is filled with small metal balls called lead shot. The extra weight of lead shot prevents a rebound of the hammer when striking. Some dead blow hammers have plastic-coated faces, which help prevent damage to the work surface. See **Figure 3-13E**.

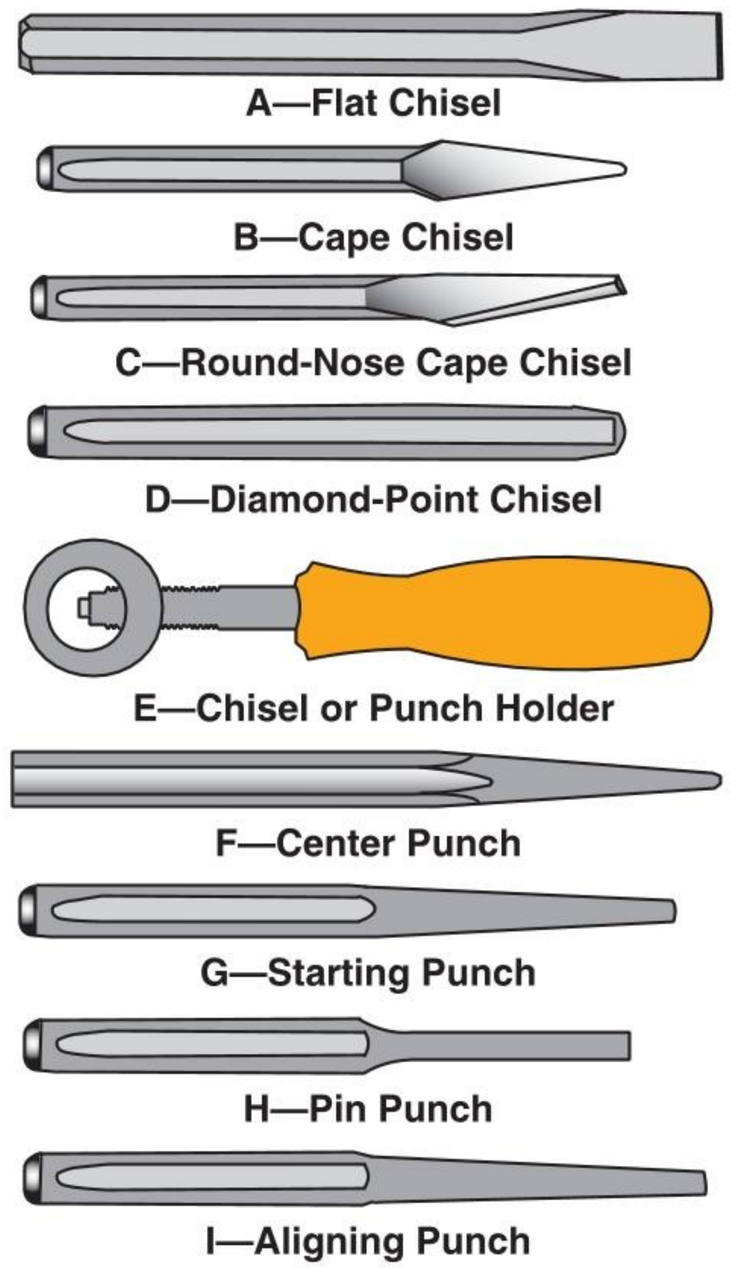
Chisels and Punches

Chisels are for cutting off damaged or badly rusted nuts, bolts, and rivet heads. There are various chisel shapes, **Figure 3-14**. Use common sense when selecting a chisel shape.

Punches also come in several configurations. See **Figure 3-14**. A center punch is frequently used to mark parts for reassembly and to start a hole before drilling. The indentation made by a center punch will keep a drill bit from moving when first starting to drill. Look at **Figure 3-15**.

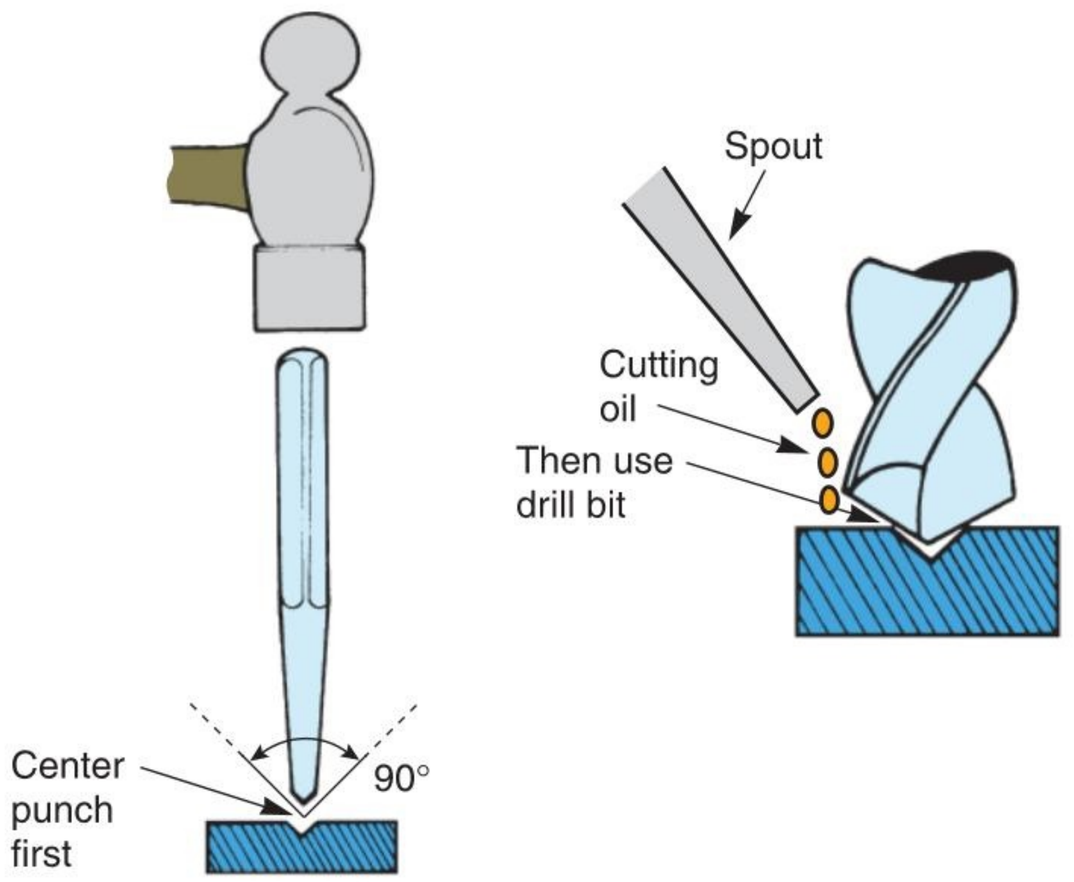
A starting punch, or drift punch, has a shank tapered all the way to the end. It is strong and can withstand moderate blows. It is used to drive pins, shafts, and metal rods partway out of a hole. A pin punch has a straight shank and is lighter than a starting punch. It is used after a starting punch to push a shaft or rod the rest of the way out of a hole.

An aligning punch has a long, tapered shaft and is handy for lining up parts during assembly. An aligning punch can be inserted into holes in mating parts and then wiggled to match up the holes. Never use an aligning punch as a center punch. Its tip is too soft and would be ruined.



Snap-on Tool Corp., OTC/SPX Corp., and Proto Tools

Figure 3-14. Note chisel and punch set with large safety handle to protect from injury.



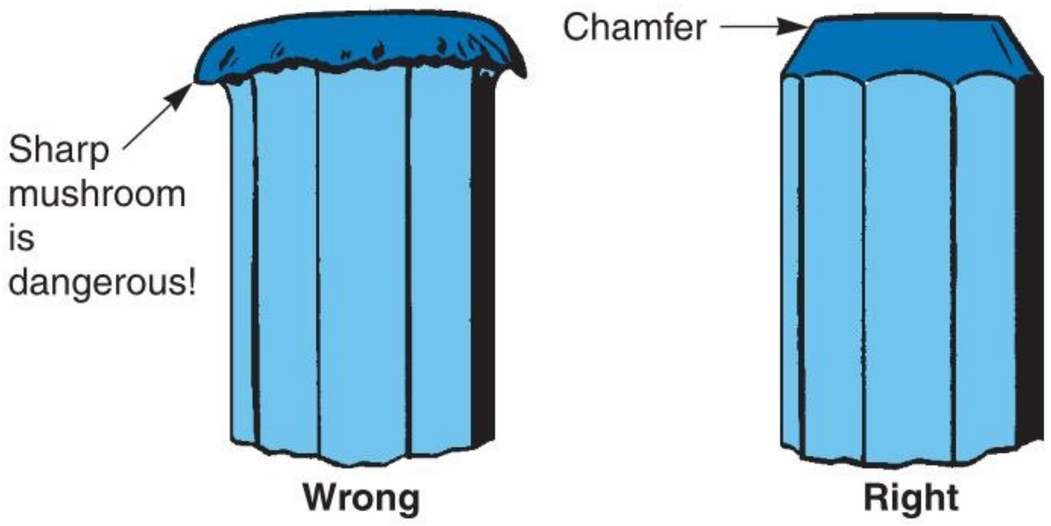
Florida Dept. of Voc. Ed.

Figure 3-15. A center punch makes a small indentation in metal parts. This can then be used to start a drill bit.

Copyright Goodheart-Willcox Co., Inc.

Remember these chisel and punch rules:

- Use the largest punch or chisel that will work. If a small punch is used on a very large part, the punch can rebound and fly out with tremendous force. The same is true for chisels.
- Keep both ends of a chisel or punch properly ground and shaped. A chisel's cutting edge should be sharp and square. A starting punch or a pin punch should also be ground flat and square. A center punch should have a sharp point.
- After prolonged hammering, the top of a chisel or punch can become deformed and enlarged. This is called mushrooming. A mushroomed chisel or punch is dangerous! Grind off the mushroom and form a chamfer, as shown in **Figure 3-16**.
- When grinding a chisel or punch, grind slowly to avoid overheating the tool. Excessive heat will cause the tool to turn blue, lose its temper, and become soft.
- Make sure to wear eye protection when using or grinding a chisel or punch.



Deere & Co.

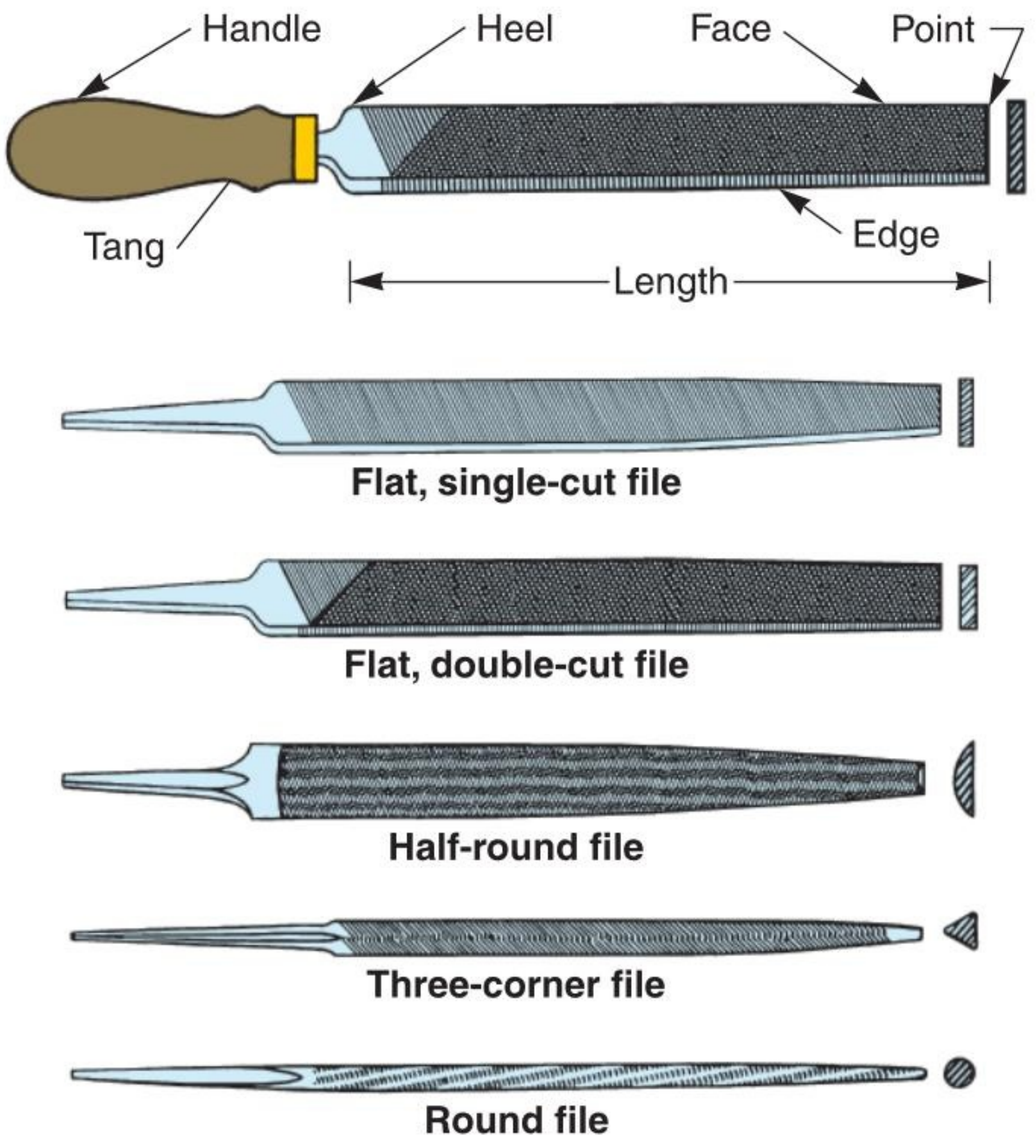
Figure 3-16. Always keep the head of a chisel or punch ground to a chamfer. A sharp, mushroomed end is dangerous.

Files

Files remove burrs, nicks, and sharp edges and perform other smoothing operations. They are useful when only a small amount of material must be removed. Refer to **Figure 3-17**.

A file is classified by its length, shape, and cutting surface. Generally, a coarse file with large cutting teeth should be used on soft materials, such as plastic, brass, and aluminum. A fine file with small cutting teeth is needed to produce a smoother surface and to cut harder materials, like cast iron or steel.

There are several file safety rules that should be remembered. These are:



Starrett

Figure 3-17. A file is used for smoothing metal. Note the different parts of a file and the different types of files available.

- Never use a file without a handle securely attached. If the file is used without a handle, the pointed tang can puncture your hand or wrist.
- To prevent undue file wear, apply pressure only on the forward stroke. Lift the file on the backstroke.
- When filing, place one hand on the handle and the other on the file tip. Hold the file firmly but do not press too hard.
- Do not file too rapidly. One file stroke every second is fast enough. Count to yourself: one thousand one, one thousand two, one thousand three, one thousand four, etc. This will time your strokes properly at about 50–60 strokes per minute.
- If a file becomes clogged, clean it with a file card or a stiff wire brush.
- Never hammer on or pry with a file! A file is very brittle and will break easily. Bits of the file can fly into your face or eyes.

Saws

A ***hacksaw*** is used to cut metal objects. Blades of various lengths can be mounted in the saw's adjustable frame. The blade teeth should point away from the handle, and the blade should be fastened tightly in the frame.

Copyright Goodheart-Willcox Co., Inc.

Select the appropriate blade for the job. As a rule of thumb, at least two saw teeth should contact the material being cut at any given time. If not, the teeth can catch and break.

When cutting, place one hand on the hacksaw handle and the other on the end of the frame. Press down lightly on the forward stroke and release pressure on the backstroke. As with a file, use 50–60 strokes per minute. If cuts are made faster than this, the blade will quickly overheat, soften, and become dull. See **Figure 3-18**.

Goodheart-Willcox Publisher

Figure 3-18. Hacksaws are sometimes used to cut metal in old exhaust systems or during fabrication of small parts. Hold the saw as shown and only push down on the forward stroke.

Holding Tools

There are several different types of tools used for holding objects in the automotive shop. It is important that you know how to use each without part damage or injury to yourself or others.

Vise

A ***vise*** is used to hold parts during cutting, drilling, hammering, and pressing operations. See **Figure 3-19**. It is mounted on a workbench. Avoid clamping a smooth, machined part in the uncovered jaws of a vise. If a machined surface is scarred, the part may be ruined.

Vise caps or wood blocks should be used to prevent damage when mounting precision or delicate parts in a vise. Vise caps are soft metal jaw covers. They will not only protect the part, but will provide a more secure grip on the part.

Snap-on Tool Corp.

Figure 3-19. A vise mounts on the workbench. It holds parts securely.

A few vise rules include:

- Never hammer on a vise handle to tighten or loosen the vise. Use the weight of your body to turn the vise handle.
- Keep the moving parts of the vise clean and oiled.
- Wear safety glasses when using a vise. Tremendous clamping force can be exerted and parts may break and fly out.
- Use vise caps when a precision part is held in a vise. This will prevent part damage.

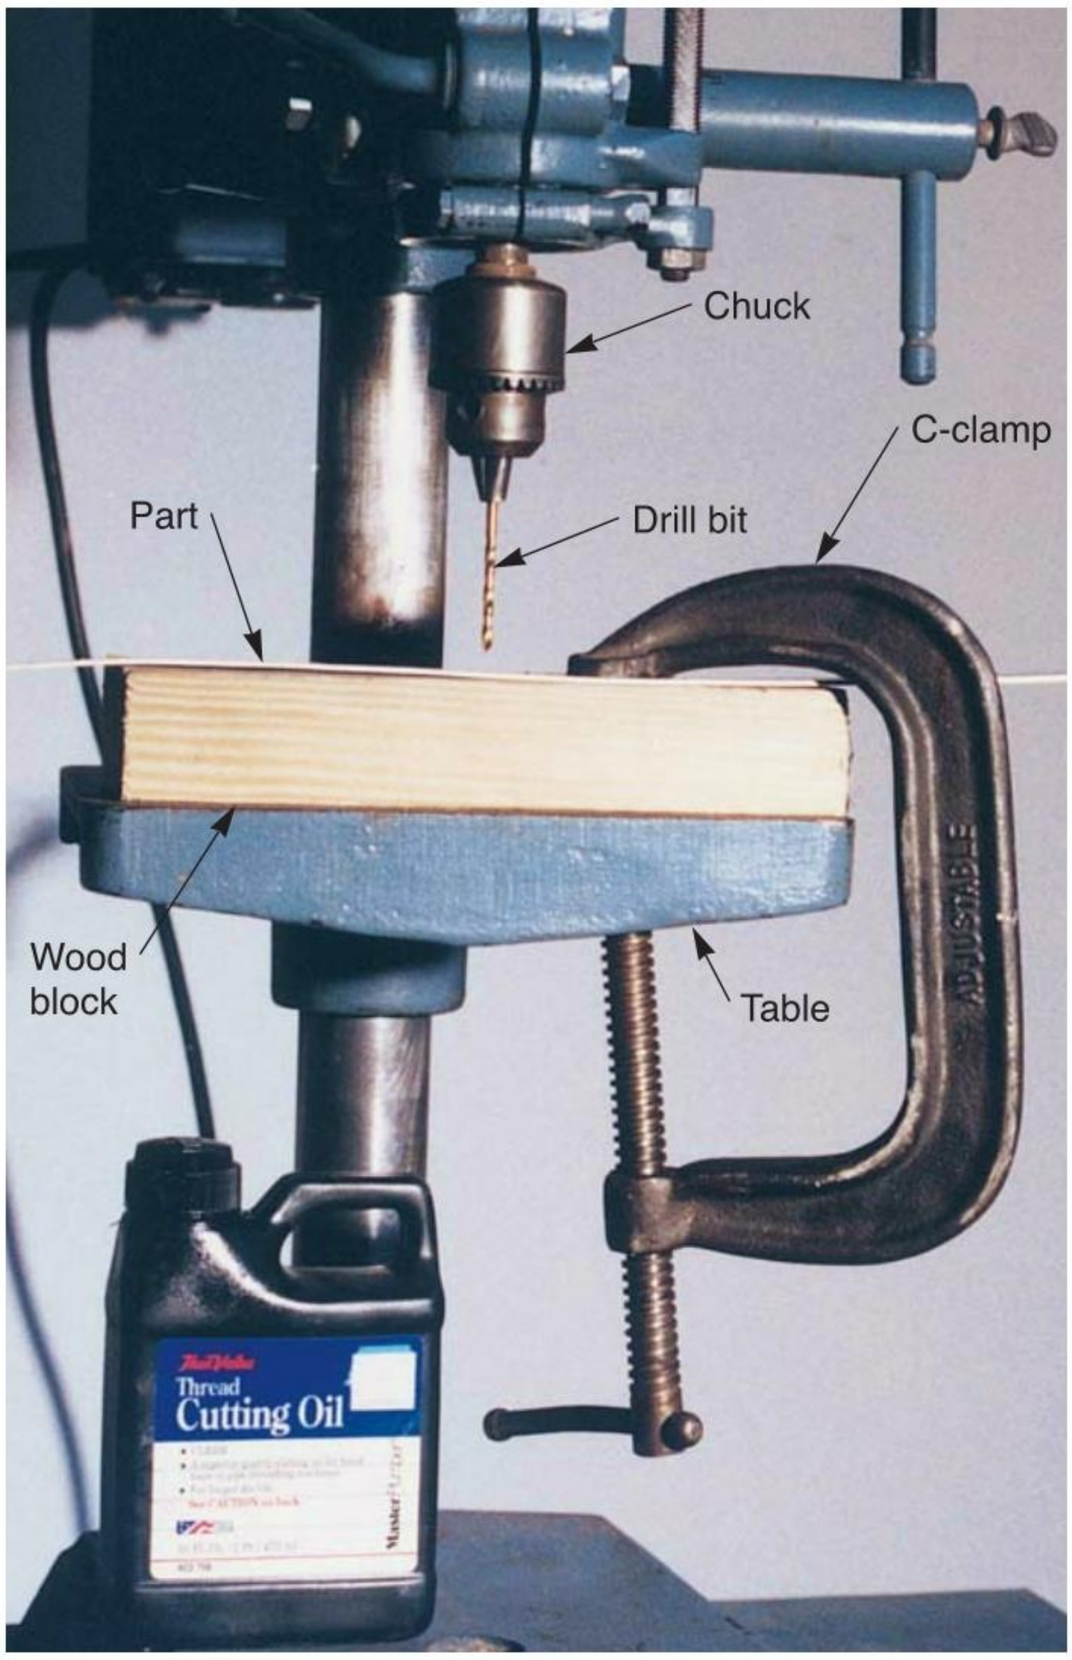
C-Clamp

A ***C-clamp*** holds parts on a work surface when drilling, filing, cutting, welding, or doing other operations. Being portable, it can be taken to the job. C-clamps come in many different sizes. Refer to **Figure 3-20**.

Stands and Holding Fixtures

Stands and ***holding fixtures*** can be used to secure heavy or clumsy parts during repairs. Cylinder head stands, transmission fixtures, rear axle holding stands, and others will make your work safer and easier. Look at **Figure 3-21**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 3-20. A C-clamp is a portable means of securing parts. It can also be used for light pressing operations.

Goodheart-Willcox Publisher

Figure 3-21. A cylinder head stand holds the head in position during valve and seat work. Other specialized stands are available for transmissions, differentials, and other parts.

Copyright Goodheart-Willcox Co., Inc.

Cleaning Tools

There is an old saying, "if you do the job right, you will spend most of your time cleaning parts." Dirt is a major enemy of a vehicle and your repairs.

Tech Tip

One grain of hard crystalline sand can cause severe part damage and failure. Sand can easily clog small internal passages in castings, or scratch and mar rubber seals and soft aluminum parts.

Cleaning tools, such as scrapers and brushes, help the technician remove carbon, rust, dirt, grease, old gaskets, and dried oil from parts.

Scrapers remove grease, gaskets, sludge, dried oil, and carbon on flat parts. Wear work gloves and keep your other hand out of the way to avoid deep cuts.

Brushes are used to remove light rust, paint, and dirt on round or irregularly shaped parts. They are slow and should be used only when heavy, flaky, chalky deposits are coming off the curved surface of the part.

Probe and Pickup Tools

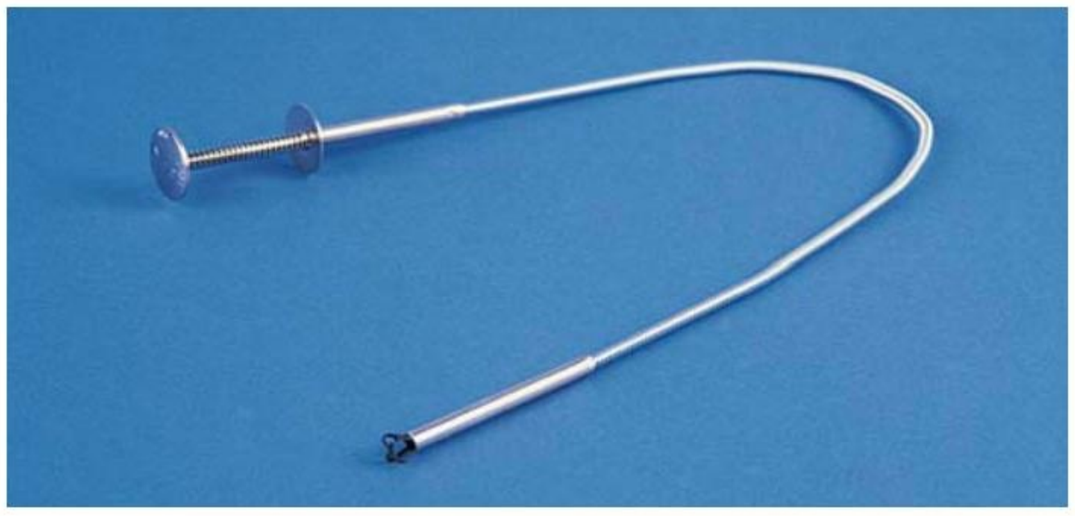
Pickup tools are needed when bolts, nuts, or other small parts are dropped and cannot be reached by hand. A magnetic pickup tool is a magnet hinged to the end of a rod. It can usually be shortened or lengthened and swiveled to reach into any area. If a ferrous (iron) metal part is dropped, it will be attracted and stick to the magnet, **Figure 3-22A**. A finger pickup tool grasps nonmagnetic parts (aluminum, plastic, or rubber), which will not stick to a magnet, **Figure 3-22B**.

A mirror probe allows you to look around corners or behind parts, **Figure 3-22C**. For example, a mirror probe will allow you to see an oil leak behind the engine.

Cutting Tools

Various cutting tools are needed to open part boxes, cut off insulation, and to do similar tasks. A few types of cutting tools used by the auto technician are shown in **Figure 3-23**.

A—Magnetic Pickup Tool



B—FInger Pickup Tool

C—Mirror Probe

A—Razor Blade Scrapers

B—Gasket Scapers or Putty Knives

C—Spring Gasket Scrapers

Snap-on Tool Corp.

Figure 3-23. Cutting and scraping tools must be used carefully.

Pry Bars

Pry bars are strong steel bars. They are helpful during numerous assembly, disassembly, and adjustment operations. They are also used to align heavy parts. When prying, always be careful to not damage any part of the vehicle.

Insulated Tools

Insulated tools are designed to protect against electric shock and electrocution when working on electric circuits. Insulated tools designed specifically for use on high-voltage circuits should be used for hybrid electric drive train service. Only use tools rated at 1000 V for high-voltage service work. You can purchase sets of insulated tools to be used for hybrid drive vehicles.

Warning

Conventional insulated steel tools, such as those intended for residential electrical work, must never be used in place of tools designed for servicing the high-voltage systems found in hybrid vehicles. A conventional steel wrench or ratchet with a rubber or plastic handle will have thin insulation that is not designed for use with high voltages.

Insulated wrenches are conventional steel coated with synthetic plastic that prevents electric current from accidentally flowing through the wrench and your body. Refer to **Figure 3-24A**.

Electrician's pliers have gripping and cutting surfaces for working with wiring, **Figure 3-24B**. An insulated handle is provided to help prevent electrocution from high-voltage sources. High-voltage pliers, or cable pliers, have jaw and handle insulation to prevent

Figure 3-24. Insulated tools are used when working with high-voltage circuits, such as electric drive trains.

electric shock from spark plug wires. Plastic pliers are made of solid insulating material for the highest protection when working with high-voltage hybrid electric drive train circuits.

Graphite and HV screwdrivers have a plastic handle and a plastic shank, while only the tip of the tool is made of conductive, hardened steel. Since the whole screwdriver, apart from the tip, is made of high-strength plastic, it will not conduct high voltage into your hand the way a conventional metal shank screwdriver would.

Workplace Skills

A properly designed tool acts as an extension of your body or mind. Tools are essential to the repair of any motor vehicle. For this reason, you should learn about new tools as they are developed. A good tool is a wise investment that will help you be a more productive, successful technician. To learn more about tools, visit tool manufacturer websites.

Summary

- It is almost impossible to do even the simplest auto repair without using some type of tool.
- Professional auto technicians invest thousands of dollars in tools. A well-selected set of tools will speed up repairs, improve work quality, and increase profits.
- Purchase quality tools. Quality tools are lighter, stronger, easier to use, and more dependable than off-brand, bargain tools.
- Keep tools organized. There should be a place for every tool and every tool should be in its place.
- Use the right tool for the job. A good technician will know when, where, and why a particular tool will work better than another.
- A 6-point wrench is the strongest wrench configuration.
- A socket is a cylinder-shaped, box-end tool for removing or installing bolts and nuts.
- Socket handles fit into the square opening in the top of the socket.
- A ratchet is the most commonly used and versatile socket handle. It can either loosen or tighten bolts.
- Extensions are used between a socket and its handle.
- Pliers are used to grip, cut, crimp, hold, and bend various parts.
- A vise is used to hold parts during cutting, drilling, hammering, and pressing operations.
- Cleaning tools, such as scrapers and brushes, help a technician remove carbon, rust, dirt, grease, old gaskets, and dried oil from parts.
- Pry bars are strong steel bars that are helpful during numerous assembly, disassembly, and adjustment operations.
- Insulated wrenches have a plastic or carbon fiber shank with metal ends. They are required when working on high-voltage hybrid drivetrain components.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

adjustable wrench
Allen wrench
ball peen hammer
C-clamp
chisel
cleaning tool
dead blow hammer
extension
file
hacksaw
holding fixture
impact driver
pickup tool
pipe wrench
plastic hammer
pliers
pry bar
punch
rubber mallet
scratch awl
screwdriver
sledgehammer
socket
socket handle
stand
tool holder
toolbox
universal joint
vise
vise cap
wrench
wrench size

Activities

1. Create a list of hand tools needed to equip an automotive shop. Provide an estimate of what it will cost to purchase the tools. Use automotive websites, such as www.snapon.com, for tool descriptions and prices.
2. Discuss tool safety with your instructor. Prepare a list of safety regulations for your shop area.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List and explain four general tool rules.
2. A bolt head is rusted and partially rounded off. Which wrench would work best for removing the bolt?
   (A) Open-end wrench.
   (B) 6-point box-end wrench.
   (C) 12-point box-end wrench.
   (D) None of the above.
3. What are the four socket drive sizes? Explain when each should be used.
4. _____ or _____ screwdrivers are useful in very tight places, such as inside a glove box.
5. Describe four rules to follow when using hammers.
6. What is the difference between a center punch, a starting punch, and an aligning punch?
7. A coarse file should be used on _____ materials. A fine file should be used on _____ materials.
8. When should you use vise caps?
9. List and explain four vise rules.
10. Which of the following tools should be used to remove old gasket material from a flat surface?
    (A) Hand scraper.
    (B) Chisel.
    (C) Probe.
    (D) Pry bar.

ASE-Type Questions

1. A bolt head is badly rusted and is difficult to loosen. Technician A says to use a pair of pliers to loosen the rusted bolt. Technician B recommends a six-point wrench or socket. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Which of the following is *not* a common socket drive size?
   (A) 1/4″
   (B) 3/8″
   (C) 5/8″
   (D) 1/2″
3. The socket handle that has a gear and lever mechanism that allows it to be moved back and forth for rapid fastener removal or installation is the:
   (A) ratchet.
   (B) flex bar.
   (C) breaker bar.
   (D) speed handle.

Copyright Goodheart-Willcox Co., Inc.

4. A(n) _____ is a swivel that lets the socket wrench reach around obstructions.
   (A) extension
   (B) hand spinner
   (C) flexible driver
   (D) universal joint

5. When working with sockets, Technician A states that a socket's "point" is the size of the square opening for the handle. Technician B states the point of a socket is the box configuration for the bolt head. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

6. Which type of screwdriver is especially good to use in tight spaces?
   (A) Torx.
   (B) Stubby.
   (C) Phillips.
   (D) Clutch head.

7. Pliers are used on various parts to do each of these *except:*
   (A) cut.
   (B) grip.
   (C) bend.
   (D) screw.

8. Which type of pliers open extra wide to hold very large objects?
   (A) Rib joint.
   (B) Locking.
   (C) Slip joint.
   (D) All of the above.

9. The heaviest kind of hammer is:
   (A) lead.
   (B) brass.
   (C) sledge.
   (D) dead blow.

10. Which punch configuration is used to mark parts for reassembly or to start a drilled hole?
    (A) Center.
    (B) Aligning.
    (C) Tapered.
    (D) Diamond.

Chapter 4
Power Tools and Equipment

After studying this chapter, you will be able to:

- List the most commonly used power tools and equipment.
- Describe the uses for power tools and equipment.
- Explain the advantages of one type of tool over another.
- Explain safety rules that pertain to power tools and equipment.
- Correctly answer ASE certification test questions that require a knowledge of power tools and equipment.

To be a productive technician in today's auto service facility, you must know when, why, and how to use power tools and equipment. ***Power tools*** are tools driven by compressed air, electricity, or pressurized liquid. They make many repair operations easier and quicker. Large shop tools, such as floor jacks, parts cleaning tanks, steam cleaners, and battery chargers, are called ***shop equipment***.

This chapter discusses the proper selection and use of common power tools and equipment. Specialized power tools and equipment are covered in later chapters. Refer to the index to find more information on them as needed.

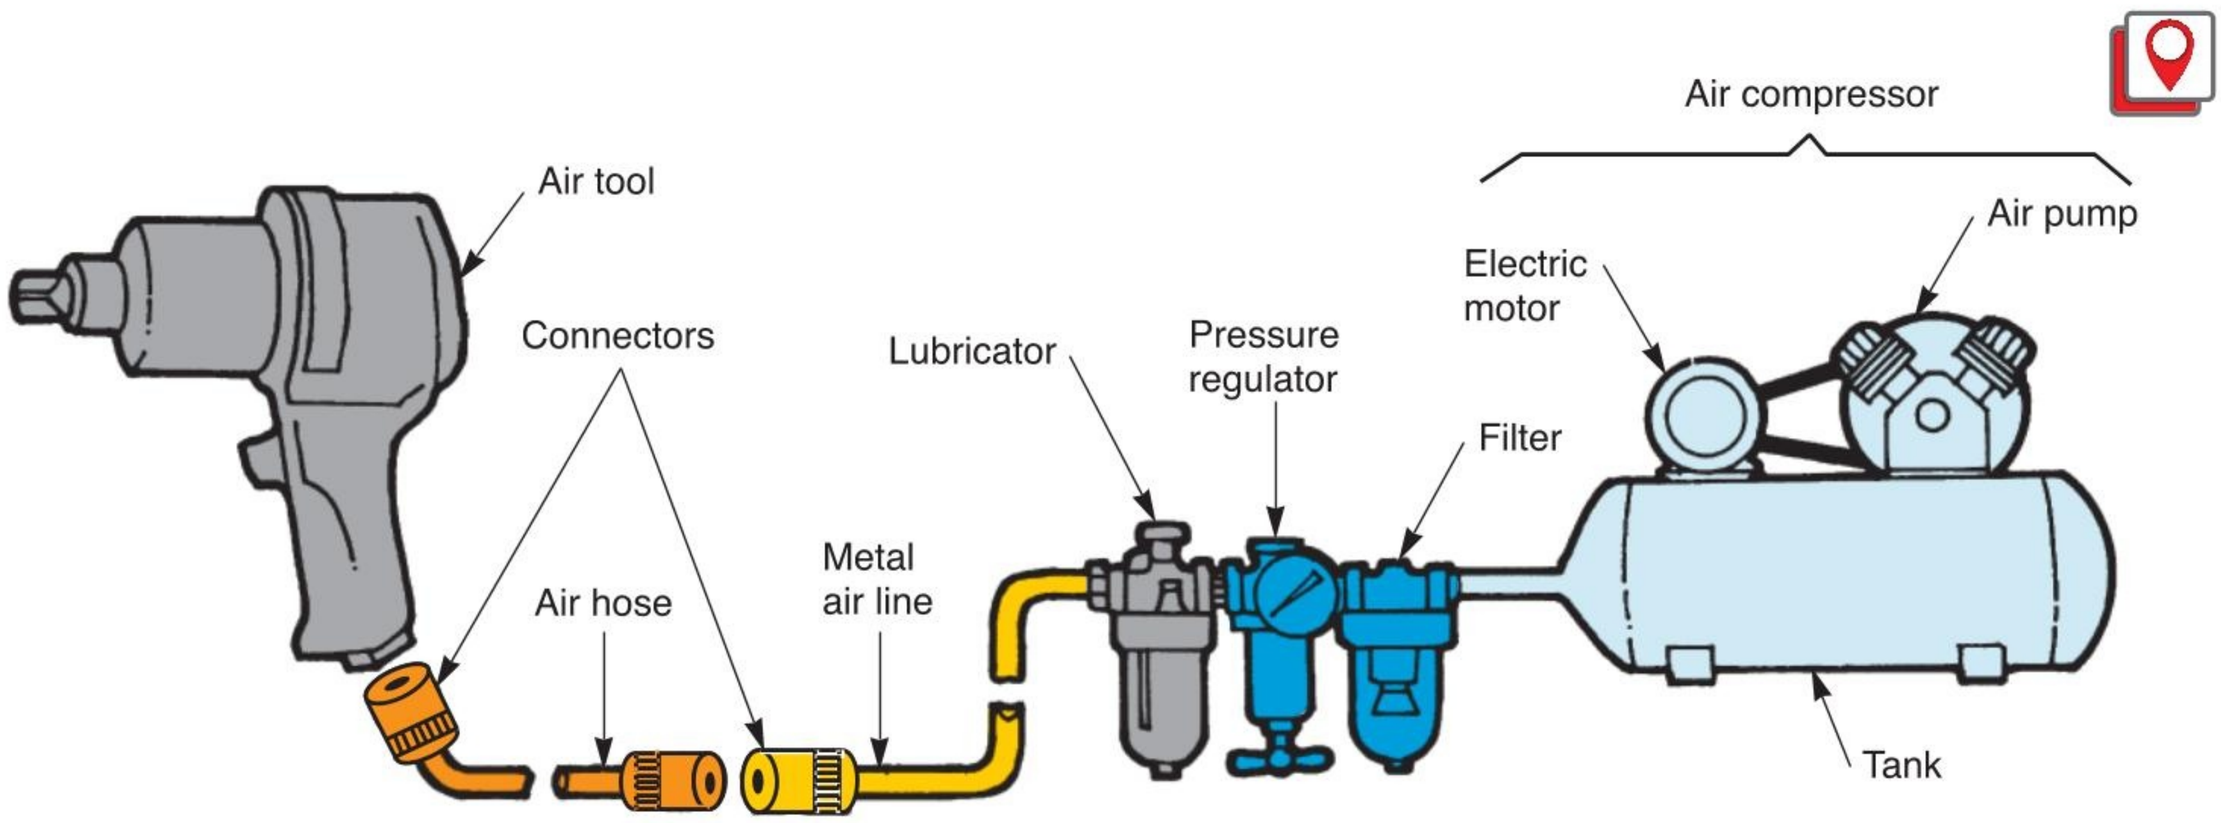
Caution

Auto shop equipment can be very dangerous if misused. Always follow the operating instructions from the equipment manufacturer. If in doubt, ask your instructor or shop service manager for a demonstration of the power tool or equipment.

Compressed-Air System

The components of a compressed-air system include an air compressor, air lines, air hoses, and air tools. In addition, a pressure regulator, filter, and lubricator may be attached to the system. Air tools are driven by the compressed-air system. Air-powered tools can be found in nearly every service facility. Look at **Figure 4-1**.

Copyright Goodheart-Willcox Co., Inc.



Florida Dept. of Voc. Ed.

Figure 4-1. Study the basic parts of a typical compressed air system. The air compressor develops air pressure. The filter removes moisture. The pressure regulator allows the technician to control system pressure. Metal lines and flexible hoses carry pressurized air to the tool. A lubricator can be added to the system to keep the air tools oiled and functioning properly.

Air Compressor

An ***air compressor*** is the source of compressed air for an automotive service facility. An air compressor normally has an electric motor that spins an air pump. The air pump forces air into a large, metal storage tank. The air compressor turns on and off automatically to maintain a preset pressure in the system.

Warning

Shop air pressure usually ranges from 100–150 psi (689–1034 kPa). This is enough pressure to kill or severely injure a person. Respect shop air pressure!

Air Lines and Hoses

Metal air lines feed out from the air compressor's tank to several locations in the shop. Technicians can then connect their flexible high-pressure ***air hoses*** to the metal lines. These hoses allow the technician to take a source of air pressure to the vehicle being repaired. ***Quick-disconnect couplings*** are used to connect air hoses and air tools to the compressed air system without using a wrench. To join or separate a quick-disconnect coupling, pull back on the coupling's outer sleeve with finger pressure. With the sleeve pulled back, you can push the coupling together or pull it apart.

Pressure Regulator, Filter, and Lubricator

A ***pressure regulator*** is used to set a specific pressure in the compressed-air system. This pressure is often called shop pressure. In most cases, shop pressure is between 100 and 150 pounds per square inch (psi). A filter may be connected to the system. The filter removes water from the compressed air. This increases the life of air tools. In addition, a lubricator may also be connected to the system. The ***lubricator*** introduces oil into the airstream. This also increases the life of air tools.

Air Tools

Air tools, or pneumatic tools, use the stored energy of compressed air for operation. Air tools are labor-saving devices and well worth their cost. Always lubricate the tool before and, more importantly, after use. While pressing the air tool's trigger, squirt a few drops of air tool oil into the tool's air inlet fitting. Not only will the oil protect internal parts of the tool, but it will also prevent the internal parts from rusting during storage. Hold a rag around the air outlet and run the oiled tool briefly to circulate the lubricant through the air motor. Excess oil will be sprayed into your shop rag. Wipe the tool clean before use or storage.

Snap-on Tool Corp.

Figure 4-2. 1/2″ drive impact wrench.

Impact Wrenches

Impact wrenches are heavy-duty air wrenches that produce a great deal of torque to remove or install fasteners. They use an air motor to produce a striking, or hammering, force that rotates the driving head. The driving head holds a special impact socket. Look at **Figure 4-2**.

Impact wrenches come in 1/4″, 3/8″, 1/2″, and 3/4″ drive sizes. The 1/4″ drive is for tiny machine screws in the interior or on trim pieces of the vehicle. A 3/8″ drive impact is ideal for small fasteners, such as 1/4″–9/16″ bolts. A 1/2″ drive is for general purpose use with medium to large fasteners, such as 1/2″–1″ bolts and wheel lug nuts. The 3/4″ drive impact is for extremely large fasteners found on trucks. A button or switch on the impact wrench controls the direction of rotation, usually clockwise to tighten and counterclockwise to loosen. The positions are typically labeled.

Caution

Until you become familiar with the operation of an impact wrench, be careful not to overtighten bolts and nuts or leave them too loose. It is easy to strip or break fasteners with this air tool. It is best to use a torque wrench on all fasteners so you are sure the repair is safe.

Air Ratchet

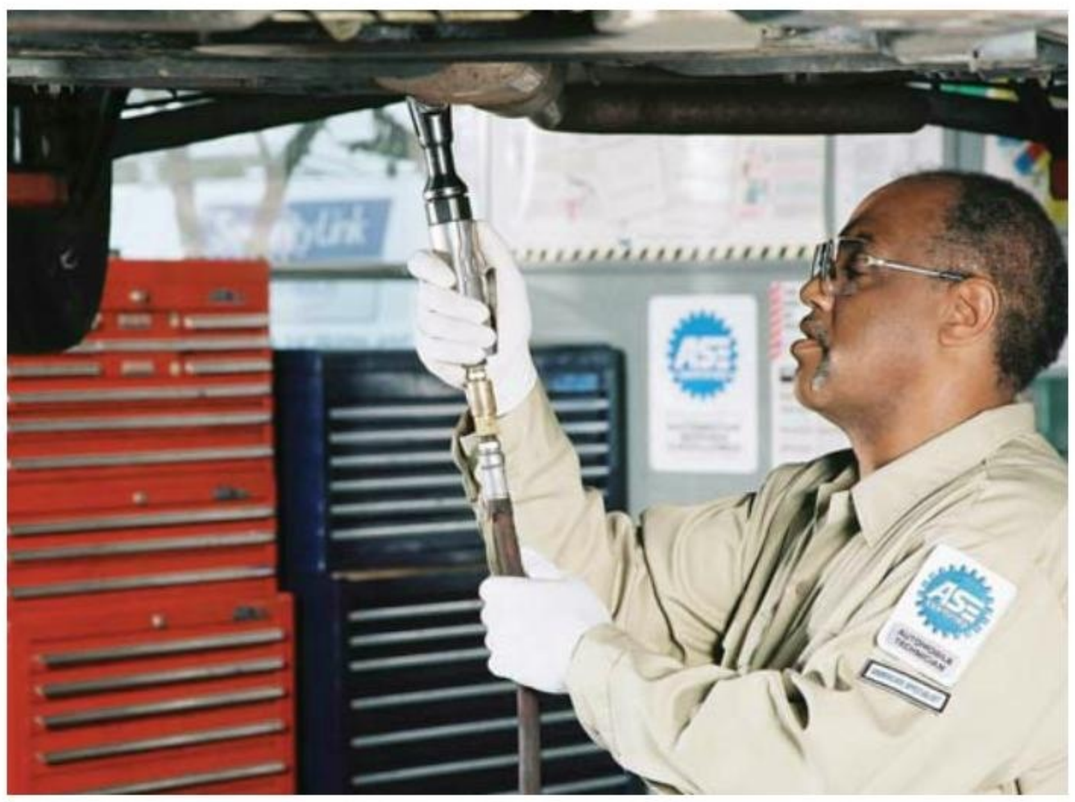
An ***air ratchet*** is a special air wrench designed to quickly install or remove fasteners. It can be used for working in limited spaces. However, it does not have very much turning power. Final tightening and initial loosening must often be done with hand tools. For instance, an air ratchet is commonly used when removing water pumps. It will fit between the radiator and engine easily. It works in much the same way as a hand-tool ratchet. Air ratchets are available as 1/4″, 3/8″, and 1/2″ drives. See **Figure 4-3**.

Impact Sockets and Extensions

Special black ***impact sockets*** and ***impact extensions*** must be used with air and electric wrenches. Impact tools are case-hardened steel, and are thicker and much stronger than conventional chrome-plated sockets and extensions. A conventional chrome socket can be easily broken or damaged by the hammering blows of an impact wrench. Impact sockets and extensions can be quickly identified because they have a flat black finish.

Caution

Know when to use power tools. In most situations, power tools will speed up your work. However, there are times when they should not be used. For example, never use an impact wrench in place of a torque wrench. An impact wrench will not torque critical fasteners to their correct specification. Vehicle problems, shop comebacks, customer complaints, and even auto accidents can result from improperly torqued fasteners.



ASE

Figure 4-3. This technician is using an air ratchet to spin out small fasteners under the vehicle.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 4-4. An air hammer is useful for tasks such as quickly cutting off a rusted exhaust system. *Always* wear safety glasses.

Air Hammer

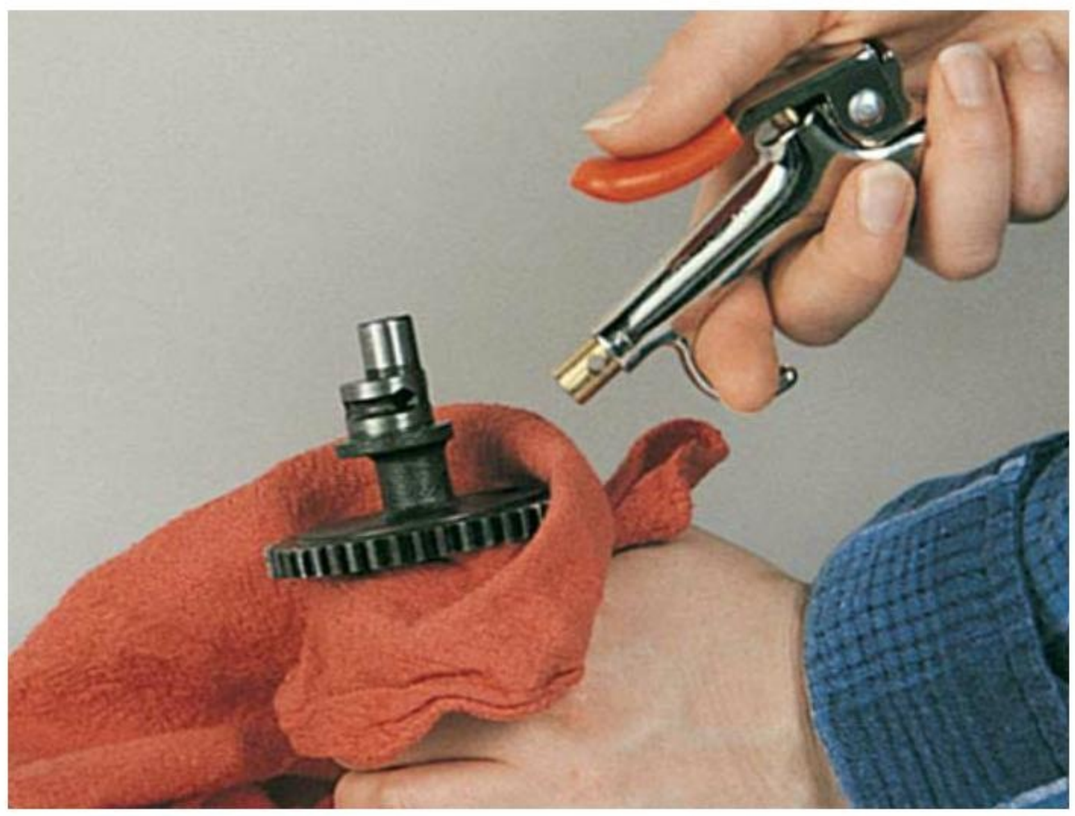
An ***air hammer***, or ***air chisel***, is useful during various driving and cutting operations. Look at **Figure 4-4**. An air hammer is capable of producing about 1000–4000 impacts per minute. Several different cutting or hammering attachments are available. Be sure to select the correct one for the job.

Warning

Never turn on an air hammer unless the tool head is pressed tightly against the workpiece. Otherwise, the tool head can fly out of the hammer with great force, as if shot from a gun!

Blowgun

An air-powered ***blowgun*** is commonly used to dry and clean parts washed in solvent. It is also used to blow dust and loose dirt from parts before or during disassembly. See **Figure 4-5**. When using a blowgun, wear eye protection. Direct the blast of air away from yourself and others. Do not blow clean brake and clutch parts. The dust from these parts may contain asbestos. Asbestos is a cancer-causing substance. Another type of blowgun is a ***solvent gun***. It can be used to wash parts that will not fit into a cleaning tank.



Goodheart-Willcox Publisher

Figure 4-5. Blowguns are used to clean parts.

Air Drill

An ***air drill*** is excellent for many tasks because of its power output and speed adjustment capabilities. Its power and rotating speed can be set to match the job at hand. With the right attachments, air drills can drill holes, grind, polish, and clean parts. Look at **Figure 4-6**.

A ***rotary brush*** is used in an air or electric drill for rapid cleaning of parts. It can quickly remove old gasket material, carbon deposits, and rust with a minimum amount of effort.

Goodheart-Willcox Publisher

Figure 4-6. The chuck speed of an air drill can be adjusted by controlling airflow into the tool. The air drill is capable of very high turning force.

Copyright Goodheart-Willcox Co., Inc.

Warning

Use a high-speed rotary brush in an air drill. A brush designed for an electric drill may fly apart. To be safe, always adjust an air drill to the slowest acceptable speed when using a rotary brush. Also, always wear eye protection.

An ***abrasive pad*** is another type of cleaning tool that can be used in an air or electric drill. It is used for removing old gasket material. It has the advantage of not scratching aluminum like a rotary brush can.

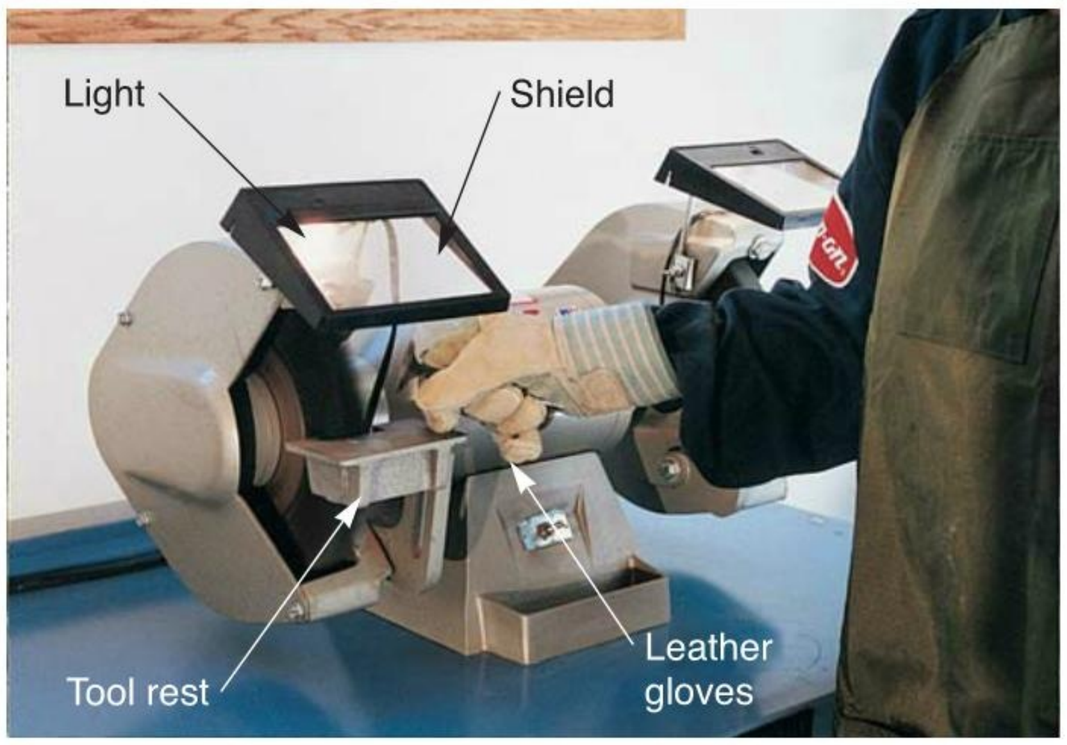
A ***rotary file***, or stone, can be used in an air drill, electric drill, or air (die) grinder. It is handy for removing metal burrs and nicks. Make sure the stone is not turned too fast by the air tool. Normally, the maximum speed is printed on the file or stone container. See **Figure 4-7**.

Goodheart-Willcox Publisher

Figure 4-7. This die grinder is equipped with a high-speed stone. This tool is used for removing burrs and for other smoothing operations. Here, the technician is making minor repairs to a damaged cylinder head combustion chamber.

Electric Tools

There are many ***electric tools*** that can be useful to a technician. Some of these tools, such as a drill press or grinder, may be fixed to the floor or a bench. Other tools, such as a rechargeable drill or a rechargeable electric impact gun, are portable and can be taken to the job site. Rechargeable power tools are becoming more common because you do not have to struggle with a clumsy, heavy air hose connected to the tool.



Snap-on Tool Corp.

Figure 4-8. The grinding wheel on a bench grinder is used to sharpen tools. The wire wheel can be used to clean and polish small parts. *Always* keep shields, tool rests, and guards in place.

Bench Grinder

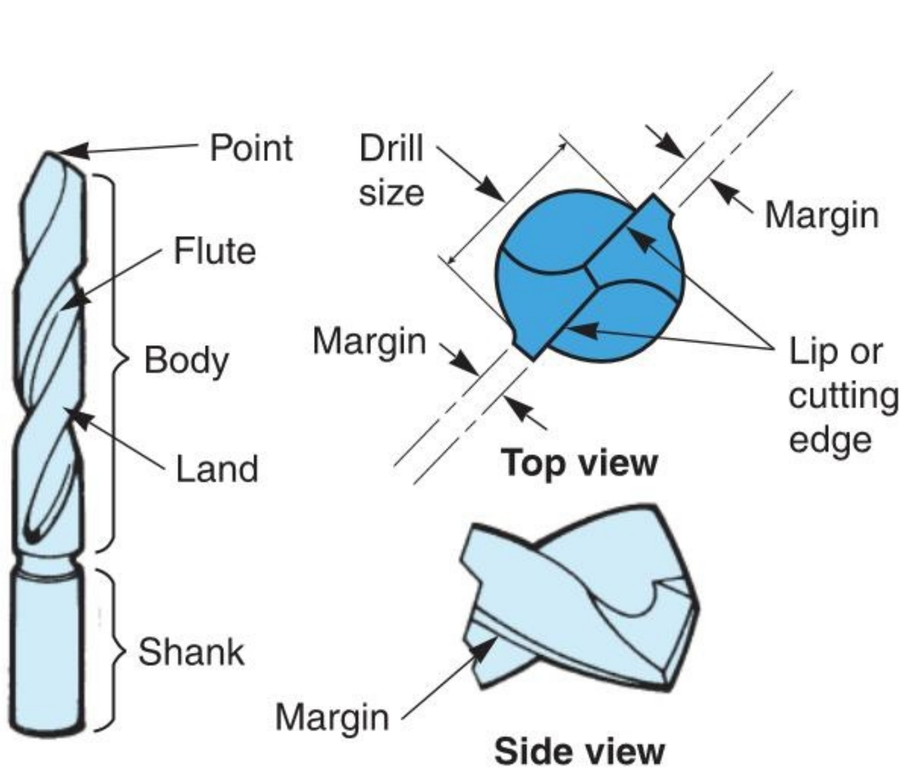
A ***bench grinder*** can be used for grinding, cleaning, or polishing operations, **Figure 4-8**. A bench grinder usually has two wheels—a grinding wheel and a wire wheel. The hard, abrasive grinding wheel is used for sharpening and deburring metal tools, such as chisels and punches. The soft wire wheel is used for cleaning and polishing metal tools, such as scrapers and putty knives. A few bench grinder rules to follow are:

- Always wear eye protection and keep your hands away from the wheel.
- Make sure the grinder shields are in place.
- Keep the tool rest adjusted close to the wheel. If the rest is not close to the wheel, the part being ground can catch in the grinder.
- Do not use a wire wheel to clean soft metal parts, such as aluminum pistons or brass bushings. The abrasive action of the wheel can remove metal or scuff the part and ruin it. Instead, use a solvent and a dull hand scraper on soft metal parts.

Drills

Drills are used to create holes in metal and plastic parts. Some drills are portable; others are mounted on a workbench or the floor. Drills use different-sized bits to create the size of hole needed.

Copyright Goodheart-Willcox Co., Inc.



Florida Dept. of Voc. Ed.

Figure 4-9. Note the basic parts of a drill bit.

Bits

Drills use ***drill bits***, or twist drills, to drill holes in metal and plastic parts, **Figure 4-9**. A drill bit is mounted in the drill chuck. A special key, called a chuck key, is sometimes needed to tighten the drill bit in the chuck, **Figure 4-10**. A keyless chuck uses a ribbed, rubber thumbwheel to adjust the chuck jaws without a key. Drill bits are commonly made of either carbon steel or high-speed steel. High-speed steel is better because of its resistance to heat. It will not lose its hardness when slightly overheated.

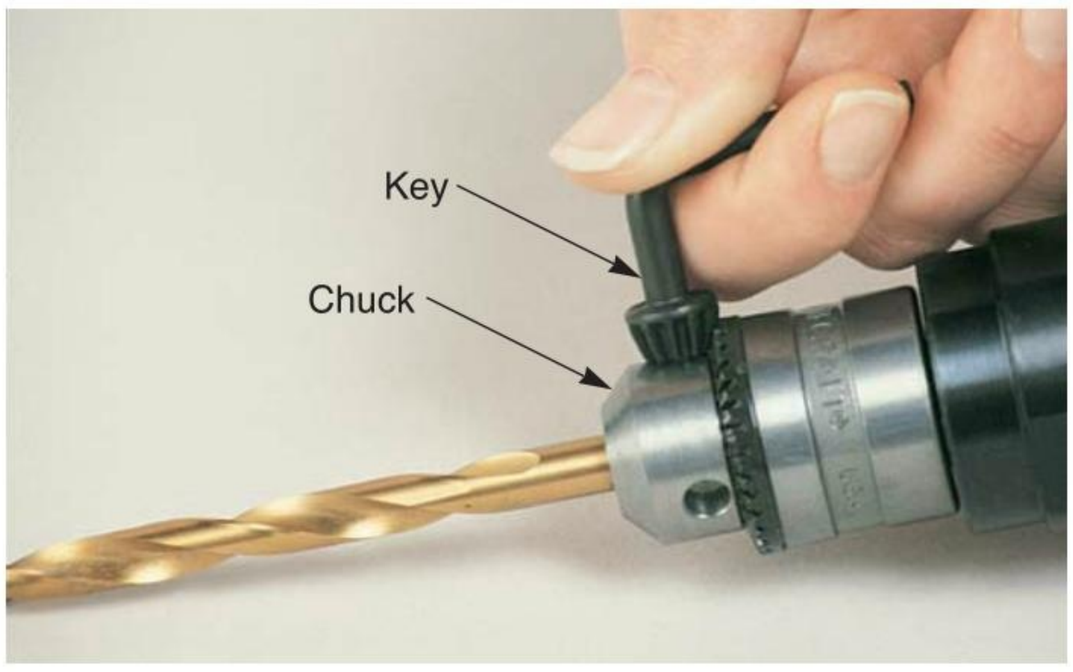
Portable Electric Drill

Portable electric drills are handheld drills. They come in different sizes. The size of a drill is an indication of the capacity of its chuck. Today's rechargeable electric drills work fine for virtually all automotive applications. However, an electric drill with a power cord is needed for difficult or high-torque operations. Commonly used sizes are 1/4″, 3/8″, and 1/2″, **Figure 4-11**.

Drill Press

A ***drill press*** is a large, floor- or bench-mounted drill needed for drilling large holes, deep holes, or a great number of holes in several parts, **Figure 4-12**. The drill press handle allows the bit to be pressed into the work with increased force. Also, very large bits can be used. A few drill press rules to follow include:

- Remove the key from the chuck before turning on the drill press.
- Secure the part to be drilled with C-clamps or other holding fixtures.



A

B

Goodheart-Willcox Publisher

Figure 4-10. The drill chuck has adjustable jaws that hold the drill bit securely in place. A—A key is sometimes used to tighten a bit in the chuck. B—Keyless drill chucks can be tightened by hand.

- Use a center punch to indent the part and start the hole.
- To prevent injury, release drilling pressure right before the bit breaks through the bottom of the part. A drill bit tends to catch when breaking through. This can cause the drill or the part to rotate dangerously.
- Oil the bit as needed. Oil pulls heat out of the bit and transfers it into the base metal being drilled. Without oil, a drill bit can overheat and lose its hardness before dulling quickly.

Hydraulic Tools

Hydraulic tools are powered by pressurized liquid. The hydraulic tools typically used in the automotive shop include jacks, cranes, and presses. These tools are discussed in the next sections.

Copyright Goodheart-Willcox Co., Inc.

A—3/8″ Drill **B—1/2″ Drill** **C—Cordless Drill**

Robert Bosch

Figure 4-11. Note the styles of portable electric drills.

a_v_d/Shutterstock.com

Figure 4-12. The parts of a drill press. A drill press is for drilling deep or large holes when a part will fit on the table.

Floor Jack

A ***floor jack*** is used to raise either the front, sides, or rear of a vehicle. To avoid vehicle damage, place the jack saddle under a solid part of the car, such as the frame, suspension arm, or axle housing. If the saddle is not properly located, it is very easy to smash the oil pan, muffler, floor pan, or another part of the vehicle. To raise the vehicle, turn the jack handle or knob clockwise and pump the handle. To lower the vehicle, turn the handle or knob counterclockwise slowly to open the pressure-release valve. Look at **Figure 4-13**.

Goodheart-Willcox Publisher

Figure 4-13. Remember to use a floor jack with jack stands to secure the vehicle. A floor jack is only for raising the vehicle off the ground.

Copyright Goodheart-Willcox Co., Inc.

When raising a vehicle, place the transmission in neutral and release the parking brake. This lets the vehicle roll, preventing it from pulling off the jack. After raising, secure the vehicle on jack stands. Place an automatic transmission in park and a manual transmission in gear. Apply the emergency brake and block the wheels. It is then safe to work under the vehicle.

Caution

Most floor jack handles tend to stick when the pressure-release valve is opened. This makes it easy for you to lower the vehicle too quickly. When opening the valve, turn it very slowly. This will prevent the car or truck from slamming to the ground violently!

Transmission Jack

Transmission jacks are designed to hold transmissions and transaxles during removal or installation. One type is similar to a floor jack. However, the saddle is enlarged to fit the bottom of a transmission. Another type of transmission jack is designed to be used when the vehicle is raised on a lift. It has a long post that can reach high into the air to support the transmission, **Figure 4-14**.

Engine Crane

A portable ***engine crane*** is used to remove and install heavy engine assemblies. It has a hydraulic hand jack for raising engines and a pressure-release valve for lowering engines. The engine crane is also handy for lifting intake manifolds, cylinder heads, engine blocks, transmissions, transaxles, and other heavy parts, **Figure 4-15**.

Hydraulic Press

A ***hydraulic press*** is used to install or remove gears, pulleys, bearings, seals, and other parts requiring a high pushing force. A hydraulic ram extends as the pump handle is worked. The ram presses the parts against a table. See **Figure 4-16**.

Warning

A hydraulic press can literally exert tons of force. Wear eye protection and use recommended procedures. Parts can break and fly out with deadly force!

A—Low-Profile Transmission Jack

B—High-Lift Transmission Jack

OTC/SPX Corp.

Figure 4-14. Note the types of hydraulic transmission/transaxle jacks found in an auto repair facility.

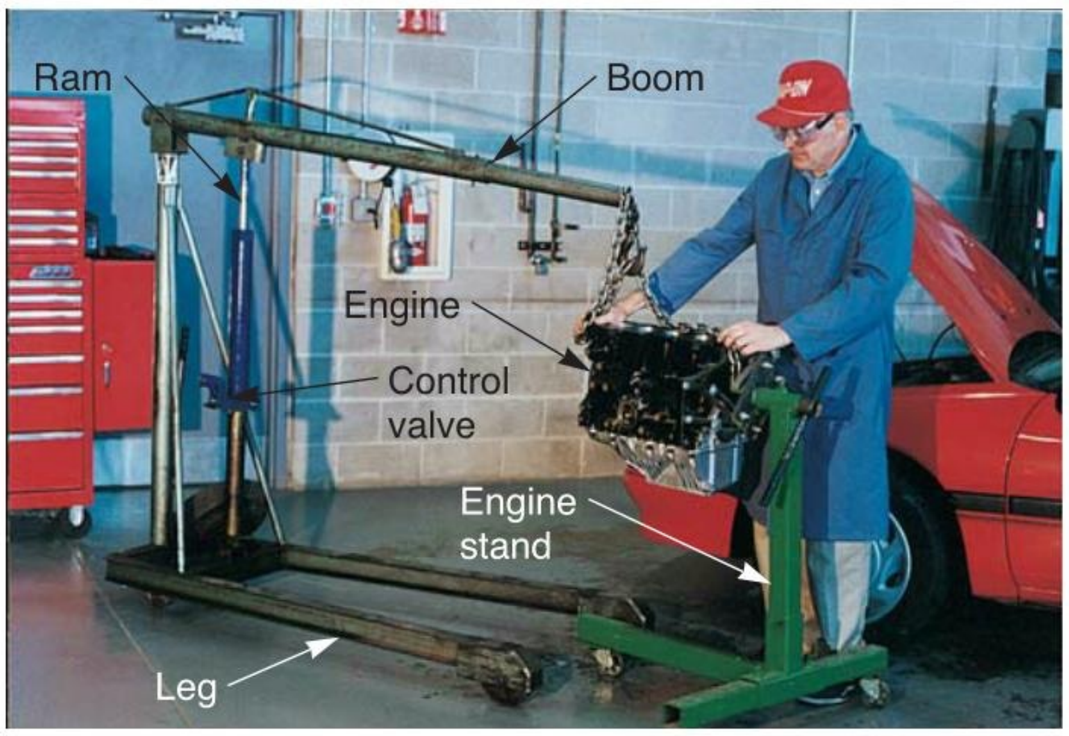
Shop Equipment

In addition to pneumatic, hydraulic, and electric tools, there are various pieces of shop equipment that a technician may find useful. These include tire changers, stands, cleaners, welders, lights, and creepers. Typical shop equipment is discussed in the following sections.

Tire Changer

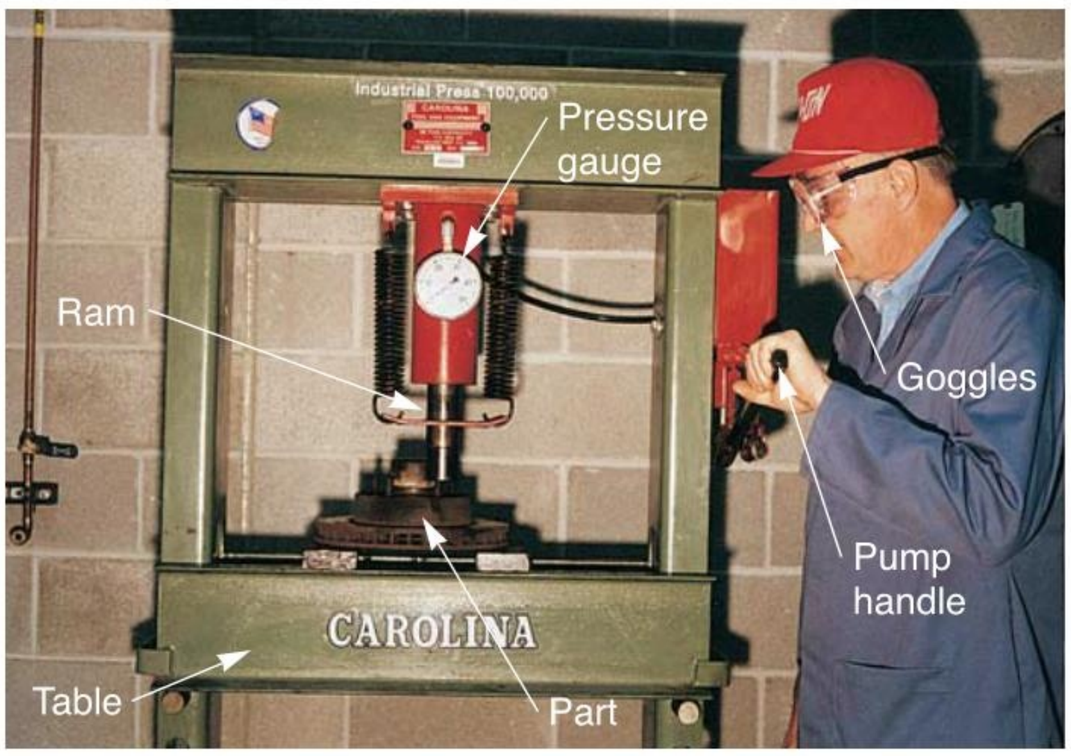
A ***tire changer*** is used to remove and replace tires on wheels. It is a common piece of shop equipment. Some tire changers are pneumatic; others

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 4-15. A hydraulic engine crane can be used to lift heavy objects, such as engines, transmissions, transaxles, and rear axle assemblies. This technician has used a crane to mount an engine on a stand.



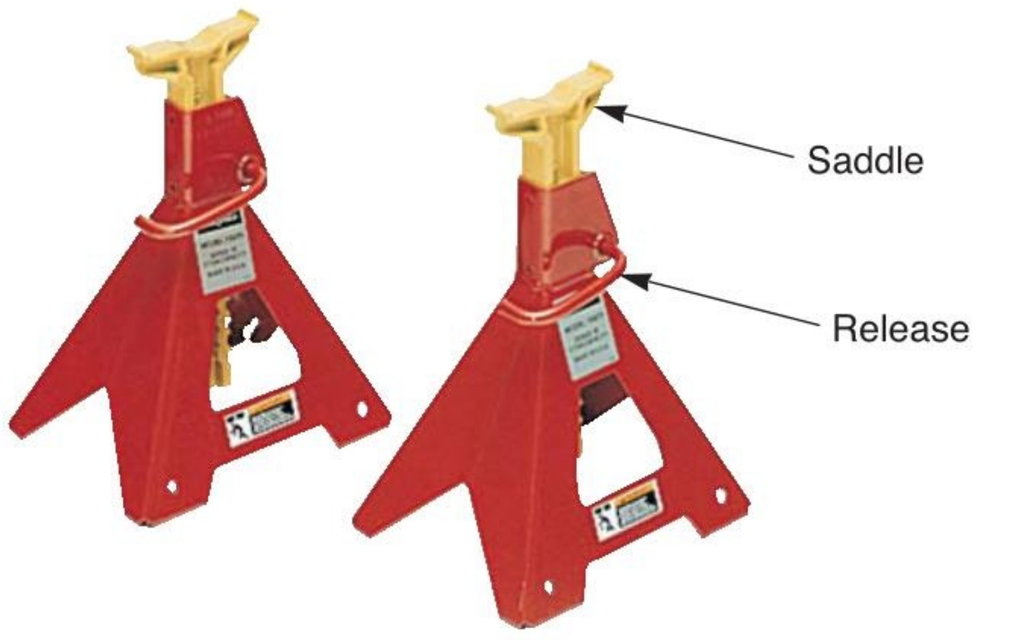
Goodheart-Willcox Publisher

Figure 4-16. A hydraulic press is needed for numerous pressing operations. It is commonly used to remove and install bearings, bushings, seals, and other pressed-on parts.

are hand operated. Do not attempt to operate a tire changer without proper instruction. Follow the directions provided with the changer.

Jack Stands

Jack stands support a vehicle during repairs. After raising the vehicle with a jack, place jack stands under the vehicle. Be sure the jack stands are placed in secure positions. For example, place jack stands under the frame, axle housing, or suspension arm, **Figure 4-17**.



Goodheart-Willcox Publisher

Figure 4-17. Jack stands are essential for safely supporting the weight of the vehicle.

Warning

It is *not safe* to work under a vehicle held up by only a jack. Secure the vehicle on jack stands before placing any part of your body under the vehicle. Even a small car can weigh well over a ton. The next chapter details the safe use of lifts, jacks, and jack stands.

Engine Stand

An ***engine stand*** is used to hold an engine assembly once it is removed from the vehicle for rebuilding or repair. The engine cylinder block bolts to the stand just as it would to the transmission or transaxle. The engine can usually be rotated and held in different positions on the stand, making it easy to work on different parts.

Cold-Solvent Tank

A ***cold-solvent tank*** contains a pump, reservoir, and solvent, and it is used to remove grease and oil from parts. After removing all old gaskets and scraping off excess grease, you can scrub the parts clean in the solvent. A blowgun is then normally used to dry the solvent. See **Figure 4-18**.

High-Pressure Washer and Steam Cleaner

A ***high-pressure washer*** or a ***steam cleaner*** can be used to remove heavy deposits of dirt, grease, and oil from the outside of large assemblies, such as engines, transmissions, and transaxles. Look at **Figure 4-19**. To help keep the environment clean, wire

Figure 4-19. A high-pressure washer will remove greasy buildup from the outside of assemblies before teardown.

brush the item to be cleaned and collect oil-soaked dirt before steaming or washing. Then, dispose of the oil-soaked material properly.

Warning

A steam cleaner operates at high pressures and temperatures. Follow the manufacturer's safety rules and specific operating instructions.

Pressure Blaster

A ***pressure blaster*** is sometimes used to clean rusty or corroded parts. It is an enclosed cabinet that has rubber gloves that extend into the cabinet for sandblasting and for cleaning dry parts.

Oxyacetylene Torch

An ***oxyacetylene torch*** can be used to heat, cut, weld, or braze metal parts. The oxyacetylene setup consists of an oxygen tank, an acetylene tank, pressure regulators, hoses, and a handheld torch. Tremendous heat is produced by the burning acetylene gas and oxygen. The oxyacetylene cutting torch is often used to remove old, rusted exhaust systems, **Figure 4-20A**.

Service Procedure

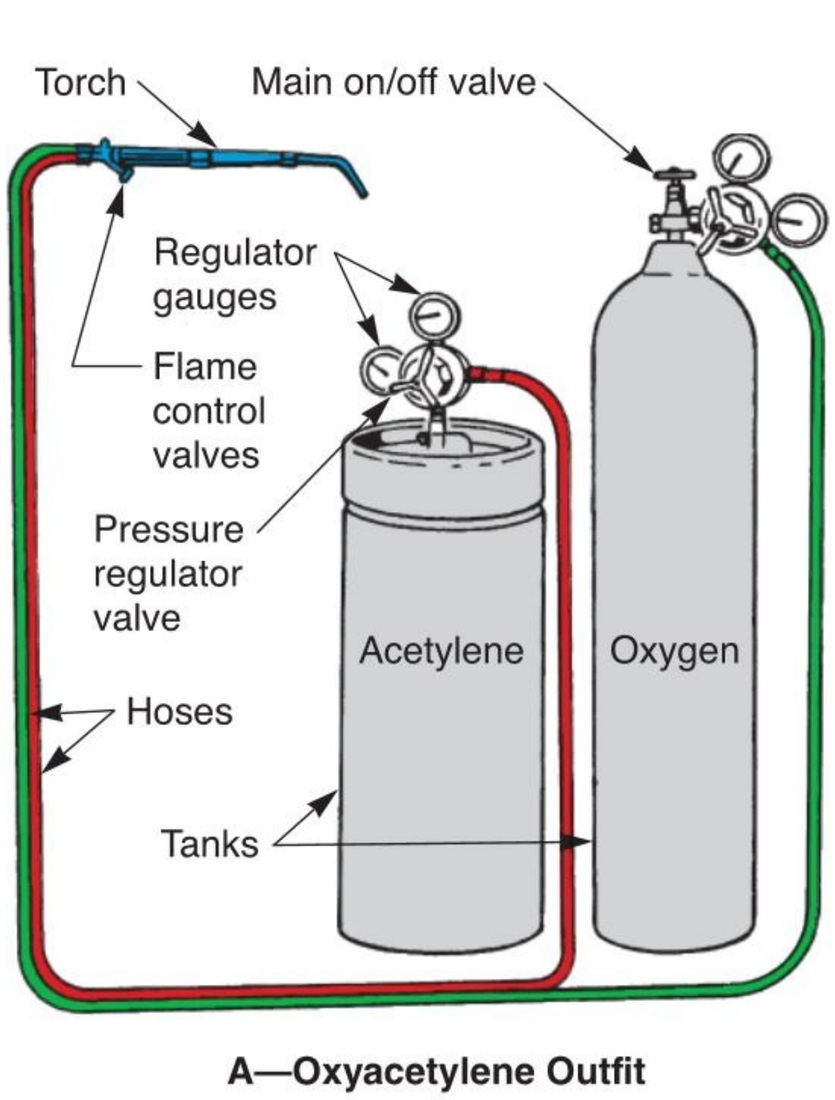
To use an oxyacetylene cutting torch:

1. Put on all necessary protective gear, including a welding helmet or tinted goggles, thick leather welding gloves, and a leather jacket.
2. Inspect the oxyacetylene equipment for damage and make sure all cylinder, regulator, and torch valves are closed. Turn on the main gas valves on both tanks and check hoses for leaks.
3. Light the cutting torch according to the manufacturer's recommendations.
4. With the torch held at a 90° angle to the workpiece, concentrate the flame on the spot where the cut will begin.
5. When the spot becomes cherry red, depress the oxygen-cutting lever to begin the cut.
6. Move the torch along the workpiece slowly and steadily to make a continuous cut.
7. As soon as the cut is complete, release the cutting lever and shut off the torch and main tank valves.

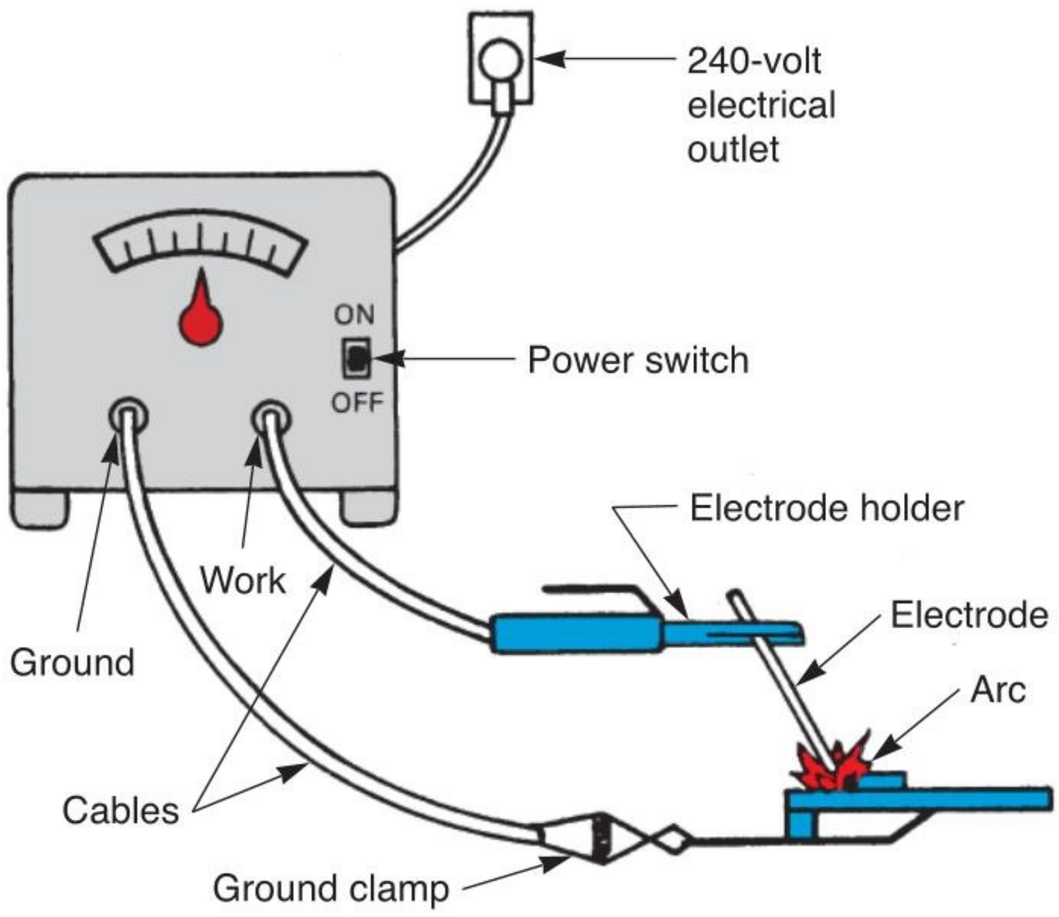
Tech Tip

There are several types of cutting torches available, and the lighting procedure may vary from one type to another. Follow the torch manufacturer's recommendations for lighting, adjusting, and shutting down the torch.

Copyright Goodheart-Willcox Co., Inc.



A—Oxyacetylene Outfit



B—Basic Arc Welder

Sun

Figure 4-20. Technicians must occasionally use welding and cutting equipment.

Welder

A ***welder*** uses high electric current to create a high-power electric arc (voltage jumping from the electrode to the workpiece) to melt and fuse metal parts together, **Figure 4-20B**. Be sure to complete proper training before attempting to weld. Using a welder improperly can result in personal injury or damage to parts.

Warning

Whenever working with a torch or welder, there is always a chance of fire. Always observe standard safety practices.

Soldering Gun

A ***soldering gun*** or ***soldering iron*** is used to join wires during electrical repairs. An electric current heats the tip of the gun or iron. The hot tip is used to heat the wires. Solder is then applied to the hot wires and it melts. Solder is a lead-tin alloy. When the solder cools, it hardens into a strong, solid connection. Look at **Figure 4-21**.

A—Soldering Iron

A—Soldering Gun

Figure 4-22. Car batteries often become discharged. This is a battery charger.

Battery Charger

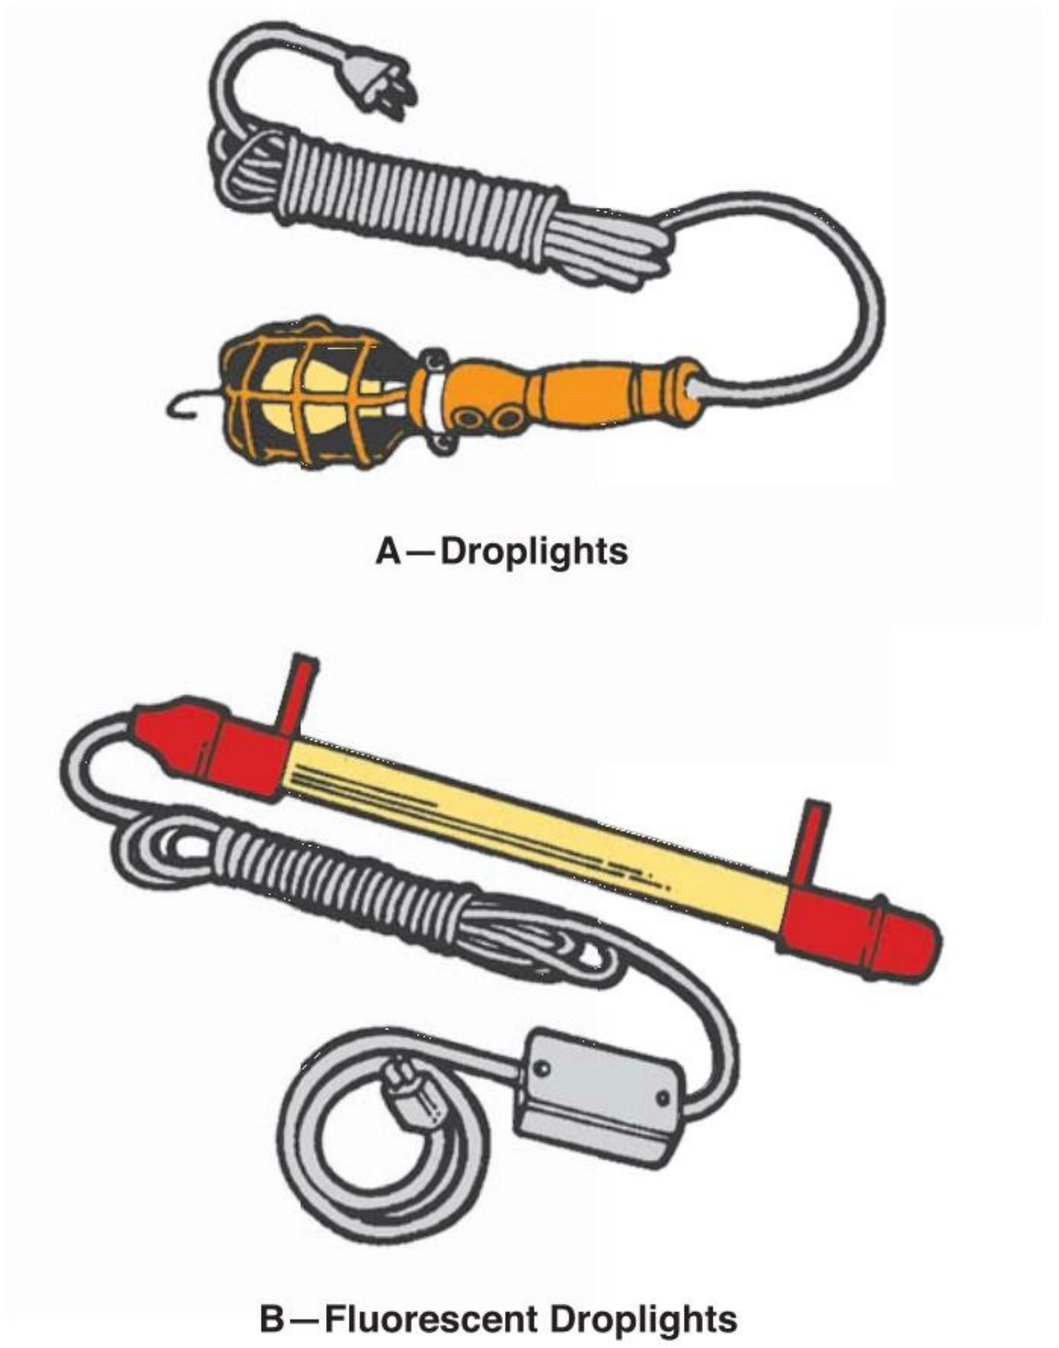
A ***battery charger*** is used to re-energize a "dead," or discharged, battery. It forces current back into the battery to recharge it. The red charger lead connects to the positive (+) battery terminal. The black charger lead connects to the negative (–) battery terminal. Refer to **Figure 4-22**.

Warning

The gases around the top of a battery can explode. Always connect the battery charger leads to the battery *before* turning on the charger. This prevents sparks, which could ignite the battery gases.

Tech Tip

HV battery chargers are quite different from 12-volt battery chargers. Always refer to the HV battery charger operating instructions for more safety-related information. Refer to the index to find more information on HV battery charger use.



Florida Dept. of Voc. Ed.

Figure 4-23. Good lighting is important for quality work.

Droplight

A ***droplight*** provides a portable source of light. The light can be taken to the repair area under the vehicle or in the trunk, passenger compartment, or engine compartment. Droplights are shown in **Figure 4-23**.

Pullers

Pullers are used to remove seals, gears, pulleys, steering wheels, axles, and other pressed-on parts. A few puller types are pictured in **Figure 4-24**. Special pulling operations are covered in later chapters.

Warning

Pullers can exert tons of force. They must be used properly to prevent personal injury or part damage. Always wear eye protection!

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 4-24. Pullers are often needed to remove the steering wheel, engine balancer pulleys, and similar pressed-on parts.

Creepers

A ***creeper*** is useful when working under a car supported on jack stands. It lets the technician easily roll under vehicles without getting dirty. A ***stool creeper*** allows the technician to sit while working on parts that are near the ground. For example, a stool creeper is often used during brake system repairs. The brake parts and tools can be placed on the creeper. The service technician can sit and still be at eye level with the brake assembly. See **Figure 4-25**.

Roll-Around Cart

A large ***roll-around cart*** or table is handy for taking a number of tools to the job. A technician can quickly place all needed tools in the cart and take them to the vehicle. The cart places the tools within hand's reach. This saves time and effort during and after the job. Refer to **Figure 4-26**.

A B

Snap-on Tool Corp.

Figure 4-25. Creepers help you work on your back or while sitting. A—A creeper is for working under a vehicle. B—The stool creeper is commonly used during brake and suspension repairs. You can sit on the stool and store tools on the bottom.

Snap-on Tool Corp.

Figure 4-26. A roll-around cart allows you to take many tools to the vehicle. This saves several trips to the toolbox. It also saves time during cleanup at the end of the day.

Covers

Fender covers are placed over the fenders, upper grille, or other body sections to prevent vehicle damage. They protect the paint or finish from nicks, scratches, and grease. Never lay tools on a painted surface. Scratches may result. ***Seat covers*** are placed over seats to protect them from dirt, oil, and grease that might be on your work clothes. These covers should be used while driving the vehicle or while working in the passenger compartment. See **Figure 4-27**.

Goodheart-Willcox Publisher

Figure 4-27. Always take good care of your customer's vehicle.

Personal Computer

A personal computer, often a laptop, is now used by some technicians to help with tasks including problem diagnosis, preprogramming of computer chips, bookkeeping, and reference to service literature. Look at **Figure 4-28**.

Workplace Skills

Social skills are the techniques you use to conduct yourself in such a way that your customers and fellow employees like and respect you. Many times, you will need the help of another technician to complete a difficult task. If your co-workers dislike you, you may have trouble finding help when you need it.

Goodheart-Willcox Publisher

Figure 4-28. This technician is using a laptop to monitor engine operating parameters as the vehicle is operated on a chassis dynamometer.

Summary

- Power tools use electricity, compressed air, or hydraulic pressure. Large shop tools, such as floor jacks, parts cleaning tanks, and steam cleaners, are classified as shop equipment.
- An air compressor is the source of compressed air for an auto shop.
- High-pressure air hoses are connected to the metal lines from the air compressor.
- Air tools, also called pneumatic tools, use air pressure for operation. They are labor-saving tools and are well worth their cost.
- Air wrenches, or impact wrenches, provide a very fast means of installing or removing threaded fasteners.
- Special impact sockets and impact extensions must be used with air wrenches.
- A blowgun is commonly used to dry and clean parts washed in solvent.
- An air drill is excellent for many repairs because of its power output and speed adjustment capabilities.
- A bench grinder can be used for grinding, cleaning, or polishing operations. The hard grinding wheel is used for sharpening or deburring. The soft wire wheel is for cleaning and polishing.
- Drill bits, or twist drills, are used to drill holes in metal and plastic parts.
- A drill bit is mounted in and rotated by a drill. A special key is sometimes needed to tighten the drill bit in the drill chuck.
- A floor jack is used to raise either the front, sides, or rear of a vehicle.
- Jack stands support a vehicle during repair. After raising a vehicle with a jack, place stands under the vehicle.
- A tire changer is a common piece of shop equipment used to remove and replace tires on wheels.
- A portable engine crane is used to remove and install engines.
- An engine stand is used to hold an engine while it is overhauled (rebuilt) or repaired.
- A cold-solvent tank can be used to remove grease and oil from parts.

Copyright Goodheart-Willcox Co., Inc.

- An oxyacetylene torch outfit can be used to heat, cut, weld, or braze metal parts.
- A welder is used to melt and fuse metal parts together.
- A soldering gun or iron is used to solder wires.
- A battery charger is used to recharge a discharged 12-volt battery.
- A droplight provides a portable source of light.
- Pullers are needed to remove seals, gears, pulleys, steering wheels, axles, and other pressed-on parts.
- Fender covers are placed over the fenders, the upper grille, or other body sections to protect them.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

abrasive pad
air chisel
air compressor
air drill
air hammer
air hoses
air ratchet
air tools
battery charger
bench grinder
blowgun
cold-solvent tank
creeper
drill bits
drill press
drills
droplight
electric tools
engine crane
engine stand
fender covers
floor jack
high-pressure washer
hydraulic press
hydraulic tools
impact extensions
impact sockets
impact wrenches
jack stands
lubricator
oxyacetylene torch
portable electric drills
power tools
pressure blaster
pressure regulator
pullers
quick-disconnect couplings
roll-around cart
rotary brush
rotary file
seat covers
shop equipment
soldering gun
soldering iron
solvent gun
steam cleaner
stool creeper
tire changer
transmission jacks
welder

Activities

1. Using the Internet or an automotive tool catalog, develop a list of power tools needed to equip your school's automotive repair shop. Find prices and add up the cost.
2. Research safety information on power equipment used in an automotive repair facility.
   (A) Develop a bibliography of resources for safe use of power equipment.
   (B) Develop a list of safety rules for their use.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Power tools use _____, _____, or _____ as sources of energy.
2. Which of the following is *not* a commonly used air tool?
   (A) Impact wrench.
   (B) Air ratchet.
   (C) Air chisel.
   (D) Drill press.
3. A 1/2″ drive impact wrench is used for fasteners with head sizes between 1/2″ to 1″. Which of the following sockets can be used by this particular tool?
   (A) 5/8″ chrome-plated socket.
   (B) 9/16″ flat black socket.
   (C) 7/16″ flat black socket.
   (D) None of the above.
4. A(n) _____ is used to blow dirt off parts and to dry parts after cleaning.
5. A rotary file is frequently used to remove _____.
   (A) old gasket materials
   (B) carbon deposits
   (C) metal burrs and nicks
   (D) None of the above.
6. List four important rules for a bench grinder.
7. List five important rules for a drill press.

Copyright Goodheart-Willcox Co., Inc.

8. _____ are used to support a vehicle while working under it.
   (A) Floor jacks
   (B) Jack stands
   (C) Transmission jacks
   (D) Bumper jacks
9. Explain the use of a solvent tank.
10. What are pullers used for?

ASE-Type Questions

1. Power tools are tools that use:
   (A) electricity.
   (B) hydraulics.
   (C) compressed air.
   (D) All of the above.
2. Technician A says that shop air pressure usually ranges from 100–150 psi. Technician B says shop air pressure is much higher, around 300 psi. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Which of the following is *not* a common impact wrench drive size?
   (A) 1/4″
   (B) 3/8″
   (C) 1/2″
   (D) 3/4″
4. Technician A says to use a 1″ drive on sockets from 1/4″ to 9/16″. Technician B says to use a 3/8″ drive on these socket sizes. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Special impact sockets and extensions are easily identified because they are:
   (A) chrome.
   (B) aluminum.
   (C) flat black.
   (D) hard rubber.
6. Each of the following can be used to clean parts *except:*
   (A) air drill.
   (B) blowgun.
   (C) air ratchet.
   (D) bench grinder.
7. Which of the following is *not* a rule to follow when using a bench grinder?
   (A) Wear eye protection.
   (B) Make sure shields are in place.
   (C) Use the wire wheel to clean soft metal parts.
   (D) Keep the tool rest adjusted close to the stone and brush.
8. When using a drill press, Technician A believes drilling pressure should not be released until the bit breaks completely through the bottom of the part. Technician B believes pressure release should occur just before the bit breaks through. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. After using a floor jack to raise the front of a car:
   (A) place the car in park.
   (B) block the car's wheels.
   (C) secure the car on jack stands.
   (D) All of the above.
10. The _____ press can be used to install gears, pulleys, bearings, seals, and other parts requiring a high pushing force.
    (A) arbor
    (B) steam
    (C) rotary
    (D) hydraulic

Chapter 5
Auto Shop Safety

After studying this chapter, you will be able to:

- Describe the typical layout and sections of an auto shop.
- List the types of accidents that can occur in an auto shop.
- Explain how to prevent auto shop accidents.
- Describe general safety rules for the auto shop.

An auto shop can be a safe and enjoyable place to work and earn a good living. Most shops are clean, well lighted, and relatively safe, **Figure 5-1**. However, if basic safety rules are *not* followed, an auto shop can be very dangerous. In this chapter, the layout of a typical automotive service facility will be discussed and the most important safety rules will be emphasized.

Tech Tip

Subject-specific safety rules will be given throughout this textbook. To live a long and productive life, follow all automotive industry safety policies.

Goodheart-Willcox Publisher

Figure 5-1. A well-maintained automotive shop can be an enjoyable place to work. Always do your part to keep the shop clean and well organized.

Copyright Goodheart-Willcox Co., Inc.

Auto Shop Layout

There are several different areas in an auto shop. You must know their names and the basic rules that apply to each. It is important that you learn your shop layout and organization to improve work efficiency and safety. The auto shop includes the following work areas:

- Repair area.
- Toolroom.
- Classroom.

Repair Area

The ***repair area*** includes any location in the shop where repair operations are performed, such as the shop stall, lift, alignment rack, and outside work area. It normally includes every area except the classroom, locker room, and toolroom.

Shop Stall

A ***shop stall*** is a small work area where a vehicle can be parked for repairs. Sometimes, each stall is numbered and marked off with lines painted on the floor.

Some auto shop facilities have an ***outside work area*** adjacent to the garage overhead doors. In good weather, this area can be used for auto repairs.

Always raise the shop doors all the way and pull cars through the doors very slowly.

Tech Tip

Check the height of trucks and campers to make sure they will clear (top of vehicle will not hit doors or be crushed when raised fully on a lift).

Lift

The ***lift*** is used to raise a vehicle into the air. It is handy for working under the car (draining oil, greasing front end ball sockets, or repairing exhaust systems). Refer to **Figure 5-2**.

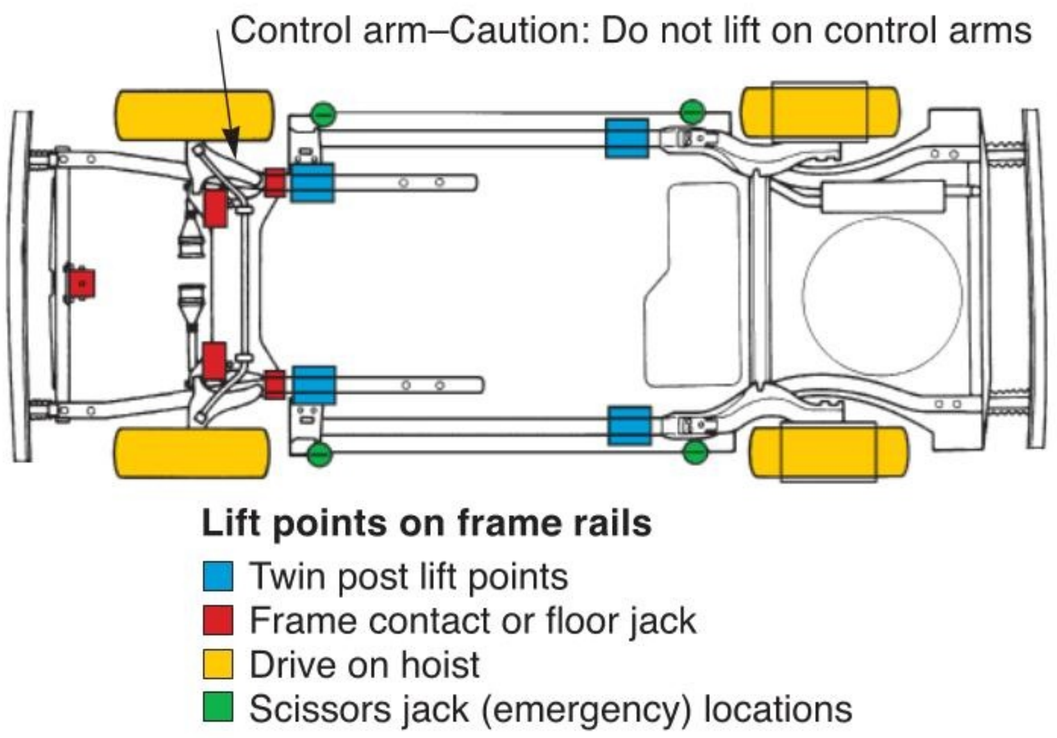
Remember these lift safety steps:

1. Ask your instructor for a demonstration and get permission before using the lift.

Eagle Equipment

Figure 5-2. A lift is handy for repairs on parts under the vehicle. Lifts are commonly used when changing oil, greasing the chassis, and repairing the exhaust system.

2. Position the vehicle's center of gravity (point of perfect balance) on the lift as described in its service manual, **Figure 5-3**. If a front-engine vehicle or a pickup truck with no weight in the bed, position the lift arms (if applicable) more to the front of the chassis. In a mid- or rear-engine car, place the lift pads more to the rear so the car will not slide or tilt off the lift.

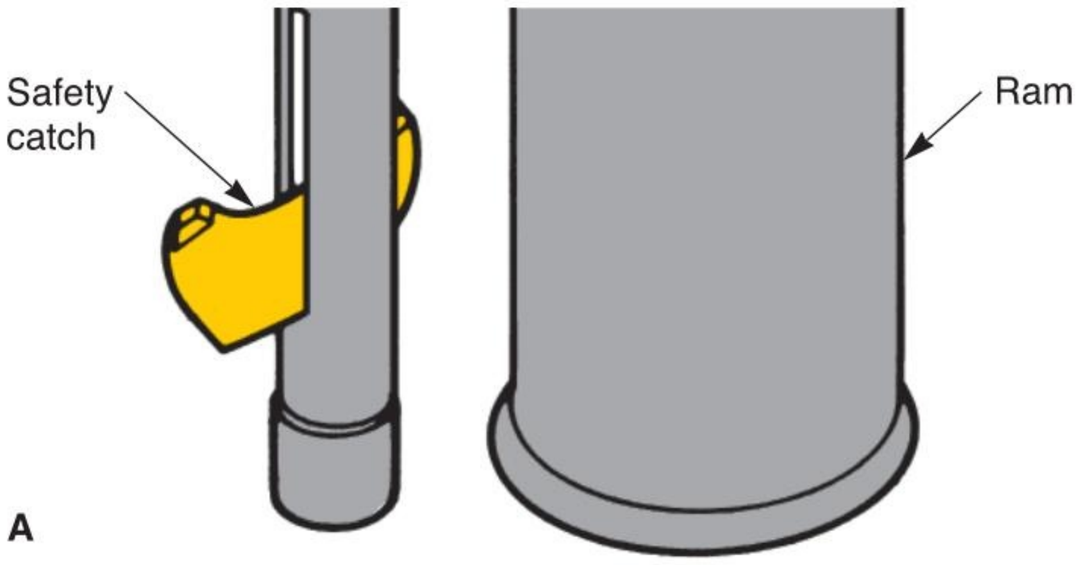


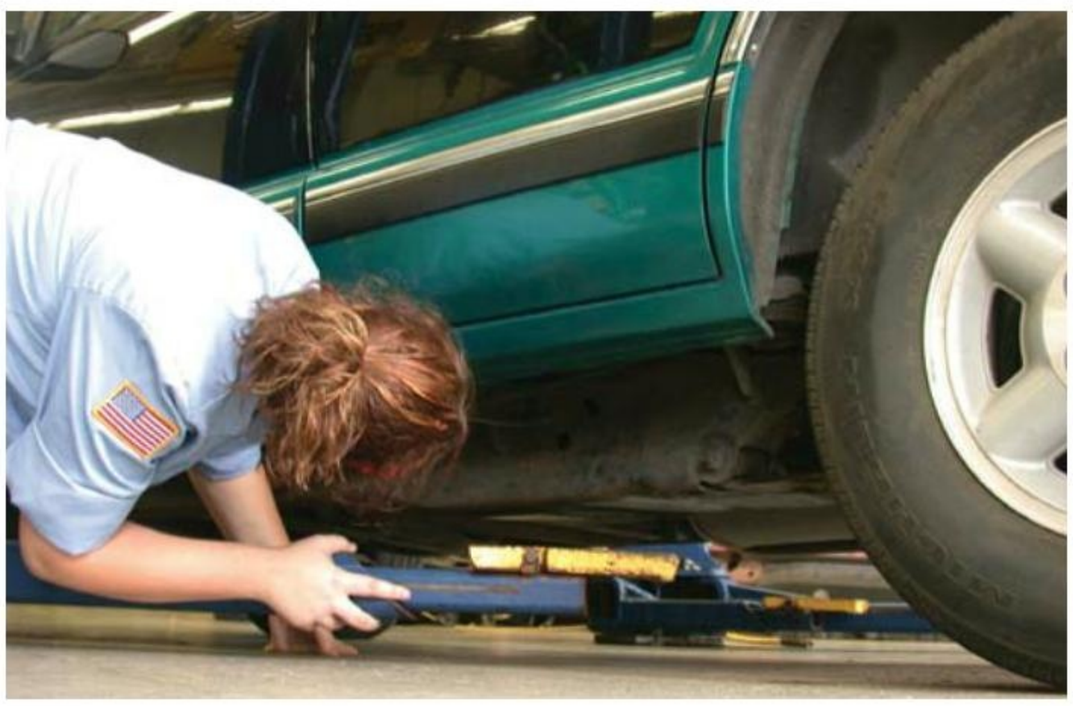
Chrysler

Figure 5-3. Follow the service manual instructions when raising a car on a lift. Note the specific lifting instructions and lift points for this specific vehicle.

Copyright Goodheart-Willcox Co., Inc.

3. Raise vehicle slowly while keeping your fingers away from any moving parts on the lift. Raise the car about one inch off the ground. Double-check your lift points and make sure the vehicle is perfectly level. Always place your head next to the shop floor so you can see the alignment of the lift pad and vehicle pinch welds or frame rails.
4. When the vehicle is high enough to be worked on, make sure the lift's mechanical safety catch is engaged. Do not walk under the lift without the catch in the fully locked position, **Figure 5-4**.





B

Ford

Figure 5-4. Always read manufacturer's operating instructions closely before using a lift. If a lift lowers a car on someone, they will be crushed and killed instantly. A—Most lifts have a mechanical safety catch. A large metal lug must be engaged fully into the metal post before working under the vehicle. Without the mechanical catch engaged, a hydraulic failure could make the vehicle drop instantly to the ground with deadly crushing force. B—Always place your head next to the shop floor so you can see the alignment of the lift pad and vehicle pinch welds or frame rails.

Alignment Rack

The ***alignment rack*** is used when working on a car's steering and suspension systems. One is shown in **Figure 5-5**. It may contain a special tool board and equipment used when replacing worn suspension and steering parts or adjusting wheel alignment.

When using an alignment rack, the car should be pulled onto the rack slowly and carefully. Someone should guide the driver and help keep the tires centered on the rack. As with other complicated and potentially dangerous equipment, obtain a full demonstration before using the alignment rack.

Toolroom

The ***toolroom*** is a shop area where larger pieces of repair equipment are stored. The toolroom is used to store shop tools, small equipment, and supplies, such as nuts, bolts, and oil. It is normally located adjacent to (next to) the repair area or classroom.

When working in the toolroom, you will be responsible for keeping track of shop tools. Every tool checked out of the toolroom must be recorded and called in or retrieved before the end of the class period.

Normally, the tools hang on the walls of the toolroom for easy access. Each tool may have a painted silhouette, which indicates where it should be kept. Your instructor will detail specific toolroom policies and procedures, **Figure 5-6**.

Figure 5-5. An alignment rack is used in most shops. It is often needed when servicing steering and suspension systems.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 5-6. Keep all shop tools clean and organized. Make sure you return every tool to its correct location.

Classroom

The ***classroom*** is usually an office-like area in a school or large repair facility, where students or mechanics can meet to increase their knowledge of auto service and repair. Either a certified instructor or the service manager presents the information to the students or experienced technicians. The classroom is used for seminars, demonstrations, and other technician training activities. It is often located adjacent to the repair area.

Shop Safety

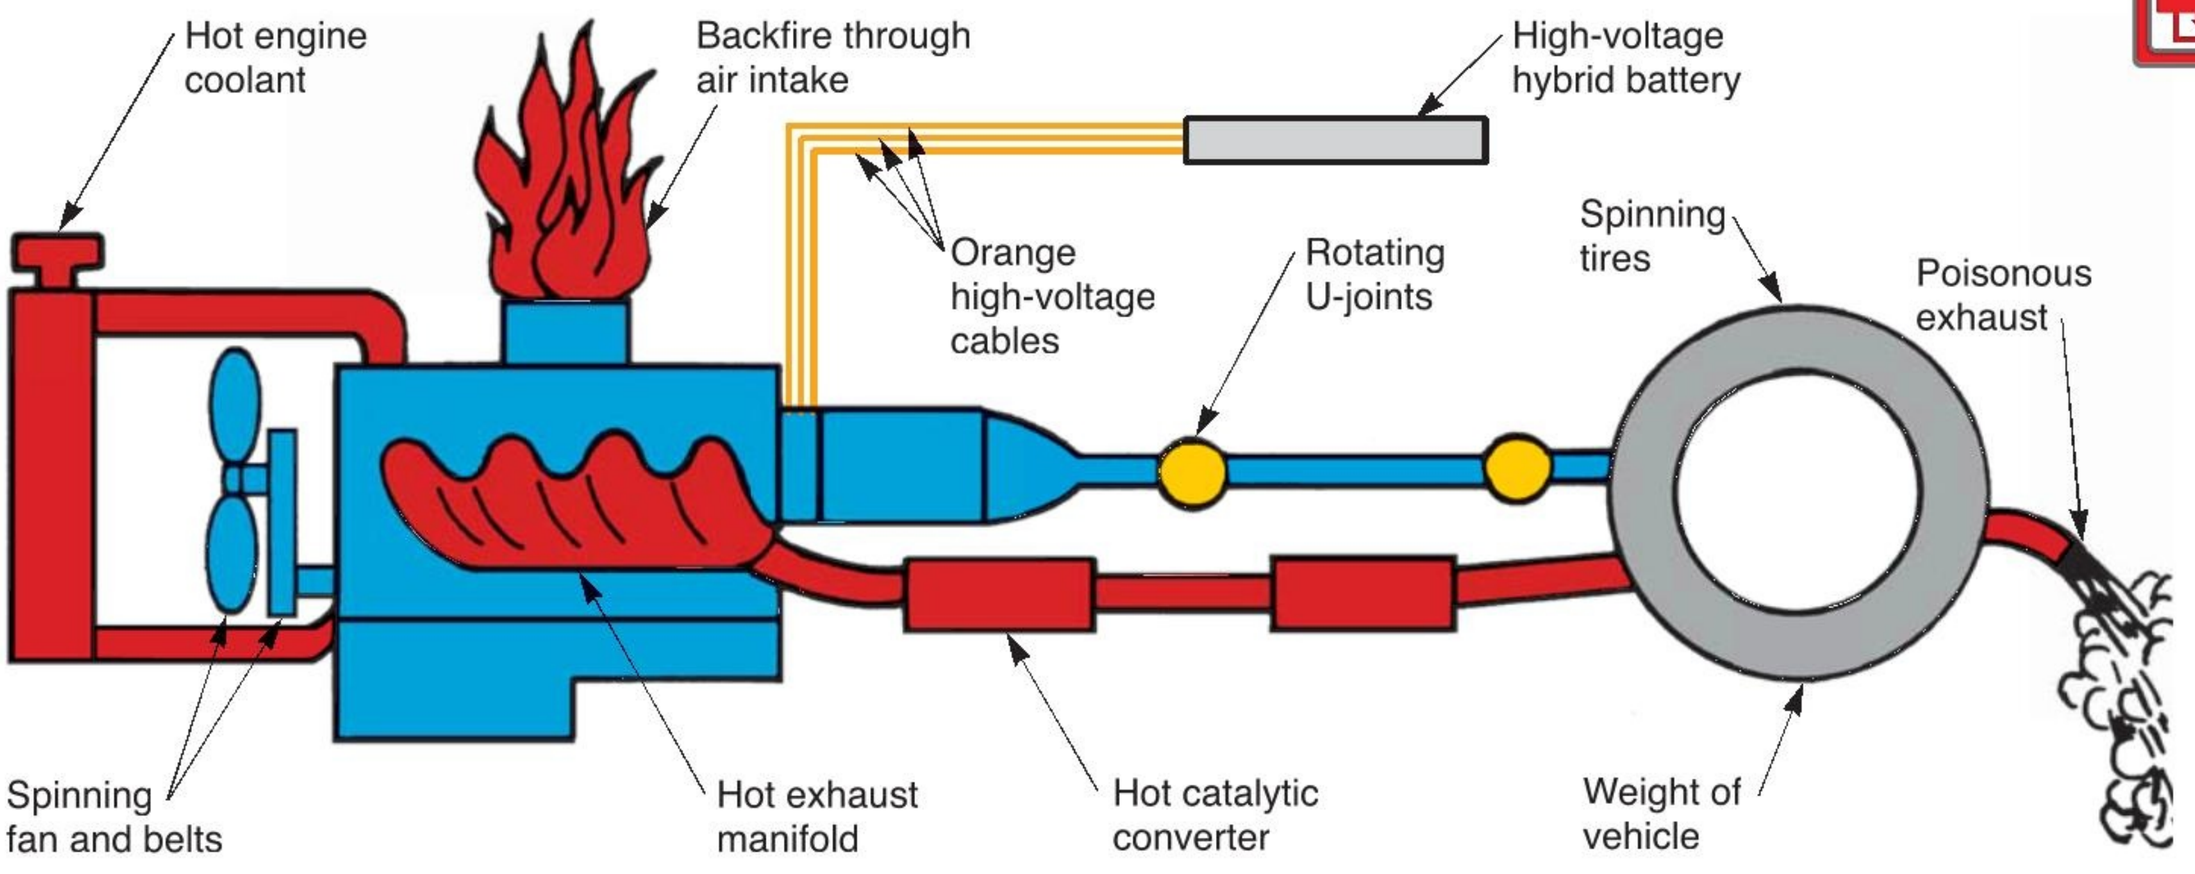
Every year, thousands of technicians are accidentally injured or killed on the job. Most of these accidents resulted from a broken safety rule. The injured persons learned to respect safety rules the hard way—by experiencing a painful injury. You must learn to respect safety rules the easy way—by studying and following the safety rules given in this book.

While working, constantly think of safety. Look for unsafe work habits, unsafe equipment, and other potentials for accidents.

Some areas in the automotive repair shop are more dangerous than others. Areas where dangerous equipment is used or toxic chemicals are stored are often identified by brightly colored floor markings or signs to alert employees to the potential hazards. When working in these marked safety areas, take extra precautions to prevent injury.

Evacuation routes should be posted in prominent areas throughout the shop. These routes show you how to quickly exit the building in case of a fire, gas leak, or other emergency. Always study the evacuation routes and be aware of your location in relation to these routes whenever you are working in the shop. Being able to quickly exit the building during an emergency could save your life.

When working in an auto shop, you must always remember that you are surrounded by other technicians. This makes it even more important that you concentrate on safety to prevent injury to yourself and to others in the shop. See **Figure 5-7**.



Goodheart-Willcox Publisher

Figure 5-7. An automotive shop has the potential to be very dangerous. Just a few of the dangers present around an automobile are shown.

Copyright Goodheart-Willcox Co., Inc.

Types of Accidents

Basically, you should be aware of and try to prevent six kinds of accidents:

- Fires.
- Explosions.
- Asphyxiation (airborne poisons).
- Chemical burns.
- Electric shock.
- Physical injuries.

If an accident or injury occurs in the shop, notify your instructor immediately. Use common sense when deciding whether to get a fire extinguisher or to take other actions.

Fires

Fires are terrible accidents capable of causing severe injury and permanent scar tissue. Therefore, every precaution must be taken to prevent fires in the automotive shop. There are numerous combustible substances (gasoline, oily rags, paints, thinners) found in an auto shop.

Gasoline is by far the most dangerous and underestimated flammable substance in an auto shop. Gasoline has astonishing potential for causing a tremendous fire. Just a cupful of gasoline can instantly engulf a car in flames.

A few gasoline safety rules include:

- Store gasoline and other flammable substances in approved, sealed containers.
- Never use gasoline as a cleaning solvent.
- When disconnecting a vehicle's fuel line or hose, wrap a shop rag around the fitting to keep fuel from squirting or leaking.
- Wipe up gasoline spills immediately. Do not place oil absorbent (oil-dry) on gasoline because the absorbent will become highly flammable.
- Keep any source of heat away from open or exposed fuel system parts.
- Disconnect the battery or HV battery pack before working on a fuel system.

Oily rags can also start fires. Soiled rags should be stored in an approved safety can.

Paints, thinners, and other combustible materials should be stored in a fire cabinet. Also, never set flammable substances near a source of sparks (grinder), flames (welder or water heater), or heat (furnace, for example).

Electrical fires can result when a "hot wire" (wire carrying current to component) touches ground (vehicle frame or body). The wire can heat up, melt the insulation, and burn. Then, other wires can do the same. Dozens of wires could burn up in a matter of seconds.

To prevent electrical fires, always disconnect the battery when told to do so in a service manual. If possible, keep the battery disconnected during repairs.

Locate the ***fire extinguishers*** in your shop and learn how to use them before they are needed. The few seconds spent learning how to operate a fire extinguisher could be the difference between life and death during a fire.

Figure 5-8 shows various fire classifications and fire extinguisher types. Always use the recommended type of extinguisher. Using the wrong extinguisher can actually cause the flames to spread. Multipurpose fire extinguishers can be used for a variety of fires. The most common type of multipurpose extinguisher is an A, B, C, dry-chemical fire extinguisher.

To use a fire extinguisher, pull the safety pin from the handle. Aim the nozzle at the flames as outlined in **Figure 5-8** and squeeze the extinguisher handle.

Explosions

An ***explosion*** is the rapid, almost instant, combustion of a material that causes a powerful shock wave to travel through the shop. Several types of explosions are possible in an auto repair facility. You should be aware of these sources of sudden death and injury.

Hydrogen gas can surround the top of a car battery that is being charged or discharged (used). This gas is highly explosive. The slightest spark or flame can ignite the hydrogen gas, causing the battery to explode. Battery acid and pieces of the battery case can blow into your eyes and face. Blindness, facial cuts, acid burns, and scars can result. Always wear eye and face protection when working around a battery. See **Figure 5-9**.

Fuel tanks, even seemingly empty ones, can explode. A drained fuel tank can still contain fuel gum and varnish. When this gum is heated and melts, it can emit vapors that may ignite.

Keep sparks and heat away from fuel tanks. When a fuel tank explodes, one side will usually blow out. Then, the tank will shoot across the shop as if shot out of a cannon. You or other workers could be killed or seriously injured.

Copyright Goodheart-Willcox Co., Inc.

Fires	Type	Use	Operation
Class A Fires Ordinary Combustibles (Materials such as wood, paper, textiles.) *Requires... cooling-quenching* Old New	**Soda-acid** Bicarbonate of soda solution and sulfuric acid	Okay for use on Not for use on	Direct stream at base of flame.
Class B Fires Flammable Liquids (Liquids such as grease, gasoline, oils, and paints.) *Requires...blanketing or smothering.* Old New	**Pressurized Water** Water under pressure	Okay for use on Not for use on	Direct stream at base of flame.
Class C Fires Electrical Equipment (Motors, switches, etc.) *Requires... a nonconducting agent.* Old New	**Carbon Dioxide (CO_2)** Carbon dioxide (CO_2) gas under pressure	Okay for use on Not for use on	Direct discharge as close to fire as possible, first at edge of flames and gradually forward and upward.
Class D Fires Combustible Metals (Flammable metals such as magnesium and lithium.) *Requires...blanketing or smothering.* 	**Foam** Solution of aluminum sulfate and bicarbonate of soda	Okay for use on Not for use on	Direct stream into the burning material or liquid. Allow foam to fall lightly on fire.
	Dry Chemical 	Multi-purpose type: Okay for Not okay for Ordinary BC type: Okay for Not okay for	Direct stream at base of flames. Use rapid left-to-right motion toward flames.
	Dry Chemical Granular type material	Okay for use on Not for use on	Smother flames by scooping granular material from bucket onto burning metal.

Goodheart-Willcox Publisher

Figure 5-8. There are several different types of fires. Fire extinguishers are rated by the type of fire on which they should be used.

Copyright Goodheart-Willcox Co., Inc.

Snap-on Tool Corp.

Figure 5-9. Wear approved eye, ear, and face protection when needed.

Various other sources can cause shop explosions. For example, special sodium-filled engine valves, welding tanks, and propane-filled bottles can explode if mishandled. These hazards will be discussed in later chapters.

Warning

Air bags should be handled with extreme care. If accidentally deployed, they can break bones or even kill. Carry them with the trim cover pointed away from your body. Keep all sources of electricity away from undeployed air bags.

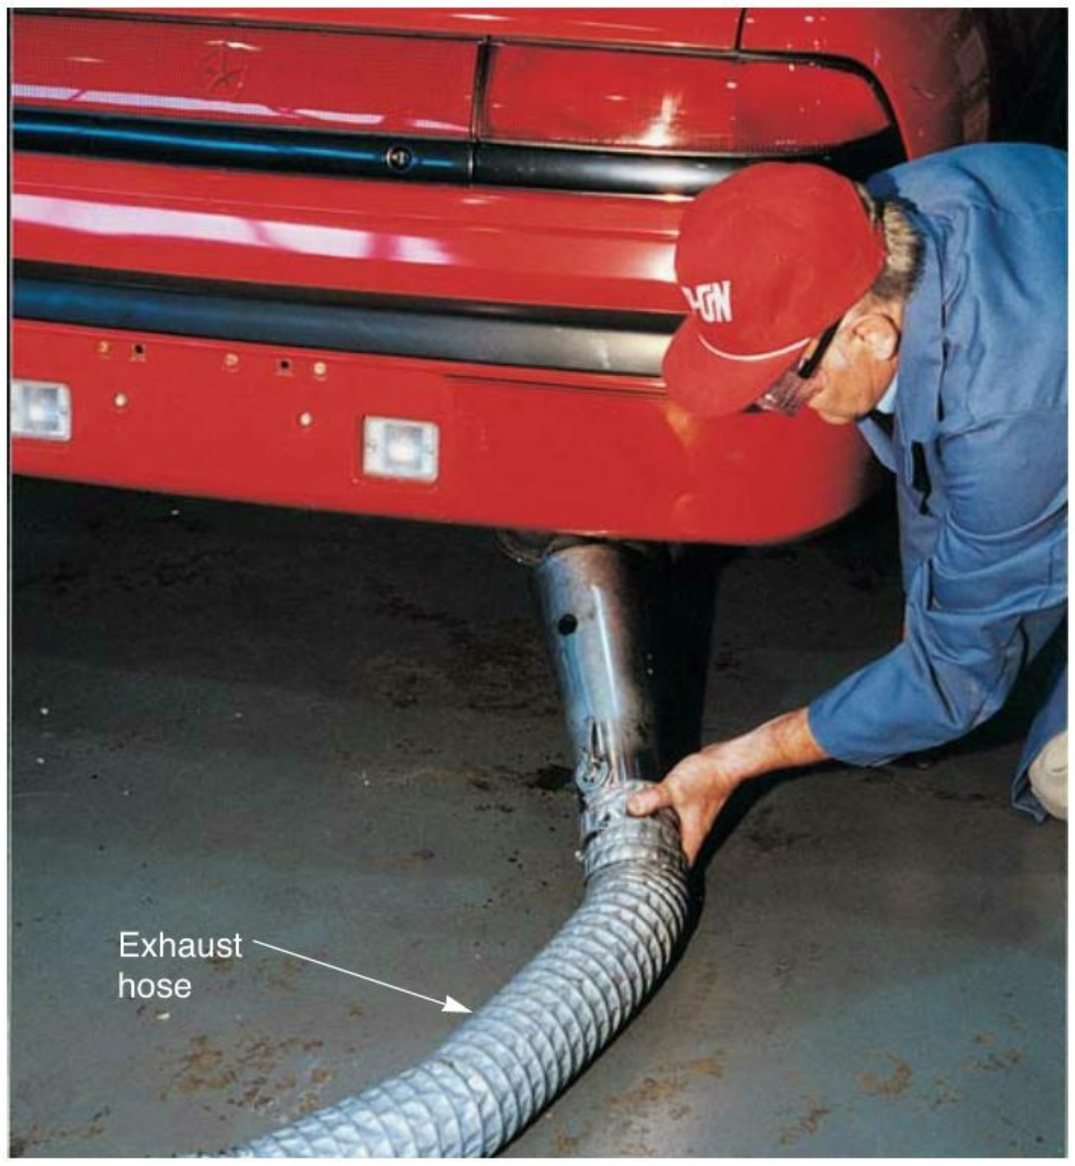
Asphyxiation

Asphyxiation is caused by breathing toxic or poisonous substances. Mild cases of asphyxiation will cause dizziness, headaches, and vomiting. Severe asphyxiation can cause death.

The most common cause of asphyxiation in an auto shop is the exhaust gases produced by an automobile engine. *Exhaust gases are poison.* If a vehicle must be operated in an enclosed shop, connect the vehicle's tailpipe to the shop's exhaust ventilation system as shown in **Figure 5-10**. Also, make sure the exhaust ventilation system is turned on.

Discussed in related chapters, other shop substances are harmful if inhaled. A few of these harmful substances include asbestos (brake lining dust, clutch disc dust), parts cleaners, and paint spray.

Respirators (filter masks) should be worn when working around any airborne impurities. Refer to **Figure 5-11**. Dust masks are made of treated paper



Kent-Moore

Figure 5-10. Place an exhaust hose over the tailpipe of any car running in an enclosed shop. This will prevent the shop from filling with deadly fumes.

Lab Safety

Figure 5-11. This technician is wearing a welding respirator to protect himself from toxic welding fumes. The welding helmet will shield the technician's face and eyes from hot sparks and the bright, blinding welding arc.

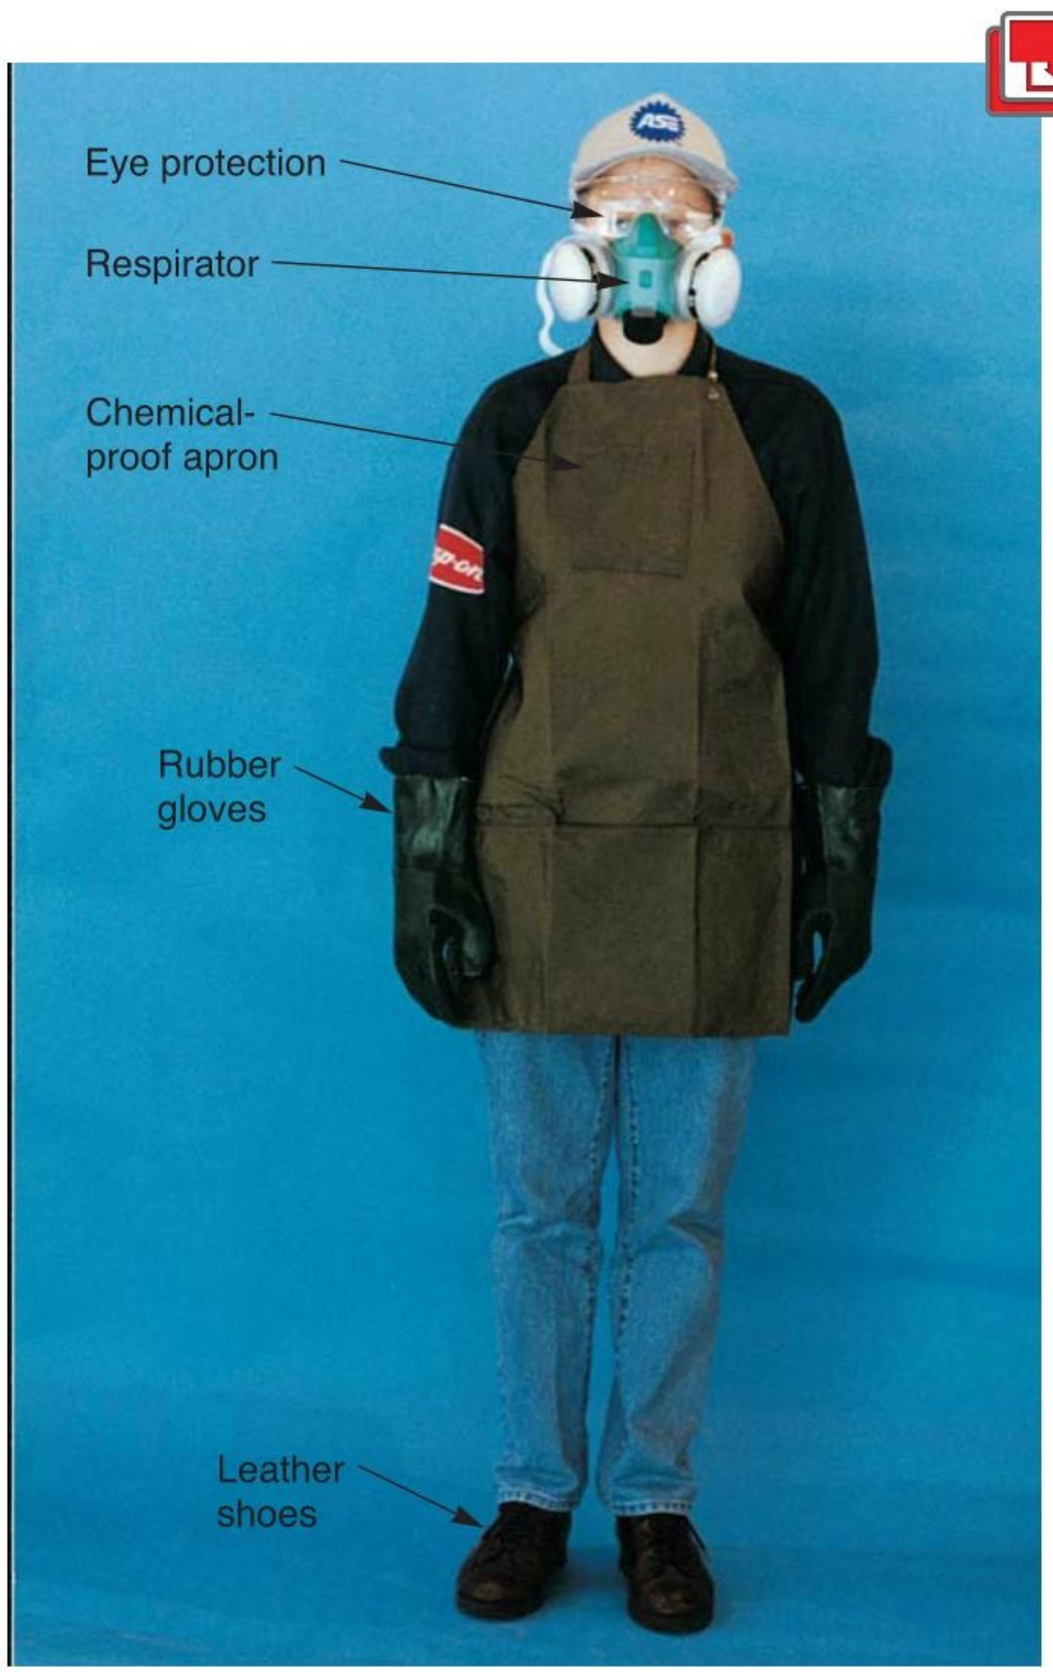
Copyright Goodheart-Willcox Co., Inc.

and will only stop large particles from entering your body. Cartridge respirators provide good respiratory protection when potentially hazardous fumes are present in the shop. An air-supplied respirator must be worn when catalyzed paint products are applied in the shop.

Chemical Burns

Solvents (parts cleaners), battery acid, and various other corrosive shop substances can cause ***chemical burns*** to the skin. Always read the directions on all chemical containers. Also, be sure to wear proper protective gear when handling solvents and other caustic materials. See **Figure 5-12**.

Throttle body cleaner (decarbonizing type), for example, is very powerful and can severely burn your skin in a matter of seconds. Wear rubber gloves and a full face shield when using a decarbonizing throttle body cleaner. If a skin or eye burn occurs, follow label directions.



Goodheart-Willcox Publisher

Figure 5-12 Always dress properly when handling substances that can cause chemical burns. Note that this technician is wearing rubber gloves, a chemical-proof apron, a respirator, and safety goggles.

Electric Shock

Electric shock is a result of electric current passing through parts of your body, causing injury or death. It can occur when using improperly grounded electric power tools.

Never use an electric tool unless it has a functional ***ground prong*** (third, round prong on plug socket). This prevents current from accidentally passing through your body. Also, never use an electric tool on a wet shop floor.

Warning

Some late-model cars have heated windshields. The alternators on these vehicles are designed to put out more than 100 volts ac to quickly warm the windshield. This is enough voltage to cause electric shock. Work carefully around this high voltage.

Hybrid Safety

Hybrid vehicles use a high-voltage motor-generator and an HV battery pack that operates on approximately 300–600 volts. This is enough electrical energy to cause serious injury or even electrocution! Voltage levels and hybrid service procedures vary. Therefore, it is important to follow the vehicle manufacturer's instructions and safety rules when working on a specific make and model hybrid.

Always wear rubber electrician's gloves (rated for 1000 volts) when working on a high-voltage hybrid drive train system. The thick rubber gloves will prevent electric shock if you accidentally touch a conductor carrying high voltage and current. You must also use fully insulated tools to service the high-power cable connections on the battery. See **Figure 5-13**.

Most hybrids have a main power cutoff switch, or high-voltage disconnect, near the output cables of the battery pack. This switch allows you to electrically disconnect the battery pack from the rest of the hybrid drive train system. It should be turned to the off or disabled position before servicing a hybrid drive train system.

Copyright Goodheart-Willcox Co., Inc.

Toyota

Figure 5-13. When working on high-voltage parts of a hybrid drive train system, always use insulated tools and thick rubber electrician's gloves to avoid electrocution.

Physical Injury

Physical injuries (cuts, broken bones, strained backs) can result from hundreds of different accidents. As a technician, you must evaluate every repair technique. Decide whether a particular operation is safe and take action as required.

For instance, if you are pulling on a hand wrench as hard as you can and the bolt will not turn, *stop!* Find another wrench that is larger. A larger tool has more leverage and is, therefore, safer. This approach will help prevent injuries and improve your mechanical abilities.

Warning

Never overexert your back by improperly lifting heavy assemblies. Once you injure your back, it can take months to recover. Sometimes, surgery is needed to repair the damage. When lifting a heavy object, keep your back straight. Bend your knees and lift the item with your legs. If necessary, use power equipment to move heavy objects.

General Safety Rules

Listed are several general safety rules that should be followed at all times.

- Wear eye protection during any operation that could endanger your eyes. This would include operating power tools, working around a running car engine, carrying batteries, etc.
- If debris or chemicals accidentally get into your eyes, flush your eyes using an ***eyewash station***. Always locate the eyewash station in your work area and learn how to use it before you need it. Refer to the eyewash station manufacturer's instructions for proper use.
- Avoid anyone who does not take shop work seriously. Inappropriate behavior leads to accidents.
- Keep your shop organized. Return all tools and equipment to their proper storage areas. Never lay tools, creepers, or parts on the floor.
- Dress in an appropriate manner. Never wear loose clothing, neckties, shorts, or open-toed shoes when working in the shop. Remove rings, bracelets, necklaces, watches, and other jewelry. They can get caught in engine fans, belts, drive shafts, and other rotating parts, causing serious injury. Also, button or roll up long sleeves and secure long hair; they too can get caught in spinning parts.
- Never carry sharp tools or parts in your pockets. They can puncture the skin.
- Wear full face protection when grinding, welding, and performing other operations where severe hazards are present.
- Work like a professional. When learning auto repair, it is easy to get excited about your work. However, avoid working too fast. You could easily overlook an important repair procedure or safety rule and be injured.
- Use the right tool for the job. There is usually a "best tool" for each repair task. Always be thinking about whether a different tool will work better than another, especially when you run into difficulty.
- Keep guards or shields in place. If a power tool has a safety guard, use it.
- Lift with your legs, not your back. There are many assemblies that are very heavy. When lifting, bend at your knees while keeping your back straight. On extremely heavy assemblies (transmissions, engine blocks, rear axles, transaxles), use a portable crane or hydraulic jack.

Copyright Goodheart-Willcox Co., Inc.

- Use adequate lighting. A portable shop light not only increases working safety, but it increases working speed and precision.
- Ventilate your work area when needed. Turn on the shop ventilation fan when fumes are present in the shop.
- Never stir up asbestos dust. Asbestos dust (particles found in older brake and clutch assemblies) is a powerful cancer-causing agent. Do not use compressed air to blow the dust from brake and clutch parts. Use an enclosed vacuum system to remove brake dust from brake assemblies to avoid contaminating the shop.
- Jack up a vehicle slowly and safely. A car can weigh more than two tons (1814 kg). Never work under a vehicle not supported by jack stands. A floor jack is only for raising the vehicle, not holding it while working. A hydraulic jack can instantly blow a seal and allow the heavy car to crash down with tremendous force. Always secure a vehicle on jack stands and block the wheels before working under it.
- Drive slowly when in the shop area. With all the other technicians and vehicles in the shop, it is very easy to have an accident.
- Report unsafe conditions to your supervisor or instructor.
- Stay away from engine fans. The fan on an engine is like a spinning knife. It can inflict serious injuries. Also, if a part or tool is dropped into the fan, it can fly out and hit someone with great force. Remember, electric fans can turn on even with the ignition key off!
- Respect running engines. Before starting an engine, make sure the transmission is fully in park or neutral, the emergency brake is set, and the wheels are blocked. If these steps are not taken and the car is accidentally knocked into gear, it could run over you or a friend.
- Do not smoke in or near the auto shop. Smoking is a serious fire hazard, considering fuel lines, cleaning solvents, lubricants, and other flammables may be exposed.
- Obtain instructor or service manager permission before using any new or unfamiliar power tool, lift, or other shop equipment. If necessary, your instructor or service manager will give a demonstration.

Tech Tip

While safety should be a priority whenever you are working in the shop, it is easy to overlook potential hazards. Therefore, it is important to perform periodic (weekly or monthly) shop safety inspections. Walk through your shop and take note of any unsafe conditions found. Report unsafe conditions to your instructor or supervisor.

Right-to-Know Laws

Right-to-know laws give essential information and stipulations for safely working with hazardous materials. The majority of states have enacted their own right-to-know laws. It is up to you to read all printed material that describes the proper handling of hazardous materials.

Safety data sheets give detailed chemical composition and precautionary information for all products that can present a health or safety hazard. See **Figure 5-14**. They are available from product manufacturers. You can easily see all the dangers and actions that should be taken when using any potentially dangerous product.

The ***Occupational Safety and Health Administration (OSHA)*** is a federal agency that gives general guidelines for the safe operation of work sites. To ensure safe working conditions, OSHA has established safety and work regulations for all industries.

Store and dispose of hazardous waste properly. Environmental Protection Agency (EPA) regulations require the proper labeling, storage, and transport of these potentially harmful materials for controlled disposal.

Customer Relations

Most shop insurance policies do not cover customers who enter the shop work area. When informing customers that they are not allowed in the repair area, explain that the insurance company, not the shop, has made this rule. This will help prevent the customer from being offended by being told to leave the work area.

Figure 5-14. Study the types of information given on a safety data sheet.

Summary

- An auto shop can be a safe and enjoyable place to work. However, if basic safety rules are *not* followed, an auto shop can be very dangerous.
- The shop repair area includes any location in the shop where repair operations are performed.
- The toolroom is a shop area normally adjacent the main shop or classroom. It is used to store shop tools, small equipment, and supplies.
- Every year, thousands of technicians are injured or killed on the job. Most of these accidents resulted from a broken safety rule.
- Fires are capable of causing permanent scar tissue. There are numerous combustible substances found in an auto shop.
- Gasoline is by far the most dangerous and often underestimated flammable in an auto shop.
- Electrical fires can result when a “hot wire” (wire carrying current to component) touches ground (vehicle frame or body).
- An explosion is rapid combustion that causes a powerful shock wave to travel out through the shop.
- Asphyxiation is caused by breathing toxic or poisonous substances in the air.
- Respirators should be worn when working around any kind of airborne impurities.
- Electric shock results when electric current passes through your body, causing injury or death.
- Physical injuries (cuts, broken bones, strained backs) can result from a variety of accidents.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

alignment rack
asphyxiation
chemical burn
classroom
electric shock
evacuation routes
explosion
eyewash station fire
fire extinguisher
fires
ground prong
lift
Occupational Safety and Health Administration (OSHA)
outside work area
physical injury
repair area
respirator
right-to-know laws
safety data sheets
shop stall
throttle body cleaner
toolroom

Activities

1. Sketch out a floor plan of your shop and label the different areas. Study the safety cautions in this chapter and determine if there are any safety hazards. Mark their location on the floor plan.
2. On the same floor plan, mark the location of fire extinguishers, exits, and eye flushing stations.
3. Examine a fire extinguisher in the shop area and read the instructions carefully. Demonstrate its use.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List four safety rules to follow when using a vehicle lift.
2. A(n) _____ is used when working on a car's steering and suspension systems. It has special equipment for aligning the vehicle's wheels.
3. _____ is the most common and dangerous flammable found in an auto shop.
4. What causes an electrical fire in an automobile?
5. Car batteries can explode. True or False?
6. Which of the following cannot cause electric shock?
   (A) A missing ground prong on cord.
   (B) Using an electric drill on wet floor.
   (C) Using electric tools with a ground prong.
   (D) None of the above.
7. Explain what must be done to prevent physical injuries.
8. If you are pulling on a wrench as hard as you can and the fastener does *not* turn, what should you do to prevent injury?
9. When lifting heavy objects, always lift with your _____.
   (A) arms
   (B) legs
   (C) back
   (D) None of the above.
10. List 20 general safety rules.
11. Why is it important to perform periodic shop safety inspections?

ASE-Type Questions

1. In which auto shop area would an exhaust system repair most likely be done?
   (A) Shop stall.
   (B) Grease rack.
   (C) Alignment rack.
   (D) Outside work area.
2. Rules to remember when using gasoline include each of the following *except:*
   (A) store gas in approved containers.
   (B) keep gas away from sources of heat.
   (C) use oil absorbent to absorb any gas spills.
   (D) never use gasoline as a cleaning solvent.
3. Which of the following is a possible source of explosions in an auto shop?
   (A) Fuel tanks.
   (B) Car batteries.
   (C) Welding tanks.
   (D) All of the above.
4. Asphyxiation can be caused by:
   (A) touching a current-carrying wire.
   (B) improper lifting techniques.
   (C) breathing toxic substances.
   (D) None of the above.

Copyright Goodheart-Willcox Co., Inc.

5. Asbestos dust, which can cause cancer, is found in:
   (A) fuel tanks.
   (B) transmissions.
   (C) propane-filled bottles.
   (D) brake and clutch assemblies.
6. A respirator is a:
   (A) filter mask.
   (B) type of chemical burn.
   (C) machine guard.
   (D) device to put out small fires.
7. Eye protection should be worn when:
   (A) carrying batteries.
   (B) operating power tools.
   (C) working by a running engine.
   (D) All of the above.
8. Which of the following is *not* a good tip when dressing for work?
   (A) Secure long hair.
   (B) Roll up long shirt sleeves.
   (C) Make sure all jewelry fits well.
   (D) Do not carry sharp tools in pocket.
9. An engine needs to be moved. Technician A says two people can slide the engine out of the way. Technician B says that an engine crane should be used to move the engine. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. When removing asbestos dust from parts, Technician A believes a vacuum system should be used. Technician B believes dust should be blown away using compressed air. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Chapter 6
Automotive Measurement and Math

After studying this chapter, you will be able to:

- Use both customary and metric measuring systems.
- Identify and use basic measuring tools
- Use decimal and metric conversion charts.
- Use basic math skills.
- Understand percentages and ratios.
- Correctly answer ASE certification test questions that require a basic understanding of measurement and math.

As an automobile is driven for thousands of miles, its moving parts slowly wear out. With enough part wear, mechanical failures and performance problems result. Manufacturers give specifications, or "specs", which are maximum wear limits and dimensions of new parts. Therefore, a technician must be able to take accurate measurements to determine whether a part is within these specifications. If the measurements of the part are not within the specifications, the part must be adjusted, machined and repaired, or replaced.

Tech Tip

Math and measuring tool use are explained throughout this textbook, where the information is applied to real-world situations and applications.

Measuring Systems

Two ***measuring systems*** are commonly used when working in the auto shop: the customary measuring system (inches, pounds, etc.) and the metric (SI) measuring system (millimeters, grams, etc.). The customary measuring system is also called the US customary units system or the English system. Most countries use the metric system. The customary system is mainly used in the United States. However, the United States uses the metric system as well. All new vehicles use metric bolts, nuts, and other parts. Manufacturer's specifications are often given in both customary and metric values for US made vehicles. See **Figure 6-1**.

Copyright Goodheart-Willcox Co., Inc.

Quantity	Customary (abbreviation)	Metric (abbreviation)
Length	Inch (in) Foot (ft) Mile (mi)	Meter (m)
Weight (mass)	Ounce (oz) Pound (lb)	Kilogram (kg)
Area	Square inch (sq-in)	Square meter (m^2)
Dry volume	Cubic inch (cu-in)	Cubic meter (m^3) Cubic centimeter (cc)
Liquid volume	Ounce (oz) Pint (pt) Quart (qt) Gallon (gal)	Liter (L) Cubic centimeter (cc)
Road speed	Miles per hour (mph)	Kilometer per hour (km/h)
Torque	Foot-pounds (ft-lb)	Newton meter (N•m)
Power	Horsepower (hp)	Kilowatt (kW)
Pressure	Pounds per square inch (psi)	Kilopascal (kPa)
Temperature	Degrees Fahrenheit (°F)	Degrees Celsius (°C)

Goodheart-Willcox Publisher

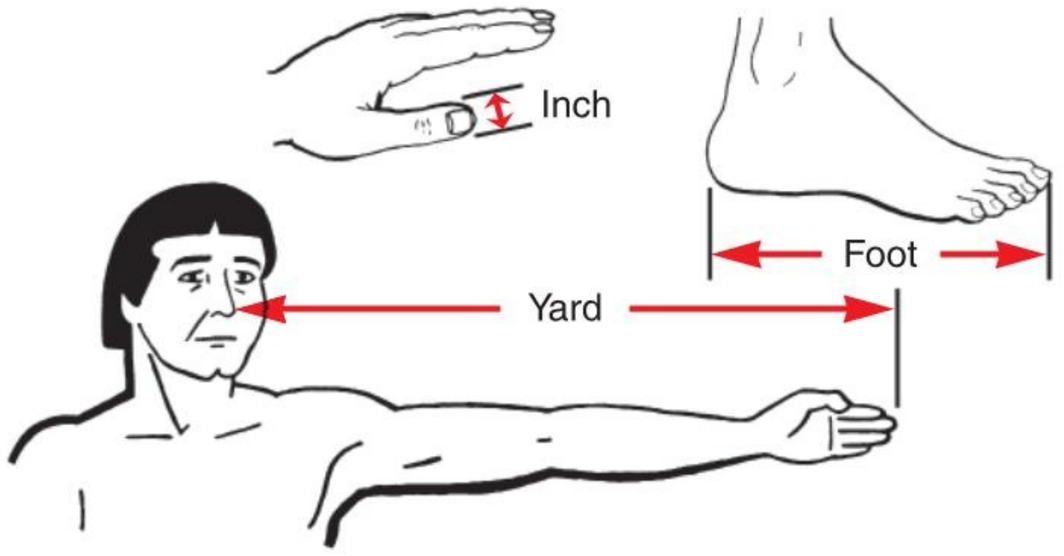
Figure 6-1. This chart compares customary and metric values. Study them carefully.

Customary Measuring System

The ***customary measuring system*** originated from sizes taken from parts of the human body. For example, the width of the human thumb was used to standardize the inch (25.4 mm). The length of the human foot was used to standardize the foot as 12″ (304.8 mm). The distance between the tip of a finger and nose was used to set the standard for the yard as 3 feet. Obviously, these were not very scientific standards since these distances vary from person to person, **Figure 6-2**.

Metric (SI) Measuring System

The ***metric (SI) measuring system*** is a simpler and more logical system than the customary system. Conversion between metric units is always based on a power of ten. Computation often requires nothing more than moving the decimal point. For instance, one meter equals 0.001 kilometer, 10 decimeters, 100 centimeters, or 1000 millimeters.



Starrett

Figure 6-2. The customary system was originally based on parts of the human body.

Conversion Charts

A measuring system ***conversion chart*** is needed when changing a value from one measuring system to another, such as when changing inches to centimeters, gallons to liters, or liters to gallons. A conversion chart lets the technician quickly convert customary values to equivalent metric values, or vice versa. One is shown in **Figure 6-3**.

A ***decimal conversion chart*** is commonly used to find equivalent values for fractional inches, decimal inches, and millimeters. These charts are typically accurate to the nearest 1/64″. For measurements that need greater precision, either decimals or millimeters should be used. A decimal conversion chart may be needed to change a fractional measurement to a decimal measurement. See **Figure 6-4**.

Measuring Tools

There are various tools used by a technician to make accurate measurements. Common measuring tools include the steel rule, caliper, micrometer, and dial indicator. Most of these are available in both customary and metric versions. These and other tools are covered in the next sections.

Steel Rule

A ***steel rule***, or ***scale***, is frequently used to make low-precision linear measurements. It is accurate to about 1/64″ (0.4 mm) in most instances. A ***customary rule*** has

Goodheart-Willcox Publisher

Figure 6-3. To convert from one system to another, multiply the known value by the number in the right column. This will give an approximately equal value.

numbered lines that represent full inches, **Figure 6-5**. The smaller, unnumbered lines, or graduations, represent fractions of an inch, such as 1/2″, 1/4″, 1/8″, and 1/16″. The shortest graduations represent the smallest fractions. In **Figure 6-5**, this is 1/16″. A ***metric rule*** normally has lines representing millimeters (mm). Each numbered line usually equals 10 mm, or 1 cm (centimeter). This is also shown in **Figure 6-5**.

A ***pocket rule***, or pocket scale, is typically 6″ long. It is small enough to fit in your shirt pocket. A ***combination square*** is a sliding square that is mounted on a steel rule. It is needed when the rule must be held perfectly square against the part being measured. See **Figure 6-6**.

A ***tape measure***, or tape rule, extends to several feet or meters in length. It is sometimes needed for large distance measurements during body, suspension, and exhaust system repairs. Look at **Figure 6-7**. A ***yardstick*** or ***meterstick*** is a rigid measuring device used for large lineal measurements up to one yard or one meter.

Calipers

A ***vernier caliper*** is a sliding measuring device that can make inside, outside, and depth measurements with considerable accuracy, **Figure 6-8**. One is pictured in **Figure 6-9**. Vernier calipers can take measurements as small as 0.001″ (0.025 mm). Modern vernier calipers have a dial gauge or digital readout attached. The dial or digital readout makes the "thousandths" part of a measurement easier to read. A caliper is fast and easy to use, making it a very useful tool for the automotive technician to have when one-thousand of an inch accuracy is adequate.

Micrometers

A ***micrometer***, nicknamed a mike, is used to make very accurate measurements. It can measure to one ten-thousandth of an inch (.0001″) or one thousandth of a millimeter (0.001 mm). There are several types of mikes used in automotive service and repair. These include outside, inside, and depth micrometers.

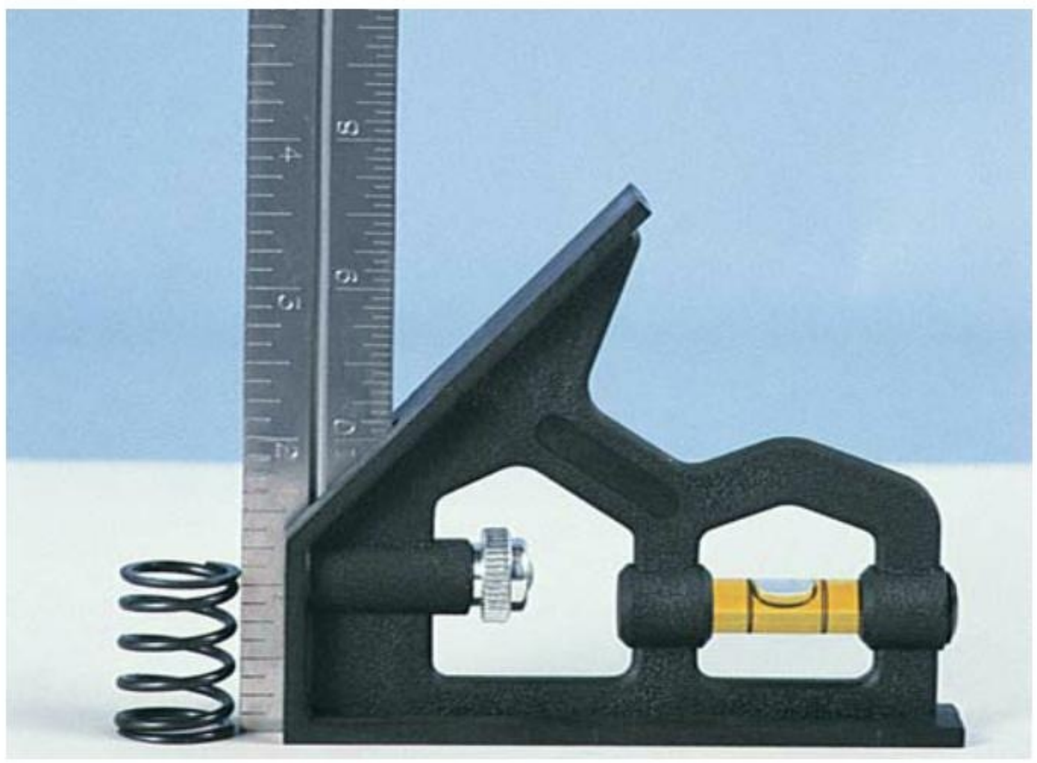
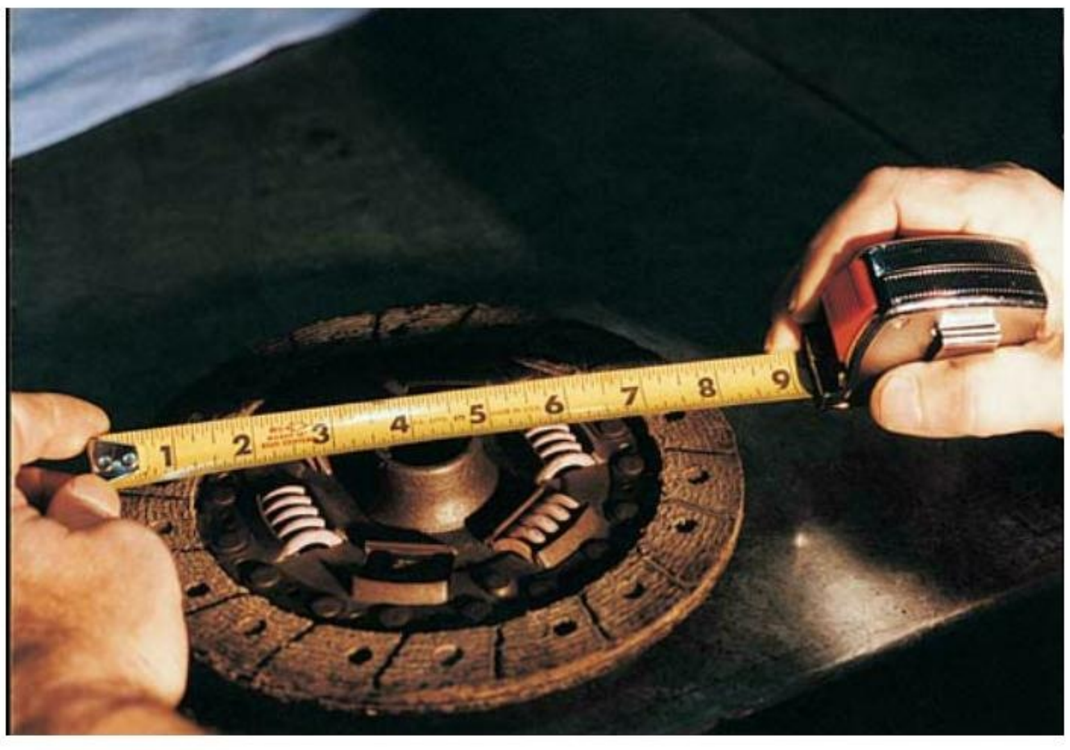
Fairgate

Figure 6-5. Compare inches to centimeters. Ten millimeters equals one centimeter. Twenty-five millimeters is a little less than one inch. The customary rule is divided into 1/16″ fractions.



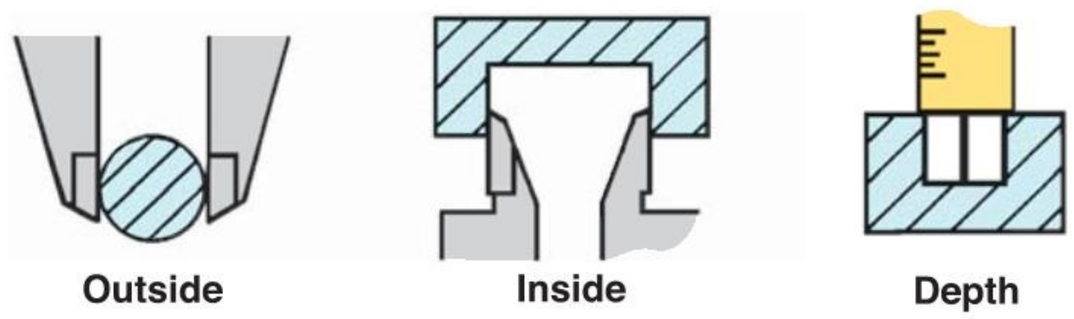
Goodheart-Willcox Publisher

Figure 6-6. A combination square is needed when the rule must be held perfectly parallel to the part.



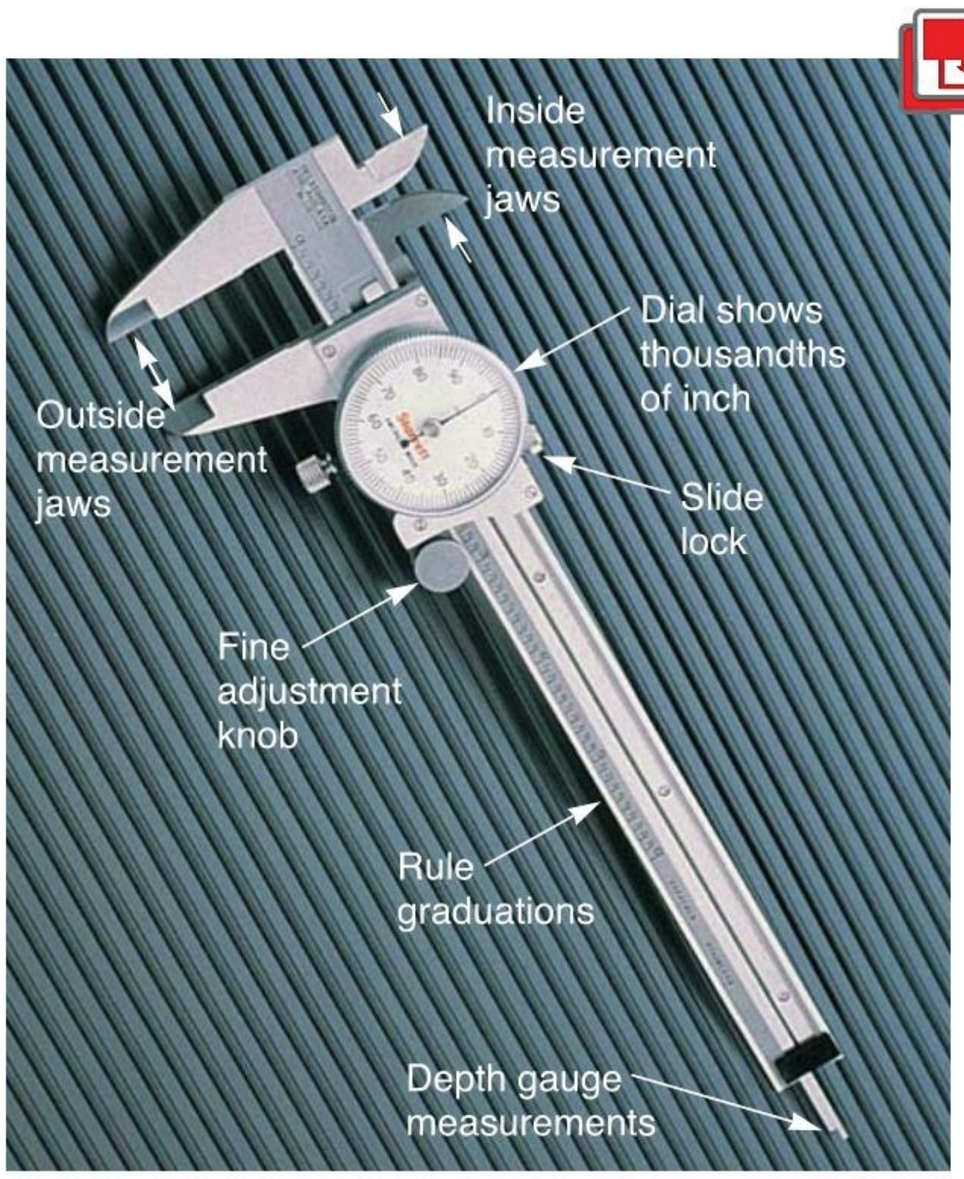
Goodheart-Willcox Publisher

Figure 6-7. Tape measures are used when taking large measurements, such as when measuring to check for major structural damage to suspension parts from a collision.



K-D Tools

Figure 6-8. Study how calipers can be used to check measurements.



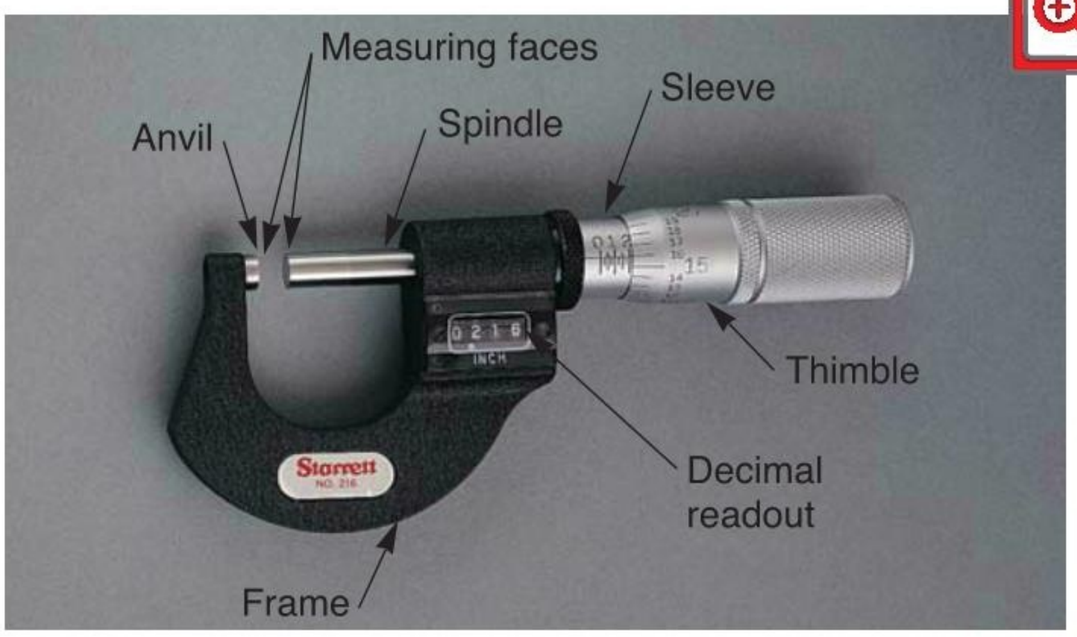
Starrett

Figure 6-9. A vernier caliper can be used to quickly check inside, outside, and depth measurements with considerable accuracy.

An outside micrometer is used for measuring external dimensions, diameters, or thicknesses, **Figure 6-10**. To use an outside micrometer, place it around the outside of the part. Then, turn the thimble until both the spindle and anvil are lightly touching the part, as in **Figure 6-11**. Finally, read the graduations on the hub and thimble to determine the measurement. It is also a good idea to check the accuracy of your micrometer, **Figure 6-12**.

An inside micrometer is used for internal measurements of large holes, cylinders, or other part openings, **Figure 6-13A**. To use an inside micrometer, place it inside the opening. Then, adjust the micrometer until it just touches the walls of the opening. Finally,

Copyright Goodheart-Willcox Co., Inc.



Starrett

Figure 6-10. A micrometer is the precision measuring tool most commonly used by a technician. This one is easy to use because it has a digital readout.

Starrett

Figure 6-11. Move the micrometer over the part while holding it squarely. When you feel a slight drag, remove the micrometer and read the measurement.

remove the micrometer and read the measurement. The inside micrometer is read in the same manner as an outside mike.

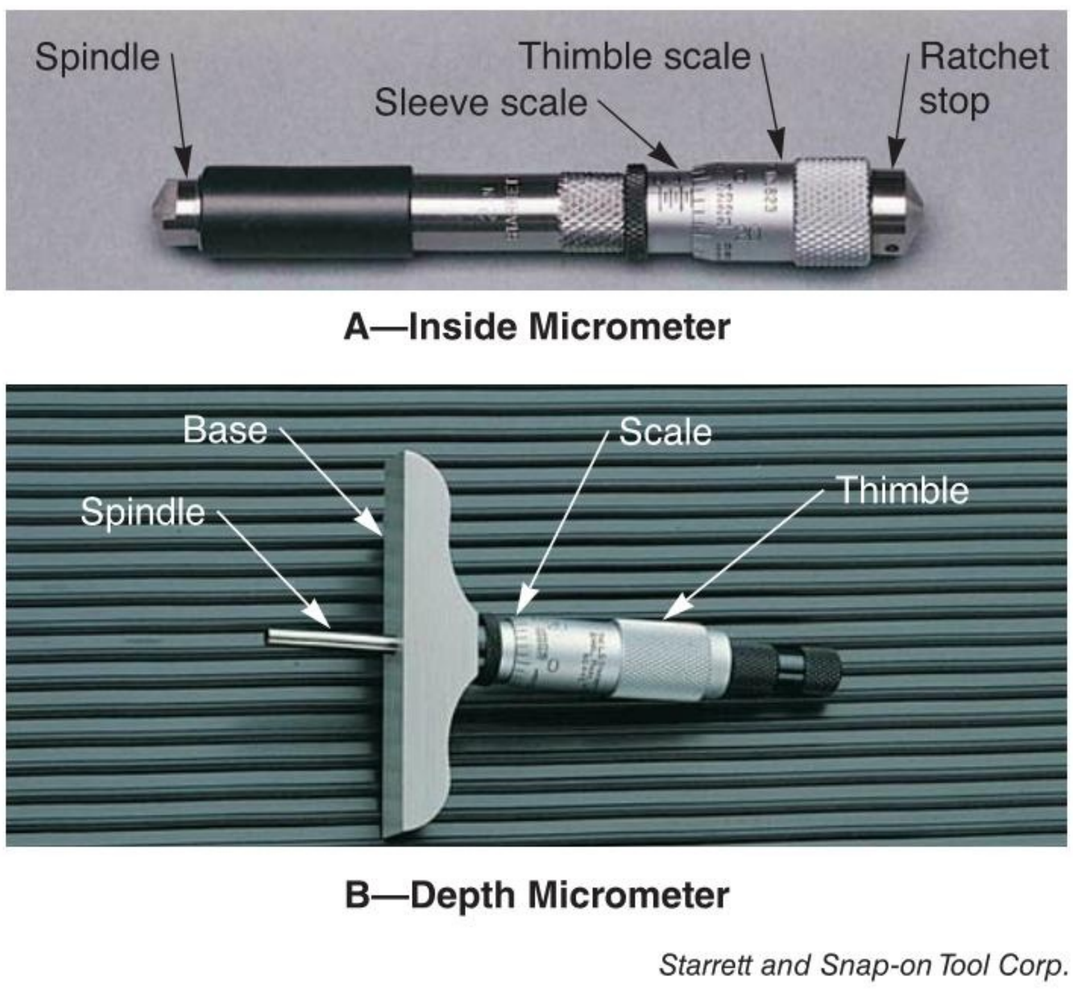
A depth micrometer is helpful when precisely measuring the depth of an opening. Look at **Figure 6-13B**. The base of the micrometer is positioned squarely on the part. Then, the thimble is turned until the spindle contacts the bottom of the opening. The depth micrometer is read in the same way as an outside micrometer. However, the hub markings are reversed.

Reading a Customary Micrometer

To read a customary micrometer, follow the four steps listed below. Refer to **Figure 6-14**.

Goodheart-Willcox Publisher

Figure 6-12. A good way to check your skill and the accuracy of your micrometer is to measure a labeled flat feeler gauge. Compare your measurement to the one engraved in the blade.

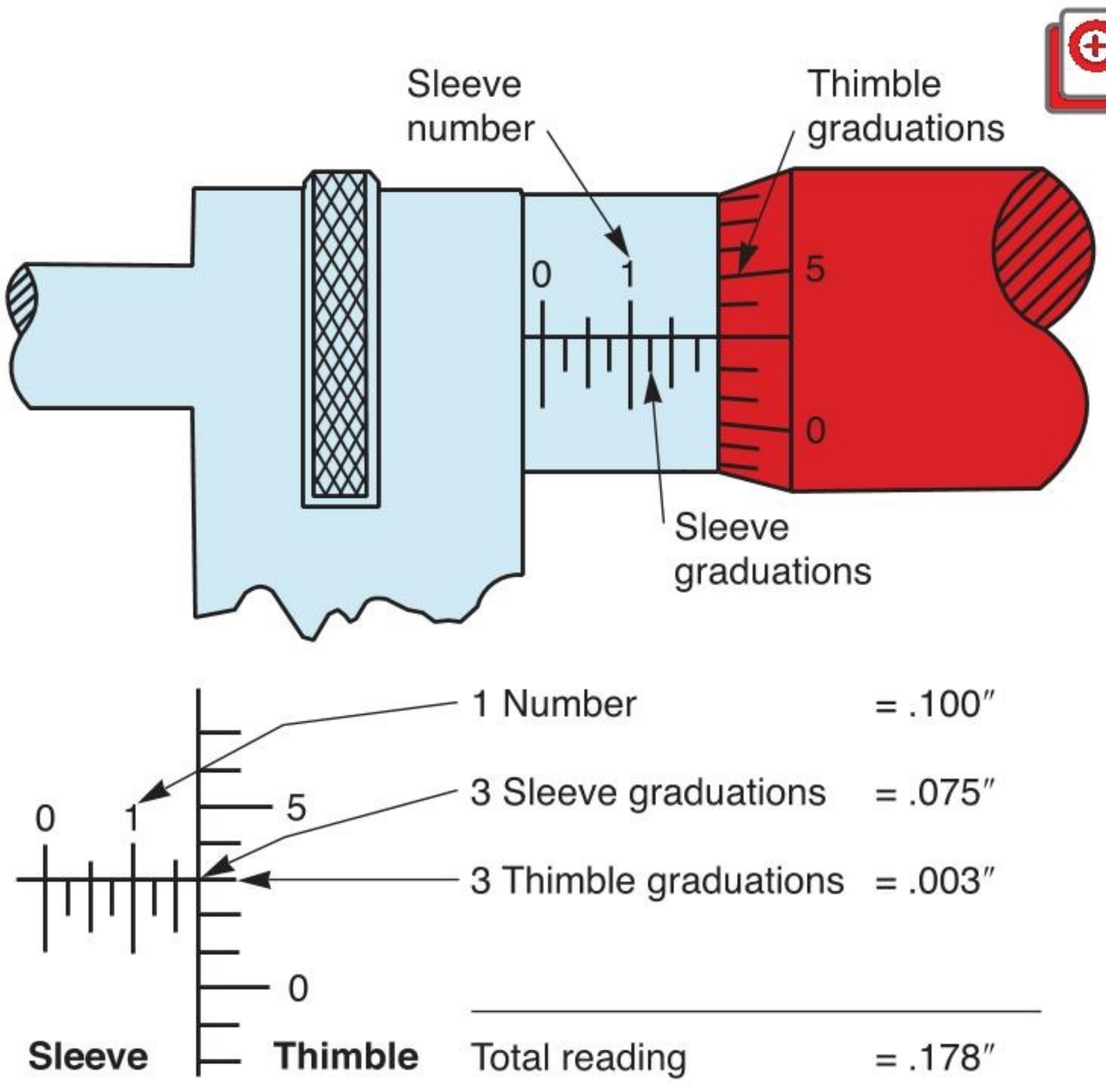


Starrett and Snap-on Tool Corp.

Figure 6-13. Compare the various types of micrometers.

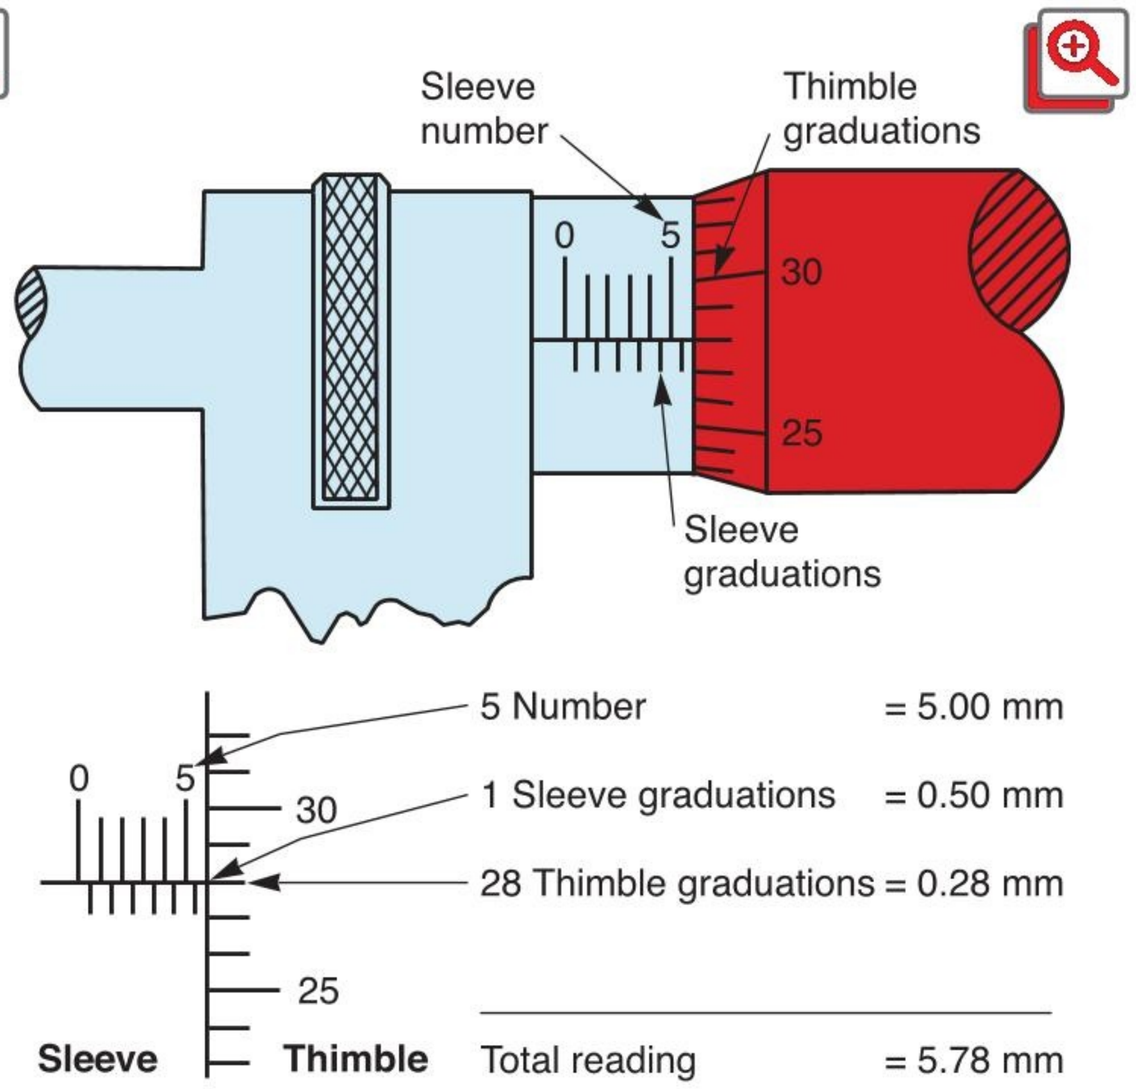
1. Note the largest number visible on the micrometer sleeve. Each number equals 0.100″ (2 = 0.200″, 3 = 0.300″, 4 = 0.400″).
2. Count the number of graduation lines to the right of the sleeve number. Each full sleeve graduation equals 0.025″ (2 full lines = 0.050″, 3 = 0.075″).
3. Note the thimble graduation aligned with the horizontal sleeve line. Each thimble graduation equals 0.001″ (2 thimble graduations = 0.002″, 3 = 0.003″). Round off when the sleeve line is not directly aligned with a thimble graduation.

Copyright Goodheart-Willcox Co., Inc.



Starrett

Figure 6-14. To read a customary micrometer, read the sleeve number first. Then, read the sleeve graduations. Finally, read the thimble number. Add these three values to obtain the measurement in thousandths of an inch.



Starrett

Figure 6-15. A metric micrometer is read like a customary micrometer. However, metric values are used for the sleeve and thimble.

4. Add the decimal values from steps 1, 2, and 3. Also, add any full inches. This sum is the micrometer reading in inches.

Tech Tip

An easy way to practice using a micrometer is to measure the thickness of feeler gauge blades. Since the thickness is printed on the blades, you can read the mike and compare your results to the actual thickness of each blade.

Reading a Metric Micrometer

Metric micrometers are also available. They are similar to customary micrometers but have graduations and numbers in metric values. For example, one revolution of the thimble equals 0.500 mm. To read a metric micrometer, follow the four steps given below. Refer to **Figure 6-15**.

1. Read the largest number visible on the micrometer sleeve. Each number equals 1.00 mm (2 = 2.00 mm, 3 = 3.00 mm).
2. Count the number of graduation lines (both above and below the horizontal sleeve line) to the right of the sleeve number. Each full sleeve graduation equals 0.50 mm (2 = 1.00 mm, 3 = 1.50 mm).
3. Read the thimble graduation aligned with the horizontal sleeve line. Each thimble graduation equals 0.01 mm (2 = 0.02 mm, 3 = 0.03 mm).
4. Add the values from the steps 1, 2, and 3. This sum is the metric micrometer reading in millimeters.

Tech Tip

Technicians also purchase digital micrometers and digital calipers. Part size readings can be taken more easily and quickly without using math.

Measuring Tool Rules

A few important rules to remember include:

- Never drop or overtighten a micrometer or caliper. They are very delicate, and their accuracy can be thrown off easily.

Copyright Goodheart-Willcox Co., Inc.

- Store micrometers, digital calipers, and other measuring tools where they cannot be damaged. Keep them in wooden or plastic storage boxes.
- Cradle the micrometer frame in the palm of your hand and turn the thimble with your thumb and fingers. The measuring faces should just drag on the part being measured.
- Hold the micrometer or caliper squarely with the work or false readings can result. Closely watch how the spindle or jaws are contacting the part.
- Rock or swivel the micrometer as it is touched on round parts. This will ensure the most accurate diameter measurement is obtained.
- Place a thin film of oil on the micrometer or caliper surfaces during storage. This will keep the tool from rusting.
- Always check the accuracy of a micrometer or caliper if it is dropped or struck, or after a long period of use. Standardized gauge blocks, available from your tool supplier, are used for checking micrometer accuracy.

Feeler Gauges

A ***feeler gauge*** is used to measure small clearances or gaps between parts. There are two basic types of feeler gauges: flat feeler gauges and wire feeler gauges. Both types are available in customary and metric versions.

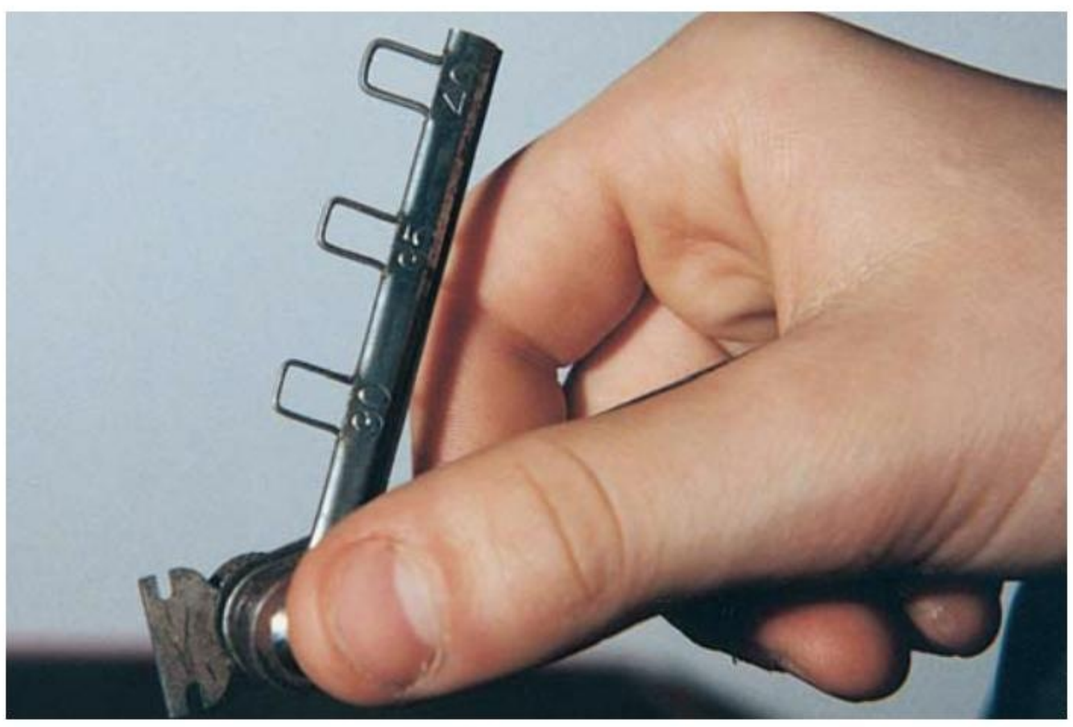
A flat feeler gauge has precision-ground steel blades of various thicknesses, **Figure 6-16**. Thickness is written on each blade in thousandths of an inch and/or in hundredths of a millimeter. A flat feeler gauge is normally used to measure distances between parallel surfaces.

A wire feeler gauge has precise-size wires labeled by diameter or thickness. It is normally used to measure slightly larger spaces or gaps than a flat feeler gauge. A wire gauge is also used for measuring the distance between unparallel or curved surfaces.

Using a Feeler Gauge

To measure with either type feeler gauge, find the gauge blade or wire that just fits between the two parts being measured. The gauge should drag slightly when pulled between the two surfaces. The size given on the gauge is the clearance between the two components.

A



B

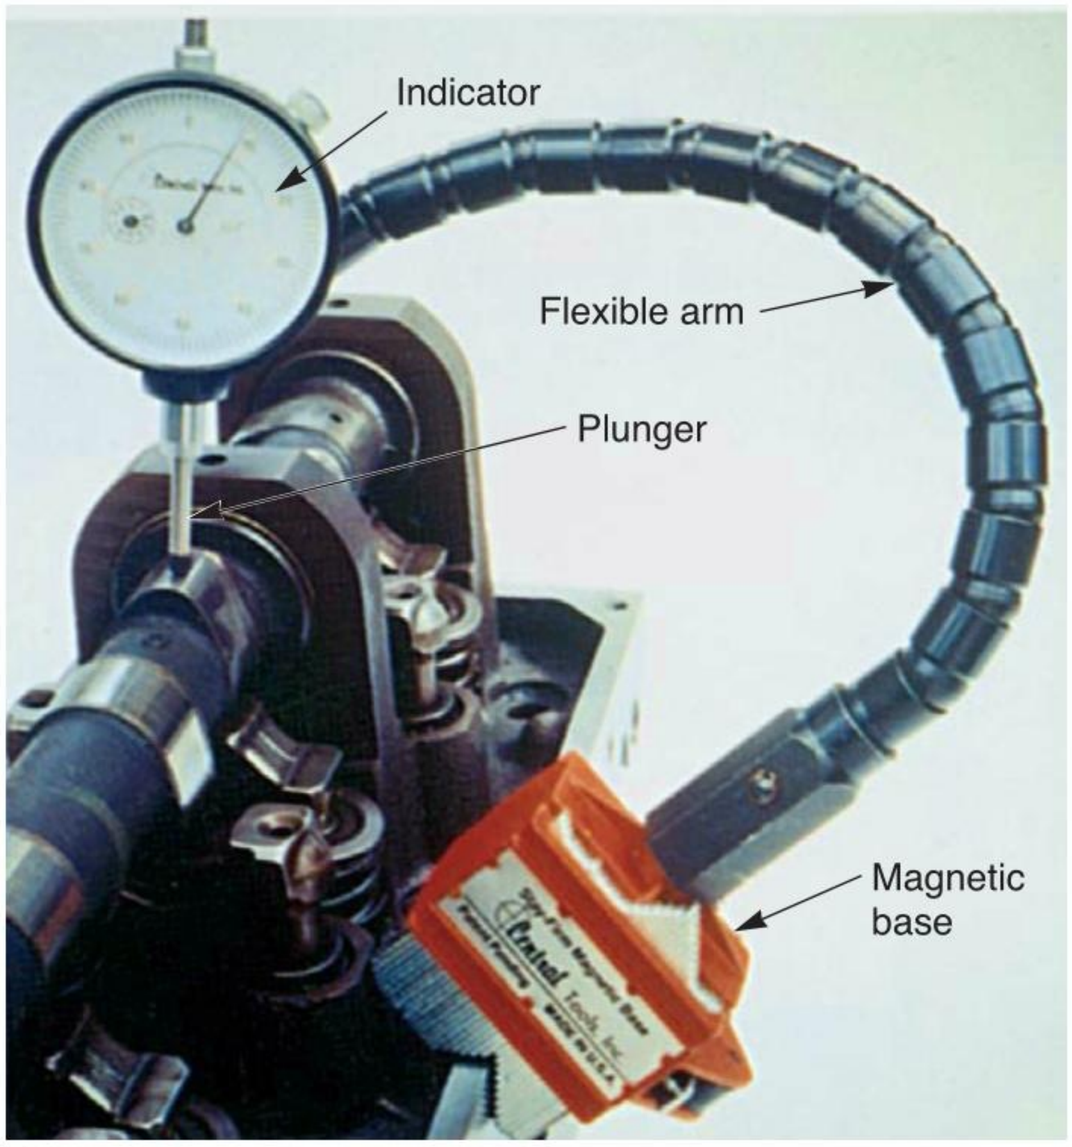
Goodheart-Willcox Publisher

Figure 6-16. Feeler gauge blades are slid between parts until a light drag or friction is felt. The size stamped on that steel blade is the measurement.

Dial Indicator

A ***dial indicator*** is used to measure part movement in thousandths of an inch (hundredths of a millimeter). The needle or digital display on the indicator face registers the amount of plunger movement. A dial indicator is frequently used to check gear teeth backlash (clearance), shaft end play, cam lobe lift, and similar kinds of part movements. A magnetic mounting base or clamp mechanism is normally used to secure the dial indicator to or near the work. Be careful not to damage a dial indicator. It is very delicate. See **Figure 6-17**.

Copyright Goodheart-Willcox Co., Inc.



Central Tool Co.

Figure 6-17. A dial indicator is used when measuring part movement or out-of-round. In this example, the tool is set up to check height and wear of a camshaft lobe. The cam is rotated and the indicator reading is taken at different degrees of rotation. Measurements are then compared to camshaft specs to find wear.

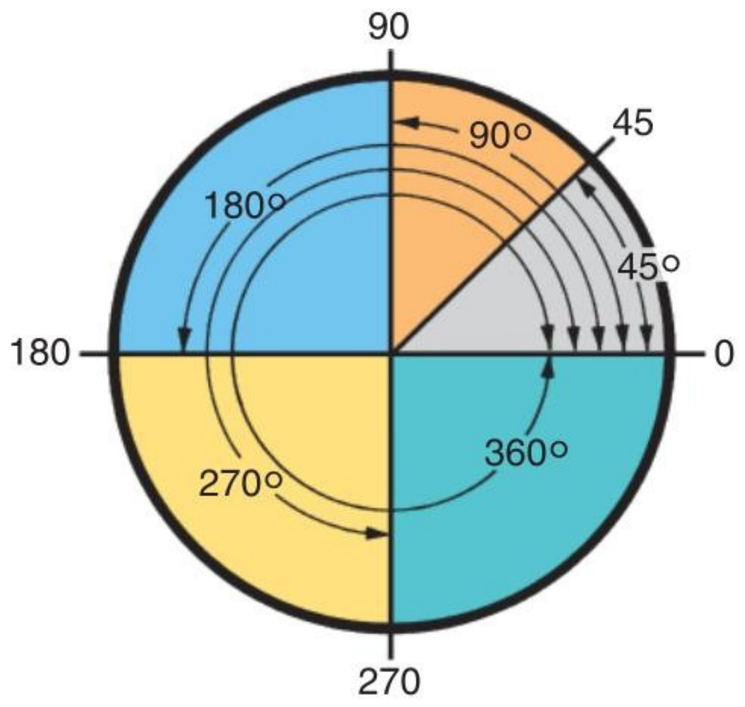
Using a Dial Indicator

To measure with a dial indicator, follow these basic rules:

1. Mount the indicator securely and position the dial plunger parallel with the movement to be measured.
2. Partially compress the indicator plunger before locking the indicator into place. This allows part movement in either direction to be measured.
3. Move the part back and forth or rotate the part while reading the indicator.
4. Subtract the lowest reading from the highest reading. The result equals the distance the part moved, the clearance, or the runout.

Other Measurements and Measuring Tools

A service technician may make other types of measurements and use other types of measuring tools than those discussed to the point. Some of these



Goodheart-Willcox Publisher

Figure 6-18. The amount of rotation and angles are measured in degrees with a full circle totaling 360°.

are discussed in the next sections. More specialized measurements are covered in later chapters.

Angle Measurement

A circle is divided into 360 equal parts called degrees, **Figure 6-18**. Degrees are abbreviated with "deg." or the degree symbol (°). One-half of a circle equals 180°, one-quarter of a circle equals 90°, and one-eighth of a circle equals 45°. Specifications are normally given in degrees when you are measuring rotation of a part or an angle formed by a part.

Temperature Measurement

Temperature gauges, or ***thermometers***, are used to measure temperature. For example, air conditioning output temperature or radiator temperature may need to be determined. The temperature obtained with the gauge can be compared to specifications. Then, if the temperature is too low or too high, you know that a repair or adjustment is needed. Temperature gauges are available that can read in either customary Fahrenheit (°F) or metric Celsius (°C), **Figure 6-19**.

Torque Wrenches

A ***torque wrench*** is not used for taking measurements. Rather, it is used to apply a specific amount of turning force to a fastener, such as a bolt or nut. A torque wrench uses the principle illustrated in **Figure 6-20**. Torque wrench scales usually read in foot-pounds (ft-lb) and Newton-meters (N•m). The four general types of torque wrenches are the flex bar, dial indicator, ratcheting, and digital types. These are shown in **Figure 6-21**.

Pressure Gauge

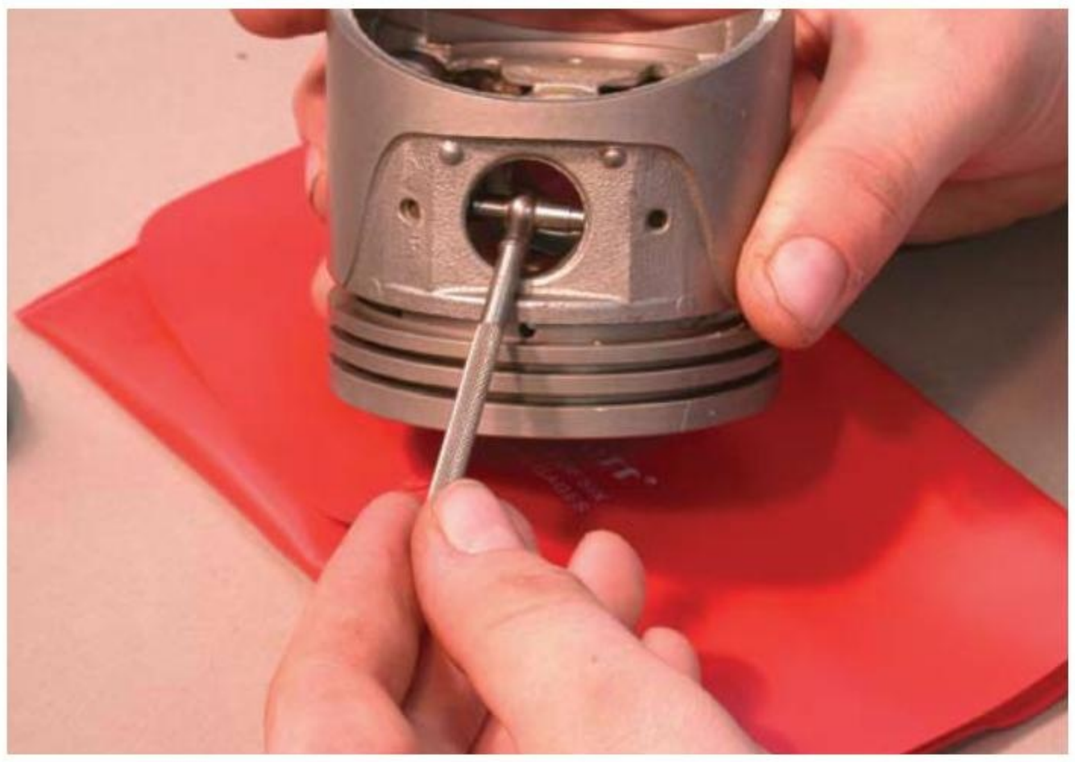
A ***pressure gauge*** is used to measure air or fluid pressure in various systems and components. For example, pressure gauges may be used to check tire air pressure, fuel pump pressure, air conditioning system pressure, or engine compression stroke pressure. Look at **Figure 6-22**. A pressure gauge normally reads in pounds per square inch (psi), kilograms per square centimeter (kg/cm^2), or kilopascals (kPa).

Vacuum Gauge

A ***vacuum gauge*** is used to measure negative pressure, or vacuum. It is similar to a pressure gauge. However, the vacuum gauge reads in inches of mercury (in/Hg) or metric kilograms per square centimeter (kg/cm^2). For example, a vacuum gauge is used to measure the vacuum in an engine's intake manifold. If the reading is low or fluctuating, it may indicate an engine problem.

Telescoping Gauge

A ***telescoping gauge*** is used to measure internal part bores or openings, **Figure 6-23A**. To use the gauge, compress the spring-loaded extensions and lock them with the thumb wheel. See **Figure 6-23B**.



A—Telescoping Gauge

B—Locked Telescoping Gauge

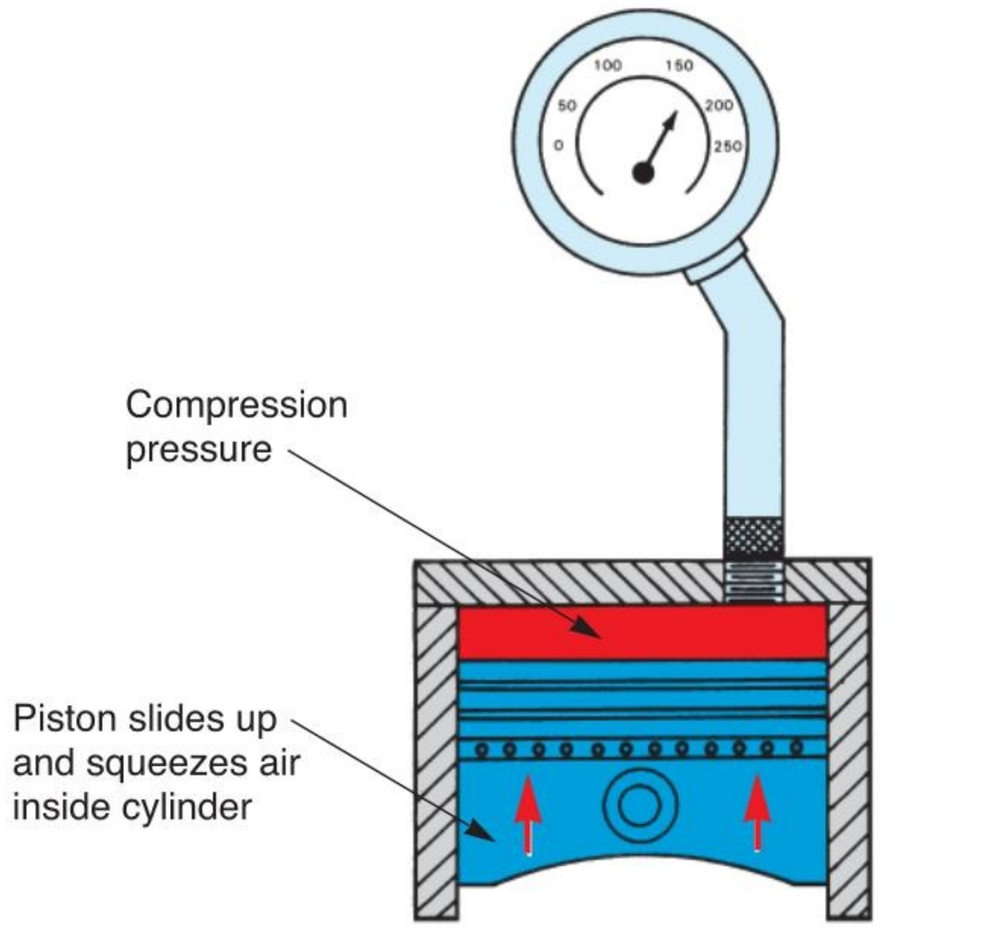
Goodheart-Willcox Publisher

Figure 6-23. Telescoping gauges measure internal part bores or openings.

Then, insert the gauge into the opening and release the thumb wheel. The extensions "snap" to the edges of the opening. Use the thumb wheel to lock the extensions to the size. Finally, use an outside micrometer to measure the distance across the extensions.

Hole Gauge

A ***hole gauge*** is used for measuring very small holes in parts. To use a hole gauge, first loosen the thumb wheel. Then, insert the gauge into the hole and tighten the thumb wheel until the gauge just touches the part. Finally, remove the gauge and measure it with an outside micrometer.



Goodheart-Willcox Publisher

Figure 6-22. A technician must frequently measure pressure. This example shows a gauge being used to measure the pressure developed during the engine compression stroke. If the pressure is not high enough, engine mechanical problems are indicated.

Review of Shop Math

Automotive technicians often use mathematics during the service and repair of vehicles. Technicians must constantly work with whole numbers, fractions, and decimals.

Math skills are needed when working with specifications. For example, if you are working on an engine, you may need to measure piston diameter and cylinder diameter. By subtracting piston diameter from cylinder diameter, you would find piston clearance. This math must be done properly if the engine is to run normally after repairs. If your measurements or calculations are wrong, the engine could knock or lock up after improper repairs.

You will also use math when filling out work orders. You must calculate part prices, labor charges, tax percentage, and total charges.

Tech Tip

If you already have good math skills, skip this section of the chapter. If you need a review of math, study the following, especially the fraction/decimal summary.

Addition

Addition is the combining of two or more numbers to find the total quantity. The result of the addition process is called the sum or the total. A plus sign (+) is used to indicate that the numbers are to be added. Numbers to be added may be written two ways:

in a string: 5 + 3 + 4 = 12 *(sum)*
or
in a column:

```
  5
  3
+ 4
 12 (sum)
```

When there are large numbers or a long series of numbers, it is best to write them in a column so sums of 10 and over can be carried to the next column. Always start adding from the right-hand column so sums exceeding 9 can be carried from that column to the next column to the left:

```
122    - - 2   First, add the right-hand
804    - - 4   column.
644    - - 4
+829   - - 9
       19

  1    Since the total is 19,
- 2 -  place the "9" under-
- 0 -  neath the right-hand
- 4 -  column and add the
- 2 -  "1" to the next
  9    column. Add up the
       2nd column.

1 - -  Now, add up the next
8 - -  column to the left and
6 - -  place the sum below
8 - -  that column.
2399   (Answer is 2399)
```

Addition is used in adding up the cost of parts and labor when preparing a customer's bill. If, for example, parts total $125, labor charges are $95, and tax is $8, the total bill would be $228.

Sample Problem 1—Addition

A vehicle's wheelbase is the distance from the centerline of the front wheels to the centerline of the rear wheels. One manufacturer's compact sedan has a wheelbase of 98″. The same manufacturer's full-size pickup truck has a wheelbase that is 47″ longer than that of its compact sedan. What is this truck's wheelbase?

To answer this question, you must add 47″ to the length of the compact sedan.

```
  98″
+ 47″
 145″
```

The wheelbase of the full size truck is 145″

Subtraction

Subtraction is taking away a certain quantity from another. The amount that is left after subtracting is called the remainder or the difference. The minus sign (–) indicates that the number to the right of it is to be subtracted. Subtraction problems might be written in two ways:

in a string: 495 – 125 = 370 *(remainder)*
or
in a column:

```
 495
–125
 370 (remainder)
```

Subtraction might be used in determining a customer's bill. It might also be used by the technician to check the deductions made on a paycheck for taxes and social security.

Copyright Goodheart-Willcox Co., Inc.

Sample Problem 2—Subtraction

A customer's bill totals $253, but a $25 deposit had been paid before the work was started. How much will the customer have to pay when picking up the vehicle?

To determine the amount due from the customer, you would subtract the amount of the deposit ($25) from the total bill ($253).

$253 *Notice that we had to borrow 10 from the second*
−25 *column, since 5 cannot be subtracted from 3.*
$228

The amount due from the customer is $228

Sample Problem 3—Subtraction

Curb weight is the total weight of vehicle with a full tank of gas but no cargo or passengers. The curb weight of a late-model sedan is 1520 kb, and the gasoline in the tank weighs 49 kg. How much would this vehicle weigh if the fuel tank were empty?

To solve this problem, you must subtract weight of the gasoline in the tank (49 kg) from the curb weight of the vehicle (1520 kg).

1520 Kg
− 49 Kg
1471 Kg

The vehicle would weigh 1471 kg if the gas tank were empty.

Division

To find out how many times one number is contained in another, we use ***division***. The division sign (÷) indicates that one number is to be divided by another. The number being divided is called the dividend. The number a dividend is divided by is called the divisor. The answer is called the quotient. A division problem can be written one of three ways:

in a string: 860 ÷ 10 = 86 *(quotient)*

$$10\overline{)860}\quad 86 \text{ (quotient)}$$

or: $\frac{860}{10} = 86$ *(quotient)*

The technician must use division frequently in an automotive repair facility. For example, suppose that 10 fuel pumps had been ordered and placed in stock. The total bill for the pumps came to $860. What is the cost of each fuel pump?

The cost of each fuel pump is found by dividing $860 (total cost) by 10 (number of pumps). The cost of each pump is $86. This information would be used to determine what the customer would be charged for the pump.

When dividing, not all answers come out to full numbers. In such cases, a decimal point is placed to the right of the last number of the dividend. A decimal point is also placed in the answer directly above the decimal point in the dividend. One or more zeros may be added to the dividend, depending on how many places the decimal number must be carried out. For example, suppose that the cost of the fuel pumps in the previous example came to $865 instead of $860.

86.50 *(quotient—each pump costs $86.50)*
10)865.00
80
65
60
50
50
0

Sample Problem 4–Division

A 140 cubic inch engine is rated at 308 horsepower. How much horsepower is generated per cubic inch in this engine?

To find the answer, you must divide the total horsepower rating of the engine by the number in cubic inches.

140 cubic inch/308 hp = 2.2 hp

2.20
140)308.00
280
28.0
28.0
0

The engine in this example puts out 2.2 horsepower per cubic inch.

Multiplication

Multiplication is a shortcut for adding the same number over and over. Suppose that the number 15 were to be added 12 times: One could set up the problem as 15 + 15 + 15 + 15 + 15..., until there were 12 additions. It is faster, however, to multiply 15 by 12 once. The multiplication sign (×) indicates that numbers are to be multiplied. The number by which another number is multiplied is called the multiplier.

Copyright Goodheart-Willcox Co., Inc.

The result of multiplication is called the product. Multiplication problems can be written two ways:

in a string: $15 \times 12 = 180$ *(product)*
or
in a column:
$$\begin{array}{r} 15 \\ \times\, 12 \\ \hline 180 \end{array}$$ *(product)*

Sample Problem 5—Multiplication

A customer purchased four new tires at a cost of $104 each. What is the total cost for all four tires?

To solve this problem, you must multiply $104 by 4.

$$\begin{array}{r} 104 \\ \times\, 4 \\ \hline 416 \end{array}$$

The price for four tires would be $416.

Numbers of more than one digit used as multipliers are multiplied one digit at a time. The products for each multiplication are stacked and then added together. Suppose that the customer in the previous example purchased 41 tires at $104 each.

$$\begin{array}{r} 104 \\ \times\, 41 \\ \hline 104 \\ 416_ \\ \hline 4264 \end{array}$$ *(product)*

Note that the second product (416) is shifted one column to the left. This is done because the multiplier is actually 40, not 4. To help make this clear, mentally place a 0 after the 6 in the second product ($104 \times 40 = 4160$).

Sample Problem 6—Multiplication

A shop orders 25 batteries that weigh 35 lb each. To determine shipping costs, the total weight of the batteries must be calculated.

To calculate the total weight, you multiply the weight of one battery (35 lb) by 25.

$$\begin{array}{r} 35 \text{ lb} \\ \times\, 25 \\ \hline 175 \\ 70_ \\ \hline 875 \text{ lb} \end{array}$$ *(product)*

The total weight of the batteries is 875 lb.

Fractions and Decimal Fractions

Fractions and decimal fractions are used to represent a portion of a whole number. Fractions are written as two numbers, one over the other or one beside the other:

$\frac{4}{5}$ or $4/5$ *(The fraction is read as "four-fifths.")*

The number below the line or after the slash is called the denominator. This number tells how many parts the whole is divided into; the number above the line or ahead of the slash tells how many parts are present in the fraction. This number is called the numerator. When reading a fraction, the top or first number is always read first; thus, read 12/32 as "twelve thirty-seconds."

Decimal fractions also have a numerator and denominator. The denominator is always a multiple of 10. However, it is never written. A dot or period, called a decimal point, is used in its place. For example, 9/10 is written as 0.9 in decimal notation. The number of digits to the right of the decimal point tells what multiple of 10 the denominator is. Thus:

0.9 is 9/10 *(nine-tenths)*
0.09 is 9/100 *(nine-hundredths)*
0.009 is 9/1000 *(nine-thousandths)*
0.0009 is 9/10,000 *(nine ten-thousandths)*

Since decimal fractions are easier to work with than fractions, it is common to convert fractions to decimal fractions. This is especially true in the automotive service field. Very small measurements are given in thousandths of an inch. However, wrenches are still sized in fractions.

Decimal fractions are used for fine measurements, such as the exact size of machined engine parts. Often, the technician must use a micrometer to check a dimension, such as the diameter of a crankshaft journal or the runout on the thickness of a brake rotor. Decimal fractions can be added, subtracted, multiplied, and divided in the same manner as whole numbers.

There are rules that must be remembered when working with decimal numbers. The first set of rules has to do with placement of zeros.

- A zero placed between a number and a decimal point changes the value of the number by a factor of ten (.45 is not the same as .045).
- A zero placed at the end of a decimal number does not change the value of the number. (.45 is the same as .450).

Copyright Goodheart-Willcox Co., Inc.

- A zero placed at the very front of a decimal number does not change the value of the decimal number (.45 is the same as 0.45).

Addition and Subtraction of Decimals

The rules for addition and subtraction of decimal fractions are:

- Line up the decimal points in a column.
- The decimal point in the answer must be in the same position as the decimal point in the column.
- Since some decimal fractions will have more numbers to the right or left of the decimal point than others, you may fill in the ends of the shorter numbers with zeros. This is optional.

Example:		*could also be written with zeros in the blanks*	
	1.5		1.500
	9.356		9.356
	3.62		3.620
	.96		0.960
	15.436		15.436

Sample Problem 7—Adding Decimal Numbers

During the engine rebuilding process, worn cylinders are sometimes bored (machined) to a larger diameter. During the boring process, a thin layer of material is cut from the cylinder, increasing the cylinder's diameter. If a cylinder with an initial diameter of 91.44 mm is bored 0.76 mm oversize, what is the final diameter of the cylinder?

To solve this problem, you must add the oversize dimension to the initial piston diameter.

```
  91.44
+ 0.76
  92.20
```

The final diameter of the cylinder is 92.20 mm

Sample Problem 8—Subtracting Decimal Numbers

Piston-to-cylinder wall clearance is calculated by subtracting the diameter of the piston from the diameter of the cylinder. If the piston's diameter is 3.625″ and the cylinder's diameter is 3.628″, what is the piston-to-wall clearance?

```
  3.628
- 3.625
  0.003
```

Piston to cylinder wall clearance equals 0.003″

Multiplication and Division of Decimals

Multiplying decimal numbers is not much different from multiplying whole numbers. The rules explain how to deal with the decimal point.

- In setting up the problem, the decimal points do not need to be aligned.
- Multiply the two numbers, ignoring the decimal points.
- Count the total number of digits (places) to the right of the decimal points of both numbers. Starting from the right-hand digit, count to the left the same number of digits in the answer. Place the decimal point to the left of the last digit counted.

  Suppose you wanted to multiply 3.23 by 2.6.

```
  3.23  (two numbers to the right of the decimal point)
× 2.6   (one number to the right of the decimal point)
 1938
 646
 8.398  (total of 3 numbers to the right of the decimal point)
```

Dividing decimals is also similar to dividing whole numbers. Several steps are involved.

- If neither the dividend nor divisor contain decimal points, but the division does not come out even:

  Place a decimal point to the right of the last number of the dividend. Add one or more zeros after the decimal and continue dividing to the number of decimal places necessary.

```
For example:   7.71      division carried out
              ------     two decimal places
           7 | 54.00
               49
               ---
                50
                49
                --
                 10
                  7
                  -
                  3
```

- When the dividend has a decimal and the divisor does not:

  Divide as usual.

  Place a decimal point in the answer directly above the decimal point in the dividend.

```
For example:   2.01
              ------
           25 | 50.25
               50
               --
                02
                 0
                --
                25
                25
                --
                 0
```

Copyright Goodheart-Willcox Co., Inc.

- When the divisor has a decimal point:

  If the dividend does not have a decimal point, add one at the far right.

  If the dividend has a decimal point, move it one place to the right for each decimal place in the divisor. Move the decimal point in the divisor accordingly to the right. Use zeros as place holders, if necessary.

  Divide as usual.

  Place a decimal point in the answer directly above the relocated decimal point in the dividend.

For example: $2.5\overline{)50.25}$

$$25.\overline{)502.5}\quad \begin{array}{r} 20.1 \\ \underline{50} \\ 02 \\ \underline{0} \\ 25 \\ \underline{25} \\ 0 \end{array}$$

Sample Problem 9—Multiplying Decimal Numbers

If each cylinder in a six-cylinder engine has a displacement of 0.5 liters, what is the total engine displacement?

To solve this problem, you should multiply the displacement for one cylinder by the number of cylinders in the engine.

$$\begin{array}{r} 0.5 \\ \times 6 \\ \hline 3.0 \end{array}$$

The total engine displacement is 3.0 liters.

Sample Problem 10—Dividing Decimal Numbers

A 2.5 liter engine is rated at 175 horsepower. How much horsepower is generated per liter in this engine?

To solve this problem, you must divide the total horsepower rating of the engine (175) by the number of liters (2.5).

$$2.5\overline{)175}\quad \begin{array}{r} 70 \\ -\underline{175} \\ 0 \end{array}$$

The engine is this example puts out 70 horsepower per liter.

Percentages

Percentages are quantities expressed as a part of 100. For example, ten percent (10%) is equal to 10 out of every 100. Seventy five percent (75%) is equal to 75 out of every 100, and one hundred percent (100%) is equal to 100 out of 100. Percentage is commonly used to calculate tax on parts.

To find a percentage of any number, you must first convert the percentage to decimal format. This is done by dropping the percentage sign and moving the decimal point two places to the left. For example, 5% = 0.05 and 50% = 0.5. Once the percentage is in decimal format, this decimal can be multiplied by the number you wish to find the percentage of. For example, suppose you want to know what 65% of 50 is. You would begin by converting 65% to a decimal. 65% expressed as a decimal is 0.65. Next, you would multiply 0.65 by 50.

$0.65 \times 50 = 32.5$

65% of 50 is 32.5

Sample Problem 11—Calculating Percentage

A tire's recommended inflation pressure is 35 pounds per square inch (psi). If the tire is inflated to 80% of the recommended pressure, how much pressure is in the tire?

To solve this problem, you must first express 80% as a decimal.

80% = 0.80

Next, you must multiply this number by the recommended tire pressure.

0.80×35 psi = 28 psi

The tire is inflated to 28 psi.

For example, if a part costs $100 and sales tax is 7%, you can determine the amount of tax that will be charged on the part by calculating 7% of $100.

7% of $100 = $0.07 \times \$100 = \$7$

You can then add $7 to the $100 to determine the cost of the part including tax.

You may find it necessary to determine the percentage variation between two or more numbers. For example, specifications may require that certain numbers not vary by more than 5%. One way to determine this is to add the specified percentage to 100% and then covert this number to a decimal. For example, if the specified percentage was 5%, you would add 5% and 100% to arrive at 105%. Converting this to a decimal would give you 1.05. Next, multiply 1.05 by the

Copyright Goodheart-Willcox Co., Inc.

lowest number and compare the new number (lowest value × 105%) to the highest value. If the new number is greater than or equal to the highest value, the variation between these readings is equal to or less than specified percentage. If the new number is less than the highest number, the variation between the numbers is greater than the specified percentage.

Sample Problem 12—Percentage Variation

If the compression test on an engine results in readings of 150 psi, 146 psi, 145 psi, and 130 psi, and the manufacturer specifies that there be no more than 10% variation between readings, does this engine pass its compression test?

Begin by calculating 10% of 130

$130 \times 10\% = 130 \times 0.1 = 13$

Add the product of the previous calculation (13) to the lowest value (130)

$130 + 13 = 143$

Compare the result of previous step (143) to the highest reading (150 psi)

Since 143 is less than 150, the variation between 150 psi and 130 psi is greater than 10%.

Ratios

A ratio is a mathematic expression comparing two numbers. It represents how many of one item there is compared to another. A ratio of 2 to 1 can be written as 2:1 or 2/1. This means that for every 2 of one item, there is one of a second item. For example, if the ratio of red cars on the road to blue cars on the road is 2:1, there are twice as many red cars on the road as there are blue ones. Notice that the ratio does not tell you how many red cars are on the road, just that there are twice as many.

Ratios are commonly used when expressing the relationship between gears. For example, if two gears have a ratio of 3:1, one gear would turn three revolutions to only one revolution for the other gear.

Workplace Skills

When working as an automotive technician, you will frequently have to take or use measurements. If your measurements are not within factory tolerances (acceptable ranges or limits), you know that the part requires repair, replacement, or adjustment. When working, remember that measuring tools are very delicate. Measuring tools can be damaged and knocked out of calibration by being dropped on the shop floor. Handle measuring tools carefully and never drop them!

Summary

- As a vehicle is driven, its moving parts slowly wear out. With enough part wear, mechanical failures and performance problems result.
- Auto manufacturers give “specs,” or specifications, for maximum wear limits and dimensions of parts.
- Our customary measuring system originated from sizes taken from parts of the human body.
- Conversion between units in the metric (SI) measuring system is based on a power of ten.
- A steel rule, also called scale, is frequently used to make low-precision linear measurements.
- A vernier caliper is a sliding caliper with a dial gauge or digital readout attached.
- A micrometer, nicknamed a “mike,” is commonly used when making very accurate measurements.
- Never drop or overtighten a micrometer. It is very delicate and its accuracy can be thrown off easily.
- A feeler gauge is used to measure small clearances or gaps between parts.
- Dial indicator will measure part movement in thousandths of an inch (hundredths of a millimeter).
- A torque wrench measures the amount of turning force applied to a fastener.
- A pressure gauge is frequently used in the auto shop to measure air or fluid pressure in various systems and components.
- Automotive technicians use mathematics during servicing and repair of vehicles and when filling out work orders for billing customers.

meterstick
metric (SI) measuring system
metric rule
micrometer
multiplication
pocket rule
pressure gauge
scale
steel rule
subtraction
tape measure
telescoping gauge
thermometer
torque wrench
vacuum gauge
vernier caliper
yardstick

Activities

1. Demonstrate the proper reading of a dial indicator.
2. Practice using a micrometer to measure a set of feeler gauges supplied by your instructor.
3. Demonstrate to the class the use of a wire feeler gauge to measure the gaps of spark plugs.
4. Use the Internet to calculate the cost of a basic set of measuring tools.

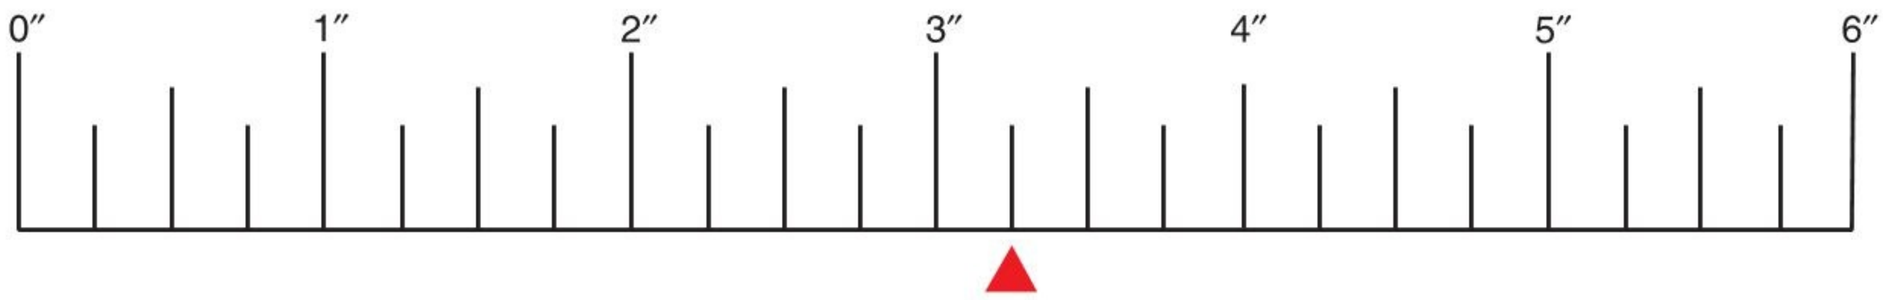
Review Questions

Answer the following questions using the information provided in this chapter.

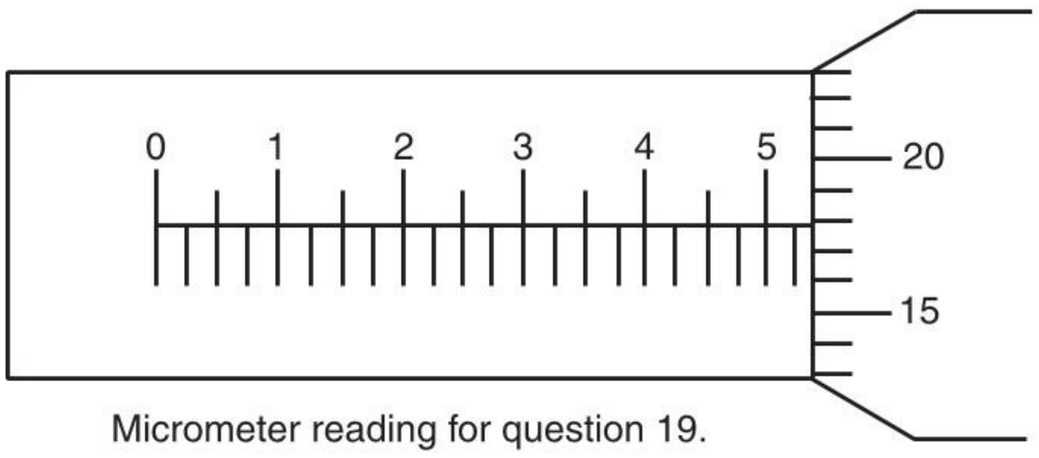
1. The two measuring systems are the _____ measuring system and the _____ measuring system.
2. Parts of the human body are used as the basis for the customary measuring system. True or False?
3. The metric system uses a power of 16 for all basic units. True or False?
4. Which of the following is a metric value?
   (A) Mile.
   (B) Psi.
   (C) Millimeter.
   (D) Inch.
5. What is a measuring system conversion chart?
6. An automotive piston's connecting rod is 8″ long. What is the approximate length of this connecting rod in millimeters?
   (A) 42 mm.
   (B) 173.6 mm.
   (C) 203.2 mm.
   (D) 307.8 mm.
7. A decimal system conversion chart is used to find equal values for _____, _____, and _____.
8. Which of the following is a special micrometer used in auto technology?
   (A) Inside micrometer.
   (B) Depth micrometer.
   (C) Width micrometer.
   (D) Both A and B.
9. Describe the four steps for reading a customary outside micrometer.
10. Describe the four steps for reading a metric outside micrometer.
11. Describe the differences between a flat feeler gauge and a wire feeler gauge.
12. A dial indicator will measure part _____ in thousandths of an inch or _____ of a millimeter.
13. List the four basic rules for measuring with a dial indicator.
14. For measuring purposes, the circle is divided into 720 degrees. True or False?
15. The four types of torque wrenches are the _____, _____, _____, and _____.

Copyright Goodheart-Willcox Co., Inc.

16. Which of the following instruments measures in pounds per square inch (psi)?
    (A) Pressure gauge.
    (B) Flat feeler gauge.
    (C) Depth micrometer.
    (D) Combination square.
17. Explain the use of a vacuum gauge.
18. Note the inch rule below and give the measurement by full inches and fractions of an inch.
19. Give the micrometer reading for the micrometer scale shown below.
20. When using a vacuum gauge, Technician A states that the gauge reads in inches of mercury. Technician B says that the gauge reads in kilograms per square centimeter. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
21. If a cylinder with an initial diameter of 3.63″ is machined 0.030″ oversize, what is the final diameter of the cylinder?
22. A technician has spacer shims of the following thicknesses: 0.050 mm, 0.003 mm, and 0.010 mm. If these shims are stacked together, what is the thickness of the stack?
23. The load carrying capacity of a tire varies with the amount of air pressure in the tire. A specific tire's load carrying capacity is 1949 lb at 32 psi. At 26 psi, the tire's capacity is 196 lb less than it was at 32 psi. What is the tire's load carrying capacity at 26 psi?
24. A tire's usable tread depth is calculated by subtracting tread depth at which tire is considered worn out (1.59 mm) from the tread depth of the tire when new. If a new tire has a tread depth of 9.94 mm, what is the tire's usable tread depth?
25. One manufacturer's hybrid vehicle contains a high-voltage battery made up of 38 battery packs that produce 7.4 volts each. What is the total voltage produced by this battery?
26. An average vehicle is driven 24,000 kilometers each year. How many kilometers is an average vehicle driven in 6 years?
27. If a vehicle averaged 30 miles per gallon on a 750 mile trip, how many gallons of fuel were used on the trip?
28. If a 2.7-liter engine produces 325 horsepower, how much horsepower does the engine produce per liter?
29. Which of the following is the decimal equivalent of 35%?
    (A) 0.035
    (B) 0.35
    (C) 1.35
    (D) 3.5



Inch rule for question 18.



Micrometer reading for question 19.

ASE-Type Questions

1. "Specs" are:
   (A) dimensions of parts.
   (B) maximum wear limits of parts.
   (C) provided by the manufacturer.
   (D) All of the above.
2. Technician A says the customary measuring system originated from sizes taken from parts of the human body. Technician B says customary units were derived from the landscape. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Volume can be measured in each of these *except:*
   (A) liters.
   (B) quarts.
   (C) kilopascals.
   (D) cubic inches.
4. A decimal conversion chart is typically accurate to the nearest:
   (A) 1/16 of an inch.
   (B) 1/64 of an inch.
   (C) inch.
   (D) foot.
5. Which of the following is used to make high-precision measurements?
   (A) Steel rule.
   (B) Pocket scale.
   (C) Vernier caliper.
   (D) Combination square.
6. Which of the following measuring devices has an attached dial gauge or digital readout that makes measurements easier to read?
   (A) Divider.
   (B) Vernier caliper.
   (C) Pocket rule.
   (D) Combination square.
7. Each number on the sleeve of a customary micrometer equals:
   (A) 0.100″
   (B) 0.200″
   (C) 0.300″
   (D) 0.400″
8. Which of the following is *not* a good rule to remember when using a micrometer?
   (A) Never drop or overtighten a micrometer.
   (B) Hold the micrometer squarely with the work.
   (C) Grasp frame with fingers and turn the thimble with your palm.
   (D) Put a little oil on a micrometer when in storage.
9. Which type of gauge is used to measure the distance between unparallel or curved surfaces?
   (A) Flat feeler gauge.
   (B) Wire feeler gauge.
   (C) Telescoping gauge.
   (D) Spring gauge.
10. A dial indicator measures part movement in:
    (A) kilopascals.
    (B) millimeters.
    (C) hundredths of an inch.
    (D) thousandths of an inch.

Chapter 7
Service Information and Work Orders

After studying this chapter, you will be able to:

- Describe the different types of service information.
- Explain the different kinds of information and illustrations used in service information.
- Describe the advantages of an online service information program.
- Understand the use and calculation of shop work orders.
- Order parts needed for vehicle repair.
- Correctly answer ASE certification test questions concerning service information.

Modern vehicles contain thousands of parts and hundreds of large assemblies. Most of these parts are assembled to close tolerances (exacting measurement standards). They constantly require you to follow intricate procedures during repairs. Often, a technician needs specific technical information to properly diagnose or troubleshoot hard to find vehicle problems. In these cases, you must refer to service information. Service information is one of the technicians' most important tools.

Service Information

Service information details how to diagnose and repair a vehicle. It may consist of step-by-step procedures, specifications, diagrams, exploded part illustrations, troubleshooting charts, descriptions of common problems for specific vehicle makes and models, and other useful information. Service information is written in a concise technical language. It is intended to be used by well-trained technicians who are already familiar with the technical language.

In the past, most service information was available in the form of printed service manuals. These manuals were used to look up procedures, diagnosis charts, specifications, illustrations, wiring diagrams, and other repair information. Today, computer-based service information is used in most shops. See **Figure 7-1**. Computer-based service information is defined as data stored on a hard drive, CD-ROM, or DVD, or accessed via the Internet.

Vehicle manufacturers host databases that provide their dealership service facilities 24/7 online access to accurate, up-to-date diagnosis, repair, and maintenance information. Additionally, online service information providers such as Identifix, Mitchell, and AllData compile service and repair information for thousands of vehicles and make this information available to independent repair facilities via the Internet. The information provided by these companies is

Copyright Goodheart-Willcox Co., Inc.

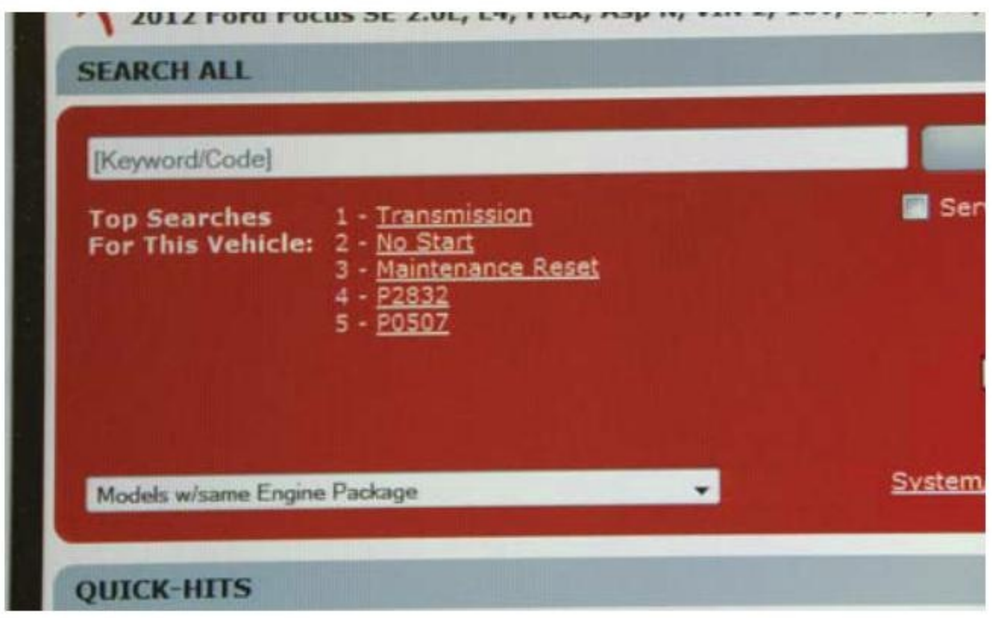
OTC/SPX Corp.

Figure 7-1. A computer is now a commonly used tool of many technicians and service managers.

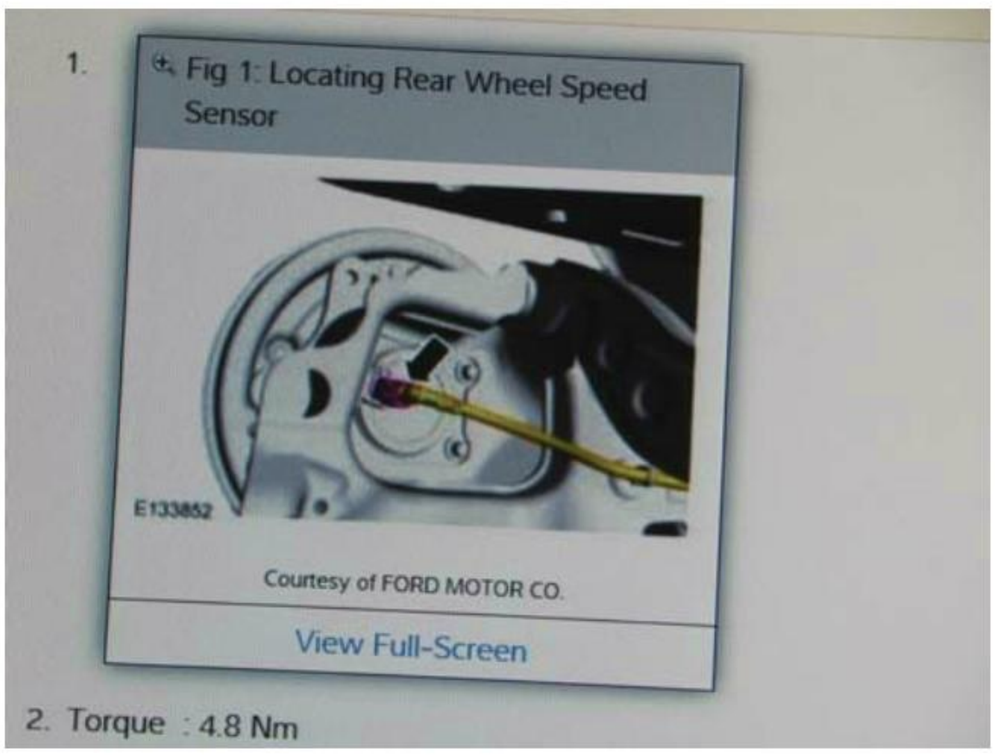
commonly offered on a subscription basis and often includes OEM service information, factory-correct wiring diagrams, part illustrations, diagnostic flowcharts, factory part numbers, component location lists (with illustrations showing the component's exact location on the vehicle), and technical service bulletins (TSBs).

Some online service information providers also offer a library of tech articles, hyperlinks to related information, and access to up-to-date diagnostic trouble codes (DTC). All this information is presented in an easily searchable format that is intuitive, fast, and functional. Additionally, many systems generate accurate quotes on mechanical repairs using original equipment parts and industry-accepted labor information. Unlike a printed product, online service information can be instantaneously updated by the provider. Refer to **Figure 7-2**.

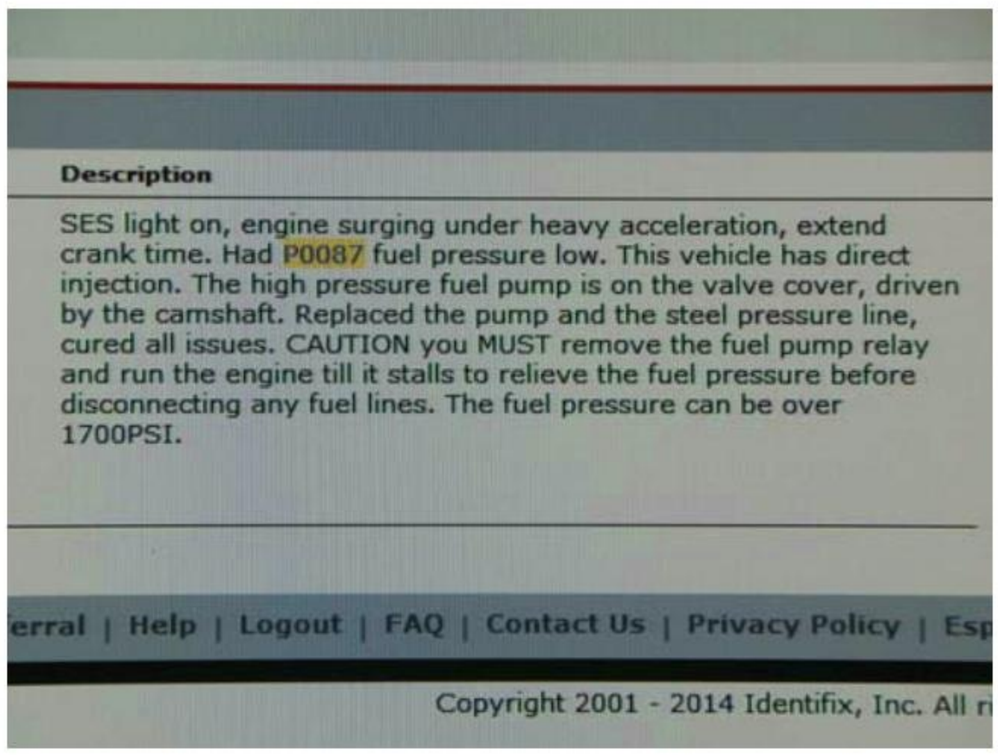
A—Buttons along top of screen allow the technician to navigate to the desired information. In this program, the technician can access service manuals, search for descriptions of actual repairs, review recommended maintenance schedules, and prepare a quote.



B—To search for common problems and fixes, simply type a description of the problem into the search box and hit the search button.



C—Illustrations can help you identify parts for repair or replacement.



D—This detailed repair description was posted by a technician who fixed a vehicle that had a P0087 trouble code and specific symptoms.

Goodheart-Willcox Publisher

Figure 7-2. Most computer-based service information systems make use of intuitive navigation features, allowing the technician to find the information they need quickly and easily.

Copyright Goodheart-Willcox Co., Inc.

Service Information Illustrations and Diagrams

Various types of illustrations are used to supplement the written service information. Some show how to measure part wear, while others show how to install parts. Others show an exploded, or disassembled, view of parts and assemblies. These illustrations may show you what parts look like, how parts fit together, the most likely places where leaks might occur, etc.

Diagrams are drawings used when working with electrical circuits, vacuum hoses, and hydraulic circuits. They represent how wires, hoses, passages, and parts connect together. Wiring diagrams show how the wiring connects to the electrical components.

Vacuum diagrams help the technician determine how vacuum hoses connect to the engine and vacuum-operated devices. Hydraulic diagrams show how a fluid, usually oil, flows in a circuit or part. They are helpful in understanding how a component operates or how to troubleshoot problems. Hydraulic diagrams are commonly given for automatic transmissions and power steering systems. See **Figure 7-3**.

Service Information Abbreviations

Abbreviations are letters that stand for an entire word. They are often used in service information. In most cases, the abbreviations are explained when they are first used. See **Figure 7-4**.

Tech Tip

This textbook uses only universally accepted SAE abbreviations. It does not use abbreviations that only apply to one manufacturer.

Service Information Diagnostic Charts

Diagnostic charts, or troubleshooting charts, commonly found in service information outline the steps for finding and correcting problems during automobile repair. If the source of the problem is hard to find, a diagnostic chart should be used. It will guide you to the most common causes of specific problems. There are four basic types of diagnostic charts. These are: tree, block, illustrated, and component location charts.

A tree diagnosis chart provides a logical sequence for what should be inspected or tested when trying to solve a problem. For instance, if a horn will not work, the top of the tree chart may tell you to check the horn's fuse. Then, if the fuse is good, it may have you measure the voltage going to the horn. You work your way down the "tree" until the problem is found, **Figure 7-5**.

A block diagnosis chart lists conditions, causes, and corrections in columns. The most common cause is at the top of the listing. For example, if an engine overheats, loss of coolant appears at the top of the "causes" column. Check the coolant level. If this is the problem, fill the radiator and check for leaks. If the coolant level is okay, go to the next listing on the chart. See **Figure 7-6**.

An illustrated diagnosis chart uses pictures, symbols, and words to guide the technician through a sequence of tests. If an engine oil pressure gauge shows low oil pressure, for example, the chart shows you exactly what to do, step by step, until the problem is found and corrected. This type of diagnosis chart not only tells you what to do, but it shows you how to do it.

A ***component location chart*** shows where various parts are located on the vehicle. This type of chart is often used for the engine compartment. The chart helps locate the numerous sensors, relays, fuses, and other components housed in this area.

Tech Tip

The layout and features of computer-based service information systems vary from one system to the next. The best way to learn how to use these systems is to practice using them. For example, on your lunch hour, look up specific service information for one make and model of vehicle. This will help you find data more quickly when working.

Other Sources of Vehicle Information

In addition to computer-based or printed service manuals, technicians often rely on other sources of information when diagnosing, servicing, or repairing a vehicle. These include owner's manuals, flat-rate manuals, and technical bulletins.

Owner's Manual

An ***owner's manual*** is a small booklet given to the purchaser of a new vehicle. It contains basic information on starting the engine, maintaining the car, fluid types, fluid capacities, and instructions on operating vehicle accessories for example.

Flat-Rate Manual

A ***flat-rate manual*** lists the flat-rate times for a variety of repairs. ***Flat-rate time*** is the average amount of time it will take a technician to complete a specific repair. Many shops use flat-rate time when calculating the labor charges for a repair. Flat-rate time is multiplied by the shop's hourly labor rate to find the labor charge in dollars. Using the flat-rate manual, you will be able to give the customer a cost estimate before beginning the actual repair and a bill after repairs have been completed.

Technical Bulletins

Technical bulletins help the technician stay up-to-date with recent technical changes, common repair problems, and other service-related information. These electronic publications are sent to the shop's main computer for use by the technicians.

Online Resources

Several websites are available that provide technical assistance and allow technicians to communicate with each other. The ***International Automotive Technicians Network (iATN)*** provides a platform for automotive technicians from around the globe to exchange service and repair information. See **Figure 7-7**. The iATN website also contains a database of repair information, a waveform library, component photos, and other useful features.

Work Orders

A ***work order***, also called repair order or shop ticket, is a form used by technicians to record information about a vehicle that is being serviced. It is often used as the invoice for the customer. In some cases, a work order is used when preparing a repair estimate.

Generally, the shop's service writer or manager initiates the work order by filling in customer and vehicle information on a computer. The work order will also contain a written description of the problems or symptoms described by the customer. The service writer often has the customer sign a printed work order, authorizing the shop to repair the vehicle.

The work order is then given to the technician electronically, who uses the information on the form as a starting point when servicing or repairing the vehicle. The technician or service writer records the services or repairs that were completed, as well as the time required to complete the repairs.

When repairs are completed, the service writer must calculate the total labor charge for the repair. The flat-rate time or the actual time required to complete the repair is multiplied by the shop's labor rate. For example, if the diagnosis and repair time is 5 hours and the labor rate is $50 per hour, the total labor charge would be $250.

Next, the technician calculates the total charges for the parts used during the repair. Most work orders have a separate section for listing the repair parts and their prices. In most cases, the part prices are based on a percentage markup of the wholesale part prices. For example, if the shop markup is 30% on a part, with a wholesale price of $25.00, the price charged to the customer is $32.50 ($25.00 x .30 = $7.50 + $25.00 = $32.00). Some shops charge an environmental fee for the disposal of hazardous wastes (oil, batteries, air bags, etc.). This charge must also be included on the work order.

Finally, the technician or service writer must calculate tax for the parts and then total the bill by adding

Copyright Goodheart-Willcox Co., Inc.

Condition	Possible Cause	Correction
• Loss of coolant.	• Pressure cap and gasket.	• Inspect, wash gasket, and test. Replace only if cap will not hold pressure test specifications.
	• External leakage.	• Pressure test system. • Inspect hose, hose connections, radiator, edges of cooling system gaskets, core plugs, drain plugs, transmission oil cooler lines, water pump, heater system components. Repair or replace as required.
	• Internal leakage.	• Check for obvious restrictions. • Check torque of head bolts. Retorque if necessary. • Disassemble engine as necessary— check for cracked intake manifold, blown head gaskets, warped head or block gasket surfaces, cracked cylinder head, or engine block.
• Engine overheats.	• Low coolant level.	• Fill as required. Check for coolant loss.
	• Loose fan belt.	• Adjust.
	• Pressure cap.	• Test. Replace if necessary.
	• Radiator or A/C condenser obstruction.	• Remove bugs and leaves.
	• Closed thermostat.	• Test. Replace if necessary.
	• Fan drive clutch.	• Test. Replace if necessary.
	• Ignition.	• Check timing and advance. Adjust as required.
	• Temperature gauge or cold light.	• Check electrical circuits and repair as required.
	• Engine.	• Check water pump and block for blockage.
	• Exhaust system.	• Check for restrictions.
• Engine fails to reach normal operating temperature.	• Thermostat stuck open.	• Test. Replace if necessary.
	• Temperature gauge or cold light inoperative.	• Check electrical circuits and repair as required. Refer to electrical section.

Ford

Figure 7-6. A block diagnosis chart lists conditions, causes, and corrections in columns. Read to the right to match a condition with possible causes and corrections.

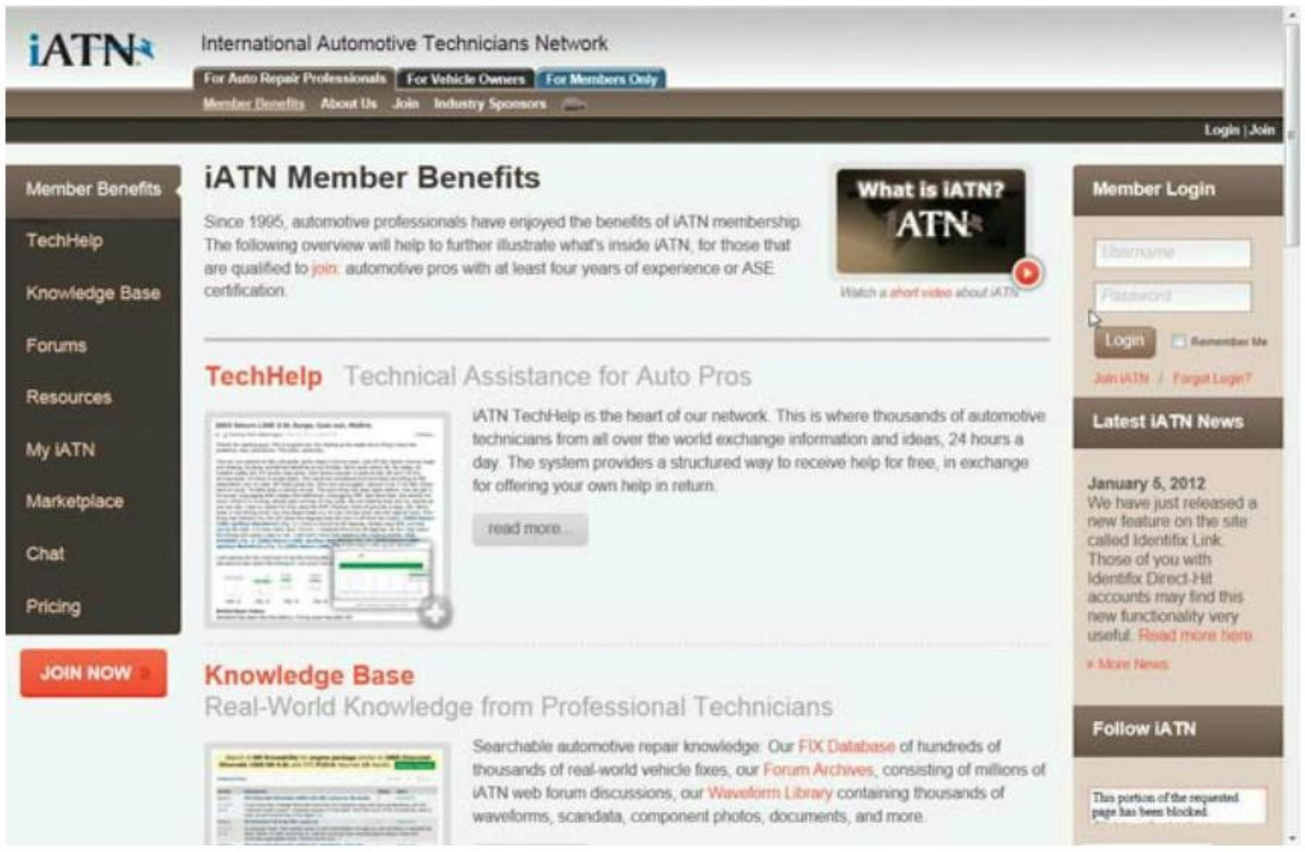
parts, labor, supplies, fees, and taxes to arrive at the final amount for the repair.

Decoding the Vehicle Identification Number

The ***vehicle identification number (VIN)*** is a unique 17-character code found on a plate located on a vehicle's dashboard or door opening. This code sets a vehicle apart from the millions of other vehicles. Most sources of service information include an explanation of what each character of the VIN means. Look at **Figure 7-8**.

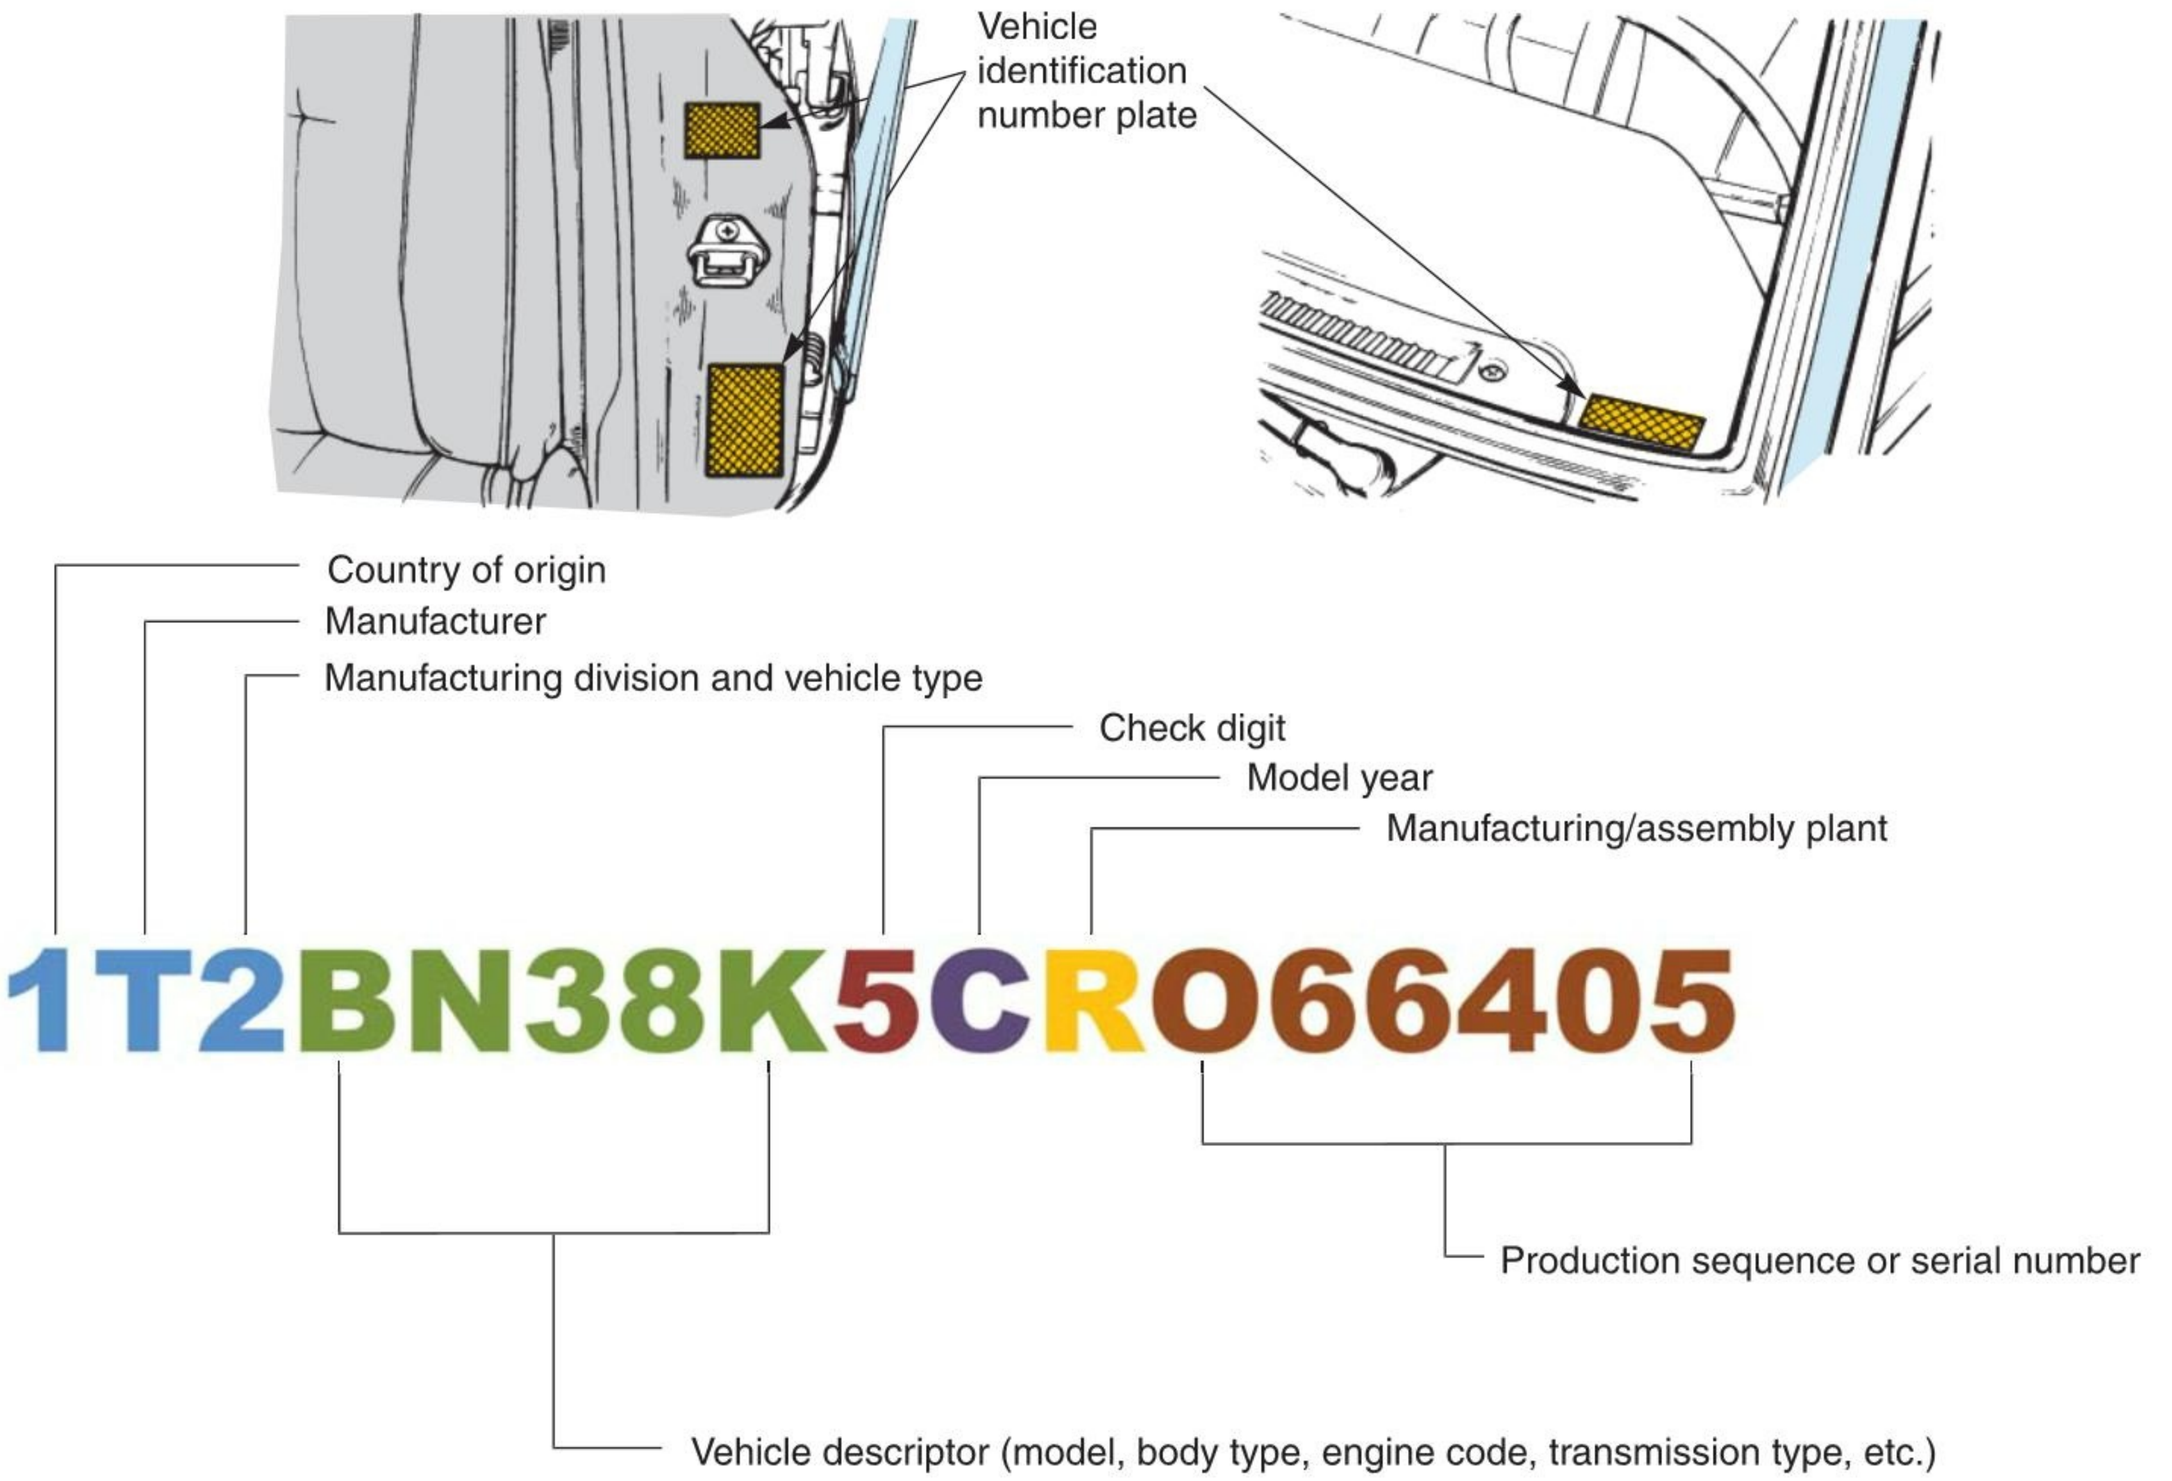
The VIN is important because it provides data about how the car is equipped and other useful information. It tells you what type of engine and transmission are in the vehicle. It can be used to track recalls, registrations, and warranty claims. Technicians are often asked to provide a vehicle's VIN to parts stores or warehouses to ensure that the correct parts are being ordered.

Copyright Goodheart-Willcox Co., Inc.



iATN

Figure 7-7. The Internet can be a valuable source of information. Some Internet sites, such as the International Automotive Technicians Network, allow technicians to share their technical knowledge.



Subaru

Figure 7-8. The VIN can be located on the door, in the door opening, on the dashboard, or in the engine compartment. Refer to the service information for the vehicle at hand to determine the meaning of each character in the VIN.

Copyright Goodheart-Willcox Co., Inc.

Obtaining Repair Parts

After you determine what repairs are needed, you must obtain the parts needed to make the repairs. Dealership repair shops generally stock a large selection of repair parts, eliminating the need for the technician to order parts from an outside vendor. Independent shops, on the other hand, keep commonly used supplies, such as oil, brake fluid, antifreeze, brake pads, hoses, filters, and batteries, in inventory. This saves time since the technician can perform common maintenance and repair tasks without having to order parts. However, less commonly used parts, such as starters and alternators, are not carried in inventory and must be ordered from an outside supplier.

New and rebuilt parts can be ordered by calling a local parts store or warehouse. You may be able to get the new parts the same day if they are in stock locally. If the parts are not in stock at a local store or warehouse, they may have to be shipped in from another state, which may take a day or two. In some cases, parts can be purchased using the Internet.

If new or rebuilt replacement parts are not available, you may have to call local salvage yards or search the Internet to find a good used part. Find out the mileage and price of the used parts, and determine if they come with a warranty. Always get an okay from the customer before ordering used components.

Large shops often employ one or more parts specialists, who maintain inventory and locate and order. In small shops, the technician may be responsible for monitoring the inventory of commonly used parts, as well as ordering and restocking these parts when the supply gets low.

Summary

- Service information provides detailed information on how to repair a vehicle. It may include step-by-step procedures, specifications, diagrams, part illustrations, and other data for each model of vehicle.
- Computer-based service information is data stored or retrieved using a personal computer.
- Various types of service illustrations are used to supplement the written information in a service manual.
- Diagrams are drawings used when working with electrical circuits, vacuum hoses, and hydraulic circuits.
- Abbreviations are letters that stand for entire words.
- A flat-rate manual is used to calculate how much labor to charge the customer for a repair.
- The International Automotive Technicians Network (iATN) provides a platform for automotive technicians from around the globe to share service and repair information via the Internet.
- Online service information programs are web-based databases that contain service information on thousands of vehicles.
- A work order, also called repair order or shop ticket, is a form used by technicians to record information about a vehicle that is being serviced.
- The VIN is a number code that indicates engine type, transmission type, and other useful information.
- After determining what repairs are needed, the technician must obtain the parts needed to make the repairs.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

abbreviations
component location chart
diagnostic chart
flat-rate manual
flat-rate time
International Automotive Technicians Network (iATN)
owner's manual
service information
technical bulletin
vehicle identification number (VIN)
work order

Activities

1. Use your shop's computer software to prepare a bill for replacement of a fuel pump on a vehicle of your choice. Check the manual for the amount of labor involved. Then, look up the cost of the part. Add up the costs plus the state tax for your state. (Figure labor cost at $48/hour.)

Copyright Goodheart-Willcox Co., Inc.

2. Using computer-based service information, demonstrate how to find the procedure for removal and replacement of a part chosen randomly.
3. Complete a mock work order for replacement of worn shock absorbers. Include a description of the customer complaint and a detailed summary of the work performed to correct the concern.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What is service information?
2. Which of the following is *not* found in service information?
   (A) Step-by-step procedures.
   (B) Driving tips.
   (C) Descriptions of common problems.
   (D) Specifications.
3. Explain the purpose of the following:
   (A) Wiring diagrams.
   (B) Vacuum diagrams.
   (C) Hydraulic diagrams.
4. List ten common abbreviations and explain them.
5. Which of the following is *not* a common type of diagnostic chart?
   (A) Track diagnosis chart.
   (B) Tree diagnosis chart.
   (C) Block diagnosis chart.
   (D) Illustrated diagnosis chart.
6. A(n) _____ manual is used to calculate how much labor to charge for a repair.
7. _____ help the technician stay up-to-date with recent technical changes, repair problems, and other service related information.
8. A _____ is a form used by technicians to record information about a vehicle that is being serviced.
   (A) Form 71D20
   (B) work order
   (C) diagnosis chart
   (D) service information form
9. What is the advantage of providing the parts supplier with the VIN when ordering repair parts?
10. What should be done if parts needed to make a repair are not carried in the shop's inventory?

ASE-Type Questions

1. Which of the following is an advantage of computerized service information when compared to a printed service manual?
   (A) Hyperlinks to related information.
   (B) Speed of search.
   (C) Service information can be instantaneously updated.
   (D) All of the above.
2. A technician who is having trouble finding the cause of a vehicle problem should refer to the following first.
   (A) Service bulletins.
   (B) Troubleshooting charts.
   (C) Spec sheets.
   (D) Repair procedures.
3. Which of the following should be used when calculating the cost of a repair?
   (A) Troubleshooting chart.
   (B) Service bulletin.
   (C) Flat-rate manual.
   (D) Cold rate manual.
4. Technician A says VIN information is needed to find information on the exact make and model car. Technician B says VIN information is no longer needed with modern vehicles. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Technician A says that in some shops, the technicians are responsible for monitoring inventory, and ordering and stocking commonly used parts. Technician B says that dealership repair shops generally stock a large selection of repair parts. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

Chapter 8
Fasteners, Gaskets, Seals, and Sealants

After studying this chapter, you will be able to:

- Identify commonly used automotive fasteners.
- Select and use fasteners properly.
- Remove, select, and install gaskets, seals, and sealants correctly.
- Summarize safety rules relating to fasteners, gaskets, seals, and sealants.
- Correctly answer ASE certification test questions that require a knowledge of fasteners, gaskets, seals, and sealants.

Fasteners, both mechanical (bolts, nuts, and clips) and chemical (adhesives), literally hold a car together.

Many different fasteners, gaskets, seals, and sealants are used by the automotive technician. It is almost impossible to connect any two parts of a vehicle without them. The information presented in this chapter is important and will prepare you for many repair operations and other text chapters.

Fasteners

Fasteners are devices that hold the parts of a car together. Thousands of metal and plastic fasteners are used in vehicles, as shown in **Figure 8-1**.

Bolts and Nuts

A ***bolt*** is a metal rod with external threads on one end and a head on the other. When a bolt is threaded into a part other than a nut, it can also be called a ***cap screw***. Head bolts and manifold bolts are also considered cap screws. A ***nut*** has internal threads and usually a six-sided outer shape. When a nut is screwed onto a bolt, a powerful clamping force is produced. Refer to **Figure 8-2**.

In automotive technology, bolts and nuts are named after the parts they hold. For instance, the bolts holding the cylinder head on the block are called cylinder head bolts. The bolts on an engine connecting rod are called connecting rod bolts.

Bolt and Nut Terminology

Bolts and nuts come in various sizes, grades (strengths), and thread types. It is important to be familiar with these differences. The most important bolt dimensions are shown in **Figure 8-3**. These dimensions include:

Copyright Goodheart-Willcox Co., Inc.

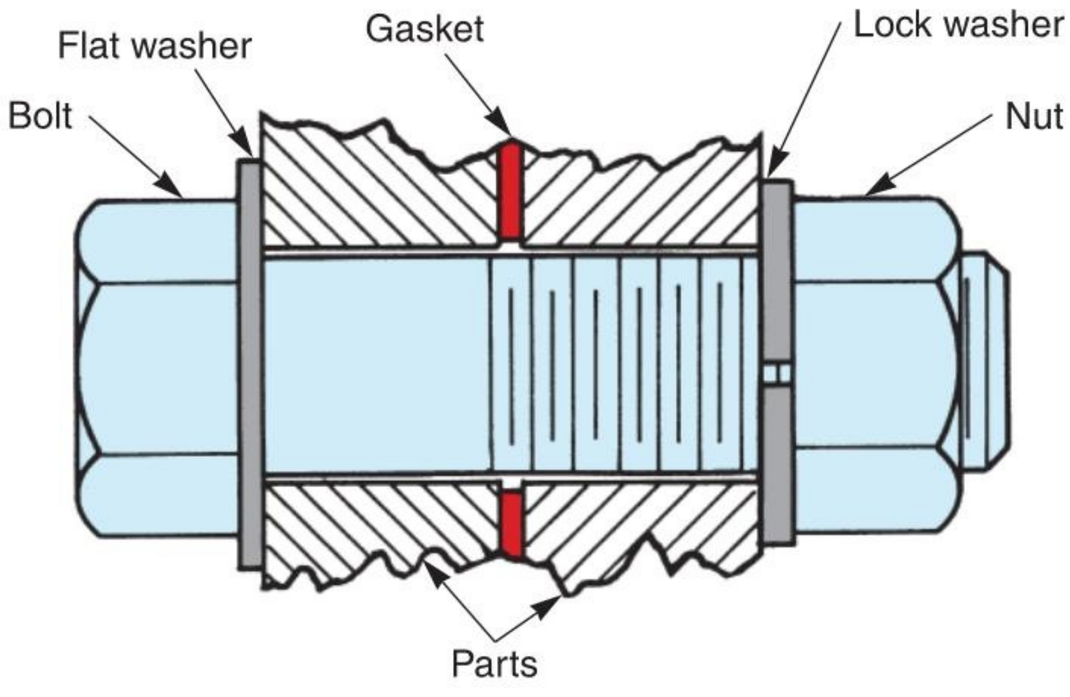
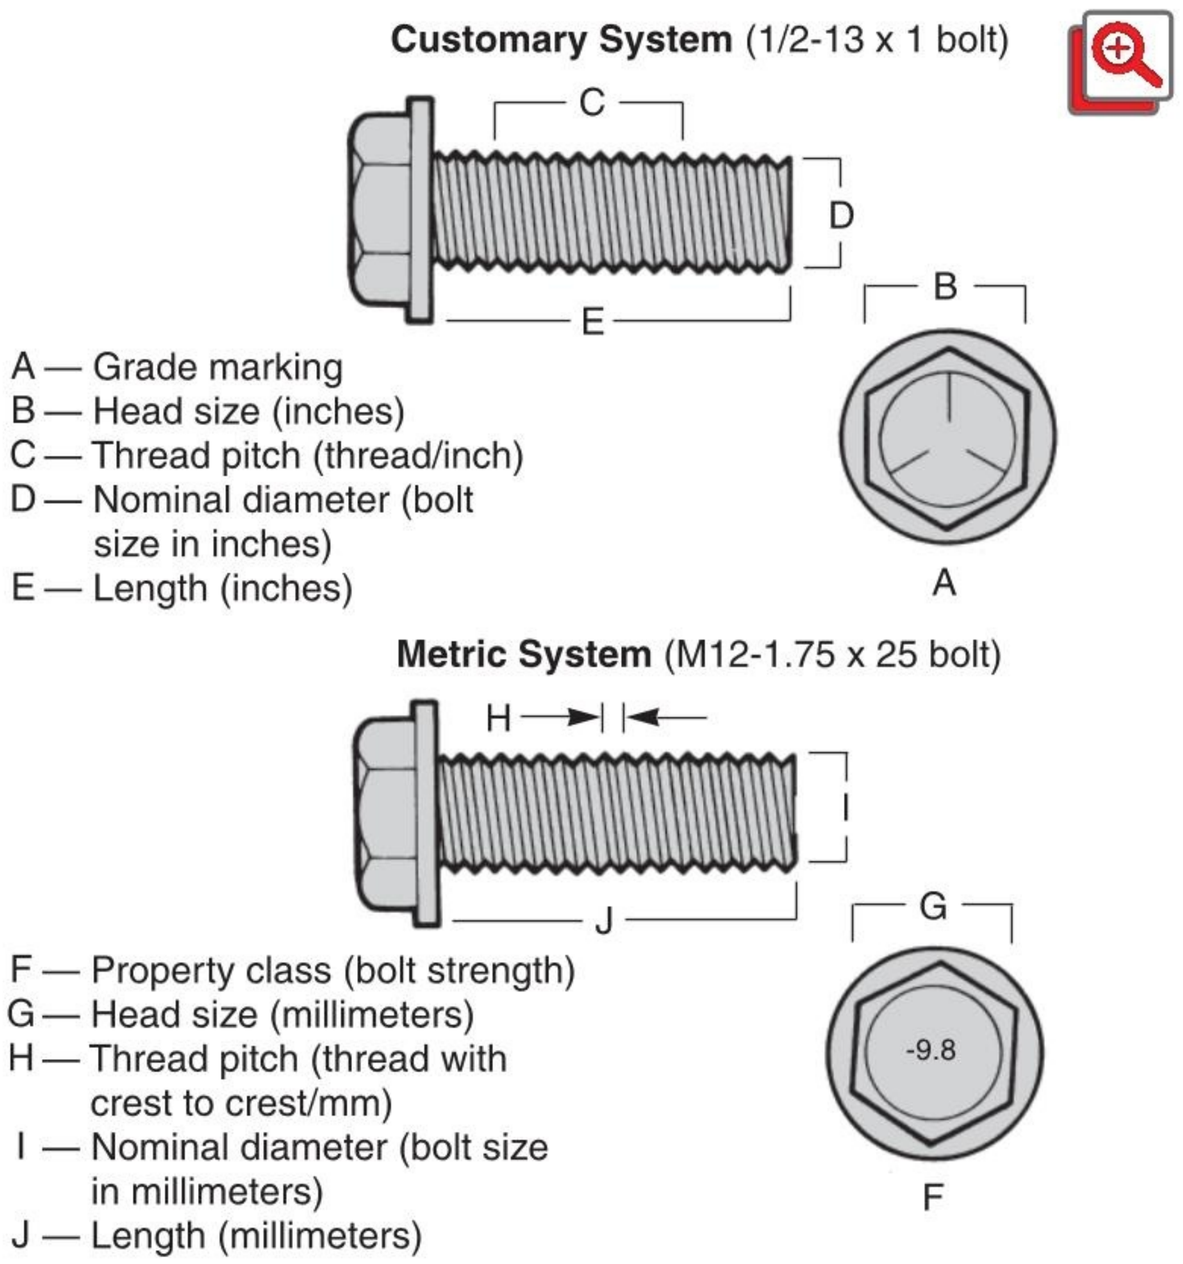
Figure 8-1. A fastener is any device or adhesive used to hold parts together. Study these basic automotive fasteners.



Goodheart-Willcox Publisher

Figure 8-2. A bolt and nut exert a powerful clamping force on parts. Notice the washers and gasket used.

- Bolt size—Bolt size is the measurement of the outside diameter of the bolt threads.
- Bolt head size—Bolt head size is the distance measured across the flats or outer sides of the bolt head. It is the same as the wrench size.
- Bolt length—Bolt length is measured from the bottom of the bolt head to the threaded end of the bolt.
- Thread pitch—Thread coarseness is the same as thread pitch. With U.S. conventional system fasteners, thread pitch is the number of threads per inch. With metric fasteners, it is the distance between each thread in millimeters.



Ford

Figure 8-3. Study the naming systems for both customary and metric bolts.

Copyright Goodheart-Willcox Co., Inc.

Thread Types

There are three basic types of threads used on fasteners:

- Coarse threads (UNC-Unified National Coarse).
- Fine threads (UNF-Unified National Fine).
- Metric threads (SI).

Never interchange thread types or thread damage will result. Metric threads look very similar to customary threads. However, if a metric bolt is forced into a hole with fine threads, either the bolt or part threads will be ruined.

Bolts and nuts also come in right- and left-hand threads. With right-hand threads, the fastener must be turned clockwise to tighten. This is the most common style of thread. With left-hand threads, turn the fastener in a counterclockwise direction to tighten. Left-hand threads are not very common. The letter *L* may be stamped on fasteners with left-hand threads.

Bolt Grade

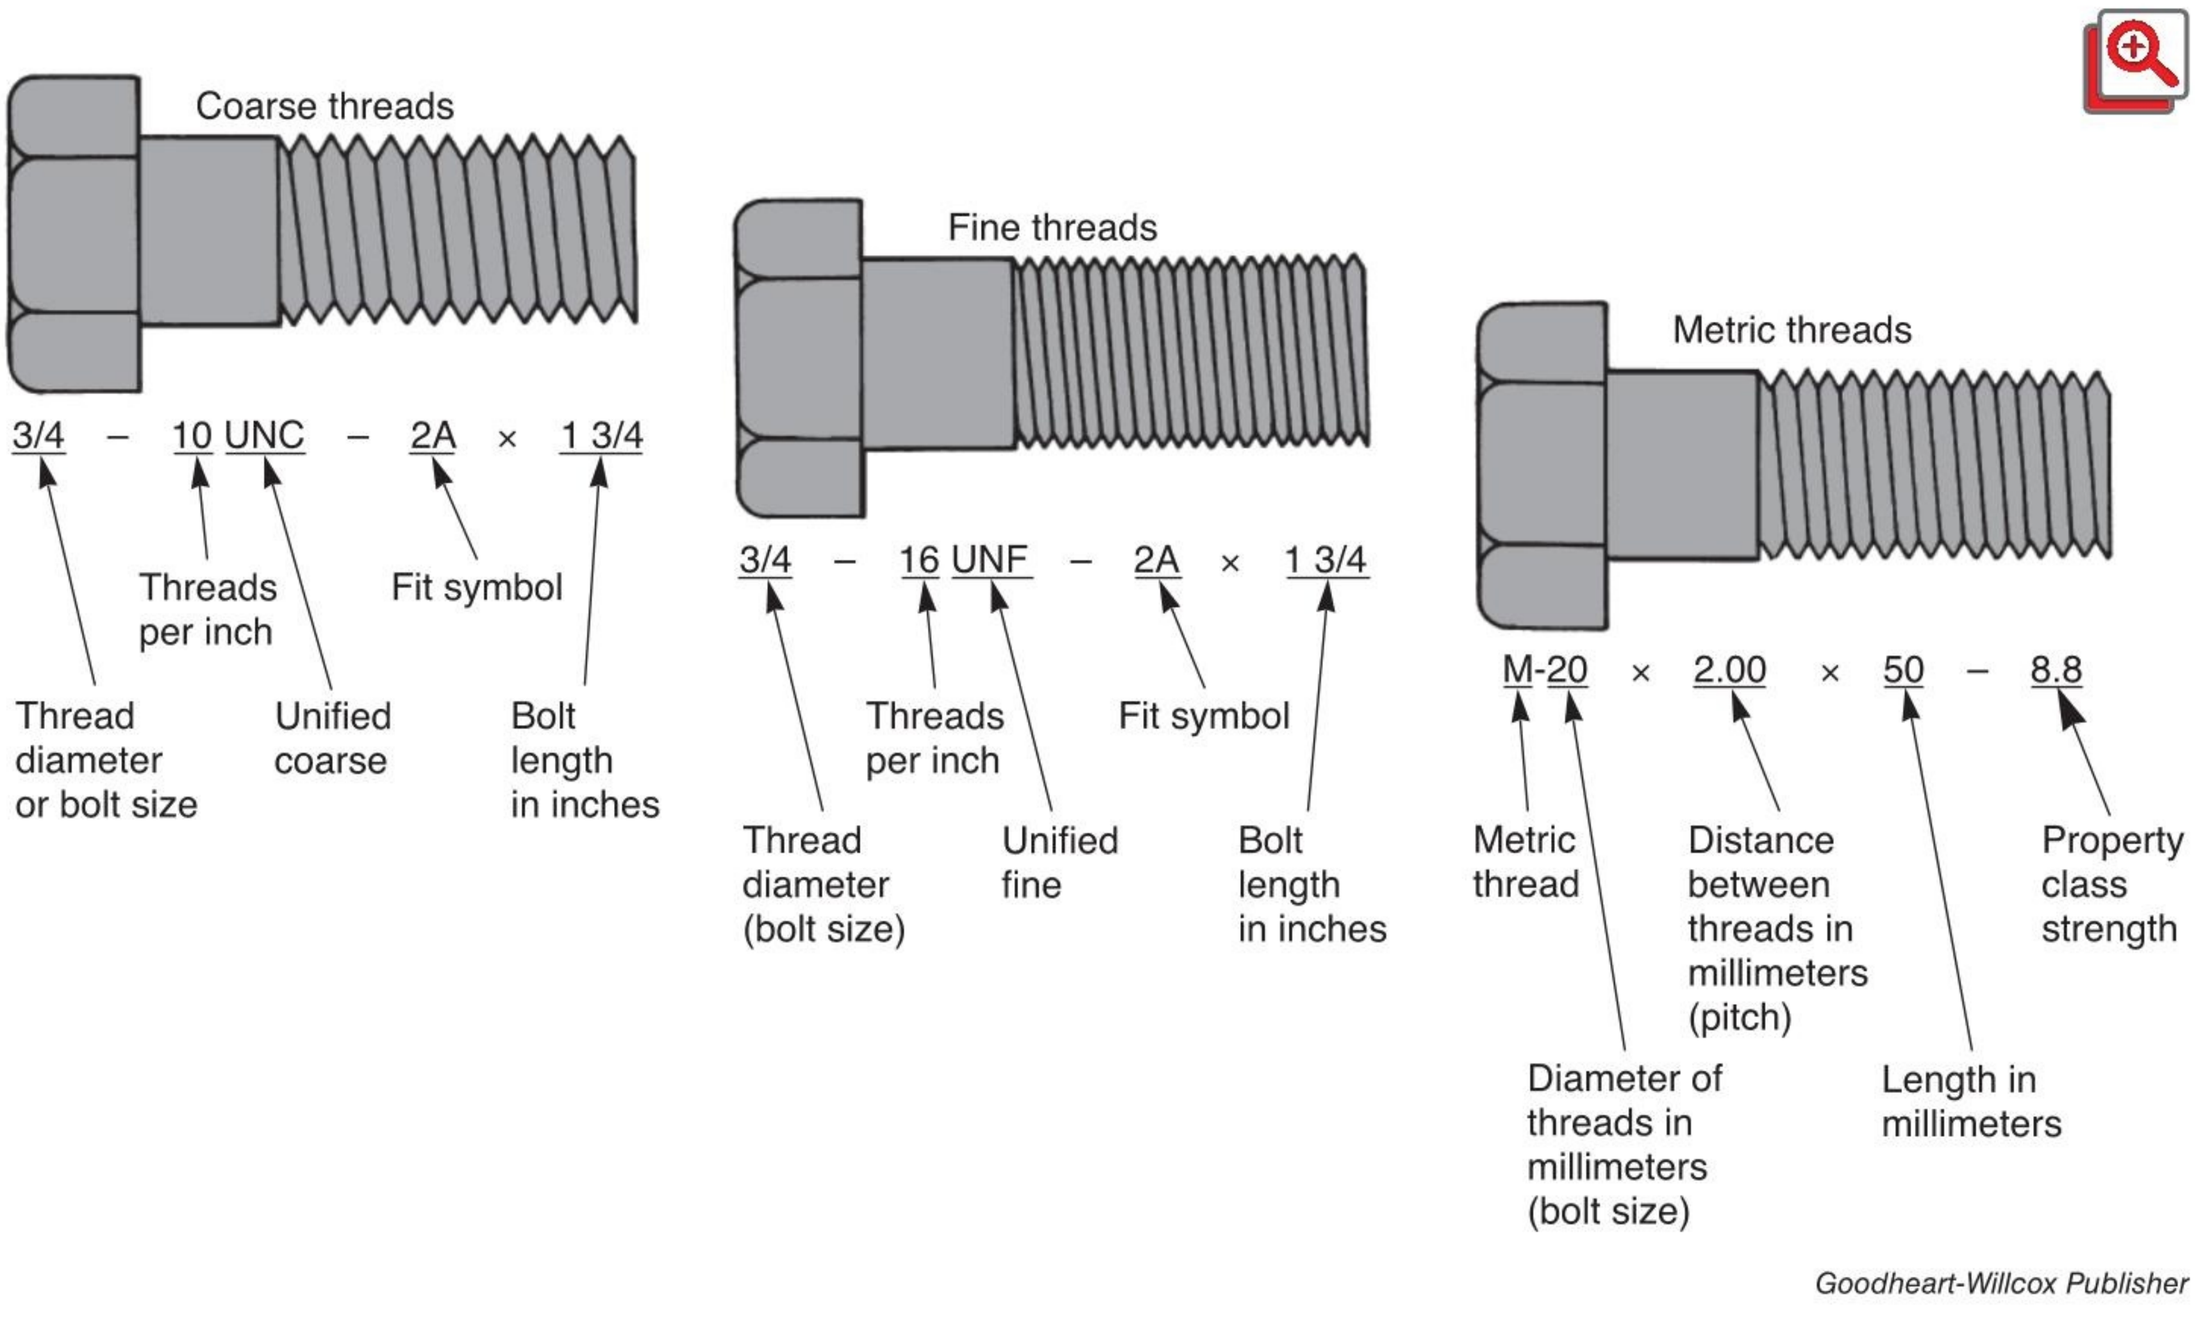
Bolt grade is an indication of a bolt's strength. A primary measure of bolt strength is its tensile strength. ***Tensile strength*** refers to the amount of pull a fastener can withstand before breaking. Bolts are made of different metals, some stronger than others. Tensile strengths can vary. ***Bolt head markings***, also called grade markings, specify the tensile strength of the bolt. US customary bolts are marked with lines or slash marks. The more lines, the stronger the bolt will be under stress. A metric bolt is marked with a numbering system. The larger the number, the stronger the bolt will be under high load or clamping stress.

Warning

Never replace a high-grade steel bolt with a lower grade bolt of inferior steel. The weaker bolt could easily snap, possibly causing part failure and a dangerous situation.

Bolt Description

A bolt description is a series of numbers and letters that describe the bolt. When purchasing new bolts, the bolt description information is needed. See **Figure 8-4**.



Goodheart-Willcox Publisher

Figure 8-4. The bolt description number gives information about the bolt. This number is commonly used when purchasing new bolts.

Nut Types

Many types of nuts are used in a vehicle. Study their names closely. A slotted nut, or castle nut, uses a safety device called a ***cotter pin***. The cotter pin fits through a hole in the bolt or part. This keeps the nut from turning and possibly coming off. Look at **Figures 8-5** and **8-6**.

Self-locking nuts produce a friction fit when threaded onto a bolt or stud. The top of the nut can be crimped inward. Some have a plastic insert that produces a friction fit to keep the nut from loosening. Self-locking nuts may need to be replaced after removal.

Jam nuts are thin nuts used to help hold larger, conventional nuts in place. The jam nut is tightened down against the other nut to prevent loosening.

Wing nuts have two extended arms that allow the nuts to be easily turned by hand. They are used when a part must be removed frequently for service or maintenance. Air cleaner housings sometimes use wing nuts.

Acorn nuts are closed on one end for appearance and to keep water and debris off the threads. They can be used when they are exposed and looks are important.

Special types of nuts are used to hold parts onto the vehicle. Sometimes a washer is formed onto the nut. Termed *body nuts*, the flange on the nut helps distribute the clamping force of the thin body panel or trim piece to prevent warpage.

Washers

Washers are used under bolt heads and nuts. The two basic types are flat washers and lock washers. A flat washer increases the clamping surface under the fastener. It prevents the bolt or nut from digging into the part.

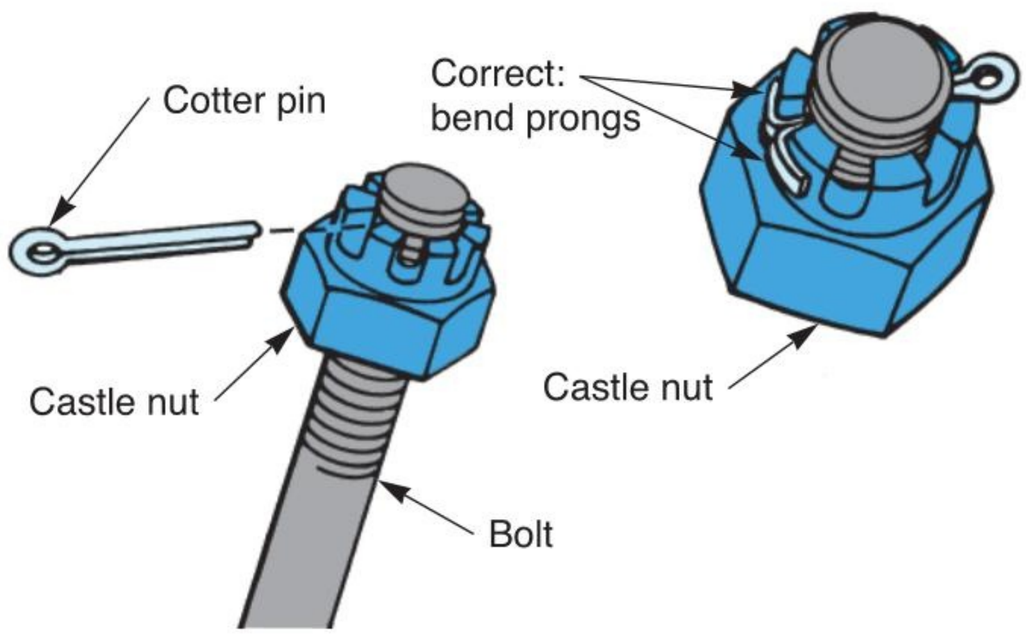
A lock washer prevents the bolt or nut from becoming loose under stress and vibration. Lock tabs, or lock plates, perform the functions of both flat washers and lock washers. They increase clamping surface area and prevent the fastener from loosening. Look at **Figure 8-7**.

Machine Screws

Machine screws are similar to bolts, but they normally have screw-type heads. They are threaded along their full length and are relatively small. Machine screws are used to secure parts when clamping loads are light. They come in various head shapes.

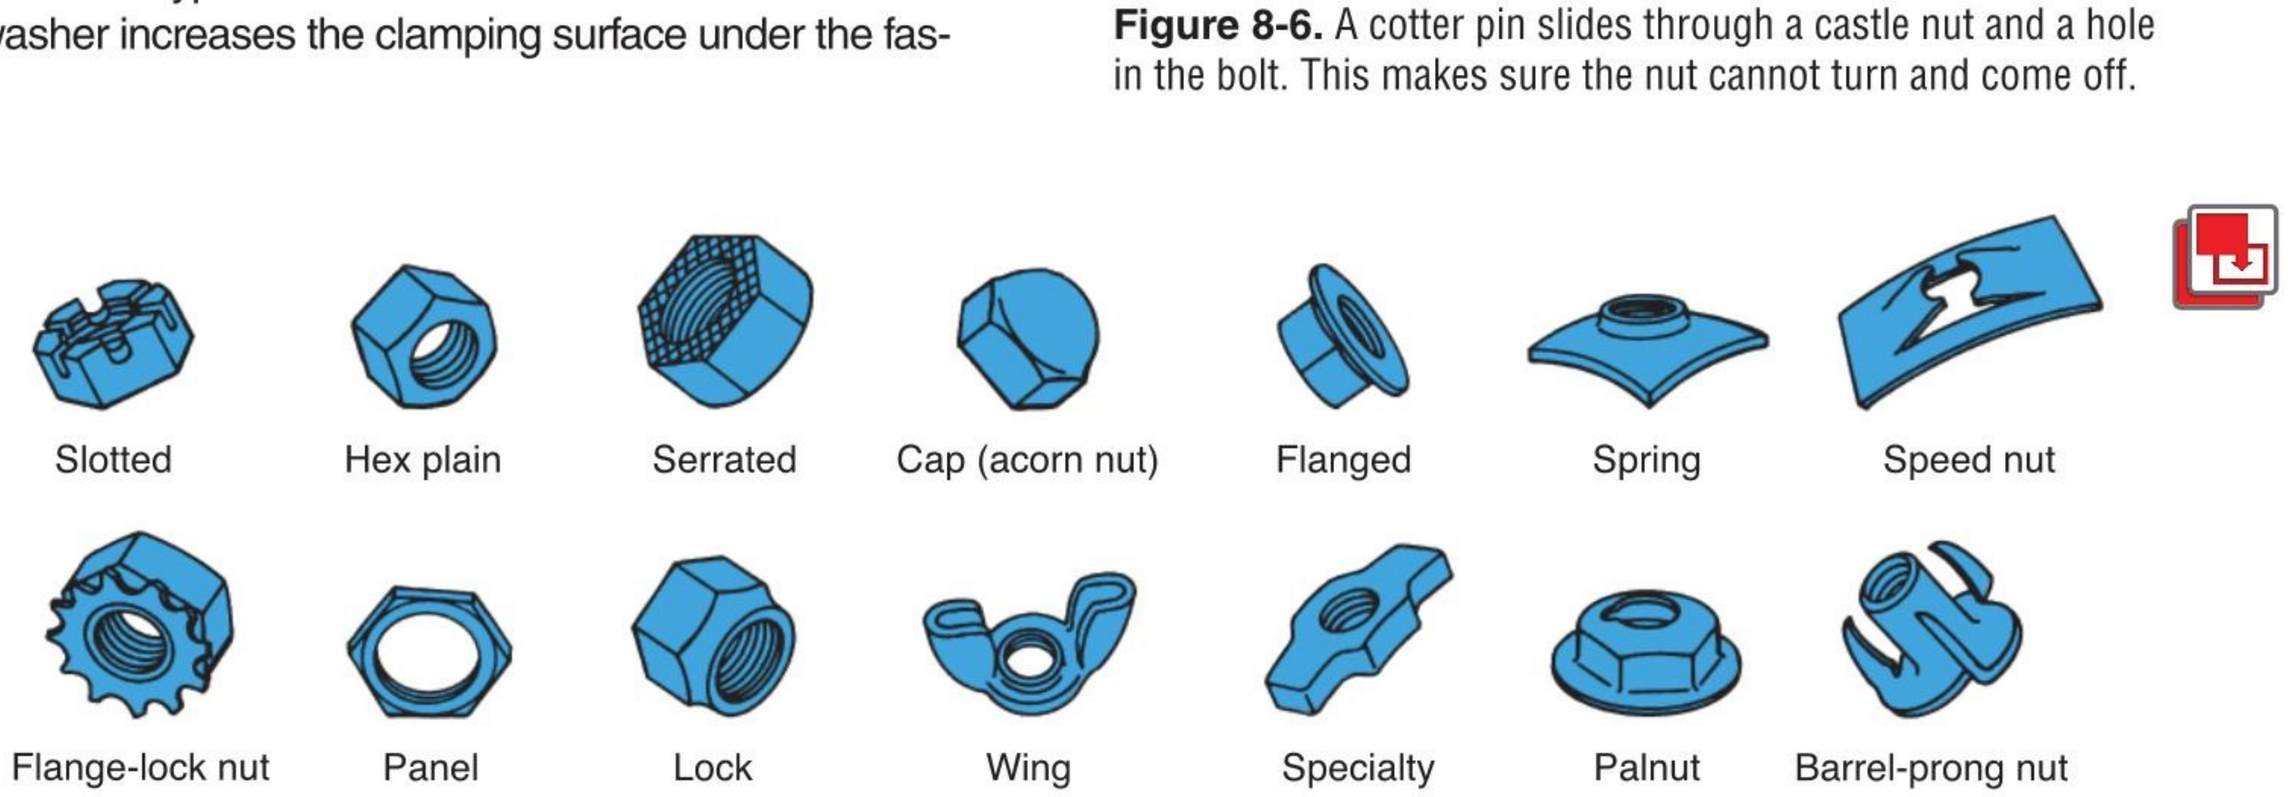
Sheet Metal Screws

Sheet metal screws, or ***tapping screws***, are commonly used on plastic and sheet metal parts, such as body trim, dashboard panels, and grilles.



Deere & Co.

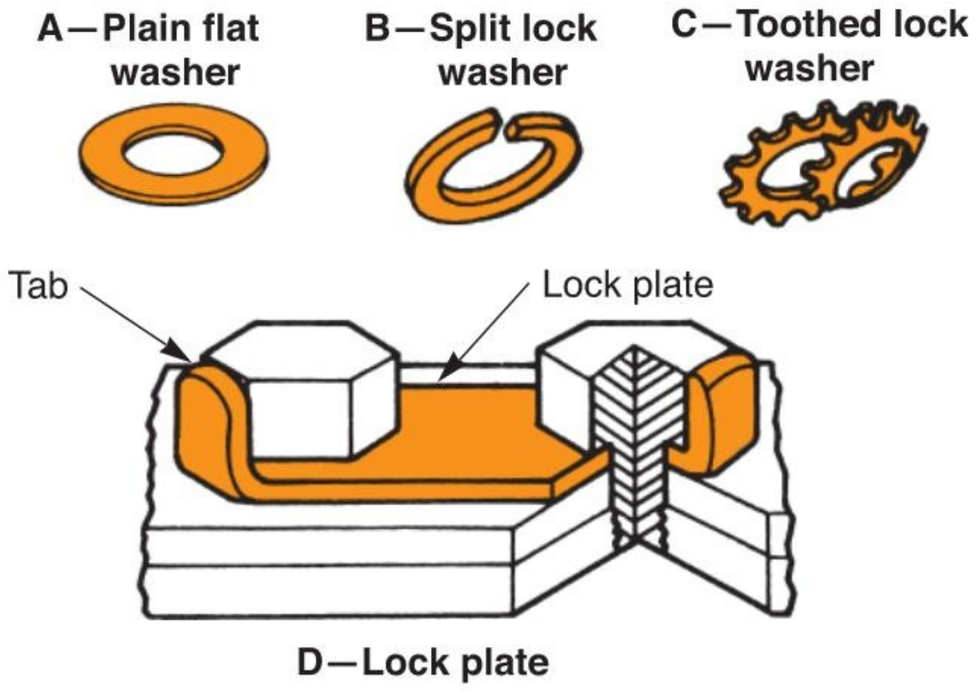
Figure 8-6. A cotter pin slides through a castle nut and a hole in the bolt. This makes sure the nut cannot turn and come off.



Deere & Co.

Figure 8-5. Memorize common types of nuts used in vehicles.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 8-7. Compare basic washer types.

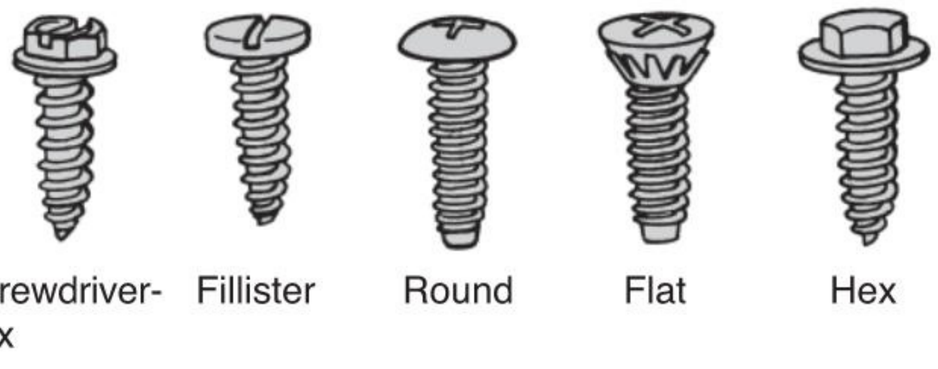
Sheet metal screws have tapering threads that are very widely spaced. They come in a wide range of head configurations and sizes. Several are shown in **Figure 8-8**.

Nonthreaded Fasteners

Numerous types of ***nonthreaded fasteners***, such as snap rings and adhesives, are used in the assembly of a vehicle. It is essential to learn the most common types.

Snap Rings

A ***snap ring*** fits into a groove in a part and commonly holds shafts, bearings, gears, pins, and other components in place. Snap ring pliers are needed to remove and install snap rings. Snap ring pliers have special jaws that fit into and grasp the snap ring, as pictured in **Figure 8-9**.



Deere & Co.

Figure 8-8. Study basic types of sheet metal screws.

Warning

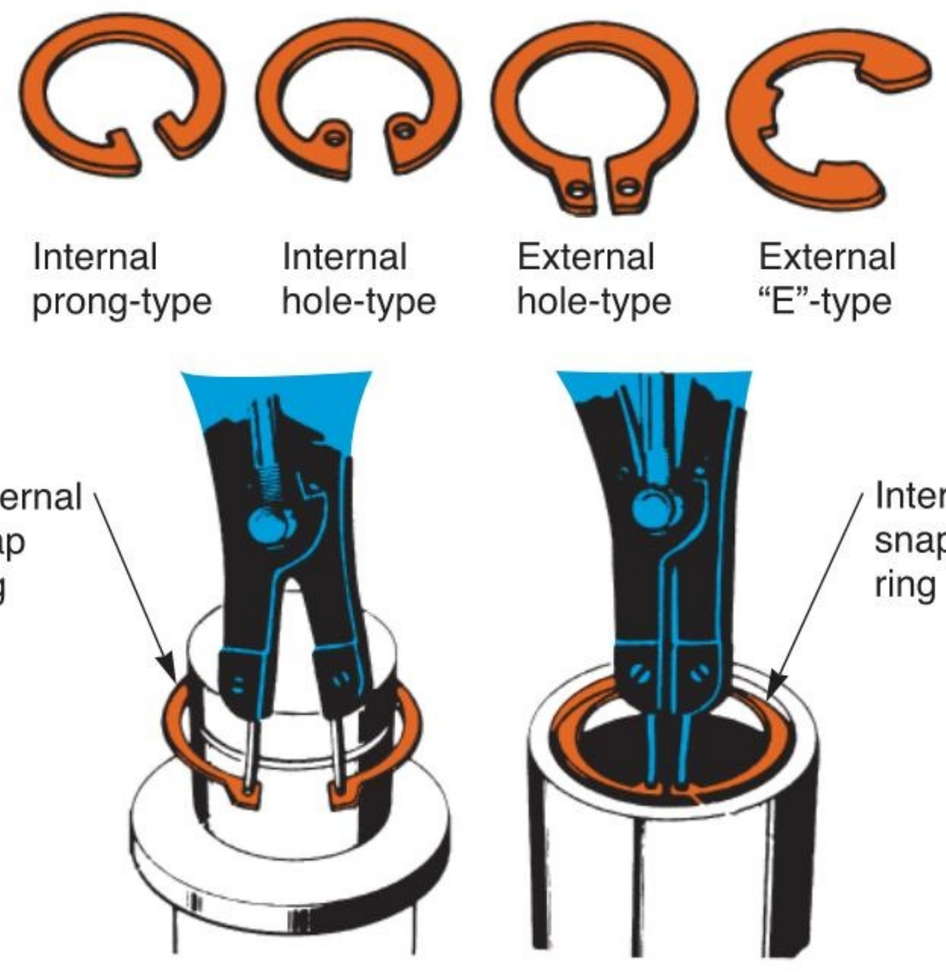
Wear eye protection when working with a snap ring. When flexed, the ring can shoot into your face with considerable force.

Keys and Set Screws

A metal ***key*** fits into a ***keyseat***, or slot, cut into a shaft and a ***keyway*** cut into the mating part, such as a gear, pulley, or collar. The key prevents the part from turning on its shaft. ***Set screws*** are normally used to lock a part onto a shaft. They can be used with or without a key. A set screw is a headless fastener normally designed to accept a hex (Allen) wrench or screwdriver. Refer to **Figure 8-10**.

Splines

Splines are a series of slots cut into a shaft and a mating part. Splines have an advantage over keys in that they allow a gear or collar to slide on a shaft but still not rotate. This sliding locking action is commonly used in manual transmissions, clutches, and drive shaft yokes. See **Figure 8-11**.



Goodheart-Willcox Publisher

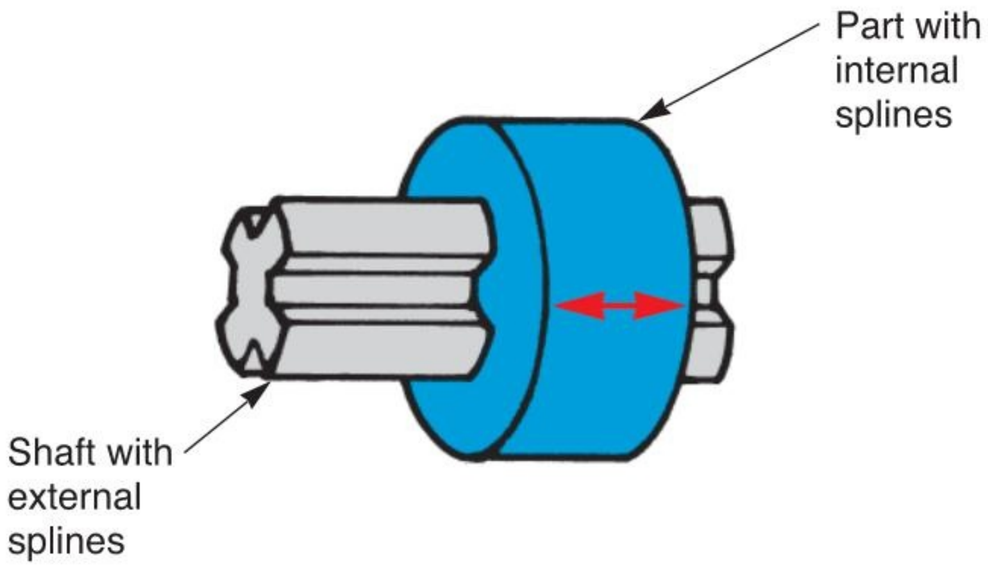
Figure 8-10. Keys and set screws are used to keep parts locked to shafts.



Goodheart-Willcox Publisher

Figure 8-11. Splines allow a part to slide on a shaft, but not turn on the shaft.

Adhesives

Adhesives are special glues widely used in vehicles. They hold body moldings, rubber weather stripping, and body emblems. Some adhesives are designed to stay soft and pliable; others dry hard. Some take hours to dry, while others dry in seconds. Observe all directions and safety precautions when using adhesives.

Torquing Bolts and Nuts

It is very important that bolts and nuts be tightened properly. This is called ***torquing***. If overtightened, a bolt will stretch and possibly break. The threads could also fail. If undertightened, a bolt may loosen and fall out. Part movement could also shear the fastener or damage a gasket, causing leakage.

Torque specifications are tightening values given by the auto manufacturer. Torque specifications are normally given for fasteners used in precision assemblies, such as engines, transmissions, and differentials. A general torque specification chart gives average bolt tightening values by fastener size and grade. It can be used when factory specifications are not available. Notice how bolt torque increases with bolt size and grade. Refer to **Figure 8-12**.

Service manuals sometimes recommend new bolts when certain parts are reassembled because of a torque-to-yield process. Discard the old bolts in such cases. ***Torque-to-yield*** is a bolt tightening method that requires the bolt to be tightened to a specific torque and then turned an additional number of degrees. After the fastener is torqued to specification, a degree wheel adapter is placed between the torque wrench and socket. The fastener is then turned until the

Caution
The torque specifications listed below are approximate guidelines only and may vary depending on conditions when used such as amount and type of lubricant, type of plating on bolt, etc.

SAE Standard / Foot-pounds

Grade of bolt	SAE 1 & 2	SAE 5	SAE 6	SAE 8	
Min. tensile strength	64,000 P.S.I.	105,000 P.S.I.	133,000 P.S.I.	150,000 P.S.I.

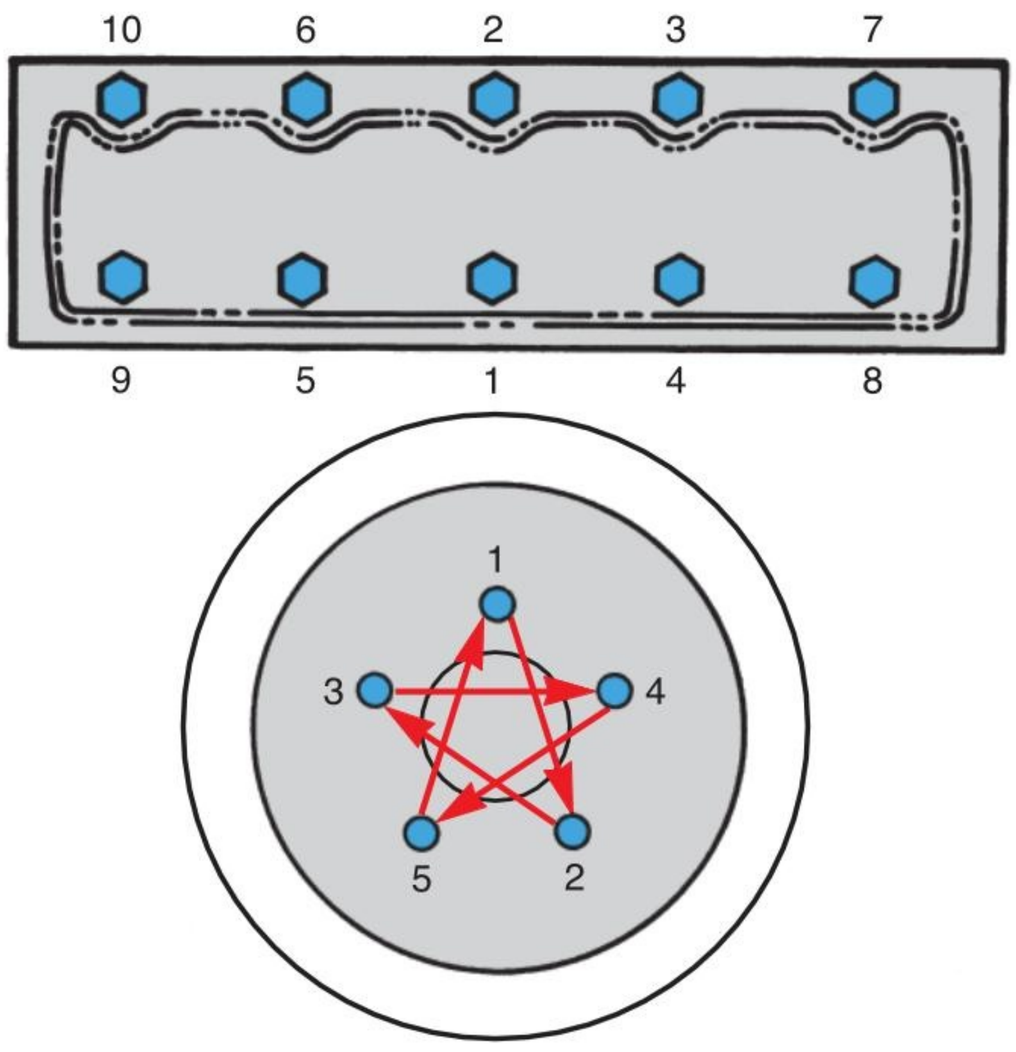
degree wheel reads as specified by the manufacturer. This stretches the bolt to its correct yield point and preloads the fastener for better clamping under varying conditions.

Torque stretch is determined by measuring bolt length change while torquing the bolt. For example, when building a racing engine, you can "mike" connecting rod bolts to measure the length before and after tightening. Too much stretch indicates bolt weakness. Not enough stretch may indicate thread problems affecting torque.

Bolt Tightening Sequence

A ***bolt tightening sequence***, or torque pattern, is used to make sure that parts are fastened evenly. An incorrect sequence can cause uneven tightening, leading to breaks, warping, leaks, and other problems. Generally, a group of fasteners on a part is tightened in a ***crisscross pattern***. This creates an even, gradual clamping force along the entire mating surface of the parts. A service manual will illustrate the proper sequence when even tightening is critical. Refer to **Figure 8-13**.



Goodheart-Willcox Publisher

Figure 8-13. A crisscross pattern is recommended when multiple fasteners hold a part.

Tech Tip

When tightening engine covers and covers on other large assemblies, remember that "less is usually better." The most common mistake is to overtighten covers and damage or split the gasket or seal. It usually takes much less torque than you may think to make a new gasket seal properly.

Using a Torque Wrench

A ***torque wrench*** is used to apply the proper amount of torque when tightening a threaded fastener. Use the following basic rules.

- Keep a steady pull on the wrench. Do not use short, jerky motions.
- Clean fastener threads.
- When possible, avoid using swivel joints. They can affect torque wrench accuracy.
- When reading a torque wrench, look straight down at the scale. Viewing the scale from an angle can give a false reading.
- A general torque value chart should only be used when the manufacturer's specifications are not available.
- When the manufacturer's torque patterns are not available, use a general crisscross pattern for tightening fasteners.
- Pull only on the handle of the torque wrench. Do not allow the beam of a beam-type torque wrench to touch anything.
- Tighten bolts and nuts in four steps: one-half recommended torque, three-fourths torque, full torque, and full torque a second time.
- Retorque when required. On some assemblies, such as cylinder heads, intake manifolds, and exhaust manifolds, bolts may have to be retightened after operation and heating. This is because expansion and contraction due to temperature changes can cause the fasteners to loosen.

Caution

Many late-model parts are made of plastic or composite materials. These parts are more delicate than metal parts and are easily damaged from overtorquing.

Copyright Goodheart-Willcox Co., Inc.

Thread Repairs

Threaded holes in parts can become damaged, requiring repairs. A technician must be capable of repairing damaged threads quickly and properly.

Minor Thread Repairs

Minor thread damage includes nicks, partial flattening, and other less serious problems with the fastener or part. Minor thread damage can usually be repaired with a thread chaser. A thread chaser "cleans up" slightly damaged internal and external threads. The chaser is run through or over the threads to restore them, **Figure 8-14**.

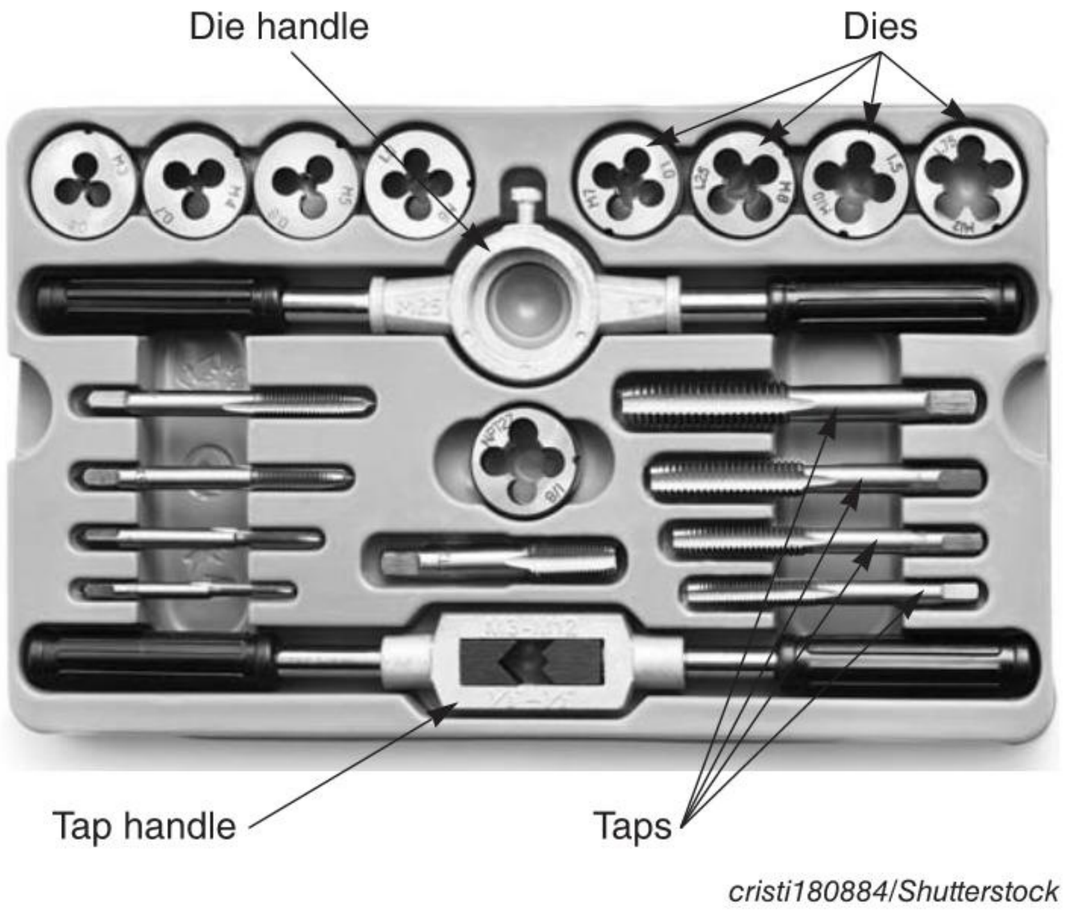
Major Thread Repairs

Major thread damage generally includes badly smashed or stripped threads. Sometimes, major thread damage is repaired with either a tap or die. A ***tap*** is a threaded tool for cutting internal threads in holes. Various tap shapes are available. Some are for starting the threads. Others are for cutting the threads all the way to the bottom of a hole. A ***die*** cuts external threads. It can be used to cut threads on metal rods, bolts, shafts, and pins. See **Figure 8-15**.

Taps and dies are mounted in special handles called tap handles or die handles. The tool must be held squarely while being rotated into the work, **Figure 8-16**. As soon as the tap or die begins to bind, back the tool off about a quarter turn. This clears away the metal cuttings. Then, the cut can be made another half turn deeper. Keep rotating the tool a half turn in and a quarter turn out until the cut is complete.

Snap-on Tool Corp.

Figure 8-14. Thread chasers can be used to clean up slightly damaged internal or external threads.

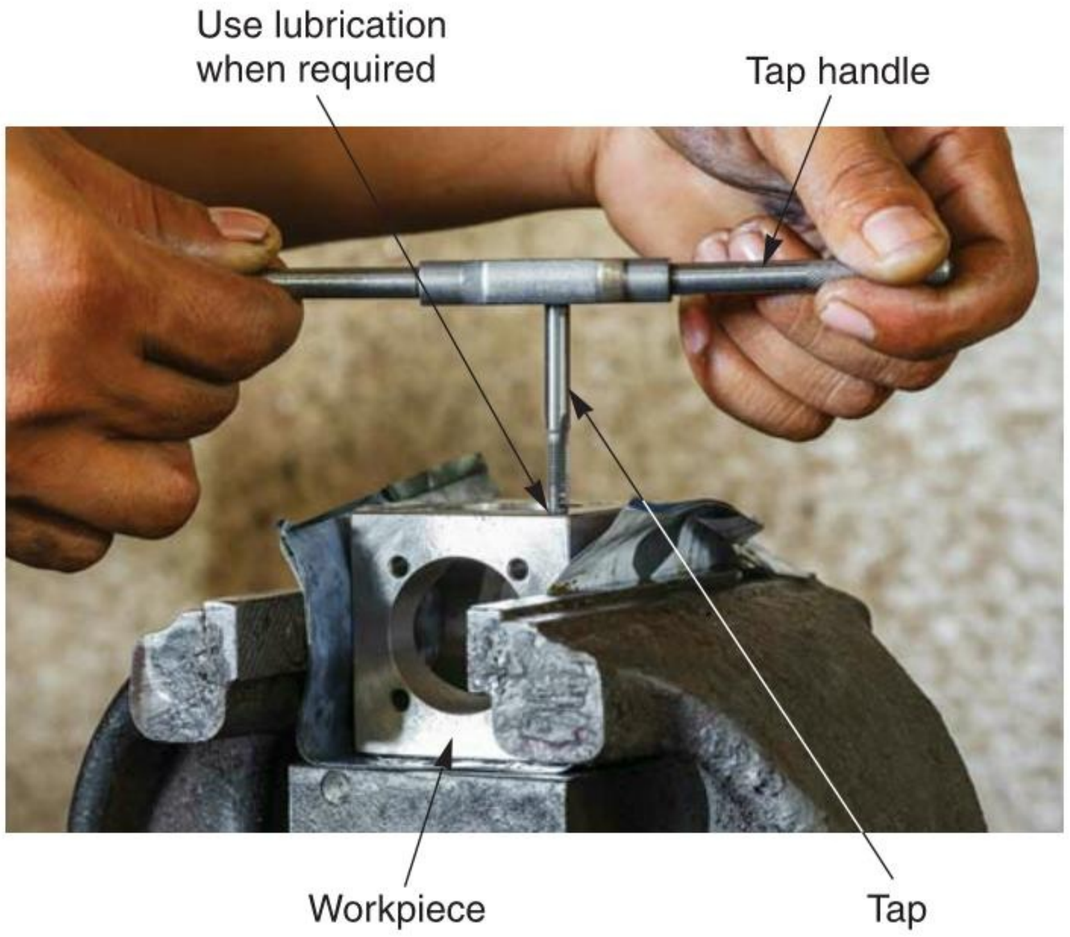


cristi180884/Shutterstock

Figure 8-15. Taps and dies can be used to repair major thread damage. They are often sold in sets that contain the tools needed to repair a variety of thread types.

Tap and Die Rules

- Never force a tap handle or the tool may break. Back off the handle to clean out metal shavings.
- Keep the tap and die well oiled to ease cutting.
- Always use the right size tap in the correct size hole.



smuay/Shutterstock

Figure 8-16. The tap or die fits into a special handle. The handle is held square as the tool is turned into the work. Back the handle off to clean metal out of the threads. A taper tap is used to start threads in a hole. Then, a plug tap and a bottoming tap are used to cut the threads to the bottom of the hole.

Copyright Goodheart-Willcox Co., Inc.

- Use coarse threads when threading or tapping into soft metal, like aluminum. Coarse threads hold better than fine threads. Use fine threads on harder metals, like steel.

Tapping Oversize

When a thread chaser or tap cannot be used to clean up damaged threads, the hole can be drilled and tapped oversize. A drill and tap size chart is used to determine right size drill bit and tap, **Figure 8-17**. For example, a 27/64" drilled hole should have a 1/2" coarse tap used in it. First, drill the hole one diameter or size larger than the original hole. Then, cut new threads in the drilled hole with the correct size tap. A larger bolt can then be installed in the threaded hole.

Thread Repair Insert

A ***thread repair insert*** should be used when the use of an oversize hole and fastener is not acceptable. The insert takes the place of damaged internal threads and allows the use of the original-size bolt.

To use a thread repair insert, drill the hole oversize as described in the insert manufacturer's instructions. Then, tap the hole. Finally, screw the insert into the threaded hole. The inside of the insert contains threads that are the same size as those in the original hole. See **Figure 8-18**.

Removing Damaged Fasteners

An automotive technician must be able to remove broken bolts, screws, and studs, as well as fasteners with rusted or rounded-off heads. Certain tools and methods are needed for removing problem fasteners. Refer to **Figure 8-19**.

- ***Locking pliers*** can sometimes be used to remove fasteners with heads that are badly rusted and rounded off. Lock the pliers tightly on the bolt or nut for removal.
- A ***stud puller***, or stud wrench, can remove studs and bolts broken off above the surface of the part. This tool is also used to install studs. Position the stud puller so it will not clamp onto and damage the threads.
- In some cases, broken fasteners are too short to grasp with any tool. Either cut a slot in the fastener with a hacksaw or weld on another bolt head. Then use a screwdriver or wrench to unscrew the broken bolt.

Chrysler and The Eastwood Company

Figure 8-18. Basic method for using an insert to repair stripped threads.

- When the fastener is broken flush with the part surface, a hammer and punch can sometimes be used to remove it. Angle the punch so the blows from the hammer can drive out the broken fastener.
- A ***screw extractor***, or "easy-out," can also be used to remove bolts that are broken flush with or below the part surface. See **Figure 8-20**. To use a screw extractor, drill a hole in the center of the broken fastener. Then, lightly tap the extractor into the hole using a hammer. Finally, unscrew the broken bolt by turning the extractor with a wrench.
- On some broken bolts, you may have to drill a hole almost as large as the inside diameter of the threads. Then, use a tap or punch to remove the thread shell. The thread shell is the thin layer of threads remaining in the hole.

Caution

Be extremely careful not to break a tap or a screw extractor. They are hardened steel and cannot be easily drilled out of a hole. You will compound your problems if you break off one of these tools in a hole.

Tech Tip

If you accidentally break a tap off in a part, screw the broken piece back into the hole until the flutes, or grooves, in the two pieces of the tap align. Next, insert nails or pieces of cotter pin into the grooves and down through both pieces of the tap. You should then be able to unscrew both pieces of the broken tap from the hole. See **Figure 8-21**.

Rust Penetrant

Rust penetrant is a chemical that dissolves rust or corrosion. It is often applied to rusted fasteners to aid in their removal. The penetrant is sprayed or squirted on the rusty fastener and allowed to soak for a few minutes. This often helps free up the fastener, allowing it to be removed without breakage. See **Figure 8-22**.

Gaskets and Seals

Gaskets and seals are used between parts to prevent leakage of engine oil, coolant, transmission oil, and other fluids. It is important to understand a few principles about gaskets and seals. If gaskets or seals are serviced improperly, customer complaints and serious mechanical failures can result.

Gaskets

A ***gasket*** is a soft, flexible material placed between parts to prevent leakage. It can be made of fiber materials, rubber, neoprene (synthetic rubber), cork, treated paper, or thin steel.

Copyright Goodheart-Willcox Co., Inc.

A—Hacksaw a slot and turn with a screwdriver.

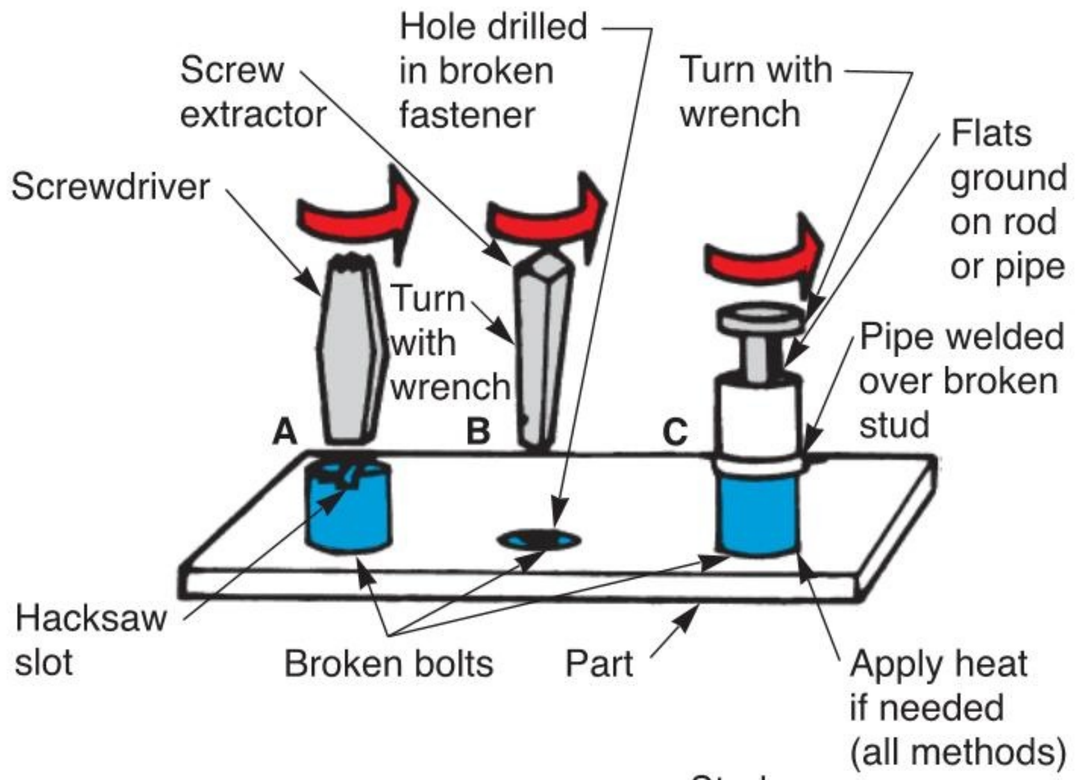
C—Weld a piece of slotted pipe onto the bolt and turn with a wrench.



D—Grasp and turn with locking pliers.
E—Use a stud extractor and ratchet.
F—Use a hammer and punch to rotate fasteners.

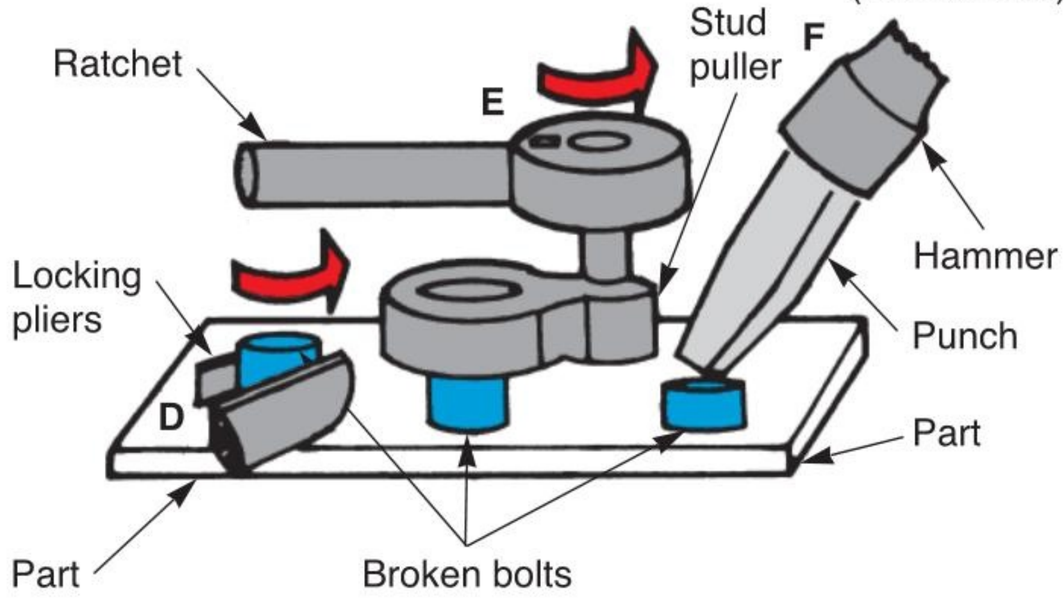


Figure 8-19. Study various ways to remove broken bolts.

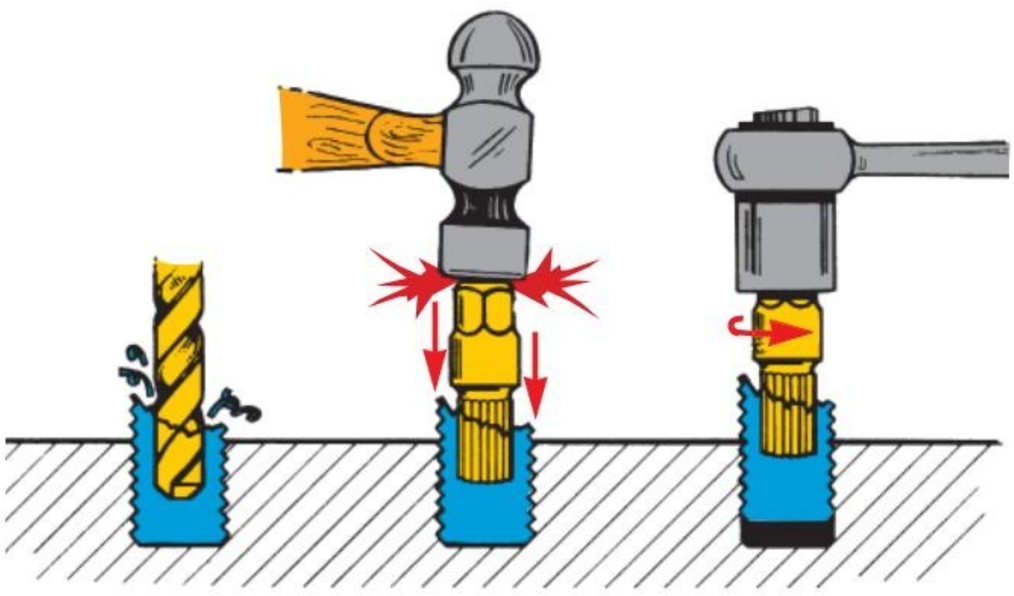

A—First, drill a hole in the center of the broken bolt. **B—Next, tap the extractor into the hole.** **C—Finally, unscrew the extractor and the broken bolt with a wrench.**

Lisle Tools

Figure 8-20. A screw extractor will usually rotate and remove broken bolts.

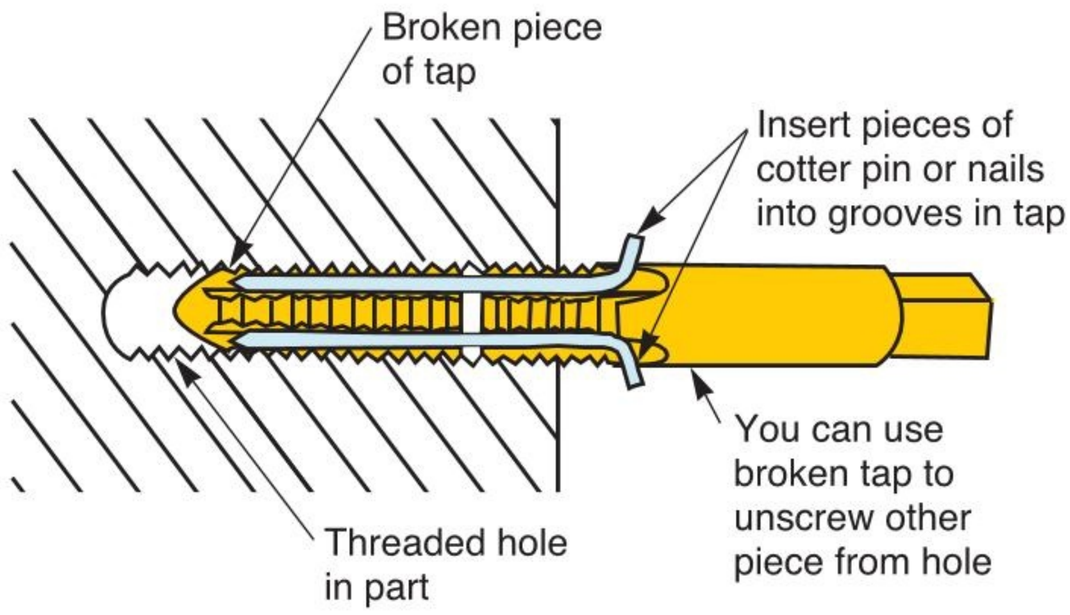

Figure 8-21. If you accidentally break a tap, try unscrewing it using nails or cotter pins to hold both pieces of the broken tap together.

When the parts are fastened tightly together, the gasket is compressed and deformed. This forces the gasket material to fill small gaps, scratches, dents, or other imperfections in the mating surfaces. A leakproof seal is produced. See **Figure 8-23**.

Using Gaskets

When using gaskets, you need to inspect for leaks before disassembly. If the two parts are leaking, the part surfaces should be inspected closely for problems. Also, be careful not to nick, gouge, or dent mating surfaces while removing parts. The slightest

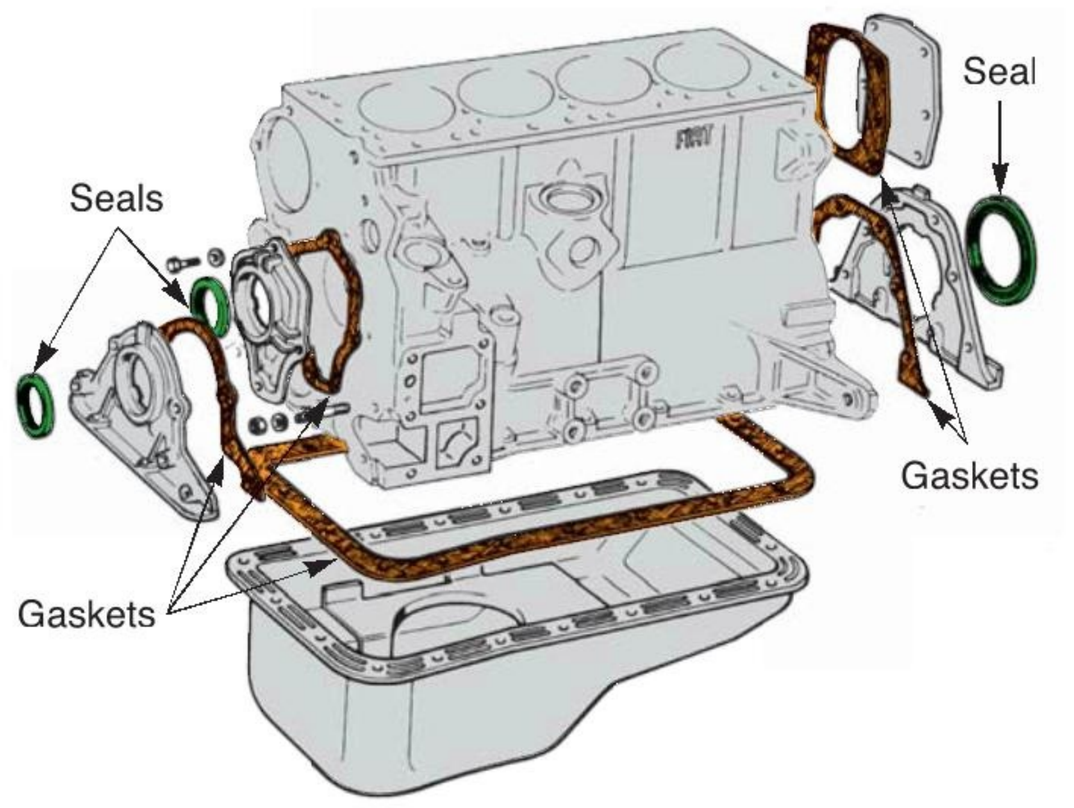
Fel-Pro Gaskets

Figure 8-22. On rusted threads, such as those on this brake bleed screw, use rust penetrant to help ease turning and prevent screw breakage.



Fiat

Figure 8-23. Gaskets prevent leakage between stationary parts. Seals prevent leakage between moving parts.

unevenness can cause leakage. While working with gaskets, remember the following:

1. Clean off old gaskets carefully. All the old gasket material must be scraped or wire brushed from the parts. Use care, especially on aluminum and brass. These soft metals are easily damaged. Use a dull scraper and wire brush lightly.
2. Wash and dry parts thoroughly using solvent. Blow them dry with compressed air. Then, wipe mating surfaces with a clean shop towel.
3. Compare the new gasket to the shape of the mating surface. All holes and sealing surfaces must match perfectly.
4. Use sealer if needed! Some gaskets require sealer. Sealer is normally used where two different gaskets come together. It will prevent leakage where gaskets overlap. Check a service manual for details. However, use sealer sparingly. Too much sealer could clog internal passages in the assembly.
5. After fitting the gasket and parts in place, screw all bolts in by hand. This will ensure proper part alignment and threading of fasteners. It also lets you check bolt lengths.
6. When more than one bolt is used to hold a part, use a crisscross tightening pattern and tighten the fasteners in steps. This will ensure even gasket compression and proper sealing. First, tighten all the bolts to about half of their torque specification. Next, tighten them to three-fourths torque. Then, tighten the fasteners to full torque. As a final precaution, retorque each fastener.

Caution

Do not overtighten fasteners. It is very easy to tighten the bolts enough to dent sheet metal parts and smash or break the gaskets. Apply only the specified torque.

Tech Tip

The trend in gasket design is to use large, synthetic-rubber O-ring-type gaskets instead of fiber or treated paper gaskets. These new gaskets can have a round, D-shaped, or odd-shaped cross-section to help seal with the cover design. Follow the manufacturer's instructions when installing these types of gaskets. See **Figure 8-24**.

Copyright Goodheart-Willcox Co., Inc.

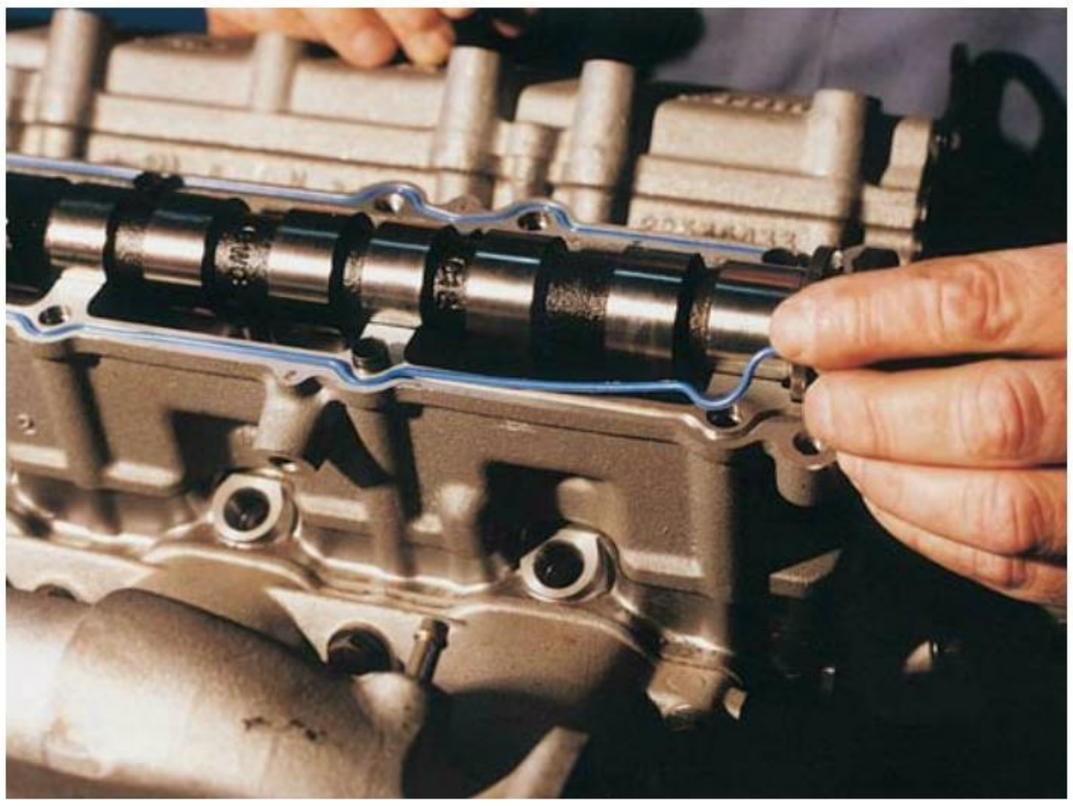


Figure 8-24. Many modern engines use synthetic O-ring-type gaskets. These specially shaped gaskets fit down into a small groove formed in the part.

Sealers

A gasket is commonly coated with a ***sealer*** to help prevent leakage and to hold the gasket in place during assembly. There are numerous kinds of sealers. They have different properties and are designed for different uses.

Hardening sealers are used on permanent assemblies, such as fittings and threads, and for filling uneven surfaces. They are usually resistant to heat and most chemicals.

Nonhardening sealers are for semipermanent assemblies, such as cover plates, flanges, threads, and hose connections. They are also resistant to most chemicals and moderate heat. Shellac is a nonhardening sealer. It is a sticky substance that remains pliable. It is frequently used on fiber gaskets as a sealer and to hold the gasket in place during assembly.

Always read the manufacturer's label and the service manual before selecting a sealer. See **Figure 8-25**.

Form-in-Place Gaskets

Form-in-place gaskets are special sealers used instead of conventional fiber or rubber gaskets. Two common types of form-in-place gaskets are room temperature vulcanizing (RTV) sealer and anaerobic sealer.

When selecting a form-in-place gasket, refer to a manufacturer's service manual. Scrape or wire brush all sealing surfaces to remove loose material. Check that all gasket flanges are flat. Using a shop towel and solvent, wipe off oil and grease. The sealing surfaces must be clean and dry before using a form-in-place gasket.

RTV sealer, also called silicone sealer, dries in contact with air. It is used to form a rubber-like gasket on thin, flexible flanges. RTV sealer normally comes in a tube, as shown in **Figure 8-26.**

Type	Temperature range	Use	Resistant to	Characteristics
shellac	–65° to 350° F (–54° to 177° C)	general assembly: gaskets of paper, felt, cardboard, rubber, and metal	gasoline, kerosene, grease, water, oil, and antifreeze mixtures	dries slowly sets pliable alcohol soluble
hardening gasket sealant	–65° to 400° F (–54° to 205° C)	permanent assemblies: fittings, threaded connections, and for filling uneven surfaces	water, kerosene, steam, oil, grease, gasoline, alkali, salt solutions, mild acids, and antifreeze mixture	dries quickly sets hard alcohol soluble
nonhardening gasket sealant	–65° to 400° F (–54° to 205° C)	semipermanent assemblies: cover plates, flanges, threaded assemblies, hose connections, and metal-to-metal assemblies	water, kerosene, steam, oil, grease, gasoline, alkali, salt solutions, mild acids, and antifreeze solutions	dries slowly nonhardening alcohol soluble

Fel-Pro Gaskets

Figure 8-25. Note the different uses and characteristics of various types of sealers.

Copyright Goodheart-Willcox Co., Inc.

Fel-Pro Gaskets

Figure 8-26. RTV sealer is commonly recommended where two different gaskets join to avoid fluid leakage.

Tech Tip

Depending on the brand, an adhesive or sealer can have a shelf life from one year to two years. Always inspect the package for the expiration date before using the sealer. If too old, RTV sealer will not cure and seal properly, which could result in engine leaks and time-consuming, costly repairs.

RTV sealer should be applied in a continuous bead that is approximately 1/8" (3 mm) wide. All mounting holes must be circled. Locating dowels are often used to prevent the sealing bead from being smeared. If the continuous bead is broken, a leak may result. Uncured RTV can be removed with a rag. Components should be torqued in place while the RTV is still wet to the touch, usually within about 10 minutes of application.

Anaerobic sealer cures to a plastic-like substance in the absence of air and is designed for tightly fitting, thick parts. It is used between two smooth, true surfaces, not on thin, flexible flanges. The RTV-sealed section contacts the flexible engine oil pan. The anaerobic-sealed section touches the strong, machined engine block.

Anaerobic sealer should be applied sparingly. Use a 1/16"–3/32" (1.5 mm–2 mm) wide bead on one gasket surface. Be certain that the sealer surrounds each mounting hole. Typically, bolts should be torqued within 15 minutes of sealer application.

Tech Tip

A few gasket manufacturers sell precut gaskets designed to replace form-in-place gaskets. When working on an engine installed in a vehicle, it can be difficult to properly clean the sealing surfaces. It may also be impossible to fit a part on the engine without hitting and breaking the bead of sealant. When this is the case, a precut gasket might work better than a form-in-place gasket during an in-vehicle repair.

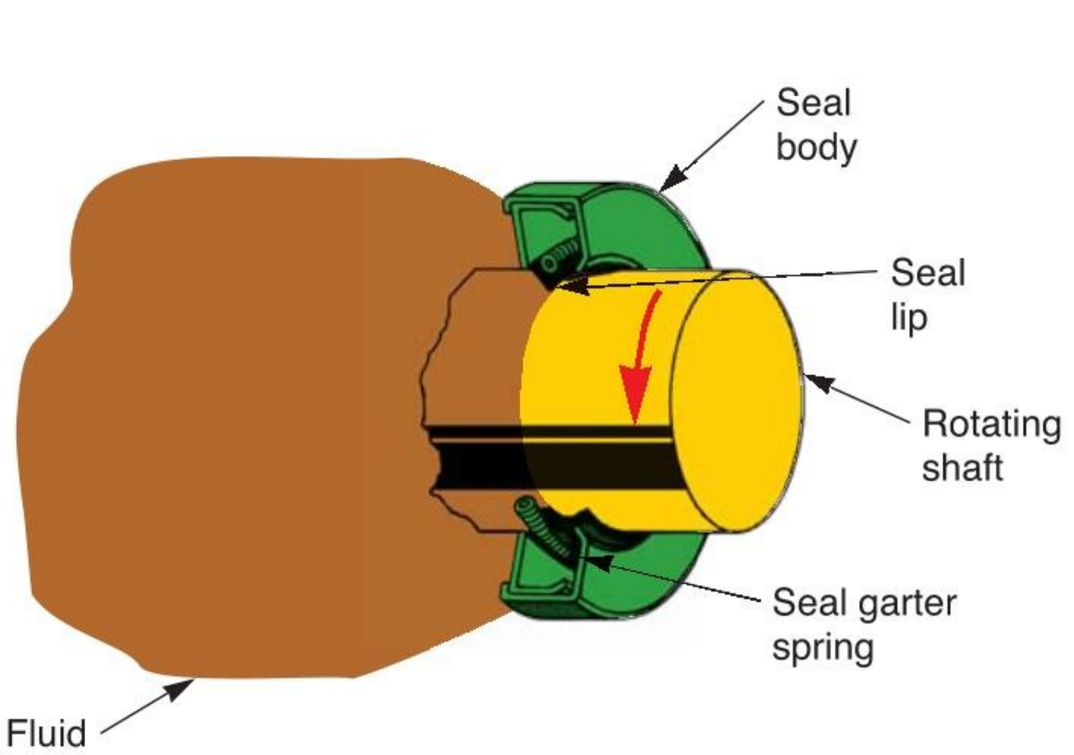
Seals

Seals prevent leakage between a stationary part and a moving part. They can be found in engines, transmissions, power steering units, and almost any part containing fluid and moving parts. A seal allows a shaft to spin or slide inside a nonmoving part without fluid leakage. Seals are normally made of synthetic rubber molded onto a metal body, **Figure 8-27**.

Seal Rules

There are several important procedures to remember when working with seals.

- Inspect the seal for leakage before disassembly. If a seal is leaking, there may be other problems besides a defective seal. Look for a bent shaft, misaligned seal housing, or damaged parts. Leakage requires close inspection after disassembly.



Caterpillar Tractor

Figure 8-27. This oil seal is mounted in a stationary part. The seal lip faces the fluid and keeps it inside the part. The shaft spins inside the seal with minimum wear because of the lubricating fluid inside the seal.

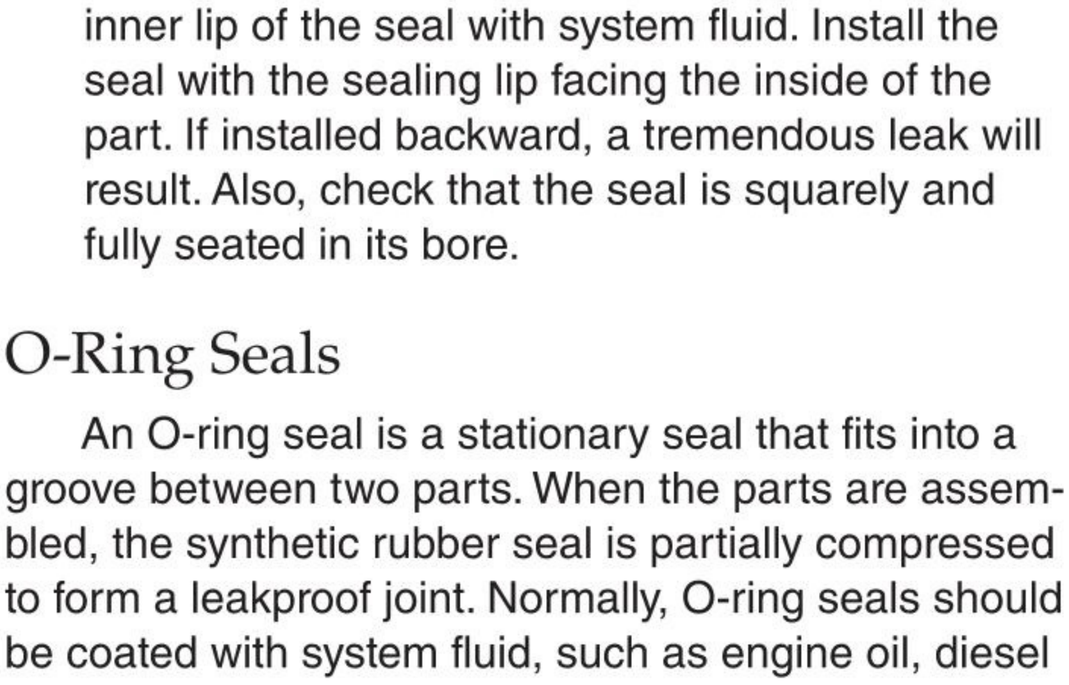
Copyright Goodheart-Willcox Co., Inc.

- Remove the old seal carefully, without scratching the seal housing. Sometimes, a special puller is required for seal removal. This is discussed in later chapters.
- Inspect shafts for wear and burrs, **Figure 8-28**. Look at the shaft closely where it contacts the seal. It should be smooth and flat. File off any burrs that may cut the new seal. A badly worn shaft will require polishing, a shaft sleeve repair kit, or replacement.
- Compare the old seal to the new seal. Hold them next to each other. Both the inside diameter (ID) and the outside diameter (OD) must be the same. To double-check the ID, slip the seal over the shaft. It should fit snugly to prevent leakage.
- Install the new seal correctly. Coat the outside of the seal housing with approved sealer. Coat the inner lip of the seal with system fluid. Install the seal with the sealing lip facing the inside of the part. If installed backward, a tremendous leak will result. Also, check that the seal is squarely and fully seated in its bore.

O-Ring Seals

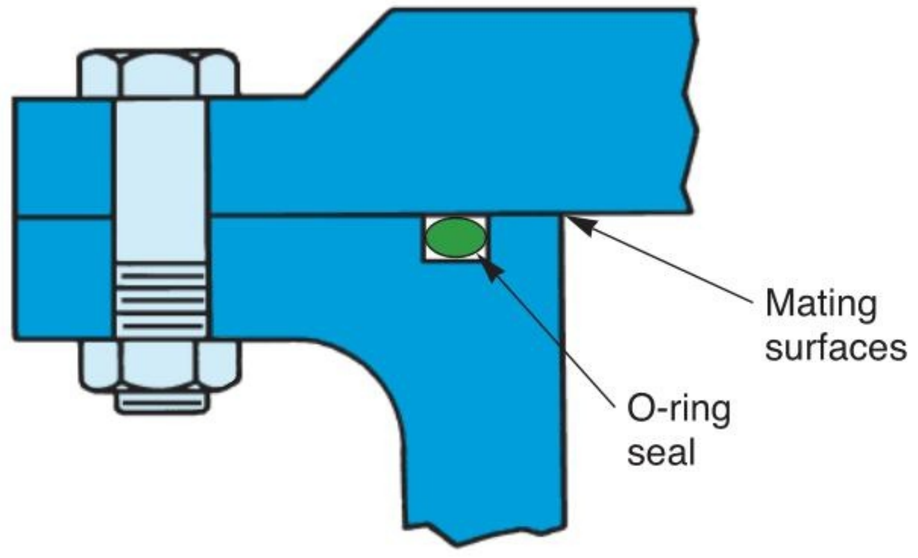
An O-ring seal is a stationary seal that fits into a groove between two parts. When the parts are assembled, the synthetic rubber seal is partially compressed to form a leakproof joint. Normally, O-ring seals should be coated with system fluid, such as engine oil, diesel fuel, or transmission fluid before installation. This helps the parts slide together without scuffing or cutting the seal. See **Figure 8-29**.

Usually, sealants are not used on O-ring type seals. When in doubt about any seal installation, refer to a shop manual.



Federal Mogul

Figure 8-28. Always inspect seals and shafts for damage. Even the smallest nicks or scratches could cause leakage.



Deere & Co.

Figure 8-29. O-ring seals prevent leakage by applying pressure to multiple surfaces, as shown. When the parts are bolted together, they partially compress and clamp the O-ring to form a good seal for air, coolant, or lubricant.

Other Information

Special gaskets and seals sometimes require other installation techniques. These special situations are discussed in later chapters.

Workplace Skills

One of the most serious and common mistakes in automotive service is not torquing wheel lug nuts properly. Improper wheel lug nut torque can warp the brake rotor or wheel, or allow the wheel nuts to loosen, which can lead to a very dangerous situation. To torque wheel lug nuts correctly, run the lug nuts down lightly with an air impact wrench and then tighten them to factory specifications with a torque wrench. If tightening the lug nuts in this way prevents even one problem per year, it was worth the extra time to do the job right.

Copyright Goodheart-Willcox Co., Inc.

Summary

- Fasteners are devices that hold the parts of a vehicle together.
- When a high-quality bolt is threaded into a part without a nut, it can also be called a cap screw.
- Bolt size is a measurement of the outside diameter of the bolt threads.
- Tensile strength, or grade, refers to the amount of pull or stretch a fastener can withstand before breaking.
- A flat washer increases the clamping surface under the fastener.
- A lock washer prevents the bolt or nut from becoming loose under stress and vibration.
- It is very important that bolts and nuts are torqued properly.
- Torque specifications are tightening values given by the vehicle manufacturer.
- Generally, tightening a group of fasteners on a part follows a crisscross pattern.
- A torque wrench measures the twisting force applied when tightening a threaded fastener.
- A tap is a threaded tool for cutting internal threads in holes. A die cuts external threads.
- Machine screws are similar to bolts, but they normally have screwdriver-type heads.
- Numerous types of nonthreaded fasteners, such as snap rings, clips, and adhesives, are utilized in the assembly of a vehicle.
- Adhesives are widely used on most vehicles.
- A gasket is a soft, flexible material placed between stationary parts to prevent leakage.
- RTV sealer, also called silicone sealer, cures in the presence of air. It is used to form a rubber-like gasket on thin, flexible flanges.
- Seals prevent leakage between a stationary part and a moving part.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

adhesive
bolt
bolt head marking
bolt tightening sequence
cap screw
cotter pin
crisscross pattern
die
fastener
gasket
key
keyseat
keyway
locking pliers
machine screw
nonthreaded fastener
nut
rust penetrant
screw extractor
seal
sealer
set screw
sheet metal screw
snap ring
stud puller
tap
tapping screw
tensile strength
thread repair insert
torque specification
torque wrench
torque-to-yield
torquing
washer

Activities

1. Prepare a large chart for the shop showing how to read information given on a bolt.
2. Demonstrate the proper methods for repairing thread damage.

Copyright Goodheart-Willcox Co., Inc.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Define the terms *bolt* and *nut*.
2. How are bolts and nuts usually named in automotive terminology?
3. List and explain the four basic dimensions of a bolt.
4. Customary bolt heads are marked with _____ or _____ marks to indicate bolt strength. Metric bolts use a(n) _____ system to indicate bolt strength.
5. A(n) _____ is a safety device commonly used with a slotted nut.
6. Describe the difference between a flat washer and a lock washer.
7. What are torque specifications?
8. What is a bolt or nut tightening sequence?
9. Which of the following is *not* used for thread repair?
   (A) Tap.
   (B) Die.
   (C) Chaser.
   (D) Chisel.
10. A(n) _____ and _____ is needed to select the right size drill and tap.
11. How do you use a thread repair insert?
12. Describe six ways to remove broken fasteners.
13. Which of the following group of sealers is used on permanent assemblies?
   (A) Hardening.
   (B) Nonhardening.
   (C) Form-in-place.
   (D) All of the above.
14. Explain when RTV and anaerobic sealers are recommended.
15. Describe five rules for working with seals.

ASE-Type Questions

1. A broken bolt must be replaced. Technician A says that thread pitch is the same as thread coarseness. Technician B says that bolt head markings specify the tensile strength of a bolt. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Which of the following is a safety device that keeps a slotted nut from turning or coming off?
   (A) Lock tab.
   (B) Snap ring.
   (C) Cotter pin.
   (D) Thread pitch.
3. Snap rings hold and fit into grooves in:
   (A) pins.
   (B) gears.
   (C) shafts.
   (D) All of the above.
4. Set screws are headless fasteners designed to accept a(n):
   (A) hex wrench.
   (B) screwdriver.
   (C) Allen wrench.
   (D) All of the above.
5. Which of the following is determined by measuring bolt length change while torquing a bolt?
   (A) Torque stretch.
   (B) Torque-to-yield.
   (C) Torquing sequence.
   (D) Torque specification.
6. Fastener tightening generally follows a:
   (A) clockwise pattern.
   (B) crisscross pattern.
   (C) left-to-right pattern.
   (D) counterclockwise pattern.
7. Which of the following is *not* a basic rule to follow when using a torque wrench?
   (A) Avoid using swivel joints.
   (B) Pull only on the wrench handle.
   (C) Clean fastener threads.
   (D) Use short, jerky pull motions for accuracy.

Copyright Goodheart-Willcox Co., Inc.

8. Which threaded tool is used for cutting internal threads in holes?
   (A) Tap.
   (B) Helicoil.
   (C) Thread chaser.
   (D) Thread repair insert.
9. Each of the following is a tool that can be used to help remove problem fasteners *except:*
   (A) hacksaw.
   (B) stud puller.
   (C) die.
   (D) screwdriver.
10. While installing gaskets, Technician A believes gaskets alone will produce leakproof seals. Technician B believes that some gaskets require sealer to further prevent leakage where gaskets overlap. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

Chapter 9
Vehicle Maintenance, Fluid Service, and Recycling

After studying this chapter, you will be able to:

- Check a car's fluid levels.
- Explain the importance of vehicle maintenance.
- Locate fluid leaks.
- Replace engine oil and filter.
- Change automatic transmission fluid and filter.
- Perform a grease job.
- Inspect for general problems with hoses, belts, idler pulleys, and other components.
- Demonstrate safe practices while working with vehicle fluids.
- Recycle or properly dispose of auto shop wastes.
- Correctly answer ASE certification test questions on fluid service and vehicle maintenance.

Vehicle fluids include engine oil, coolant, brake fluid, transmission fluid, power steering fluid, and other liquids. When working as a technician, you must be proficient with checking and changing vehicle fluids. Service station attendants, oil change technicians, and even master technicians must check, add, or replace fluids.

Your first job might involve working in an oil change shop or a tire specialty shop. Apprentice technicians "cut their teeth" doing fluid service, grease jobs, rotating and changing tires, and light mechanical repairs. Therefore, this chapter is extremely important to your future employment. It is your chance to learn basic service tasks essential to what may be your first job in an auto shop. Study this material carefully.

The last section of the chapter discusses recycling. To help save our environment, you should recycle as many automotive parts, fluids, and materials as possible. Used batteries, tires, antifreeze, and oil can all be recycled into new products while saving energy

Lubrication Service

Lubrication service is vital to keeping a vehicle in good working order. A technician must be familiar with all aspects of lubrication service, which include:

- Checking fluid levels and fluid condition.
- Changing engine oil and filter.
- Changing automatic transmission fluid.
- Lubricating (greasing) chassis parts that have grease fittings.
- Locating fluid leaks and other obvious problems.
- Following state regulations for recycling and disposal of waste fluids.

Copyright Goodheart-Willcox Co., Inc.

Vehicle Maintenance

Vehicle maintenance includes any operation that will keep a vehicle in good operating condition. Without proper care, the life of an automobile may be reduced by thousands of miles. For example, fluids can become contaminated and change chemically after prolonged use. This can cause wear, corrosion, and mechanical failure of parts.

Tech Tip

A wise saying goes, "You can pay now or you can pay later." In the automotive field, this means that your customers can pay a little now for maintenance or pay a whole lot more later for repairs. A poorly serviced vehicle will wear out and break down much sooner than a well-maintained vehicle. In the long run, vehicle maintenance saves your customers money.

Fluid Service

A service manual contains detailed information on how to check fluid levels. The manual will usually describe:

- Location of all fluid checkpoints, **Figure 9-1**.
- Location of all fluid fill points.
- Correct interval (time or mileage) between fluid checks and changes.
- Correct type and quantity of fluids to be used.

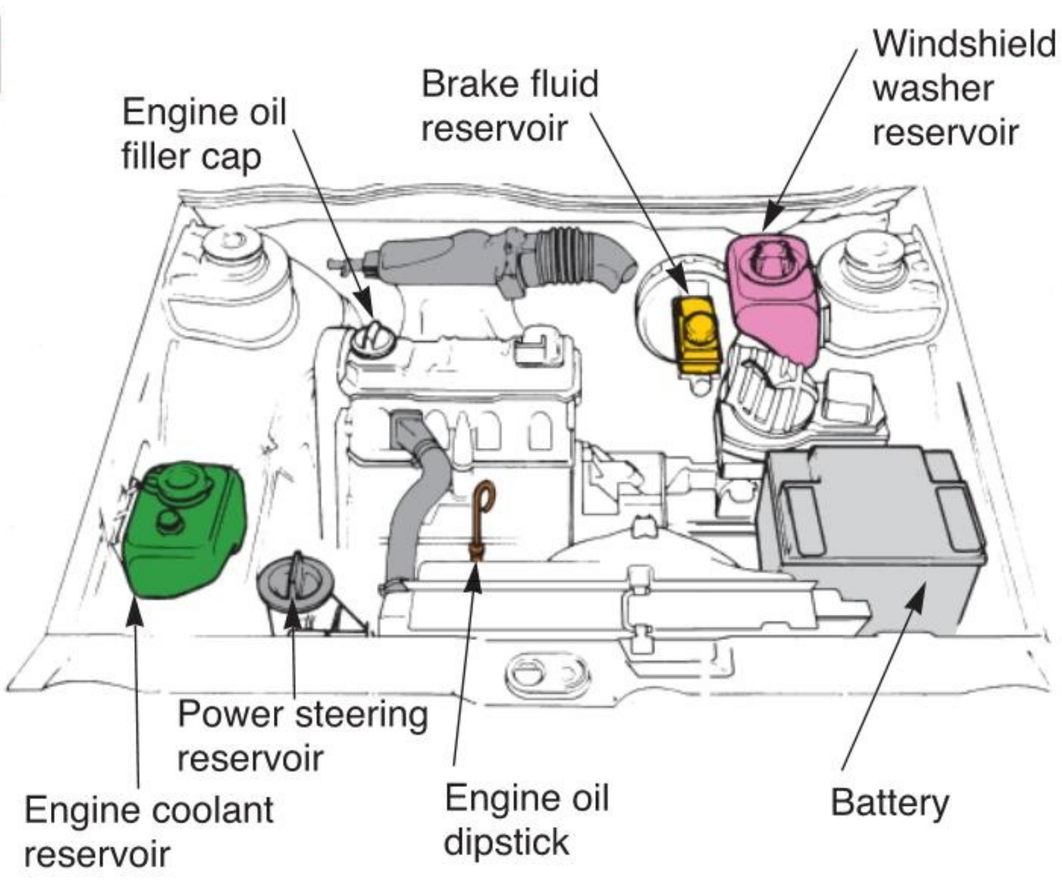


Figure 9-1. A service manual gives the locations of all fluid checkpoints. This illustration shows engine compartment fluid checkpoints.

This information varies by make and model of vehicle. For example, a diesel, supercharged, or turbocharged engine often requires more frequent oil changes than typical engines. Automatic transmission or transaxle fluids, differential lubricants, and other fluids can also vary slightly in chemical content to match the internal design of the assembly.

Tech Tip

A car's warranty may become void if incompatible fluids, incorrect service procedures, or improper intervals are used. For this reason, refer to the manufacturer's recommendations and specifications when servicing fluids.

Fluid capacity is the maximum amount of fluid a reservoir or assembly will hold. The vehicle manufacturer will list fluid capacities for the engine, transmission/transaxle, power steering system, and differential.

Checking Engine Oil

Service Procedure

To check engine oil:

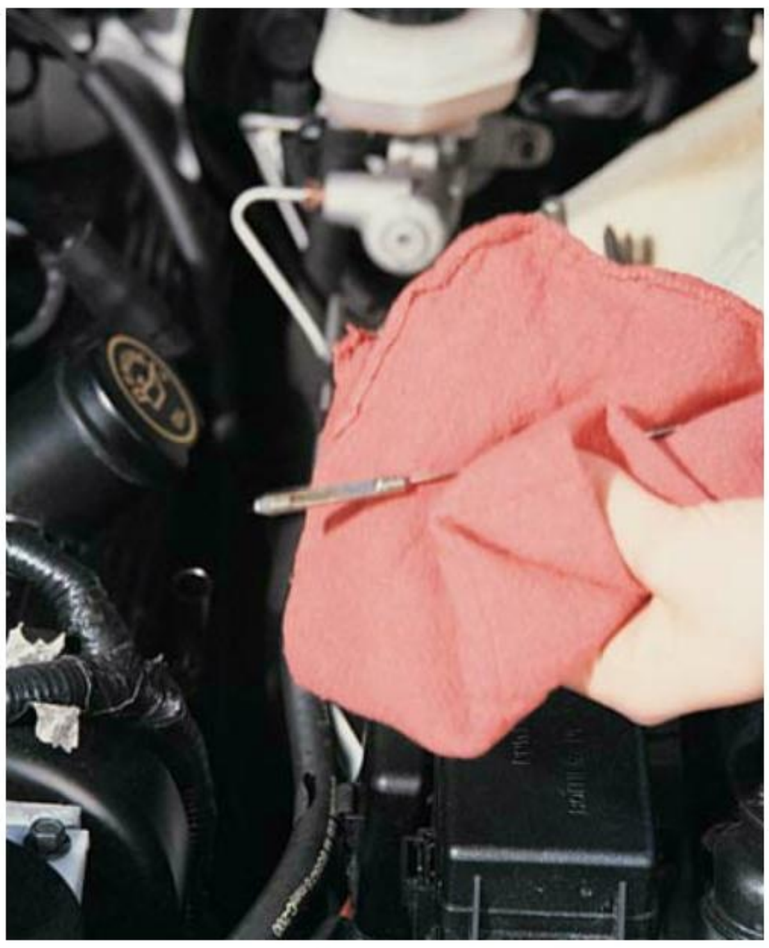
1. Warm the engine to operating temperature.
2. Shut off the engine and allow it to sit for a few minutes.
3. Locate and remove the engine oil dipstick.
4. Wipe off the dipstick and replace it all the way into its tube.
5. Pull the dipstick back out and hold it over your shop rag.
6. Observe the highest point on the dipstick wet from oil. The oil level should be between the ADD (LOW) and FULL marks on the dipstick.

Before reinstalling the dipstick, inspect the condition of the oil. The oil should not be too thick or thin, smell like gasoline, or be too dirty.

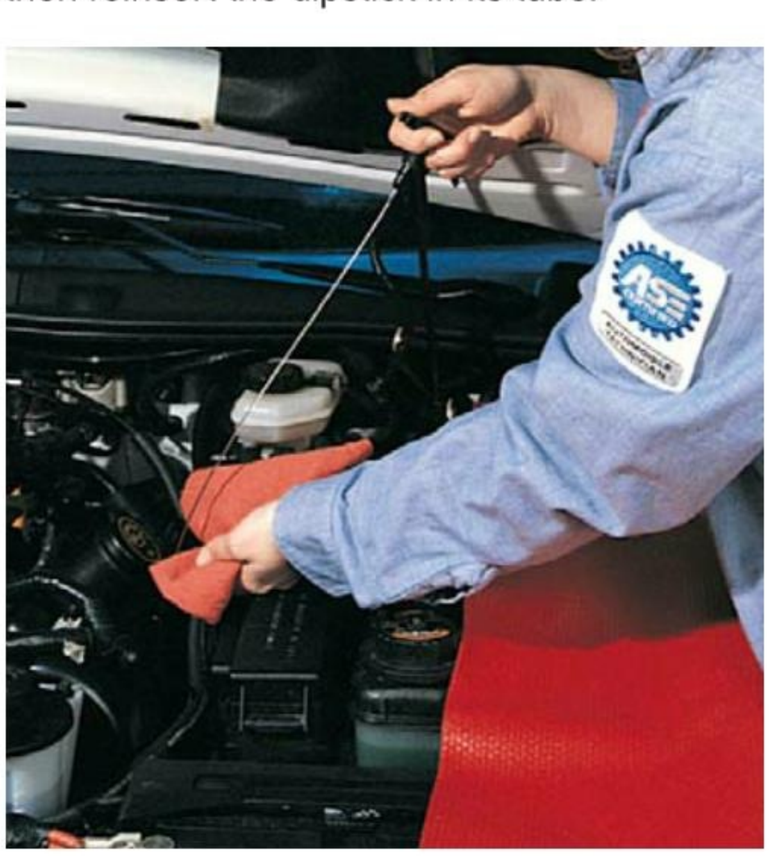
If the oil level is low, you must add the correct amount and type of oil. If the oil level is down to the ADD mark, typically one quart is needed. If the dipstick reads halfway between ADD and FULL, you would need to add only one-half quart. See **Figure 9-2**.

Copyright Goodheart-Willcox Co., Inc.

A—Remove the dipstick.

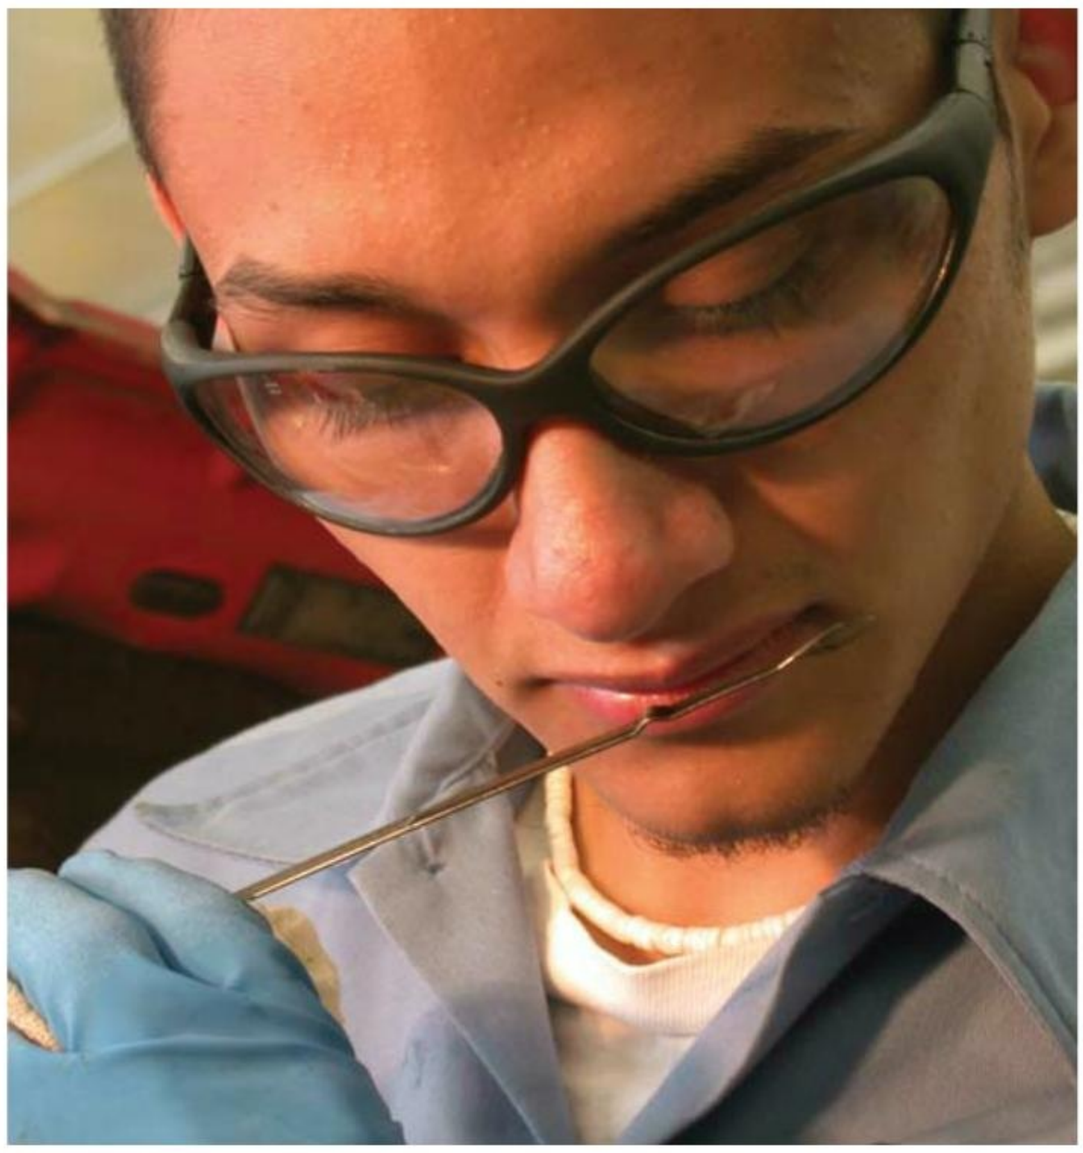


B—Wipe the oil from the dipstick; then reinsert the dipstick in its tube.



C—Remove the dipstick.

D—Look closely to see how far the oil goes up on the dipstick.



E—Determine if the oil smells burned or has turned black and is dirty.

F—Use the recommended type and weight of oil when adding oil to the engine.

Goodheart-Willcox Publisher

Figure 9-2. Check the amount of oil in the engine using the dipstick.

Copyright Goodheart-Willcox Co., Inc.

Never add too much oil to an engine. Pour in only enough oil to reach the FULL mark. Overfilling can cause ***oil foaming*** (the oil absorbs air bubbles), which reduces the oil's lubricating ability.

Warning

Be careful when checking or changing vehicle fluids. At operating temperature, oil and other fluids can be hot enough to burn your hand, arm, and face. Wear a face shield and oil-resistant gloves when changing an engine's oil and filter.

Adding Engine Oil

Before adding engine oil, obtain the right kind of oil (weight, detergent, synthetic). Unless you have a very high mileage engine, use the same weight of oil that was installed during the last oil change. Use heavier or thicker oil in engines with very high mileage, especially if the engine is knocking, smoking, or has low oil pressure. Thicker oil will help raise oil pressure, cushion excessive bearing clearance, reduce light knocking, and help lower engine blow-by and smoking slightly. For example, some engines require zero weight oil when new. When these engines reach 200,000 miles, they will normally benefit from heavier oil.

To add oil to the engine, remove the oil cap, which is usually on the valve cover. Install a small, clean funnel into the engine opening. Without spilling, pour the oil slowly into the funnel and engine.

Changing Engine Oil and Filter

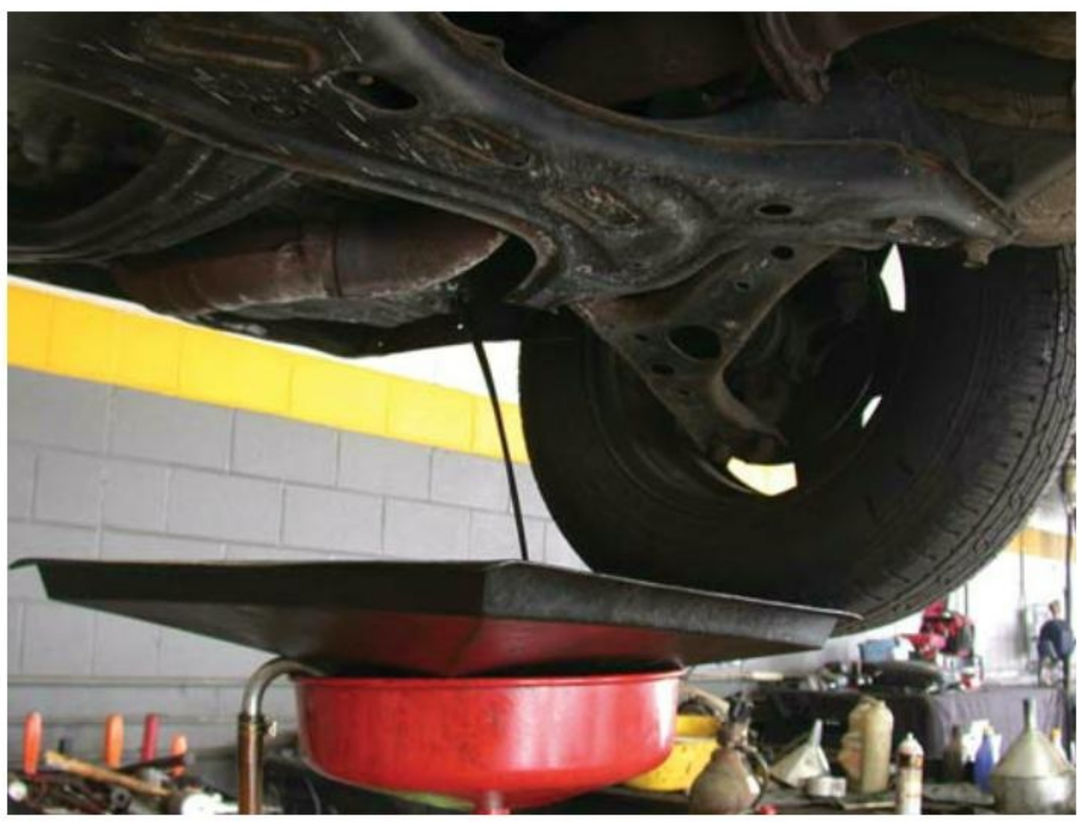
When changing engine oil, make sure the engine is warm and the vehicle is sitting level. This will ensure that more of the oil contaminants are suspended in the oil and are drained out of the engine. If the oil is cold, the oil will drain more slowly and debris will settle to the bottom of the oil pan and cylinder heads.

Service Procedure

To change the engine oil:

1. Warm the engine to operating temperature.
2. Put on eye or face protection and work gloves.
3. Raise the vehicle on a lift or place it on jack stands in a level position.
4. Place a catch pan under the oil drain plug.
5. Unscrew the drain plug by turning it counterclockwise. Be careful, as the oil is hot. Allow enough time for the oil to drain completely and stop dripping out of the pan. See **Figure 9-3**.

A—Warm engine to full operating termperature. Then unscrew oil drain plug in counterclockwise direction.



B—Be careful not to let hot oil burn your hand or arm. Allow all old oil to drain into catch pan for several minutes.

Goodheart-Willcox Publisher

Figure 9-3. Note the basic steps for draining old oil from an engine.

Copyright Goodheart-Willcox Co., Inc.

6. Reinstall the drain plug without crossthreading. The threads in the pan and on the drain plug can strip easily. Torque the drain plug to minimum torque specifications. Apply only enough torque to draw the drain plug snug on its seal and prevent leakage.
7. Position your catch pan under the oil filter.
8. Using an oil filter wrench, as in **Figure 9-4**, unscrew the filter. Again, be careful that hot oil does not run down your arm and burn you.
9. Obtain the correct replacement filter. Compare the old and new filters. The threads and O-ring seals must be the same size.
10. Wipe some clean oil on the rubber O-ring and thread the new oil filter onto the engine. See **Figure 9-5**.
11. Tighten the oil filter by hand. Placing a clean shop rag over the filter before tightening will help you get a proper grip, **Figure 9-6**. Never use an oil filter wrench to install an oil filter, or you will have to cut the filter off the next time. Overtightening may also distort the O-ring and cause a severe oil leak.
12. Lower the car to the ground and add the correct amount and type of oil.
13. Start the engine and make sure the oil pressure light goes out.
14. Let the engine run while checking for leaks under the engine compartment.
15. Shut off the engine and check the oil level again.

Goodheart-Willcox Publisher

Figure 9-4. An oil filter wrench is needed to remove the oil filter. Rotate the wrench in a counterclockwise direction to unscrew the filter.

Goodheart-Willcox Publisher

Figure 9-5. When installing a new filter, coat the O-ring seal with clean oil and only hand tighten the filter.

Goodheart-Willcox Publisher

Figure 9-6. A clean, dry shop rag will help you snug down the new oil filter.

Automatic Transmission/Transaxle Fluid and Filter Service

Like engine oil, automatic transmission and transaxle fluid should be checked and changed at specified intervals. The fluid can become contaminated with metal, dirt, moisture, and friction material (nonmetallic, heat-resistant fibrous substance) from internal parts.

Copyright Goodheart-Willcox Co., Inc.

This can cause rapid part wear and premature transmission failure.

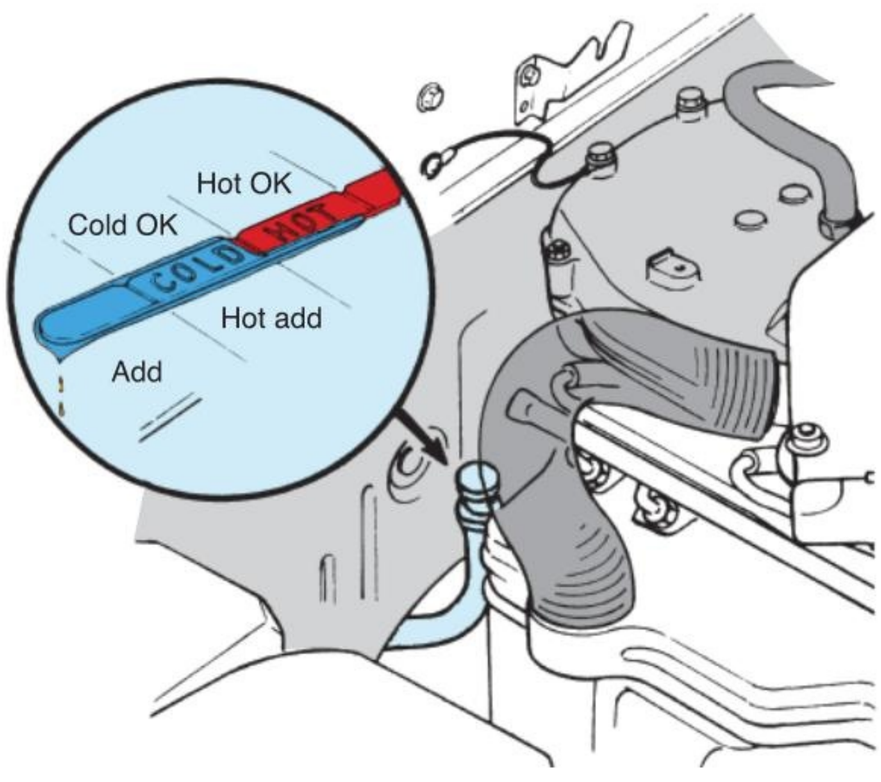
To check the fluid in an automatic transmission or transaxle, warm up the engine and move the gear selector through all positions. Apply the parking brake. Place the transmission in park and block the wheels. With the engine still running, locate the transmission dipstick. See **Figure 9-7**.

Tech Tip

Don't "go crazy" looking for the transmission dipstick on some new cars and trucks. You may not find one. Some transmissions and transaxles are sealed at the factory. They are designed to not require fluid changes and periodic checking of fluid level. Some manufacturers provide screw plugs on the side of the transmission case for checking and adding transmission fluid. The procedure is similar to that for a manual transmission.

Pull out the dipstick. Wipe it off and reinsert it into the tube. Remove the dipstick again and hold it over a shop rag. The fluid should read between the ADD and FULL marks. Also, inspect the fluid for discoloration and odor. If it smells burned or looks dirty, the fluid should be changed.

It is very easy to overfill an automatic transmission. Seldom do you have to add a full quart. Normally, if the dipstick reads ADD, only a fraction of a quart is needed to fill the transmission. Sometimes, instructions are written on the dipstick. If in doubt, check a shop or owner's manual.



Saab

Figure 9-7. Check automatic transmission fluid level with the engine running and the transmission in park. Compare the fluid level to the marks on the dipstick. If needed, add the correct amount and type of fluid.

Service Procedure

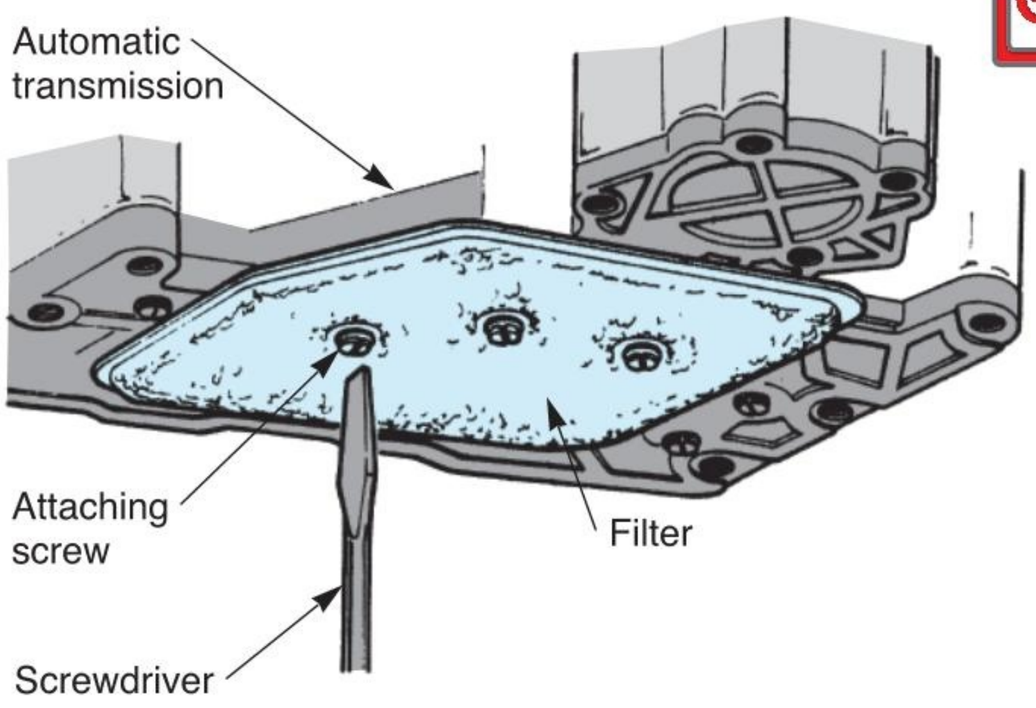
To change the fluid and filter in an automatic transmission or transaxle:

1. Warm the engine and transmission or transaxle to full operating temperature so the fluid will drain more fully.
2. Raise the vehicle on a lift or secure it on jack stands. If the transmission pan has a drain plug, remove it and allow the old fluid to drain into your catch pan. If the pan does not have a drain plug, remove the pan as outlined in steps 3-10.
3. Remove all but one of the bolts securing the transmission pan, **Figure 9-8**. Be careful not to spill the hot transmission fluid. It can cause painful burns!
4. Loosen but do not remove the last pan bolt while holding the pan in place with a shop rag.
5. Allow the pan to drop and let the fluid pour into a catch pan.
6. Unscrew the last pan bolt and remove the pan. If needed, replace or clean the transmission filter, **Figure 9-9**.
7. Scrape the old gasket off the transmission pan and housing.
8. Position the new pan gasket using an approved sealer. Use the sealer sparingly. You do not want any to squeeze out of the gasket and into the transmission or transaxle housing.
9. Start all the pan bolts with your fingers.
10. Tighten the pan bolts in a crisscross pattern to their recommended torque specification. Overtightening can split the gasket or distort the transmission pan.
11. If recommended, drain the torque converter (fluid coupling in front of the transmission). A drain plug may be located in the converter. It is usually under a rock shield on the front of the transmission housing.
12. Refill the transmission with the correct type and amount of transmission fluid. If required, check a service manual for details. In most cases, you must pour fresh fluid into the dipstick tube.
13. Start the engine and shift through the gears.
14. Check under the car for leaks and recheck the transmission fluid level.

Copyright Goodheart-Willcox Co., Inc.

Subaru

Figure 9-8. Usually, the transmission pan must be removed to drain the fluid. A few pans, however, have a drain plug. Do not spill hot fluid on yourself.



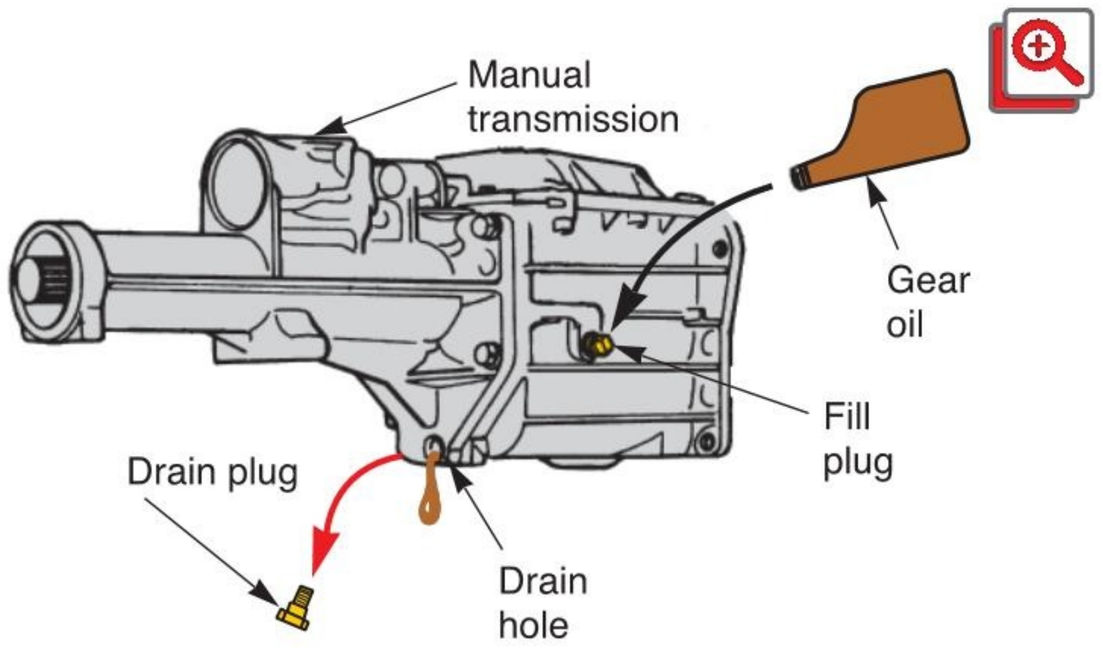
Goodheart-Willcox Publisher

Figure 9-9. Some manufacturers recommend periodic replacement of the automatic transmission filter. It is located inside the transmission pan. Tighten all fasteners to specs when assembling.

Manual Transmission Fluid Service

To check the fluid in a manual transmission, locate and remove the transmission fill plug, **Figure 9-10**. It is normally on one side of the transmission. Generally, warm fluid in a recently driven vehicle should be even with the fill hole. When the transmission fluid is cold, the fluid can be slightly below the fill hole.

Some manufacturers suggest that manual transmission fluid be changed periodically; others do not.



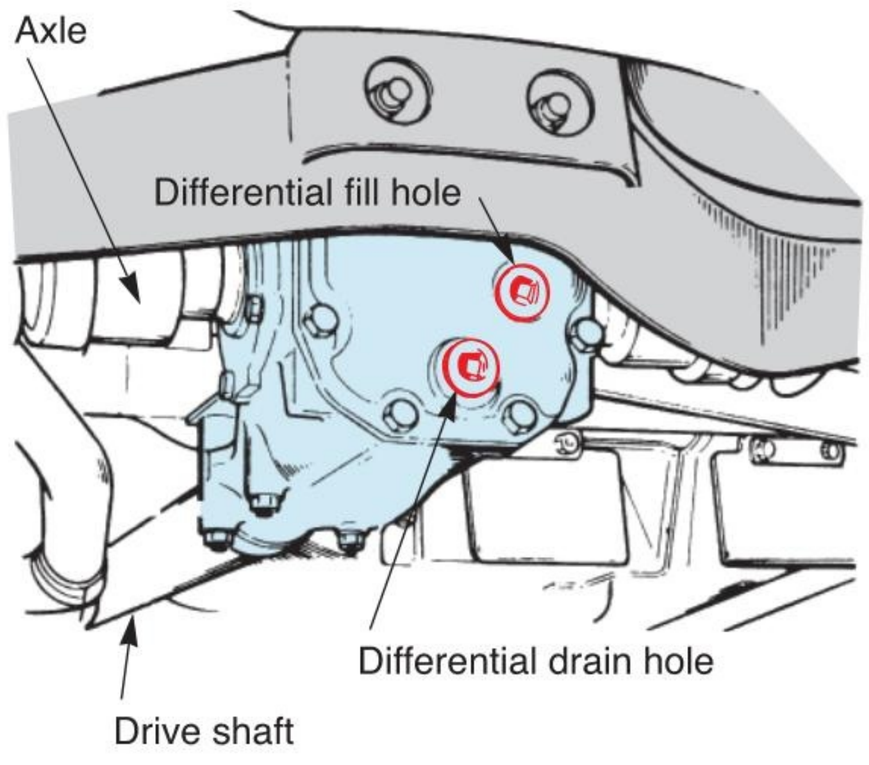
Chrysler

Figure 9-10. A manual transmission will have a fill plug for checking the fluid level. The fluid should be almost even with the hole when the fluid is warm. Check the service manual for details.

If a fluid change is needed, remove the drain plug on the bottom of the transmission case and allow all the fluid to pour into your catch pan. Replace the drain plug and install the right type and quantity of fluid. Lubricate the gearshift mechanism and clutch release as described in service literature.

Differential Fluid Service

To measure the fluid level in a differential (rear axle assembly), remove the fill plug. It will normally be on the front, back, or side of the differential. See **Figure 9-11**. The lubricant should be even with the fill hole when hot. When cold, it should be slightly below the fill hole.



Subaru

Figure 9-11. The differential fill hole allows for a check of the lubricant level. Do not accidentally remove the drain plug.

Copyright Goodheart-Willcox Co., Inc.

At the manufacturer's recommended change interval, remove the drain plug. It will be on the bottom of the differential. After draining, reinstall the plug and fill the differential with the proper lubricant. If a drain plug is not provided, a special siphon (suction) gun can be used to draw out the old fluid.

Caution

Positive-traction, or limited-slip, differentials (both wheels turn for added traction) often require a special lubricant. Refer to the vehicle identification number and a service manual for details. If you install the wrong lubricant, differential action and traction can be adversely affected.

Checking Engine Coolant

Engine coolant (mixture of water and antifreeze) is used in an engine's cooling system. Engine coolant must be changed periodically. After prolonged use, the coolant will deteriorate. It can become very corrosive and filled with rust. This may result in premature water pump, thermostat, and radiator failure.

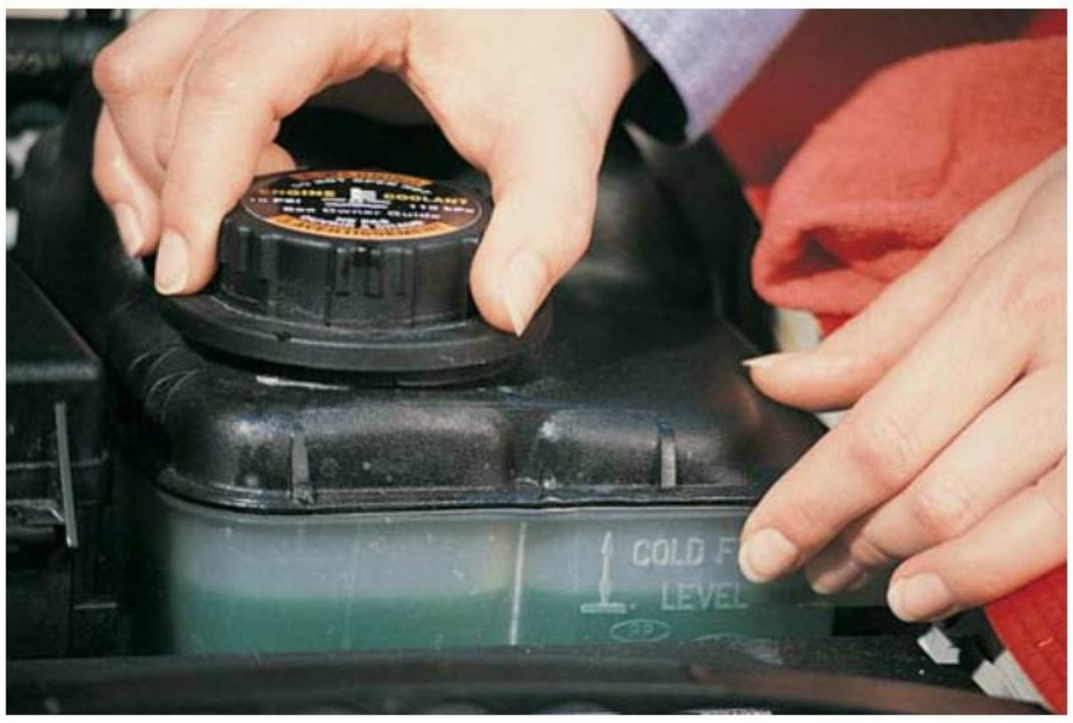
To check the coolant level, look at the side of the plastic overflow tank connected to the radiator. The coolant should be between the hot and cold marks on the side of the tank. See **Figure 9-12**.

When an overflow tank is used, the radiator cap does not need to be removed to check coolant level. However, some older cars do not use an overflow tank. In this case, the radiator cap must be removed to check the coolant level.

Warning

Never remove a radiator cap while the engine or radiator is hot. Extremely hot coolant can spray out of the radiator, causing serious burns.

The coolant should be about 1″ (25 mm) down in the radiator. Also, inspect the condition of the coolant. If rusty, the coolant should be drained and replaced. Watch for system leaks.



A—Plastic Reservoir Tank

B—Clean Funnel

Goodheart-Willcox Publisher

Figure 9-12. Do not remove the pressure cap when checking modern engine cooling systems. Only remove the non-pressurized plastic reservoir cap.

Checking Power Steering Fluid

Power steering fluid level should be checked regularly. The engine should not be running when checking power steering fluid. If the fluid is contained in a clear plastic reservoir, simply compare the fluid level to the markings on the side of the reservoir. See **Figure 9-13A**. In some vehicles, the level is checked by removing a dipstick from the power steering pump, **Figure 9-13B**. Inspect the fluid level on the dipstick closely. If low, inspect for and correct any leaks. Then add the correct type and amount of power steering fluid.

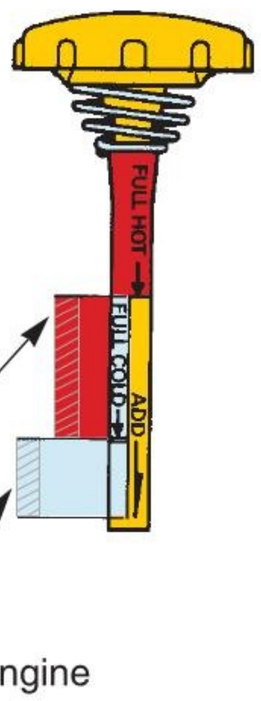
Burned power steering fluid has been overheated from pump wear or a clogged line or passage in the hydraulic system. It will smell like burned rubber. The old fluid must be flushed and replaced.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

A common and troublesome mistake is accidentally overfilling the power steering system. If you add too much power steering fluid and fill the reservoir to the very top, the extra fluid will spray out all over the engine compartment. Remember that liquids cannot be compressed. If you overfill the reservoir, use a clean squeeze bulb to suck out the extra fluid.

A



Power steering pump

Warm engine

Dipstick

Cold engine

B

Subaru

Figure 9-13. Note how to check the power steering fluid level. A—Compare fluid level markings on the side of the reservoir. B—On some vehicles, the power steering pump has a cap with a dipstick. Check the fluid with the engine off. Compare the fluid level to markings on the dipstick. Normally, you need to add only a fraction of a quart, not a whole quart.

Checking Brake Fluid

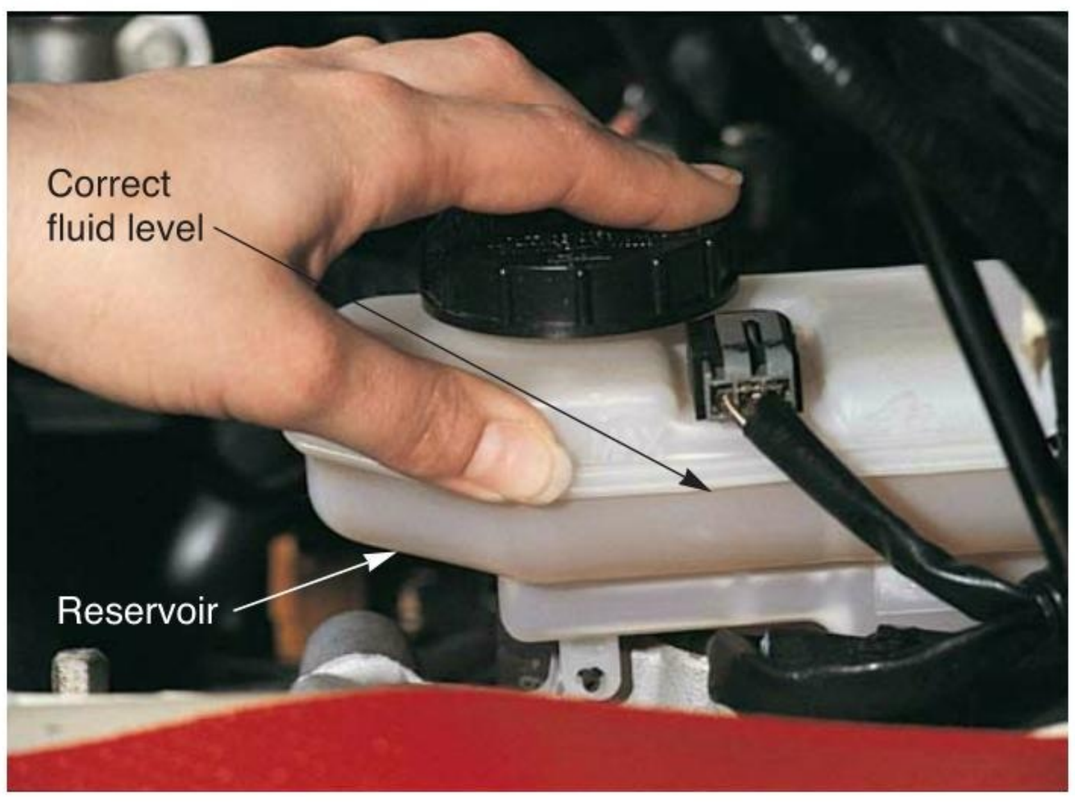
The amount of brake fluid in a master cylinder should be inspected at least twice a year. Look at **Figure 9-14**. The master cylinder is normally mounted on the firewall (body section between the engine and the passenger compartment). When the master cylinder reservoir is clear plastic, simply compare the fluid level to the markings on the reservoir. The fluid should be between the ADD and FULL marks. With some master cylinders, you must remove the reservoir cover to check the fluid. Generally, the fluid should be about 1/4″ (about 6 mm) down from the top of the reservoir. Add the recommended type of brake fluid as needed.

Caution

Never let anything (oil, grease, dirt) contaminate the brake fluid. Oil and grease, for example, will attack the rubber parts in the brake system. Major repairs would be needed and the vehicle could lose braking ability.

Checking Hydraulic Clutch Fluid

Some manual transmission clutches do not use mechanical linkage rods or cables. Instead, they use



Goodheart-Willcox Publisher

Figure 9-14. Check the brake fluid level at the master cylinder reservoir. The master cylinder is mounted on the firewall, in front of the driver. The maximum fluid level is often indicated on the side of the reservoir. If not, fluid should be slightly below the top of the reservoir.

Copyright Goodheart-Willcox Co., Inc.

a hydraulic system to disengage the clutch. A clutch master cylinder, similar to a brake master cylinder, produces hydraulic pressure to activate the clutch release. The fluid in the clutch master cylinder should be checked. If the fluid level is low, add brake fluid to fill the reservoir almost full. Always watch for leaks.

Checking Manual Steering Fluid

Manual steering fluid is checked by removing either a fill plug or a designated bolt from the top of the box or rack. The lubricant should be almost even with the plug or bolt opening. If not, add the recommended amount and weight of fluid.

Checking Windshield Washer Solution

The windshield washer solution is normally visible through the side of the plastic storage tank. If low, add an approved washer solution. The solution will aid windshield cleaning and also prevent ice formation in cold weather.

Checking Battery

New cars use maintenance-free batteries, which do not require an electrolyte (acid) check. However, make sure that the battery terminals and case top are clean. A battery post and cable cleaning tool can be used on corroded connections. If the top of the battery is dirty, it can be cleaned with a solution of baking soda and water. See **Figure 9-15**.

Filter Service

Quite often, various filters used in a vehicle are replaced during lubrication service. Besides the engine oil and transmission filters, the technician may need to change or clean the air and fuel filters.

If an air filter is extremely dirty, it is normally replaced. However, some manufacturers permit light dirt and dust to be tapped from the filter. Special foam or oil-bath (oil-filled) air filters can be cleaned as described in a service manual.

Cabin filters are air filters that clean the air flowing into the passenger compartment. They are often high-density filters for blocking pollen and other airborne particles. Cabin filters are usually located and accessed under the right side of the dash.

Fuel filters can be located almost anywhere in the fuel circuit. Modern fuel systems often use inline fuel filters between the fuel tank and the engine. In older

A

C

Goodheart-Willcox Publisher

Figure 9-15. Checking battery condition is important to vehicle maintenance. Battery problems are the number one cause of engine "no start" problems. A—Dirty battery top will drain the battery. Corroded terminals can prevent charging and starting. B—Battery post cleaning tool will remove resistance-causing corrosion from the high current conducting surfaces. C—Wash the top of the battery with baking soda and secure terminals.

Copyright Goodheart-Willcox Co., Inc.

systems, the fuel filter can be located at the inlet to the throttle body injector or in the carburetor. Most fuel systems also have a fuel strainer on the pickup tube in the fuel tank. Refer to the service manual for exact filter locations.

Warning

Wear a full face shield and work gloves when servicing fuel lines. Hold a shop rag around fuel line fittings when loosening them. The shop rag will keep fuel from spraying out due to any residual pressure, preventing a possible explosion and fire.

Chassis Lubrication

Chassis lubrication generally involves greasing high-friction points on the vehicle. It may also involve lubricating locks, hinges, latches, and other body parts. Chassis lubrication of control arms and ball joints is often done when the engine oil and filter are serviced.

Tech Tip

Control arms and ball joints are sealed on most passenger vehicles, so further lubrication may not be necessary anymore on these parts.

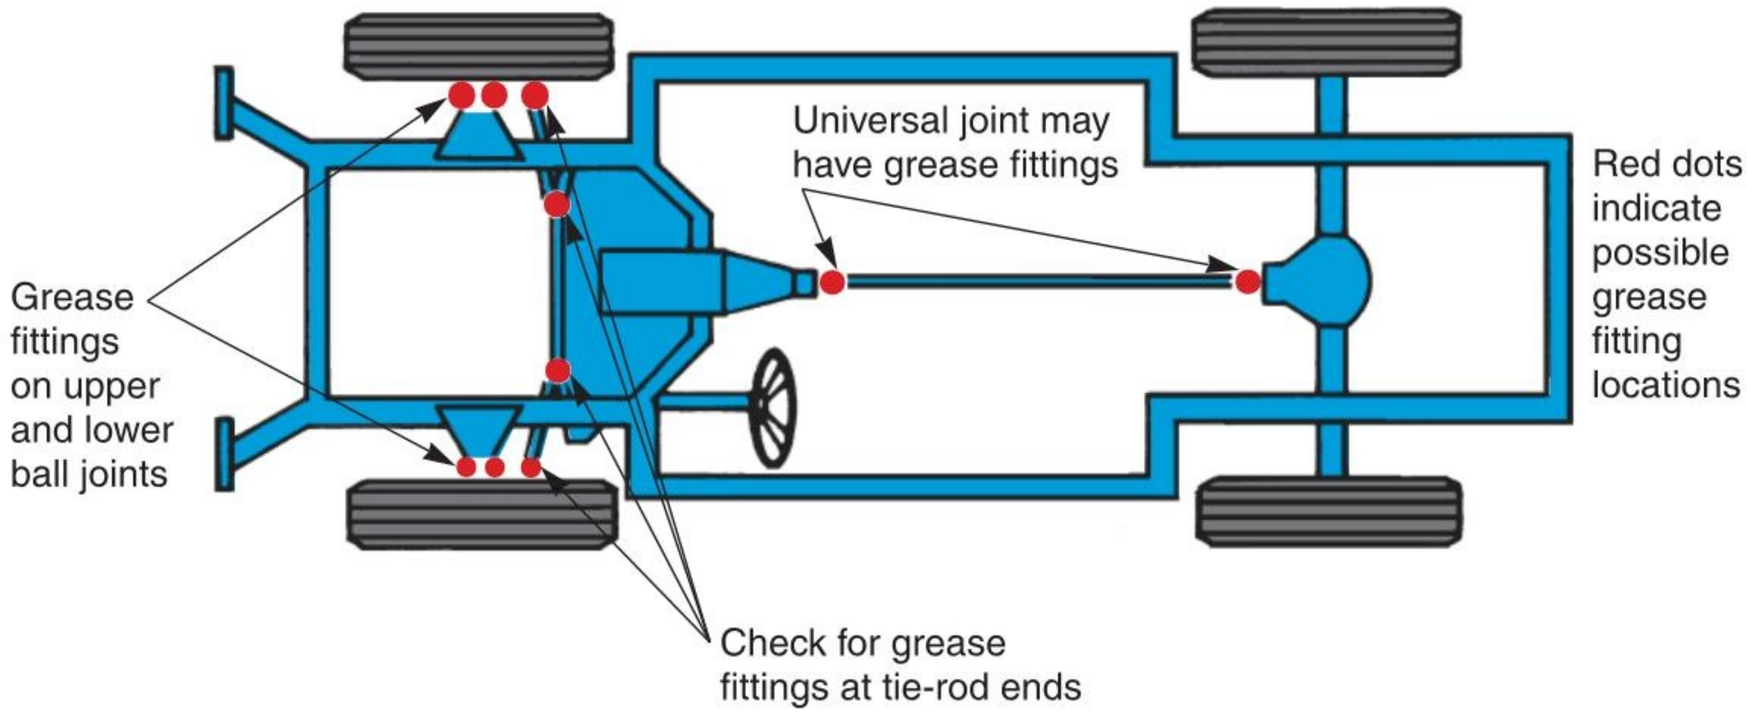
Grease Job

During a ***grease job***, you must lubricate high-friction pivot points on the suspension, steering, and drive train systems. Most service manuals illustrate which parts must be lubricated, **Figure 9-16**.

A ***grease gun***, **Figure 9-17**, is used to force lubricant (chassis grease) into small fittings. Inject only enough grease to fill the cavity in the part. Overgreasing can sometimes rupture the rubber boot surrounding the joint.

Goodheart-Willcox Publisher

Figure 9-17. This technician is using a power grease gun to lubricate fittings on a suspension system.



Goodheart-Willcox Publisher

Figure 9-16. A grease job involves lubricating the pivot points shown. Some cars have more grease fittings than others. Check closely on steering and suspension components, as well as on drive shafts.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

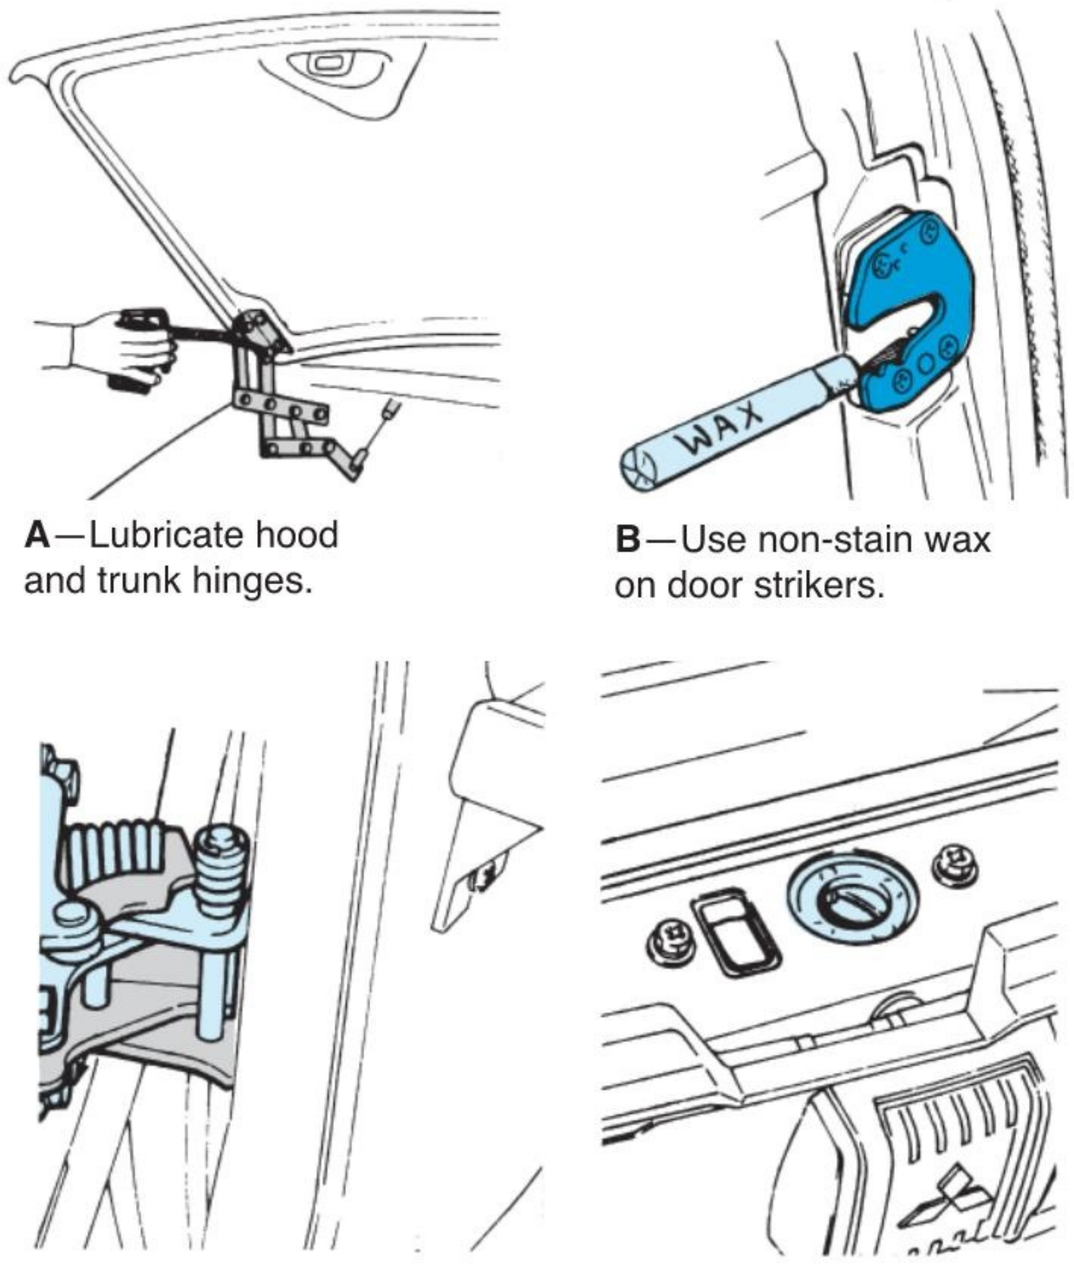
When doing any kind of lubrication service, protect the customer's vehicle from oil and grease damage. Use seat covers, paper floor mats, and fender covers to protect surfaces from oil and grease stains. A stained carpet or seat cover can be very expensive to replace!

Body Lubrication

When performing a complete chassis lubrication job, you should also lubricate high-friction points on the body (hinges and latches on doors, hood, and trunk). This will help prevent squeaking doors, sticking hinges, and wear problems.

Always use the prescribed lubricant. Normally, rubber and plastic parts will deteriorate if exposed to petroleum-based lubricants (oils and grease). Silicone lubricant should be used on plastic and rubber components. See **Figure 9-18**. The most common types of body lubricants are:

- ***Engine oil***—Engine oil is used on hard-to-reach high-friction points.
- ***Graphite***—Graphite is excellent for door and trunk locks. It will not collect dust and dirt, which could upset lock operation.
- ***Dry stick (wax) lubricant***—Dry stick lubricant is desirable on door latches and strikers (post that engages door latch). It will not stain clothing.
- ***Chassis grease***—Chassis grease is good all-around body lubricant. It can be used on easy-to-reach hinges and latches.
- ***Silicone lubricant***—Silicone lubricant often comes in a spray can. It is especially suited for rubber door weather stripping and windows. It is a dry lubricant that will not soil windows and clothing.



A—Lubricate hood and trunk hinges.

B—Use non-stain wax on door strikers.

C—Place a dab of grease on door hinges.

D—Lubricate the hood latch to prevent it from rusting.

Volvo

Figure 9-18. During lubrication service, lubricate body components to prevent squeaks and wear.

Checking Tires

Service Procedure

To check a vehicle's tires for safety:

1. Inspect the condition of the tire treads. Generally, all grooves in the tire should be at least 1/8" (3.2 mm) deep. If they are worn more than this, inform the shop foreman or vehicle owner. New tires are recommended to improve traction and prevent a dangerous tire failure or "tire blow out."
2. If tire tread wear is minimal, measure tire inflation pressure.
3. Remove the valve stem cap and press the tire gauge squarely over the valve stem.
4. Read and compare the air pressure indicated on the gauge with the vehicle manufacturer's inflation specifications, which are listed on

Copyright Goodheart-Willcox Co., Inc.

the sticker that is generally located in the door jamb or on the fuel filler door. The air pressure listed on the tire's sidewall is maximum pressure, not the pressure recommended by the vehicle manufacturer.

5. If the tire pressure is low, add air. If the pressure is high, press in on the valve core pin to release air from the tire.
6. Recheck tire pressure with your gauge until correct.
7. Reinstall the valve stem cap and repeat on the other three tires.

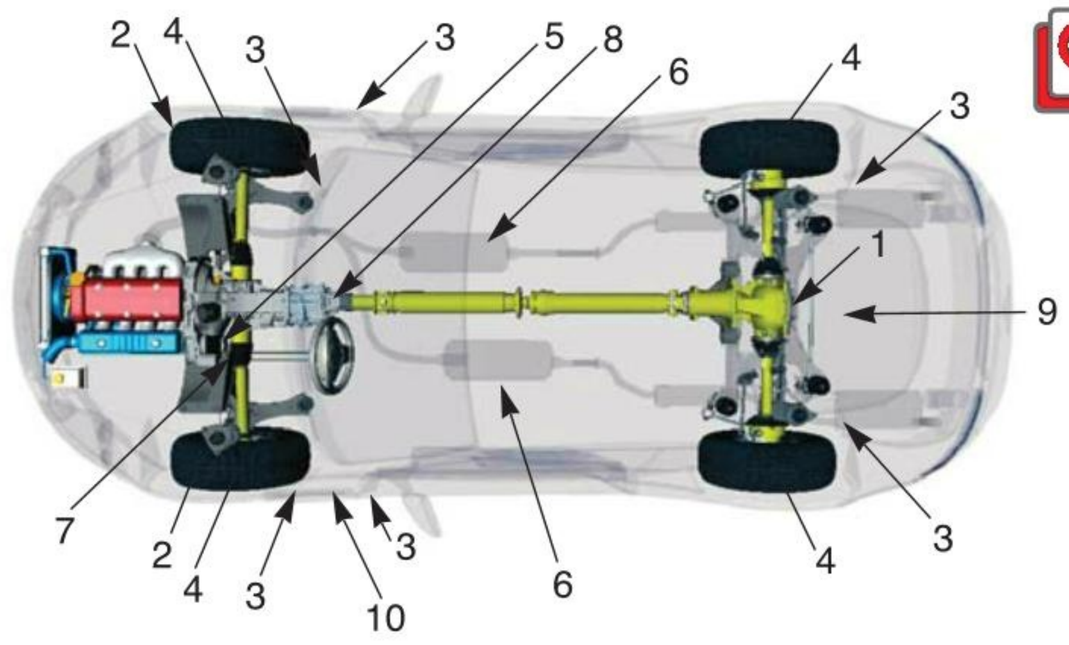
Tech Tip

Remember the tire inflation pressure on the sidewall is the maximum recommended pressure. The ideal tire pressure for the vehicle is given in the owner's manual. It can also be found on the sticker located on the door (B) pillar, door jamb, fuel filler door, deck lid, or other location. Ideal tire pressure depends on several variables, such as vehicle curb weight, suspension stiffness, and temperature.

Most tire manufacturers recommend a cold inflation pressure that is 1 psi (6.9 kPa) to 3 psi (21 kPa) below the maximum listed air pressure. This allows for tire heating, air expansion, and pressure increase without exceeding maximum pressure limits on the tire carcass.

Service Intervals

A service interval is the amount of time (in months) or the number of miles between recommended service checks or maintenance operations. The factory service manual will give exact intervals for the particular make, model, and year of vehicle. New vehicles tend to have longer intervals before service is required. Service manual recommendations for chassis maintenance vary slightly with the make of the vehicle. Note typical service intervals in **Figure 9-19**.



Component	Service	Interval
1. Axle differential		5000 mi (8 000 km)
		30,000 mi (48 000 km)
2. Bearings, front wheel	a.	30,000 mi (48 000 km)
3. Body lubrication	b.	15,000 mi (24 000 km)
4. Brake inspection	c.	15,000 mi (24 000 km)
5. Clutch lever		30,000 mi (48 000 km)
6. Exhaust system inspection	d.	15,000 mi (24 000 km)
7. Manual steering gear	e.	5000 mi (8 000 km)
8. Manual transmission	e.	5000 mi (8 000 km)
9. Spare tire	f.	7500 mi (12 000 km)
10. Stored service reminders	g.	15,000 mi (24 000 km)
		30,000 mi (48 000 km)

Goodheart-Willcox Publisher

Figure 9-19. Study the chassis maintenance information from a service manual. Recommendations for other parts of the car are also given.

Tech Tip

If a transmission has over 100,000 miles on it without a previous fluid change, the worst thing you can do is change the transmission fluid. The old transmission fluid is full of friction material that prevents band and clutch slippage. If you install "fresh slippery oil" in the worn automatic transmission, it will slip and fail quickly. You or the shop could be liable since the transmission worked fine before the fluid change.

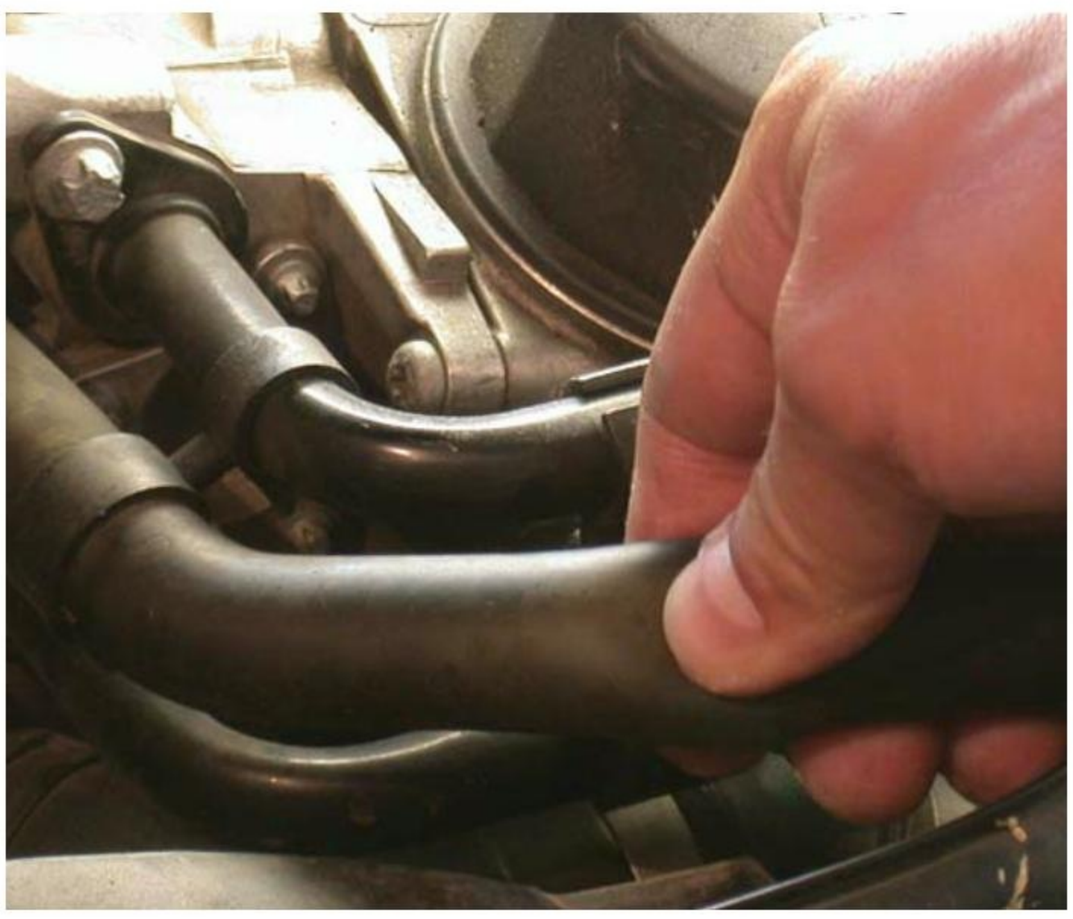
Copyright Goodheart-Willcox Co., Inc.

General Inspection and Problem Location

As you perform lubrication service or any kind of auto repair, always watch for mechanical problems. Visually inspect the vehicle for any signs of wear, deterioration, loose parts, or leaks. Check the condition of fan belts, water hoses, fuel hoses, vacuum hoses, and wiring. This can be done as you are working.

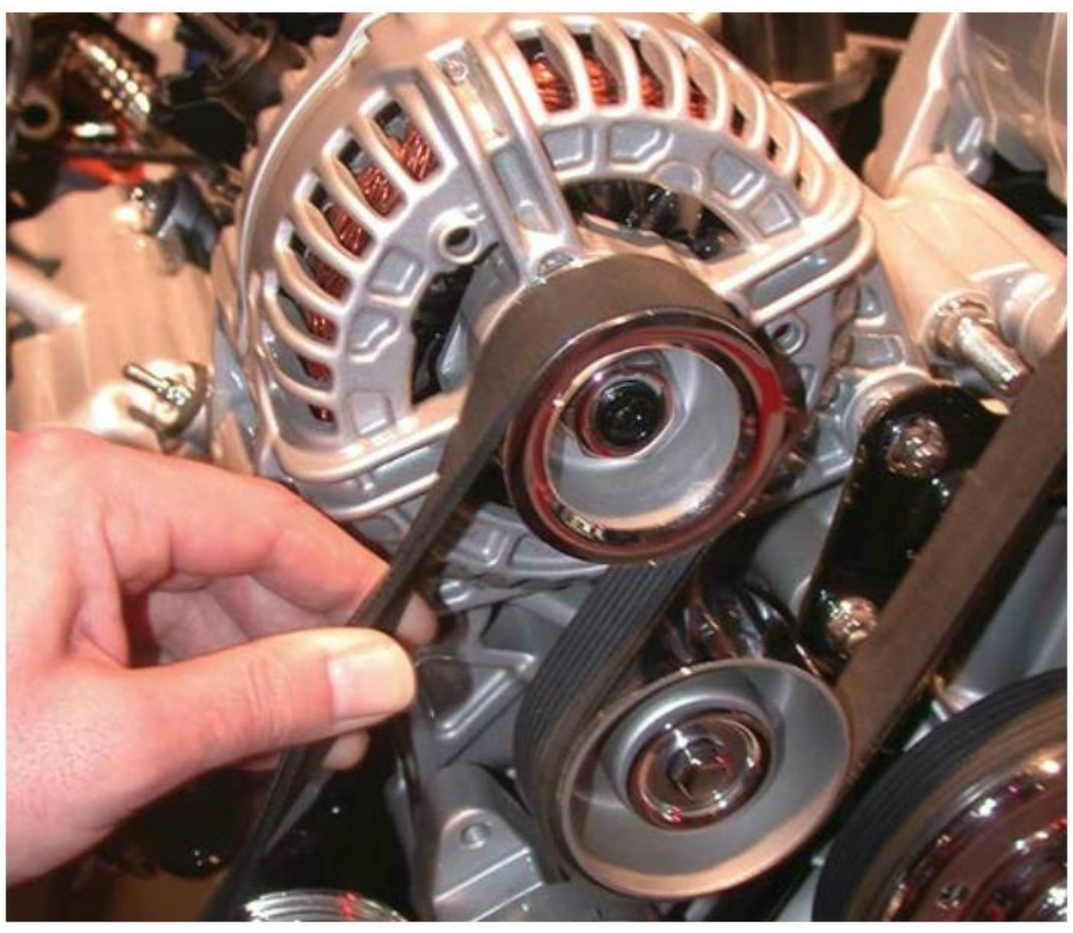
- ***Hose inspection***—This type of inspection includes checking for hardening, softening, cracking, splitting, or other signs of impending failure. Squeeze all the hoses. If the hoses are deteriorating (hard or soft), inform the customer or shop supervisor of the problem. See **Figure 9-20**.
- ***Drive belt inspection***—Drive belt inspection includes looking for splits, tears, cuts, and wear. If worn or wear hardened, the belt may slip and squeal. Refer to **Figure 9-21**.
- ***Wiring inspection***—This type of inspection involves looking for improper routing, cracked or brittle insulation, or other obvious problem signs. Make sure wires are away from all moving or hot parts.
- ***Tire inspection***—Tire inspection is performed by looking for excessive wear, improper inflation, or physical damage. Tire maintenance is very important from a safety standpoint. Badly worn tires can blow out, causing you to lose control of the vehicle and resulting in collisions, injuries, or even death.
- ***Steering system inspection***—Steering system inspection includes checking for excessive wear and play in moving parts. The steering wheel should not move more than about 1″ (25 mm) without causing front wheel movement. If it does, wear in the steering mechanism is indicated.
- ***Exhaust system inspection***—This type of inspection involves looking for damaged, rusted, or leaking parts. The exhaust system should be inspected any time a vehicle is raised on a lift. A leaking exhaust system can be very dangerous, as it may allow poisonous exhaust gases to enter the vehicle's passenger compartment. Look for rust holes in the pipes, muffler, and other parts.
- ***Brake inspection***—Brake inspection involves removing the wheels and tires so you can visually examine the brake pads and rotors. If they are damaged or worn, your shop should inform the customer of the need for brake repairs.

When working on a vehicle, be alert for these kinds of problems. This will show the shop supervisor and the customer that you are a concerned, competent technician.



Goodheart-Willcox Publisher

Figure 9-20. Check the condition of all hoses. Feel hoses for hardening or softening. Look for leaks during hose inspection.



Goodheart-Willcox Publisher

Figure 9-21. Inspect belts for glazing, cracking, and fraying. Most modern belts use a spring-loaded tensioner, so belt adjustment is no longer necessary.

Fluid Leaks

Fluid leaks result from bad gaskets, seals, or hoses; cracks in parts; and similar troubles. Leaks are very common problems that should be corrected. See **Figure 9-22**. To become good at leak detection and correction, you should:

- Become familiar with the *color*, *smell*, and *feel* (texture) of the different fluids. Then, you will be able to quickly identify a fluid leak. Does the fluid feel more like water or oil? Dab a white paper towel into a puddle of fluid to show its color more accurately. Oil will be slippery to the touch and will be dark brown or black if used for an extended period of time. If the fluid is clear or brown and feels "squeaky" when rubbed between your fingers, it is probably brake fluid or hydraulic clutch fluid. Antifreeze can be green, orange, or rust colored and will feel slick. Automatic transmission fluid can be dark brown, red, or dark green. Power steering fluid can be amber, red, or clear and will feel like transmission fluid.
- Fluid leaks tend to flow downward and to the rear of the vehicle. For this reason, look for leaks above and slightly in front of where you find fluid dripping off the vehicle.
- If multiple leaks are indicated, fix the leak located the highest and farthest forward on the vehicle. Then, repair other leaks.
- If the leaking part is badly soiled, clean the area thoroughly. Then it will be easier to see fresh fluid leaking out of the part.
- The most frequent cause of fluid leakage is broken gaskets and worn seals. Replacement will usually correct the problem. However, you should always check the parts for warpage, cracks, and dents.

Goodheart-Willcox Publisher

Figure 9-22. When working under a vehicle, always look for signs of fluid leakage and other obvious problems. Inspect rubber boots and hoses for signs of damage.

Noise Detection and Location

Abnormal noises are unwanted sounds that indicate part wear or other mechanical problems. They are common to almost all systems of a vehicle. When test-driving or idling the engine in the shop, listen for unusual sounds (knocks, clunks, rattles, clicks, and hisses). Locating the source of these sounds will help you identify problems that might not trip a trouble code.

A stethoscope (similar to that used by a doctor to listen to a patient's heart) is commonly used by an auto technician. It will help the technician pinpoint the source of internal part noises. To use the stethoscope, touch the probe on the component near the unwanted sound. Move the stethoscope around until the sound is the loudest, **Figure 9-23**.

A long screwdriver can be used in place of a stethoscope. Place the tip of the screwdriver on the part. Place the handle next to your ear. Sound will travel through the screwdriver and permit noise diagnosis. Make sure you keep the screwdriver away from moving parts or you could be injured.

A section of vacuum hose is a handy device for finding sounds not coming from internal parts. The hose is useful for locating hissing sounds, rattles, whines, and squeaks. Place one end of the hose to your ear. Then, move the other end around the area of the sound. When the sound becomes the loudest, you have pinpointed the problem. Again, keep the hose away from moving or hot parts. By removing the metal end from a stethoscope, you can also listen for these kinds of noises, especially hissing vacuum leaks.

B

Goodheart-Willcox Publisher

Figure 9-23. You must often listen to the sounds outside and inside an assembly to find the source of the problem. A—A stethoscope can be used to quickly find knocks and rattles inside components. Move the tip around on parts. When noise becomes the loudest, you have found the source of the problem. B—A piece of vacuum hose can be used like a stethoscope to find external noises. It will help you find vacuum leaks, squeaks, wind noise, and other abnormal sounds.

Recycling and Disposal of Auto Shop Wastes

Recycling and the proper disposal of auto shop wastes are needed to help save our planet's natural resources and reduce the amount of materials being sent to landfills. Laws have been passed that require specific procedures when handling and discarding potentially harmful materials.

Auto Shop Wastes

Automotive maintenance may generate hazardous wastes that come under the requirements of the Resource Conservation and Recovery Act. This federal act covers businesses that generate, transport, and manage hazardous wastes. Any business that maintains or repairs vehicles, heavy equipment, or farm equipment is classified as a vehicle maintenance facility by this act.

Vehicle maintenance fluid and solid wastes include:

- Used motor oil (can be combustible and may contain toxic chemicals).
- Other discarded lubricants, such as transmission and differential fluids (may contain toxic chemicals).
- Used parts.
- Cleaners and degreasers that are contaminated from parts-cleaning operations.
- Fuel injection system cleaners (flammable and may contain toxic chemicals).
- Rust removers (may contain strong acidic or alkaline solutions).
- Paint thinners or reducers (may be ignitable or contain toxic additives).
- Worn out batteries contain lead and sulfuric acid).
- Tires and catalytic converters.

Repair and maintenance facilities (service stations, automotive dealerships, independent auto repair shops, etc.) that generate 220 lb. (100 kg) of hazardous waste monthly must file a Uniform Hazardous Waste Manifest before removing the wastes. The manifest must list the proper Department of Transportation (DOT) shipping descriptions for a number of wastes. Tables listing these descriptions are available from each state's hazardous waste management agency or a regional EPA office.

Copyright Goodheart-Willcox Co., Inc.

However, EPA regulations also state that no manifest is needed for used oil or lead-acid batteries if they are sent for recycling. In such cases, the material is not regarded as hazardous. Your state may have its own requirements; check with your state hazardous waste management agency.

Unless recycled for scrap metal, used oil filters are considered hazardous waste. If not recycled, they must be listed on the monthly manifest as hazardous. Before disposal, filters should be gravity drained so they do not contain free-flowing oil. Store them uncrushed in a closed, labeled container for pickup by a recycler.

Recycling Motor Oil

Used motor oil is considered hazardous waste unless it is destined to be recycled. The old oil should be stored in an approved container for recycling. One gallon of used motor oil can be refined into two and one-half quarts of high-quality motor oil. It takes about 40 gallons of crude oil to produce this much motor oil. Recycling old oil not only saves our environment from pollution, but it also helps save our natural resources. Always send used motor oil to a recycling center! Put the oil in an approved container. Some recycling companies provide a pickup service, while others require you to take the old oil to their facility.

Recycling Coolants

Antifreeze has been classified as a hazardous waste due to heavy metal and chlorinated solvents that it picks up circulating through cooling systems. It should never be mixed with used oil. The entire mixture would then be classified as a hazardous waste, even though the used oil may not be, under federal regulations.

Regulations require that spent antifreeze solutions be collected by a registered hazardous waste hauler. Several major companies offer pickup and recycling services.

Recycling Refrigerants

Refrigerants, such as R-134a, removed from automotive air conditioning systems during servicing should not be vented to the atmosphere. State regulations require that refrigerants be recovered and recycled.

As you will learn in later chapters, systems are now available for recovering, cleaning, and recycling air conditioning refrigerants.

Other Automotive Recyclables

Other recyclable materials that are commonly removed from service during maintenance and repair of vehicles include:

- Catalytic converters, which contain platinum.
- Worn tires, which can be sold to a retreader company (if the carcass is sound) or to a shredder. Shredded rubber is an ingredient in road resurfacing materials and other products that give the rubber a second use.
- Batteries can be recycled and used to make new batteries. This prevents lead, acid, and other materials from adding to our waste disposal problems.
- Brake shoes can be recycled and sold as cores for making reconditioned brake shoes.
- Many small assemblies (alternators, starters, master cylinders, etc.) can be recycled and made into rebuilt assemblies.
- Plastic bumpers and other body parts can be recycled into a variety of new products.

Diagnostic Case Study

Concern: Ms. Jones brought her 2012 KIA in for repair because she noticed a puddle of fluid on her garage floor.

Cause: Duff, the shop owner, questions Ms. Jones to find out more about what is wrong with the vehicle. He asks her about unusual sounds and odors. He also asks if she knows approximately where the fluid is leaking from (front of engine, back of engine, right side, left side, etc.). Ms. Jones says the puddle seems to be coming from the left front corner of the vehicle and that she often hears a growling noise when driving around corners. After listening carefully to Ms. Jones, Duff suspects that the power steering system might be leaking and that the growling noise may be caused by air in the power steering system. Duff then turns the repair over to the shop's suspension and steering technician. Duff discusses the symptoms with her and tells her what he thinks the problem is.

Copyright Goodheart-Willcox Co., Inc.

The technician checks for dripping under the engine compartment and finds a small fresh puddle that looks and smells like power steering fluid. She then opens the hood and looks for the source of the leak. As she feels around the power steering pump and hoses, she finds a leak at the hose behind the power steering pump. She then starts the engine and uses a mirror to observe the fluid dripping from the crimped metal fitting on the hose.

Correction: The technician orders and installs a new power steering hose. She then fills the system with fluid, starts the engine, and rotates the steering wheel back-and-forth between the stops to purge air from the system. After test-driving the vehicle, she lets it run for approximately 15 minutes and then rechecks the system for leaks. After verifying that the problem has been corrected, the technician rechecks the power steering fluid level and releases the vehicle to the customer.

Summary

- Vehicle fluids include engine oil, coolant, brake fluid, transmission fluid, power steering fluid, and other liquids.
- Vehicle maintenance includes any operation that will keep a vehicle in good operating condition.
- A car's warranty can become void if improper fluids or incorrect service procedures or intervals are used.
- Be careful! Oil and other fluids at operating temperature can be hot enough to burn.
- EPA (Environmental Protection Agency) guidelines and state regulations affect how you must handle and dispose of used fluids, solvents, and other shop chemicals.
- Never remove a radiator cap while the engine or radiator is hot. Boiling coolant can spray out of the radiator, causing serious burns.
- Hold a shop rag around fuel line fittings when loosening. This will keep fuel from spraying or leaking out, preventing a possible explosion and fire.
- During a grease job, you must lubricate high-friction pivot points on the suspension, steering, and drive train systems.
- As you perform a lubrication job or any kind of auto repair, always watch for mechanical problems. Visually inspect the vehicle for any signs of wear, deterioration, loose parts, or leaks.
- A stethoscope (similar to that used by a doctor to listen to a patient's heart) is commonly used by a technician.
- A section of vacuum hose can be used as a handy device for finding sounds not coming from inside parts.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

brake inspection
chassis grease
chassis lubrication
drive belt inspection
dry stick (wax) lubricant
engine oil
exhaust system inspection
fluid leak
graphite
grease gun
grease job
hose inspection
lubrication service
oil foaming
silicone lubricant
steering system inspection
tire inspection
vehicle fluid
vehicle maintenance
wiring inspection

Activities

1. On a vehicle chosen by your instructor, determine the capacity of the cooling system. Then determine the amounts of water and antifreeze needed to produce a 50/50 mixture.
2. Survey the motor oils offered for sale at a local outlet. Determine the cost to change the motor oil in a vehicle. Add labor cost at $36/hour.
3. Change the oil and filter on a vehicle designated by your instructor.

Copyright Goodheart-Willcox Co., Inc.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List the six aspects of lubrication service.
2. _____ includes any operation that will keep the car in good operating condition.
3. When checking engine oil, allow the engine to cool completely. True or False?
4. What can happen when too much oil is added in an engine?
5. Which of the following should *not* be done when changing an engine's oil and filter?
   (A) Torque the drain plug only enough to prevent leaking and loosening.
   (B) Use an oil filter wrench to remove the old filter.
   (C) Wipe clean engine oil on the new filter O-ring seal.
   (D) Use an oil filter wrench to tighten the new oil filter.
6. The automatic transmission dipstick is normally located in front of the engine. True or False?
7. Check automatic transmission or transaxle fluid with the engine running. Check engine oil with the engine off. True or False?
8. Explain how to check the following:
   (A) Engine coolant level and condition.
   (B) Power steering fluid.
   (C) Brake fluid.
   (D) Manual steering fluid.
   (E) Battery condition.
9. A(n) _____ involves lubricating the steering, suspension, and drive train of a vehicle.
10. List and explain the use of five lubricants.
11. A(n) _____ is the amount of time between recommended service or maintenance operations.
12. Describe six general inspection points that should be checked during vehicle maintenance.
13. Which of the following should be done to help with leak detection and troubleshooting skills?
    (A) Become familiar with the color and smell of different fluids.
    (B) Trace the problem to the highest point of wetness or leakage.
    (C) Clean the area around the leak if the leak is difficult to isolate.
    (D) All of the above.
14. A(n) _____ is commonly used to find the source of noises inside parts.
15. List four automotive items that should be recycled.

ASE-Type Questions

1. During a complete lubrication service, all of the following are done *except:*
   (A) change engine oil.
   (B) change oil filter.
   (C) check all fluid levels.
   (D) check ride height.
2. During an oil change, Technician A says to use an oil filter wrench to remove the old oil filter. Technician B says to apply a little oil to the seal on the new filter to aid installation. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   D) Neither A nor B.
3. When changing engine oil, Technician A says the engine oil should be cool. Technician B says the oil should be warm. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. When checking automatic transmission fluid, the following should be done.
   (A) Engine off, transmission in park.
   (B) Engine running, transmission in park.
   (C) Engine off, transmission in neutral.
   (D) Engine on, transmission in neutral.

Copyright Goodheart-Willcox Co., Inc.

5. Engine coolant consists of:
   (A) water and antifreeze.
   (B) oil and antifreeze.
   (C) water and stop leak.
   (D) water only.
6. A vehicle with an automatic transaxle enters the shop with 150,000 miles on its odometer. Technician A tells the customer that she should change the transmission fluid. Technician B says this could be a big mistake because the loss of friction material in the old fluid could make the worn bands and clutches slip, stopping the car "dead in its tracks." Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

Chapter 10
Career Success

After studying this chapter, you will be able to:

- List the traits employers look for in their employees.
- Summarize the different systems used to pay technicians.
- Explain the types of repair facilities.
- Explain how to find job openings in the automotive field.

This chapter briefly covers factors that can determine your degree of success when employed as an automotive technician. There is more to being a good technician than just being able to work on vehicles. There are many simple things you can do to help you succeed in the auto repair shop.

Traits of Desirable Employees

There are several common traits that most employers look for in their employees. Good employees are dependable, cooperative, curious, efficient, professional, and honest. They are also good leaders and communicators. To be a successful technician, you should strive to excel in all these areas.

Dependability

Dependability is the capability to be relied on in the workplace. This trait is critical to career success. Failure to report to work on time, leaving early, or taking too many days off can have a detrimental effect on both your fellow technicians and your customers. The shop owner or service writer is responsible for scheduling repair work based on a certain number of technicians. If one or more technicians do not report to work, this schedule is useless and customers may have to wait for their vehicles longer than planned.

If customers are unhappy about being inconvenienced, they will not return to the shop. The technicians will have less work and the shop will not be as profitable. Everyone can suffer when a technician is constantly absent from or late for work. The number one reason technicians are fired is lack of dependability.

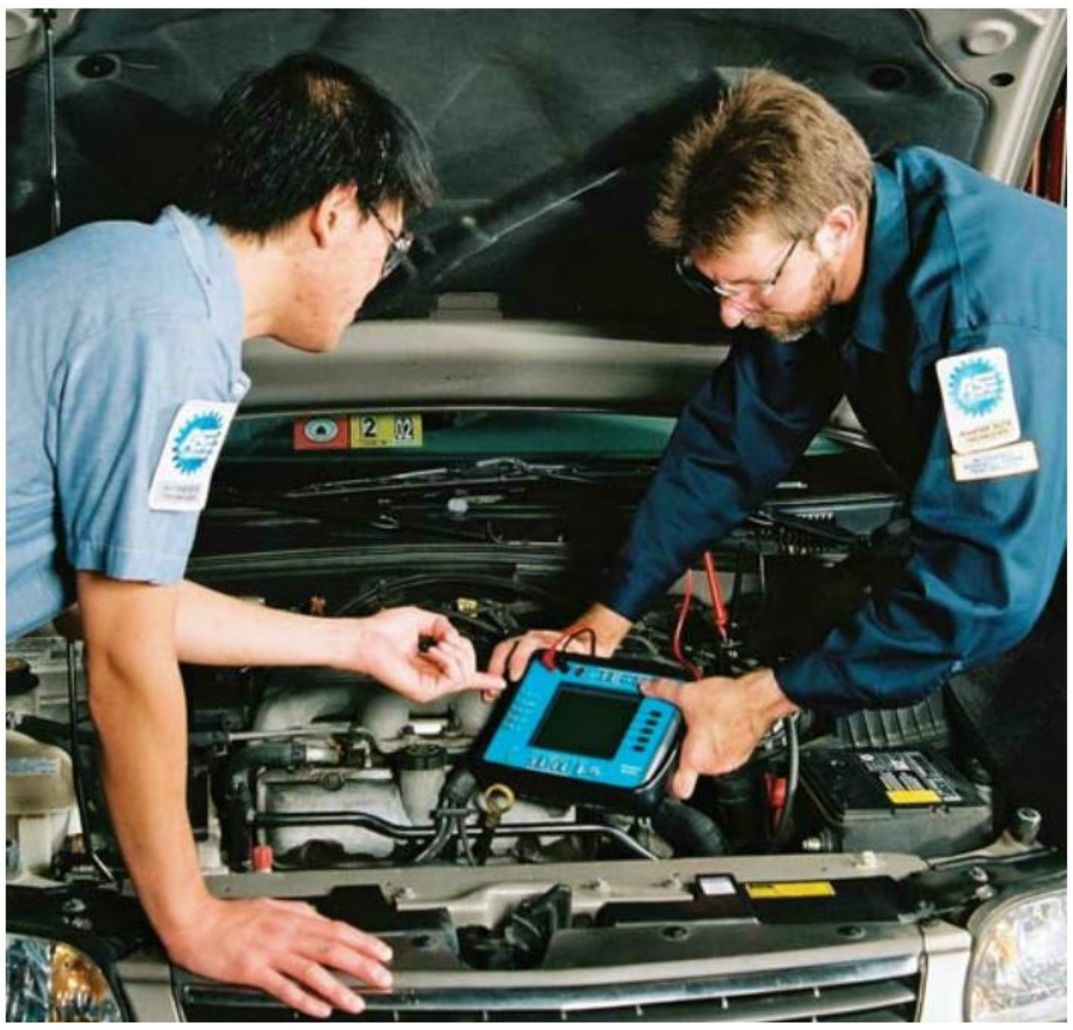
Copyright Goodheart-Willcox Co., Inc.

Cooperativeness and Initiative

Cooperativeness is the ability to work with others to achieve a goal. Technicians must cooperate with other employees in the shop. In other words, they must be able to work as part of a team. Cooperativeness also involves following directions. Failure to follow directions can lead to improper repairs and, in some cases, unsafe actions. Refer to **Figure 10-1.**

If technicians do not get along and do not cooperate, morale and work output suffer. There are times when employees and employers must negotiate on a task or work-related issue. Negotiation is the process of agreeing to an issue that requires all parties to give and take. The goal is a "win-win" solution in which both parties get some or all of what they are seeking. ***Negotiation*** begins with trying to understand the other party's interests. Possible solutions that meet their mutual concerns can be developed. Often the best solution becomes clear when both parties have ample time to explain what they are trying to accomplish.

Taking ***initiative*** means that you start activities on your own without being told. When you finish one task, you should not wait to hear what to do next. If you do not have a vehicle to work on, offer to assist another technician who is completing a job. He or she may be willing to return the favor at a later date. As a result, you will make more money and so will the other employees.



ASE

Figure 10-1. Automotive technicians sometimes work together when diagnosing difficult problems.

Leadership

Leadership is the ability to guide and motivate others to complete tasks or achieve goals. It involves communicating well with others, accepting responsibility, and making decisions with confidence. Leaders often seem to carry the most responsibility in a group. Other group members look to them for answers and direction.

The most important role of leaders is to keep the team advancing toward its goal. Leaders do this by inspiring their groups and providing the motivation to keep everyone working together. Good leaders encourage teamwork, because a team that is working well together is more likely to reach goals. Leaders also want to set a good example by doing a fair share of the work. In these ways, leaders cultivate a sense of harmony in the group.

Curiosity

Curiosity is the desire to learn. Automotive technology is changing at a frantic pace. To be successful in automotive repair, you must want to learn about new technologies and repair techniques.

To keep up with changes in technology, read service manuals, service bulletins, automotive magazines, and other literature. Continuing education is another way to stay abreast of new and changing engine technologies. Try to learn something new each day.

Efficiency

Efficiency is the ability of a technician to produce high quality work quickly. A primary concern of any engine technician, shop owner, or customer is work quality. Repairs must be done correctly following factory specifications.

It is tempting for a technician to work too fast in an attempt to make more money. This strategy usually backfires. When a technician works too quickly, comebacks increase. A ***comeback*** is a repair that must be done over because it was done incorrectly the first time. Comebacks are an indication of poor work quality.

When customers return unsatisfied with the repairs done to their vehicles, the technician must do the repairs again, this time without charging the customer. The technician loses money on lost work time, the shop owner loses money on wasted stall time, and the owner of the vehicle loses because the vehicle had to be returned to the shop.

While working too fast may lead to poor work quality, work speed is still very important to the automobile technician. For those working on a commission basis, income will depend on the amount of work completed each week.

Copyright Goodheart-Willcox Co., Inc.

To increase work speed without affecting work quality, constantly think about new methods to increase work efficiency. Consider a new tool or technique that will save time without lowering the quality of the repair. This kind of mental attitude will help you improve your skills. As a result, you will become more productive each day.

Professionalism

Professionalism involves presenting yourself in an appropriate manner in the workplace. You must always project a professional image. Your work clothes reflect your mechanical abilities and work attitudes. If you look dirty and sloppy, customers will suspect that your work may be less than desirable. See **Figure 10-2**.

In addition to a professional appearance, the technician must act professionally. Be courteous when addressing customers and other technicians.

Honesty

Employers demand that their employees be honest and ethical. ***Ethical behavior*** on the job means conforming to accepted standards of fairness and good conduct. It is based on a person's sense of what is right to do. Individuals and society as a whole regard ethical behavior as highly important. Integrity, confidentiality, and honesty are crucial aspects of ethical workplace behavior. Integrity is firmly following your moral beliefs.

For example, intentionally failing to install a couple hard-to-reach bolts is unethical and dishonest. It may cause the repair to fail prematurely, and you have not properly completed the repair the customer is paying for.

Most shops have a set of workplace policies that employees are expected to follow. For example, all shops support a drug-free workplace and many require their employees to have a clean driving record. Employees who do not comply with these policies may be disciplined or dismissed. In cases of criminal behavior, employees may lose their jobs and be arrested. If proven, the charge of criminal behavior stays on the employee's record. Such an employee will have a difficult time finding another job.

ASE

Figure 10-2. A technician must maintain a professional appearance. To your customers, your appearance reflects your abilities and attitudes.

Strong Communication Skills

Communicating effectively with others is important for success as an automotive technician. Being a good communicator means that you can share information well with customers and co-workers. It also means you are a good listener.

Good communication is central to a smooth operation of any business. Communication is the process of exchanging ideas, thoughts, or information. Poor communication is costly to an employer, as when time is lost because a work order was filled out incorrectly or the wrong parts were ordered. Poor communication can result in lost customers, too.

There are two primary forms of communication: verbal and nonverbal. Verbal communication includes writing, reading, speaking, and listening. You must be able to write clearly to describe symptoms and report repairs on work orders. You must be able to read and comprehend service information and procedures. You must be able to prepare and deliver effective oral presentations, such as service training, and speak clearly in casual conversation, as when describing a proposed repair to a customer. Listening is also an important part of verbal communication. If you do not understand something that is said, ask questions.

Nonverbal communication is the sending and receiving of messages without words. It includes facial expressions and body language. For example, leaning forward while a person is talking signals interest and keen listening. Slouching back in a chair and yawning give the opposite signal—that you are bored and uninterested.

Copyright Goodheart-Willcox Co., Inc.

The message you convey in telephone communication involves your promptness, tone of voice, and attitude. Answering the phone quickly with a pleasant tone conveys a positive image for the company. Learning to obtain accurate information from the caller without interrupting that person's message is important.

Communication tools have advanced with the development of new technologies. To be an effective employee, you must know how to communicate well with the common tools of your workplace. For example, when sending e-mail communications, remember to think through each message before sending it. Often, messages are sent quickly without thought of how the recipient may interpret them. The same is true of voice mail.

It is not uncommon to encounter customers from different cultures in the automotive repair shop. When communicating with non-native English speakers, do not assume that they fully understand you. Make sure your message is clear and to the point. Also, be aware that individuals from different cultures may have different business customs. Practices common in the U.S. are not necessarily accepted worldwide and may be interpreted as impolite or even offensive. For example, in some cultures, a firm handshake is considered rude.

Earnings

There are three basic methods shops use to pay their technicians. These are hourly rate, commission, and commission plus parts.

Hourly Rate

The ***hourly rate*** is simply a stated amount of pay given for each hour worked. This pay method may be desirable if you do not like the pressure of producing a specific quantity of work each week. However, you may make less money per year being paid an hourly rate than with other pay systems.

Commission

When you earn a ***commission***, you obtain a set percentage of the amount charged to the customers. For example, with a 50% commission on a $300 job, you would get $150 when the work is completed.

The flat-rate manual is a book that states how long each repair should take. If you are fairly quick and can match or beat the repair times listed in a flat-rate manual, you can earn a good wage. However, if you are slow or if there is not enough work to keep you busy, your income could be as low or lower than a technician paid an hourly rate.

Commission Plus Parts

Some technicians earn ***commission plus parts***. This is a variation of the commission system. In this pay system, a technician being paid on commission also receives a small commission for the parts installed during a repair.

Types of Shops

There are several different types of repair shops in which you can find employment. Each type of shop has advantages and disadvantages.

Dealerships

Large auto ***dealerships*** usually pay well and have a large volume of work to be done. Generally, dealerships also offer good benefits. In addition, since a dealership is aligned with a vehicle manufacturer, specialized training may be available for the types of vehicles you will be servicing. If you are fairly experienced and fast, a large dealership may be a good place to seek employment.

However, dealerships are required to perform warranty work. Warranty work consists of repairs done on vehicles that are still under warranty. The rate of pay for warranty work is considerably lower than that for customer-pay work. Refer to **Figure 10-3**.

Independent Shops

An ***independent shop*** is a service facility that is not affiliated with a vehicle manufacturer, retail store, or franchise operation. This type of shop can also be an excellent place to work. The pay is normally good and independent shops do not perform warranty work. The shop owner controls the work atmosphere and conditions for the technicians. If you want to work in an independent shop, locate a reputable shop that has plenty of volume to keep you busy. The shop should encourage ASE certification. Inquire about insurance and other benefits; many independent shops offer these.

Service Stations

A ***service station*** that has a repair area (not a gas station) may be an excellent place to work, especially

Copyright Goodheart-Willcox Co., Inc.

when you are a beginner. Much of the work will be quick service repairs that only take an hour or two. You will replace belts, hoses, water pumps, thermostats, tires, and other items. Many service stations offer a parts percentage incentive, which can increase your earnings. You can learn much about vehicle repair in a service station.

Specialty Shops

A ***specialty shop*** specializes in one type of work. Many specialty shops are franchise operations. The drawback to a specialty shop is a lack of variety.

An example of a specialty shop is a muffler shop. This type of shop will have specialized tubing benders and pipe cutting equipment for exhaust pipe fabrication. See **Figure 10-4**.

Getting a Job as an Automobile Technician

Normally, it is not difficult to find a job as an automobile technician. Job openings are available in service stations, specialty shops, independent shops, and large dealerships. You must match your training and experience to the openings available.

Preparing a Résumé

The first step in any job search should be to prepare a detailed résumé. A ***résumé*** is a document that summarizes your qualifications for a position. Even if employers do not require a résumé, preparing this document will help you assess your qualifications for the types of jobs you are seeking. It will also help you review your skills in preparation for interviews with potential employers.

The résumé should include your contact information (name, address, phone number, and e-mail address), an objective identifying the type of job you are seeking, and a summary of your education, skills, and work experience.

Be sure to include the names and telephone numbers of two or three people who can provide a recommendation. Examples of good references include previous employers, supervisors, or instructors. A sample résumé is given in **Figure 10-5**.

The Internet is a good resource of information to help you develop an effective résumé. Public libraries have many references available to assist in résumé preparation. There are also computer software packages designed for writing a résumé.

Job Application Forms

A prospective employer may ask you to complete a job application form before having an interview. The job application form highlights the information the employer needs to know about you, your education, and your prior work experience. Employers often use these forms to screen applicants for the skills needed on the job. You might complete a form in a personnel or employment office. Sometimes you may get the form by mail.

Goodheart-Willcox Publisher

Figure 10-3. Automobile dealerships provide many opportunities for competent technicians.

Pat Johnson
1407 W. Gasoline Alley
Speedway, IN 12345
pjohnson@speedy.net
Phone: 1-317-555-3272, Cell: 1-317-555-4094

Objective

To obtain a challenging position utilizing my training and experience in automotive technology.

Education

Allied Technical College—Indianapolis, IN
- Associate's Degree in Automotive Technology
  - Specialized in Advanced Automotive Diagnostics

Speedway High School—Speedway, IN
- Graduated with Academic Honors
- Two years of automotive technology instruction

Experience

July 2012–Present
Spritle's Auto Repair, Indianapolis, IN—Apprentice Service Technician
- Performed oil changes and chassis lubrication
- Serviced cooling systems
- Performed brake jobs
- Serviced air conditioning systems

September 2010–July 2012
Ray's Motors, Speedway, IN—Helper, Detailer
- Detailed vehicles that were sold on used car lot
- Performed minor vehicle repairs
- Attended automobile auctions
- Performed lot and office maintenance

References:

Figure 10-5. A résumé should provide potential employers with a summary of your qualifications.

The appearance of the application form can give an employer the first opinion about you. Fill out the form accurately, completely, and neatly. How well you accomplish that can determine whether you get the job. When asked about salary, write open or negotiable. This means you are willing to consider offers.

Finding Job Openings

You may want to begin your job search by looking through the help-wanted ads in your local newspaper. If you are a student, ask your automotive instructors if they know of any job openings. Often, local repair facilities will contact instructors when looking for new employees.

Copyright Goodheart-Willcox Co., Inc.

You can also search the Internet for leads. This is especially helpful if you plan to relocate to a new city. Visit websites that post job opportunities and allow you to post your résumé. See **Figure 10-6**. You can also use social networking sites, such as www.linkedin.com, to connect with prospective employers.

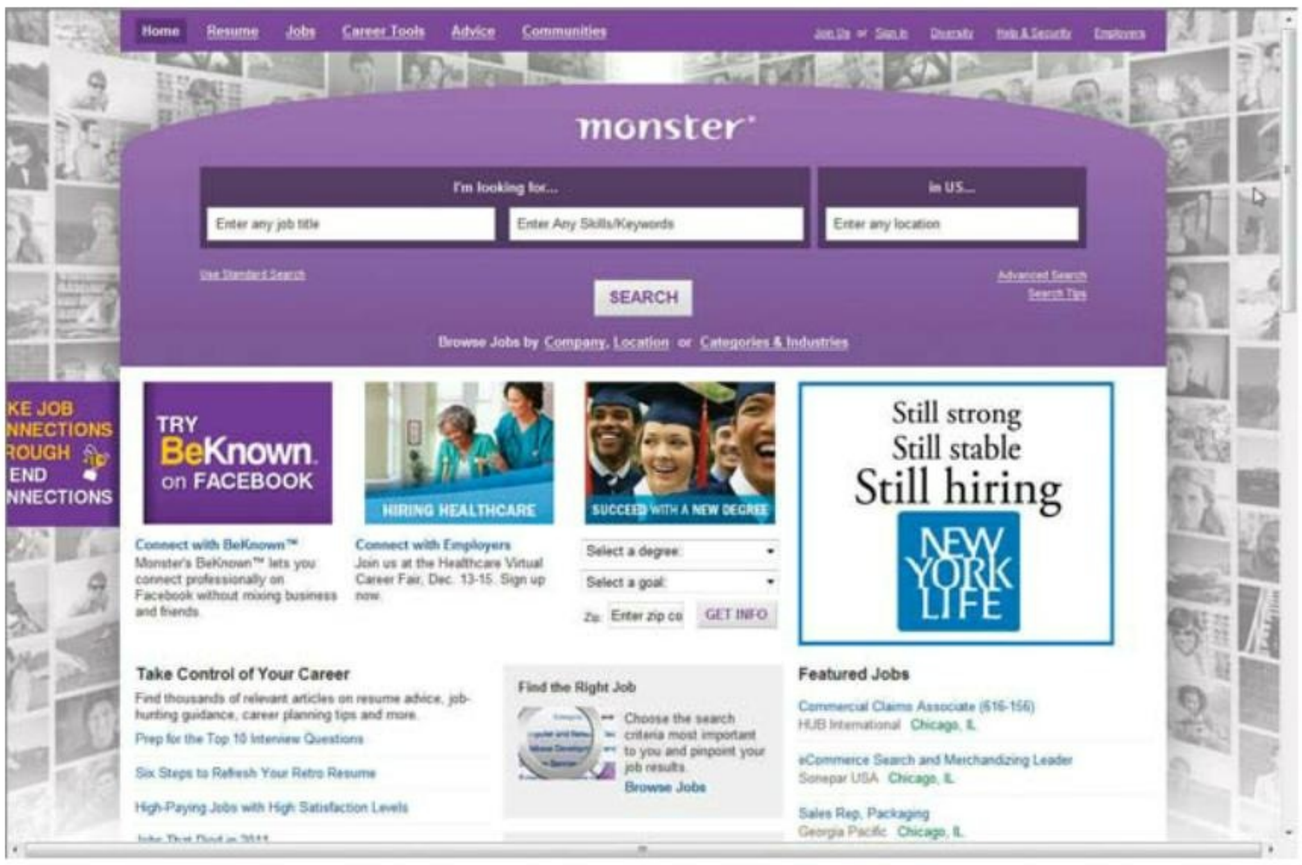
State and local governments operate employment agencies that can help you identify job openings. Check the local telephone directory to locate the agency in your area. Private employment agencies are also an option. However, do not enter into a contract with a private agency until you fully understand the services they provide and the fees they charge. Also, make sure the agency works with employers offering the types of jobs you are seeking.

If you cannot find job openings, look in the yellow pages of your local phone book. Instead of calling, go to each shop or garage. Ask if you can fill out an application. Then, even if there are no openings at that time, you will be on record if the shop needs someone to fill a position. When going to shops to apply for a position, take your résumé with you. At the very least, it will help you fill out any application required by the potential employer. In many cases, you can leave a copy of your résumé with the completed employment application. When visiting shops, dress appropriately. If you look and talk like a professional, your chances of getting a job will increase tremendously.

Interviewing

In some cases, a potential employer will ask you to come in for an interview. An ***interview*** is a meeting between a job candidate and an employer that allows the employer to more thoroughly evaluate the candidate's qualifications. It also gives the candidate the opportunity to ask questions about the job opening.

Be sure to arrive at the interview site a few minutes early. This will indicate that you are a punctual person. If necessary, drive to the interview site the day before the scheduled interview so you know how long it will take to get there. Dress neatly for the interview. This shows your professionalism. During the interview, sit upright in the chair, and talk slowly and plainly. Maintain eye contact with the person asking the questions and answer all questions thoroughly and honestly. Don't be afraid to ask questions about the job opening or to emphasize your qualifications. However, do not brag or act like you know everything there is to know about automotive technology. A good technician is willing to continue his or her education, even on the job. If you have passed ASE certification tests, be sure to mention this during the interview. At the conclusion of your interview, thank the interviewer for taking the time to meet with you. It is a good idea to send a follow-up letter thanking the interviewer for the opportunity to interview and offering to answer any additional questions that may arise. Be sure to include your contact information on the follow-up letter.



Goodheart-Willcox Publisher

Figure 10-6. Visit various websites to search for jobs in your area and to post your résumé.

Copyright Goodheart-Willcox Co., Inc.

Accepting an Offer of Employment

If you are offered a job, make sure you know the terms of employment before accepting. Ask about the work hours, responsibilities, wages, benefits, and company policies. In many cases, you will be expected to provide your own tools. In other instances, tools will be provided for you. Before accepting a job, ask the potential employer when you would be expected to start work. Once you have worked out all the details and are comfortable with the terms of employment, you can formally accept the employment offer.

Workplace Skills

When applying for a position at an automotive shop, be sure to submit a resume, even if it is not required. It will give your prospective employer information about your qualifications, such as your education and work experience. For the interview, be sure to dress appropriately and have a positive attitude. Remember that the employer is looking not only at what you know, but also at your potential for learning on the job.

- In the commission plus parts pay system, a technician is paid on commission but also receives a small commission for the parts installed during a repair.
- Large auto dealerships usually pay well and have a large volume of work to be done. They also offer good benefits and specialized training for the types of vehicles you will be servicing.
- Warranty work consists of repairs done on vehicles that are still under warranty. The rate of pay for warranty work is considerably lower than that for customer-pay work.
- A specialty shop specializes in one type of work. For example, engine machine shops will rebuild or overhaul engines.
- The first step in getting any job should be to prepare a detailed resume.
- A good way to begin your job search is to look through the help-wanted ads in your local newspaper or at various job-related websites. Additionally, state and local governments operate employment agencies that can help you identify job openings.
- If you are offered a job, make sure you know the terms of employment before accepting.

Summary

- Good employees are dependable, cooperative, curious, efficient, and professional.
- Failure to report to work on time, leaving early, or taking too many days off can have a detrimental effect on both your fellow technicians and your customers.
- All employees should work together to make the service facility a safe, enjoyable, and efficient operation.
- Efficiency is the ability of a technician to produce high quality work quickly.
- An hourly rate is a stated amount of pay given for each hour worked.
- When you earn a commission, you obtain a percentage of the flat rate charged to the customers.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

comeback
commission
commission plus parts
cooperativeness
curiosity
dealership
dependability
efficiency
ethical behavior
hourly rate
independent shop
initiative
interview
leadership
negotiation
professionalism
résumé
service station
specialty shop

Copyright Goodheart-Willcox Co., Inc.

Activities

1. Write a résumé and have your instructor review it.
2. Schedule a visit to a local garage. Ask permission to watch the workers do their jobs. Write a report on what you observed.
3. Do a practice interview with a friend or relative.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Briefly explain why *dependability* is important to career success.
2. Why is it important to be able to work cooperatively with other technicians?
3. Why is *leadership* an important trait in a technician?
4. Name three crucial aspects of ethical workplace behavior.
5. What issues should be taken into consideration when communicating with customers from different cultures?
6. Explain three ways in which you can be paid as an engine technician.
7. This would be used to determine how long a specific repair should take.
   (A) Service manual.
   (B) Service bulletin.
   (C) Commission manual.
   (D) Flat-rate manual.
8. A(n) _____ shop performs one type of work.
9. What information should be contained in a résumé?
10. What is the purpose of an interview?

ASE-Type Questions

1. The number one reason a technician is usually fired is due to lack of _____.
   (A) mechanical skills
   (B) dependability
   (C) education
   (D) productivity
2. Which of the following determine(s) the success of a technician?
   (A) Efficiency.
   (B) Dependability.
   (C) Professionalism.
   (D) All of the above.
3. Technician A says that some shops pay their technicians on an hourly rate basis. Technician B says that some shops pay their technicians on a commission basis. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Which of the following is typical of the work normally performed at a service station?
   (A) Water pump replacement.
   (B) Serpentine belt replacement.
   (C) Thermostat replacement.
   (D) All of the above.
5. Technician A says you should arrive at an interview a little early to show that you are punctual. Technician B says that you should never ask questions of a potential employer during an interview. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Engine Technology

Chapter 11
Engine Fundamentals

Chapter 12
Engine Design Classifications

Chapter 13
Engine Top End Construction

Chapter 14
Engine Bottom End Construction

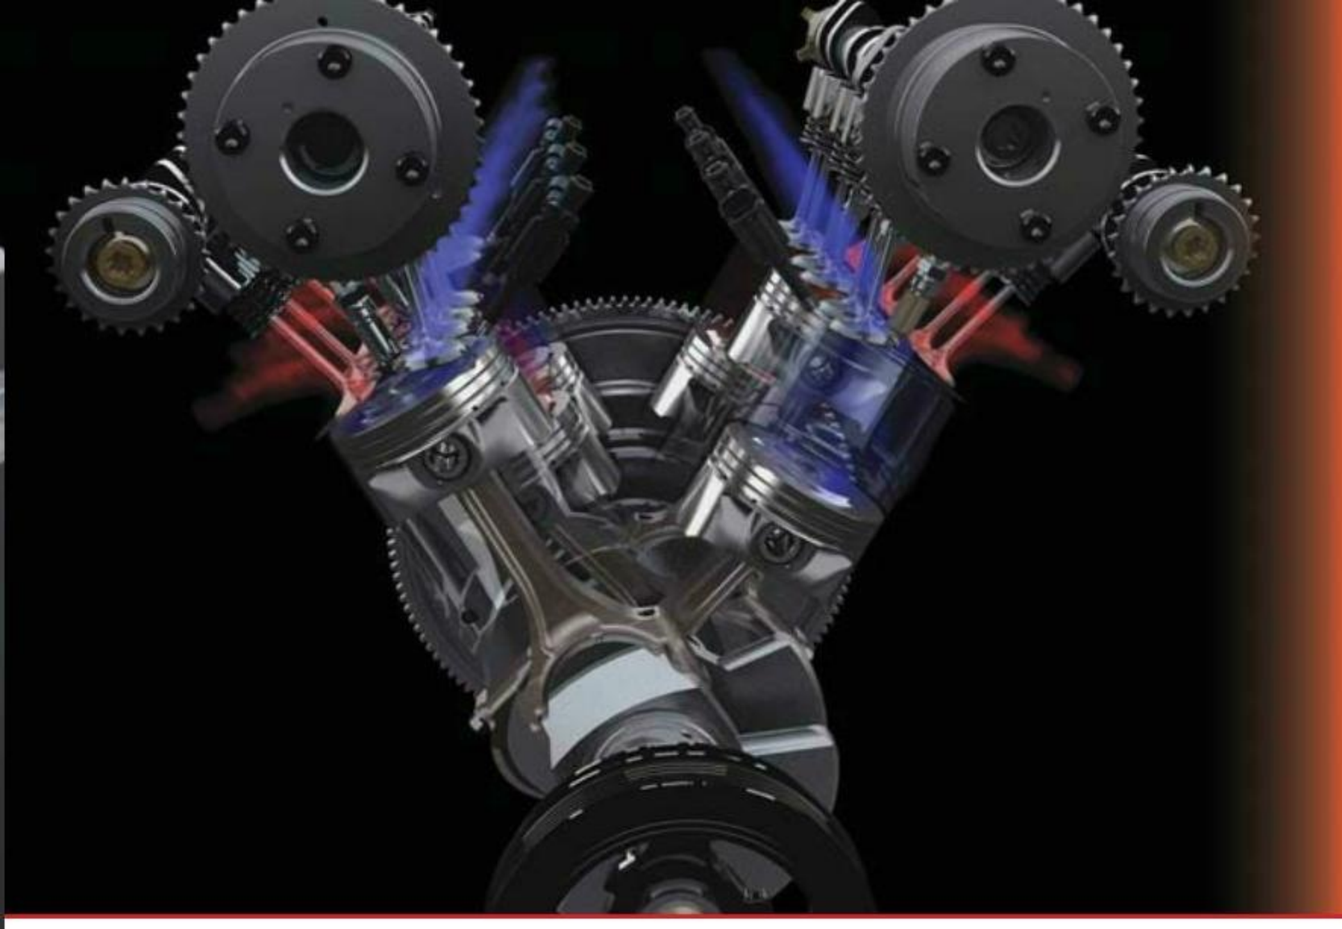
Chapter 15
Engine Front End Construction

Chapter 16
Engine Size and Performance Measurements

The engine is the "power plant" that produces the energy needed to propel the vehicle and operate other systems. It converts the heat energy of a fuel (gasoline, diesel oil, alcohol, etc.) into movement. If you know how an engine is constructed and how it is designed to operate, you will be better prepared to diagnose problems when it malfunctions.

Section 2 details the construction and operation of late-model automotive engines. It explains the four-stroke cycle, describes the function and location of major engine parts, details engine design variations, and summarizes engine size and performance measurements.

The information presented in this section will help you pass ASE Test A1, Engine Repair, and will also help you prepare for later chapters on engine diagnosis, service, and repair.



Chapter 11
Engine Fundamentals

After studying this chapter, you will be able to:

- Identify the major parts of a typical automotive engine.
- Describe the four-stroke cycle.
- Define common engine terms.
- Explain the basic function of the major parts of an automotive engine.
- Cite and demonstrate safe working practices related to engines.
- Correctly answer ASE certification test questions that require knowledge of the basic operation of piston engines.

In the first chapter, you learned a little about how an engine operates. This chapter will build on that information by explaining each engine part in more detail. It will help you understand the information on engine types, engine construction, engine diagnostics, and engine service, presented in later chapters.

Engine Operation

The ***engine*** is the source of power for the vehicle. For this reason, it is sometimes called a power plant. An energy source, or ***fuel*** (usually gasoline, gas/alcohol mix, or diesel oil), is burned inside the engine's ***combustion chamber*** (hollow area between the top of the piston and the bottom of the cylinder head). This burning, or combustion, produces heat. The heat causes ***expansion*** (enlargement) of the gases in the engine.

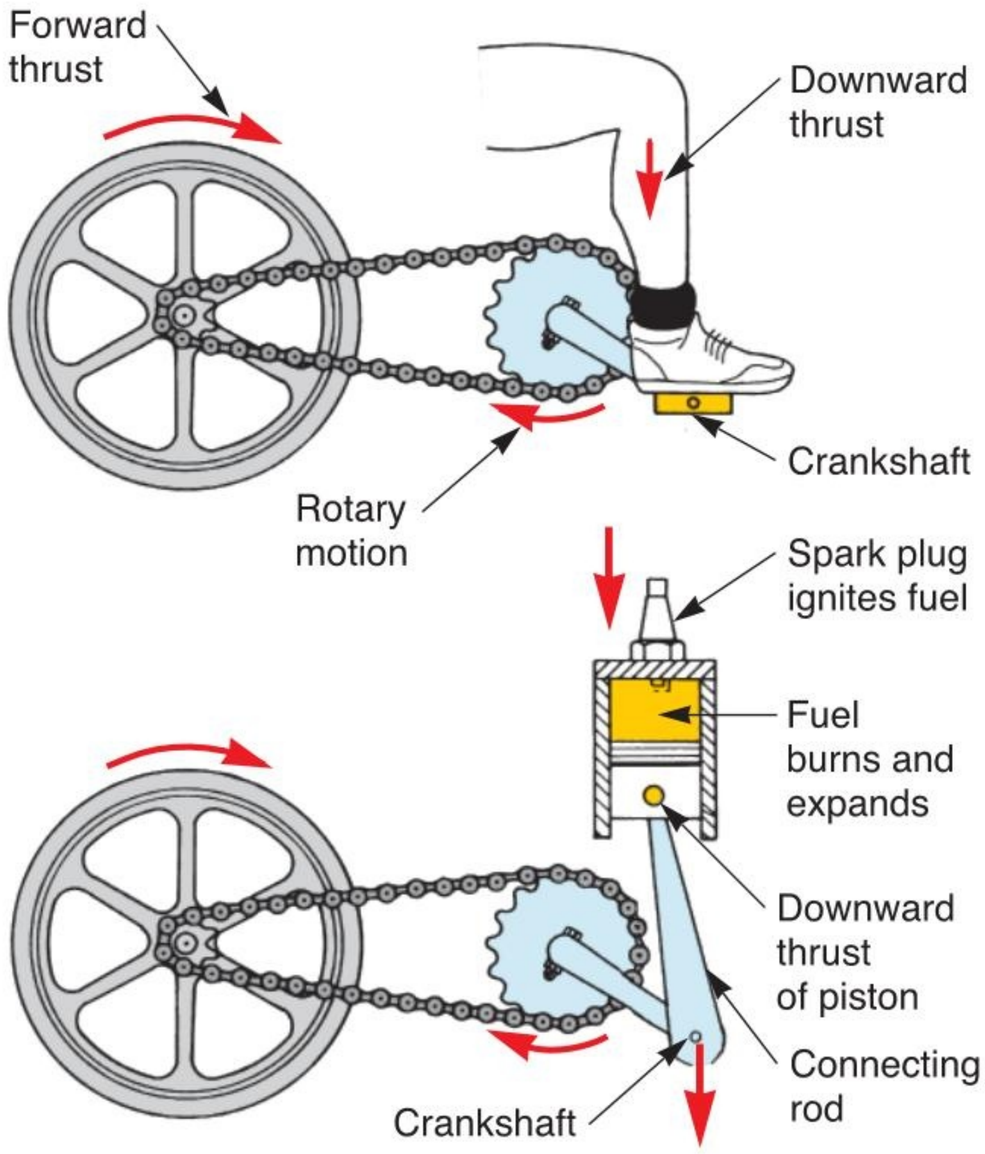
The burning and expansion of the gases in the combustion chamber produces pressure. The engine piston, connecting rod, and crankshaft convert this pressure into motion for moving the car and operating its other systems. See **Figure 11-1**.

Combustion pressure forces the piston down. By linking the piston to the crankshaft, an engine can produce a powerful rotating motion. The rotating crankshaft can be used to drive gears, chains and sprockets; belts and sprockets; and other drive mechanisms.

Piston Travel (TDC, BDC)

The distance the piston can travel up or down in the cylinder is limited by the crankshaft. When the piston is at the *highest point* in the cylinder, it is at ***top dead center (TDC)***. When the piston slides to its *lowest point* in the cylinder, it is at ***bottom dead center (BDC)***.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

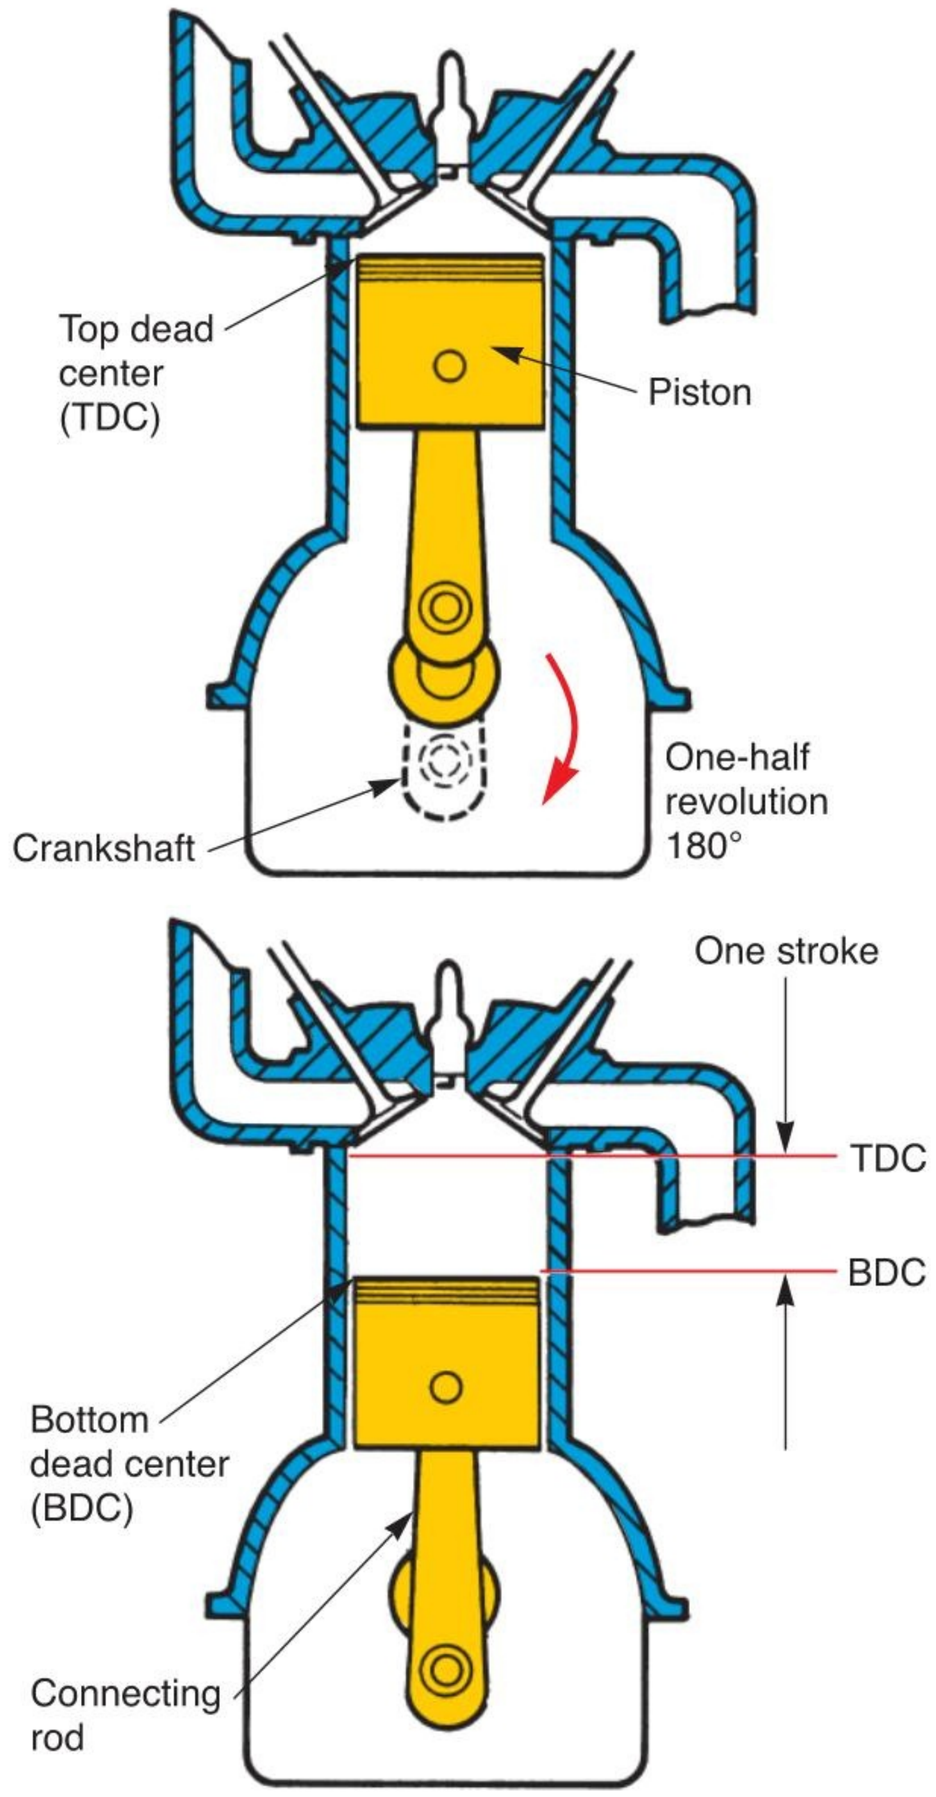
Figure 11-1. A crankshaft converts the downward thrust of the piston into useful rotating motion. The rotating motion can be used to operate the drive mechanism.

Piston stroke is the distance the piston slides up or down from TDC to BDC. The crankshaft rotates 180° (one-half turn) during one piston stroke. Refer to **Figure 11-2**.

Four-Stroke Cycle

The ***four-stroke cycle*** requires four piston strokes to complete one cycle (complete series of events). Every four strokes, the engine produces one power stroke (useful energy). Almost all automobiles use four-stroke-cycle engines.

The ***intake stroke*** of a direct injection engine draws air into the combustion chamber. During this stroke, the intake valve is open and the exhaust valve is closed. The piston slides down and forms a low-pressure area, or vacuum, in the cylinder. Atmospheric pressure then pushes the air past the open intake valve and down into the cylinder. Fuel is often injected into the cylinder during the intake stroke.



Ford

Figure 11-2. TDC means the piston is at the top of its stroke. BDC means the piston is at the bottom of its stroke. A stroke is one piston movement.

Tech Tip

Many engines still use multiport fuel injection systems. In these engines, fuel is injected into the intake manifold rather than into the cylinder. Therefore, the engine must pull both air and fuel into the combustion chamber during the intake stroke.

Copyright Goodheart-Willcox Co., Inc.

During the ***compression stroke,*** the piston slides up with both valves closed. This squeezes the air-fuel mixture to prepare it for combustion (burning). The air-fuel mixture becomes hotter when pressurized.

Tech Tip

Injection timing in a direct gasoline injection engine depends on operating conditions. During moderate or heavy load operation, fuel is injected during the intake stroke. Under light load conditions, fuel is injected during the compression stroke. This will be covered in detail in later chapters.

During the ***power stroke***, the air-fuel mixture burns and pushes the piston down with tremendous force. This is the only stroke that does not consume energy—it produces energy. When the spark plug fires (gasoline engine), it ignites the air-fuel mixture. Since both valves are still closed, pressure forms on the top of the piston. The piston is forced down, spinning the crankshaft.

The ***exhaust stroke*** removes the burned gases from the engine and readies the cylinder for a fresh charge of air and fuel. During this stroke, the piston moves up. The intake valve is closed and the exhaust valve is open. The burned gases are pushed out the exhaust port and into the exhaust system.

The crankshaft must rotate two complete revolutions to complete the four-stroke cycle. With the engine running, this series of events happens over and over very quickly. Look at **Figure 11-3**.

Engine Bottom End

The term ***engine bottom end*** generally refers to the block, crankshaft, connecting rods, pistons, and related components. Another name for engine bottom end is the short block. It is an assembled engine block with the cylinder heads, intake manifold, exhaust manifold, and other external parts removed.

Engine Block

The ***engine block***, also called cylinder block, forms the main body of the engine. Other parts bolt to or fit inside the block. Refer to **Figure 11-4**.

The ***cylinders***, also known as the cylinder bores, are large, round holes machined through the block from top to bottom. The ***pistons*** fit into the cylinders. The cylinders are slightly larger than the pistons. This lets the pistons slide up and down freely.

The ***deck***, or deck surface, is the top of the block surrounding the cylinders. It is machined perfectly flat. The cylinder head bolts to the deck. Oil and coolant passages through the deck surface allow lubrication and cooling of the cylinder head parts.

Water jackets are coolant passages through the block. They allow a solution of water and antifreeze to cool the cylinders.

Core plugs, or freeze plugs, are round, metal plugs on the outside of the block. They seal holes left in the block after casting (manufacturing in a foundry). The plugs prevent coolant leakage out of the water jackets. Some new engines do not have freeze plugs.

The ***main bearing bores*** are holes machined in the bottom of the block to hold the crankshaft. Removable ***bearing inserts*** fit into these bores.

Main caps bolt to the bottom of the block and hold the crankshaft and main bearing inserts in place. Two or four large bolts normally secure each cap to the block. The caps and the block together form the main bearing bores.

An ***engine bedplate*** is a large metal girdle that replaces all the main bearing caps. It is a large, one-piece casting that has the lower half of the main bores machined into it to accept the main bearing inserts. A bedplate strengthens the bottom of the block, allowing the engine to develop more power without bearing failure.

The crankcase is the lowest portion of the block. The crankshaft rotates inside the crankcase.

Crankshaft

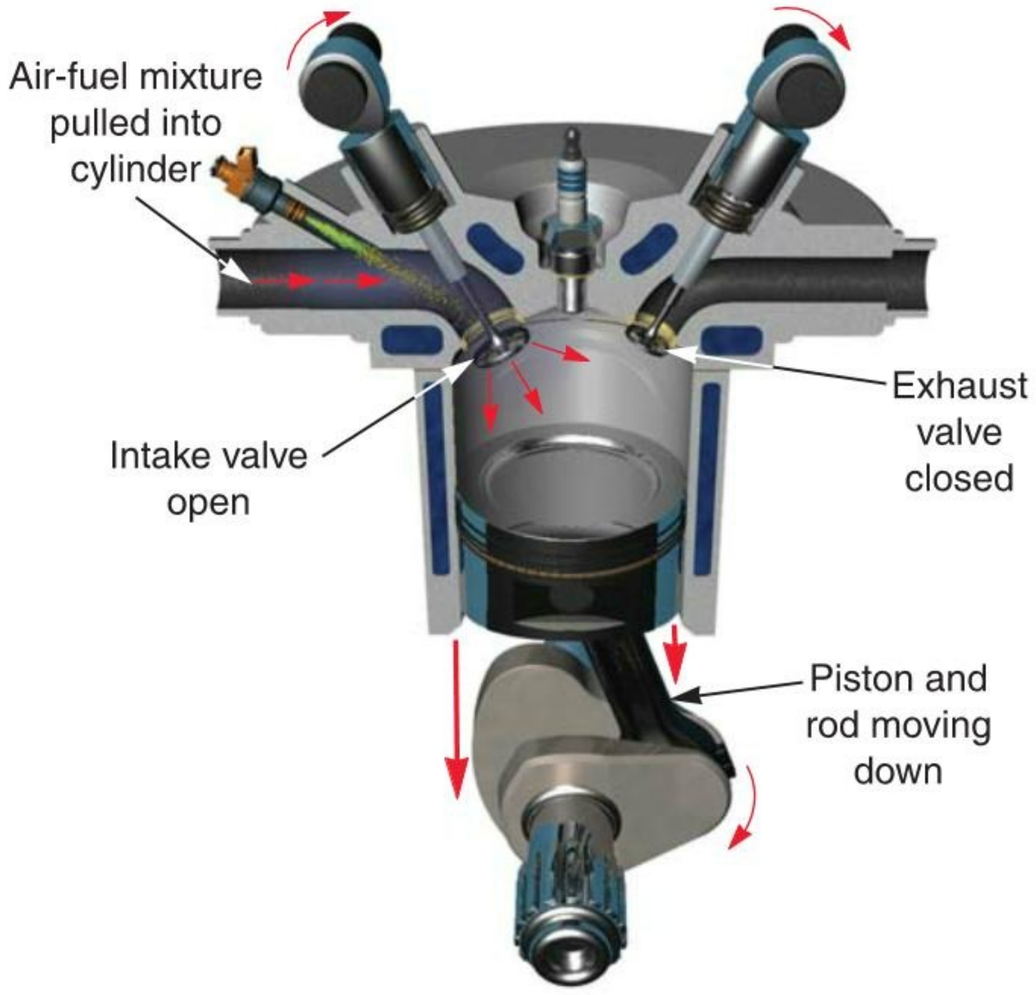
The ***crankshaft*** harnesses the tremendous force produced by the downward thrust of the pistons. It changes the up-and-down motion of the pistons into a rotating motion. The crankshaft fits into the bottom of the engine block.

The crankshaft main journals are surfaces that are precisely machined and polished. They fit into the block's main bearings.

The crankshaft rod journals are also machined and polished surfaces, but they are offset from the main journals. The connecting rods bolt to the rod journals. With the engine running, the rod journals revolve around the centerline of the crankshaft, **Figure 11-5**.

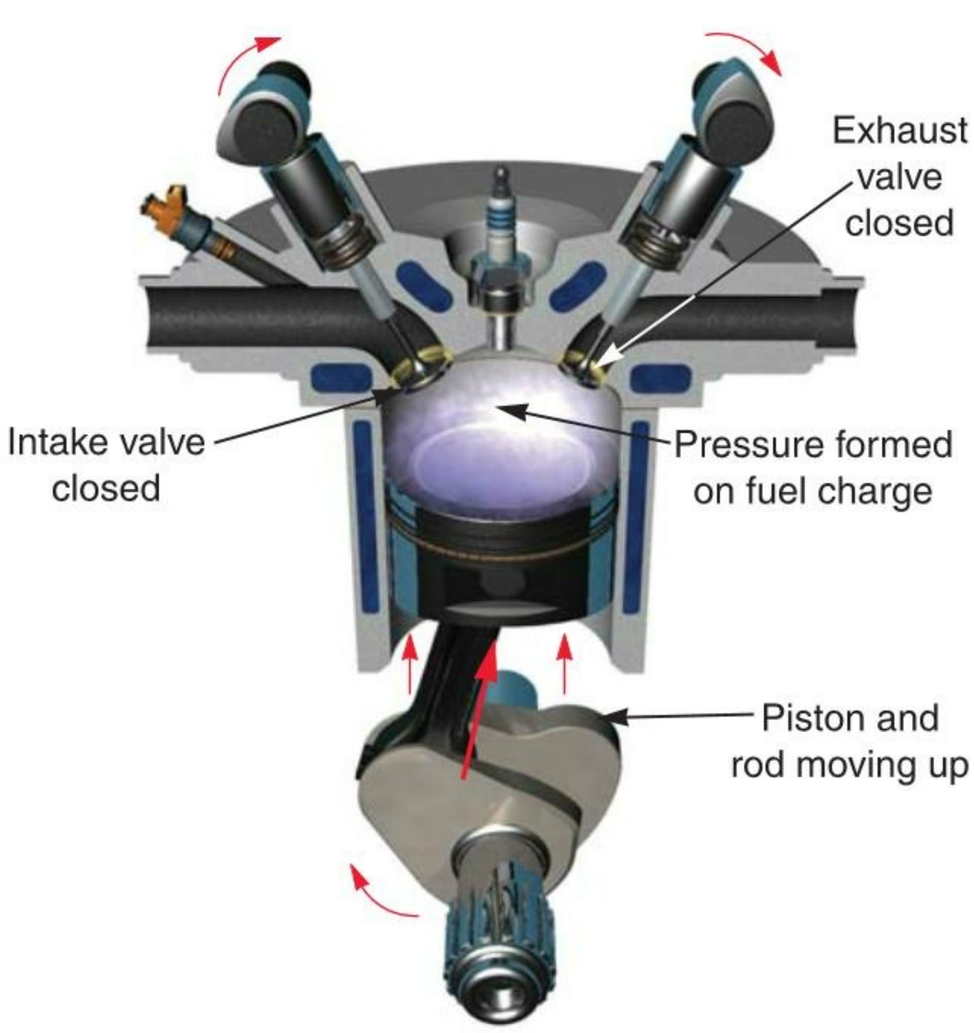
Counterweights are formed on the crankshaft to prevent vibration. These weights counteract the weight of the connecting rods, pistons, rings, and rod journal offset.

Copyright Goodheart-Willcox Co., Inc.



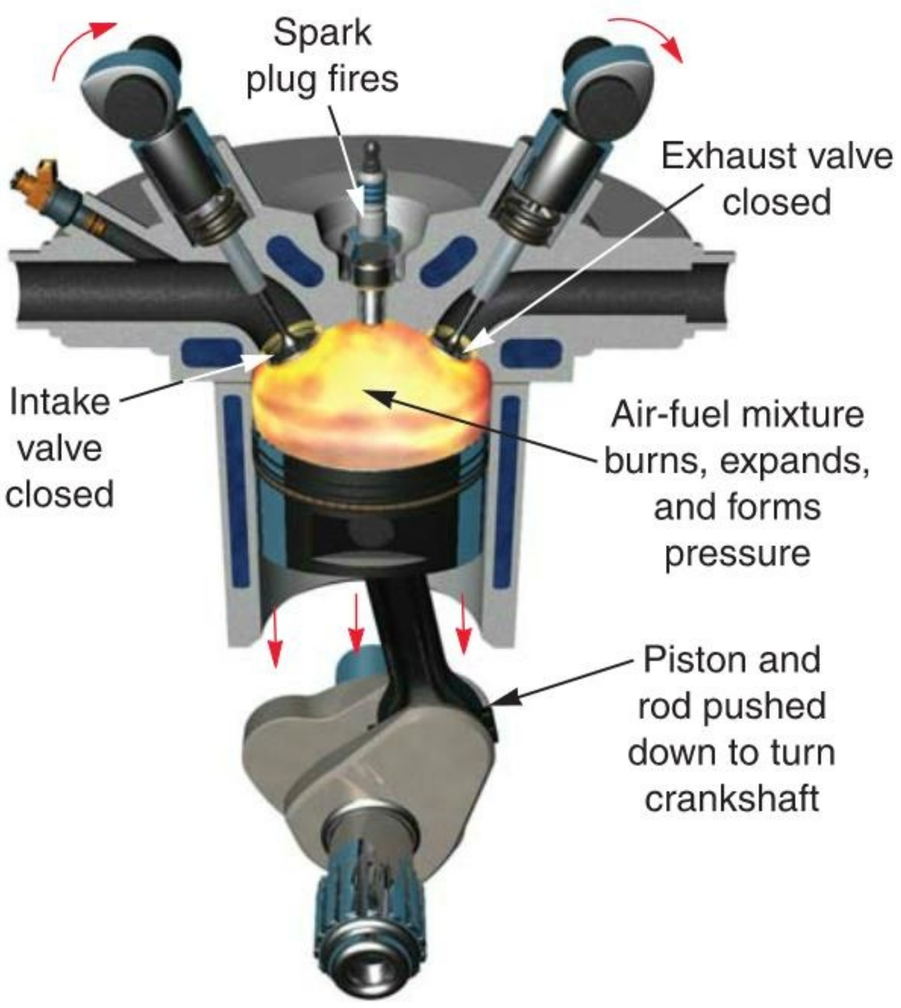
A—Intake Stroke

The piston slides down with the intake valve open and the exhaust valve closed. The air-fuel charge is pulled into the cylinder.



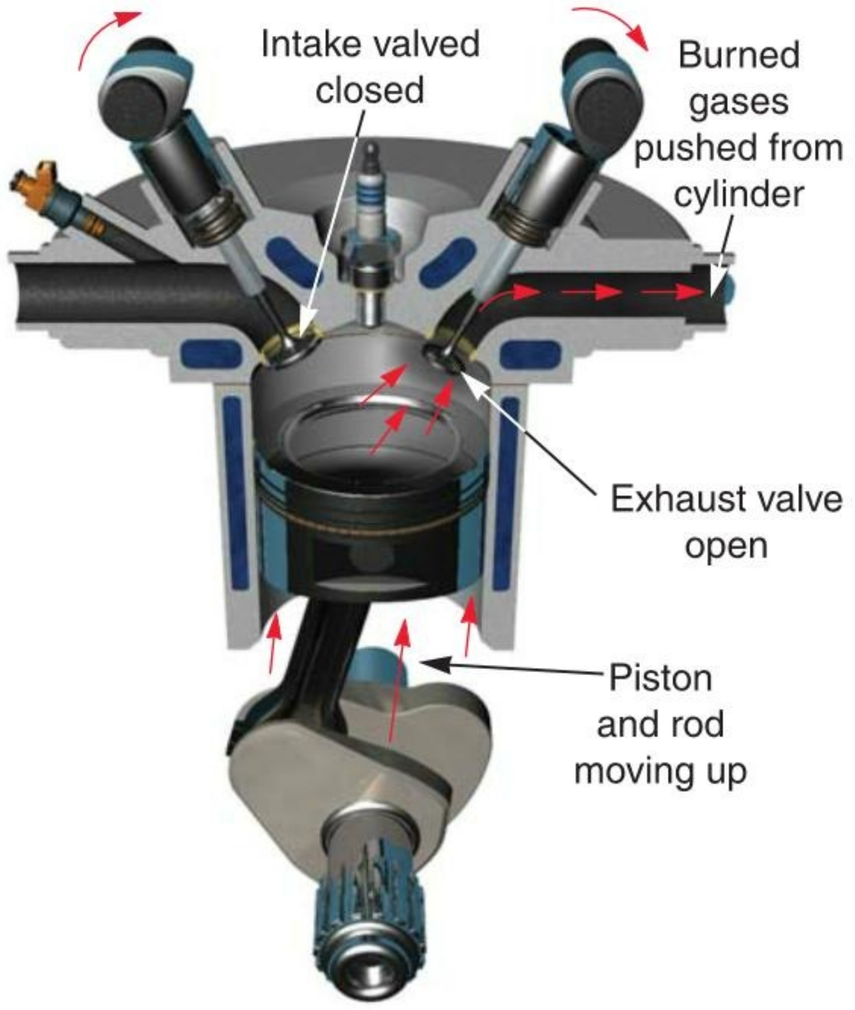
B—Compression Stroke

Both valves are closed and the piston slides up. This compresses the air-fuel charge and prepares it for combustion.



C—Power Stroke

The spark plug fires and the fuel begins to burn. The heat of combustion causes expansion of the gases and creates pressure. This pushes the piston down with tremendous force to spin the crankshaft.



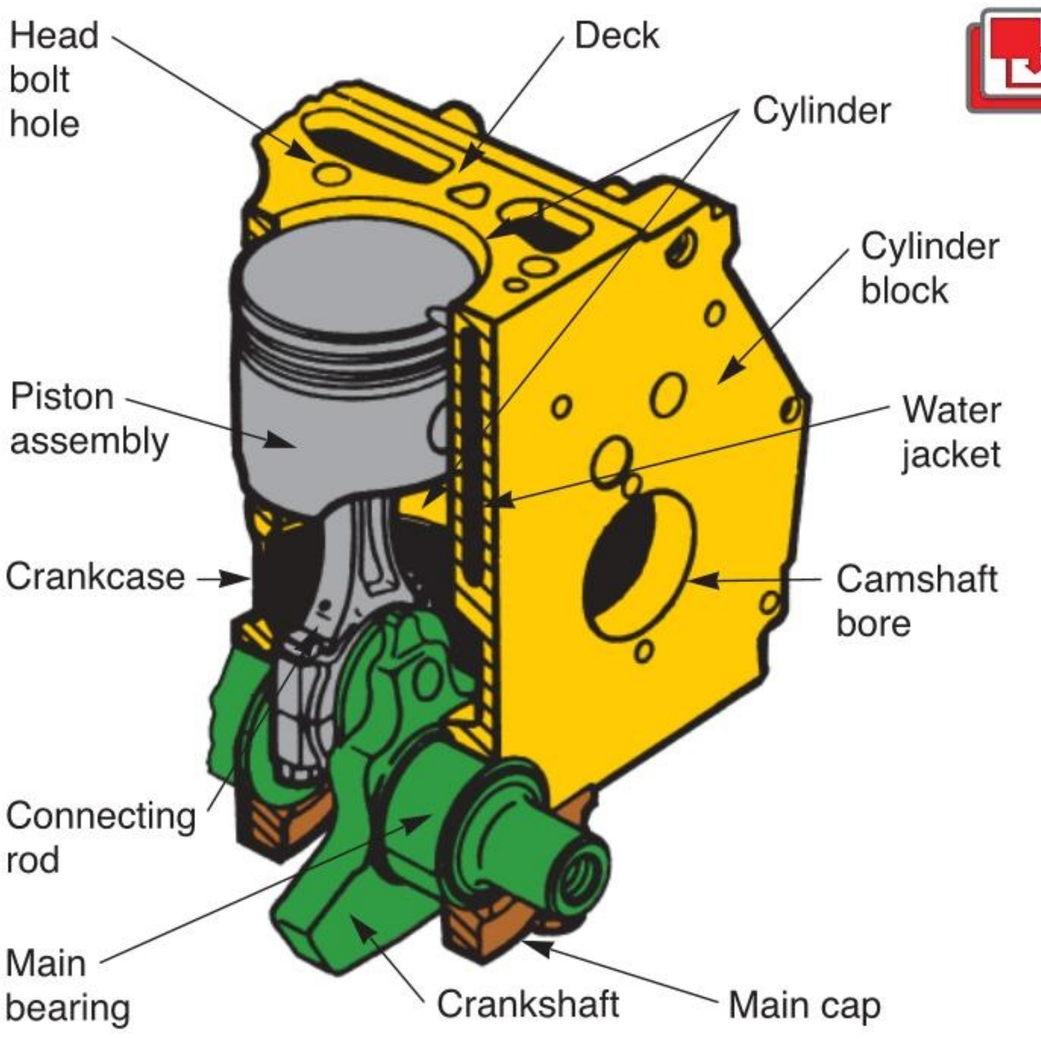
D—Exhaust Stroke

The piston slides up with the intake valve closed and the exhaust valve open. This pushes the exhaust gases out of the cylinder so a fresh charge can enter.

Goodheart-Willcox Publisher

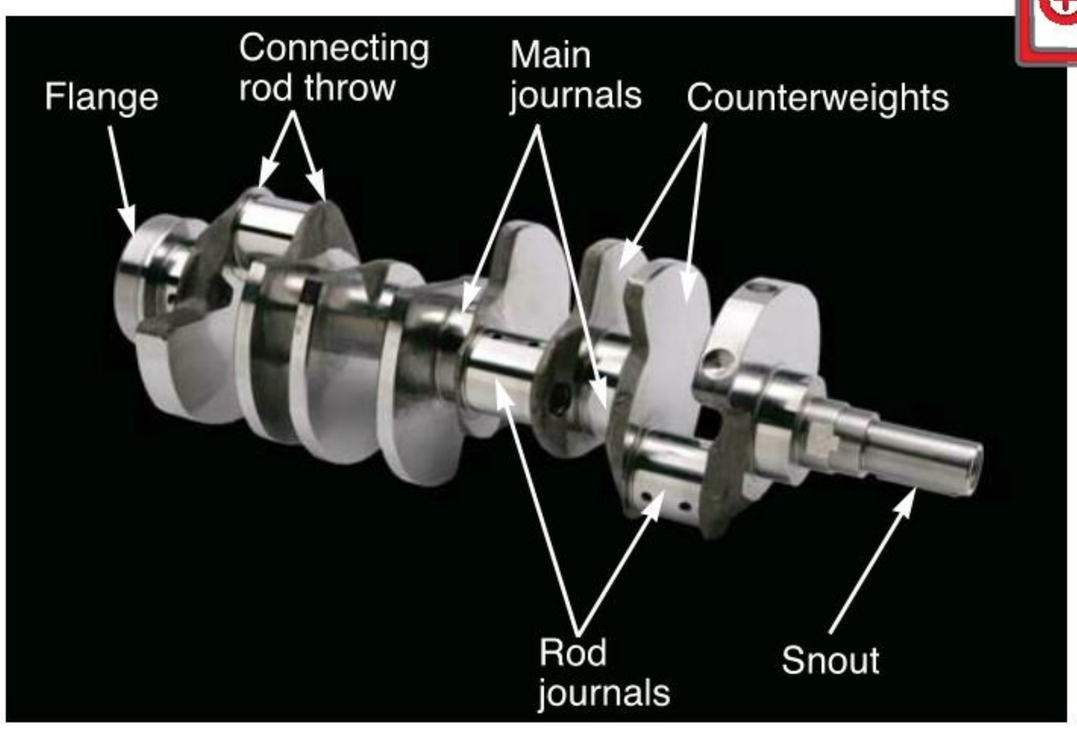
Figure 11-3. Study the phases of the four-stroke cycle.

Copyright Goodheart-Willcox Co., Inc.



Ford

Figure 11-4. The block is the main supporting member of the engine. Note how the other parts fit into the block. The crankshaft fits into the bottom of the block.



Ford

Figure 11-5. Study the basic parts of a crankshaft. Journals are very smooth surfaces for the bearings.

The crankshaft snout sticks through the front of the block. It provides a mounting place for the camshaft drive mechanism, front damper, and fan belt pulleys.

A crankshaft flange holds the flywheel. The flywheel bolts to this flange. The center of the flange has a pilot hole or bushing for the transmission torque converter or input shaft.

Automobile engines can have 2, 3, 4, 5, 6, 8, 10, or 12 cylinders. The crankshaft rod journals are arranged so there is always at least one cylinder on a power stroke. As a result, force is always being transmitted to the crankshaft to smooth engine operation.

Engine Main Bearings

The ***engine main bearings*** fit between the block main bores and the crankshaft main journals. Each engine main bearing consists of two removable inserts. The upper main bearing insert fits into the cylinder block. The lower main bearing insert fits into the main caps or the bedplate.

Oil holes in the upper main bearing inserts line up with oil holes in the block. This allows oil to flow through the block and main bearings, and into the crankshaft. The oil flows through the crankshaft to lubricate the main bearings and the connecting rod bearings. This prevents metal-to-metal contact.

A main thrust bearing limits the distance the crankshaft can slide forward or rearward in the block. Flanges are formed on the main thrust bearing. These flanges almost touch the thrust surfaces on the crankshaft. This limits crankshaft end play (front-to-rear movement). Normally, only one of the main bearings serves as a thrust bearing.

Main bearing clearance is the space between the crankshaft main journal and the main bearing insert. Clearance allows lubricating oil to enter and separate the journal and bearing. This allows the journal to rotate without rubbing on the bearing and causing excess wear. Refer to **Figure 11-6**.

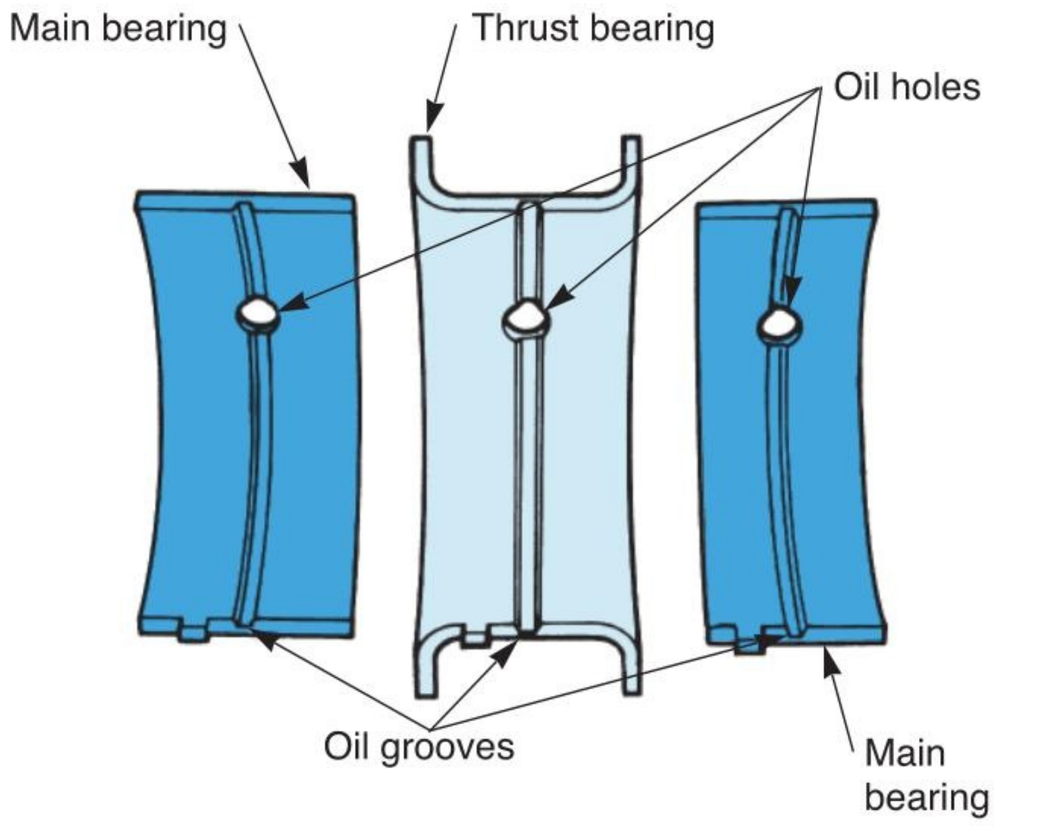
Crankshaft Oil Seals

Crankshaft oil seals keep oil from leaking from the front and rear of the engine. The oil pump forces oil into the main and rod bearings. This causes oil to spray out of the bearings. Seals are placed around the front and rear of the crankshaft to contain this oil.

The ***rear main oil seal*** fits around the rear of the crankshaft to prevent oil leakage. It can be a one- or two-piece seal. The seal lip rides on a machined and polished surface on the crankshaft.

The front seal prevents oil leakage around the crankshaft snout. It is normally a one-piece seal that is pressed into the engine's front cover (metal housing that bolts to the front of the engine). The seal lip may contact the crankshaft directly, or it may contact a sleeve that fits over the crankshaft snout.

Copyright Goodheart-Willcox Co., Inc.



Federal Mogul

Figure 11-6. Main bearing inserts fit between the crankshaft main journals and the block. One bearing has thrust surfaces to control crankshaft end play. Oil holes and grooves allow oil to lubricate the bearings.

Flywheel

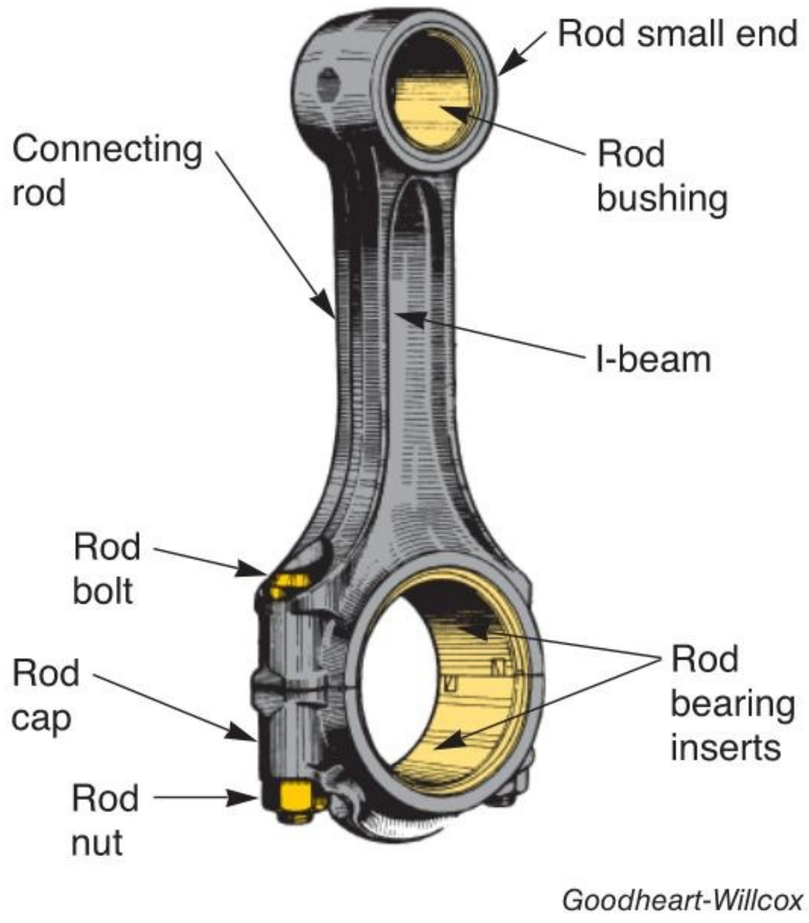
A ***flywheel*** is a large metal disk mounted on the rear of the crankshaft. A flywheel can have several functions:

- The flywheel connects the engine crankshaft to the transmission or transaxle. Either the manual clutch or the automatic transmission torque converter bolts to the flywheel.
- The flywheel for a vehicle with a manual transmission is very heavy and can help smooth engine operation.
- The flywheel generally contains a large ***ring gear***, which is used to start the engine. A small gear on the starting motor engages the flywheel ring gear and turns the flywheel.

Connecting Rod

The ***connecting rod*** fastens the piston to the crankshaft. It transfers piston movement and combustion pressure to the crankshaft rod journals. The connecting rod also causes piston movement during the non-power-producing strokes (intake, compression, and exhaust). Refer to **Figure 11-7**.

The connecting rod small end, or top end, fits around the piston pin. Also called the upper end, it contains a one-piece bushing. The bushing is pressed into the rod small end.



Goodheart-Willcox Publisher

Figure 11-7. The connecting rod is the link between the piston and crankshaft.

The connecting rod I-beam is the center section of the rod. The I-beam shape provides a very high strength-to-weight ratio. It prevents the rod from bending, twisting, and breaking.

The connecting rod cap bolts to the bottom of the connecting rod body. The connecting rod big end, or lower end, is a hole machined in the rod body and cap. The connecting rod bearing fits into the big end.

Connecting rod bolts and nuts clamp the rod cap and rod together. They are special high tensile strength fasteners. Some rods use cap screws without a nut. The cap screws thread into the rod itself. This design reduces rod weight.

Connecting Rod Bearings

The ***connecting rod bearings*** ride on the crankshaft rod journals. They fit between the connecting rods and the crankshaft. Like main bearings, the rod bearings are removable inserts.

Rod bearing clearance is the small space between the rod bearing and crankshaft journal. As with main bearing clearance, it allows oil to enter the bearing. The oil prevents metal-to-metal contact that would wear out the crank and bearings.

Piston

The piston transfers the pressure of combustion (expanding gas) to the connecting rod and crankshaft. It must also hold the piston rings and piston pin while operating in the cylinder.

Copyright Goodheart-Willcox Co., Inc.

The piston head is the top of the piston and is exposed to the heat and pressure of combustion. This area must be thick enough to withstand these forces. It must also be shaped to match and work with the shape of the combustion chamber for complete combustion. Study **Figure 11-8**.

Piston ring grooves are slots machined in the piston for the piston rings. The upper two grooves hold the compression rings. The lower groove holds the oil ring.

Piston oil holes in the bottom ring groove allow the oil to flow through the piston and onto the cylinder wall. The oil then drains back into the crankcase.

The piston ring lands are the areas between and above the ring grooves. They separate and support the piston rings as they slide on the cylinder.

The piston skirt is the side of the piston below the last ring. It keeps the piston from tipping in its cylinder. Without a skirt, the piston could cock and jam in the cylinder.

The piston boss is a reinforced area around the piston pin hole. It must be strong enough to support the piston pin under severe loads.

A piston pin hole is machined through the pin boss for the piston pin. It is slightly larger than the piston pin.

Piston clearance is the amount of space between the sides of the piston and the cylinder wall. Clearance allows a lubricating film of oil to form between the piston and the cylinder. It also allows for expansion when the piston heats up. The piston must always be free to slide up and down in the cylinder block.

Piston Pin

The ***piston pin***, also called wrist pin, allows the piston to swing on the connecting rod. The pin fits through the hole in the piston and the connecting rod small end. This is pictured in **Figure 11-9**.

Piston Rings

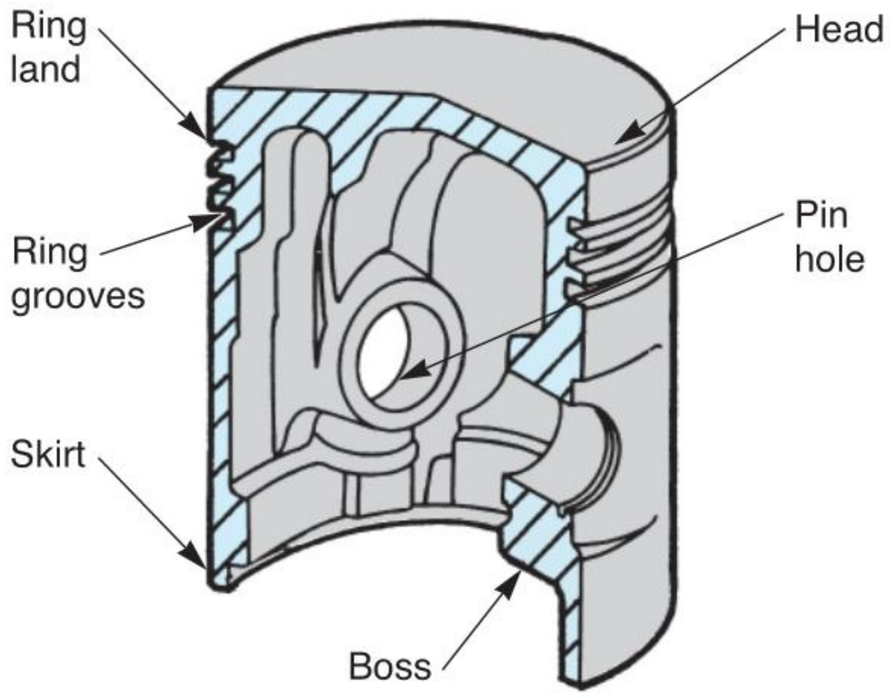
The ***piston rings*** seal the clearance between the outside of the piston and the cylinder wall. They must keep combustion pressure from entering the crankcase. They must also keep oil from entering the combustion chambers.

Most pistons use three rings: two upper compression rings and one lower oil ring. Note piston ring locations in **Figure 11-10**.

The ***compression rings*** prevent blowby (combustion pressure leaking into engine crankcase). **Figure 11-11** shows how compression rings function in an engine. On the compression stroke, pressure is trapped between the cylinder and piston grooves by the compression rings. Combustion pressure pushes the compression rings down in their grooves and out against the cylinder wall. This produces an almost leakproof seal.

The main job of ***oil rings*** is to prevent engine oil from entering the combustion chamber. They scrape excess oil off the cylinder wall. If too much oil got into the combustion chamber and was burned, blue smoke would come out of the vehicle's exhaust pipe. Study **Figure 11-12** closely.

Ring gap is the split, or space, between the ends of a piston ring. The ring gap allows the ring to be spread open and installed on the piston. It also allows the ring to be made slightly larger in diameter than the



Deere & Co.

Figure 11-8. The piston rides in the cylinder and is exposed to the combustion flame. It must be light and strong.

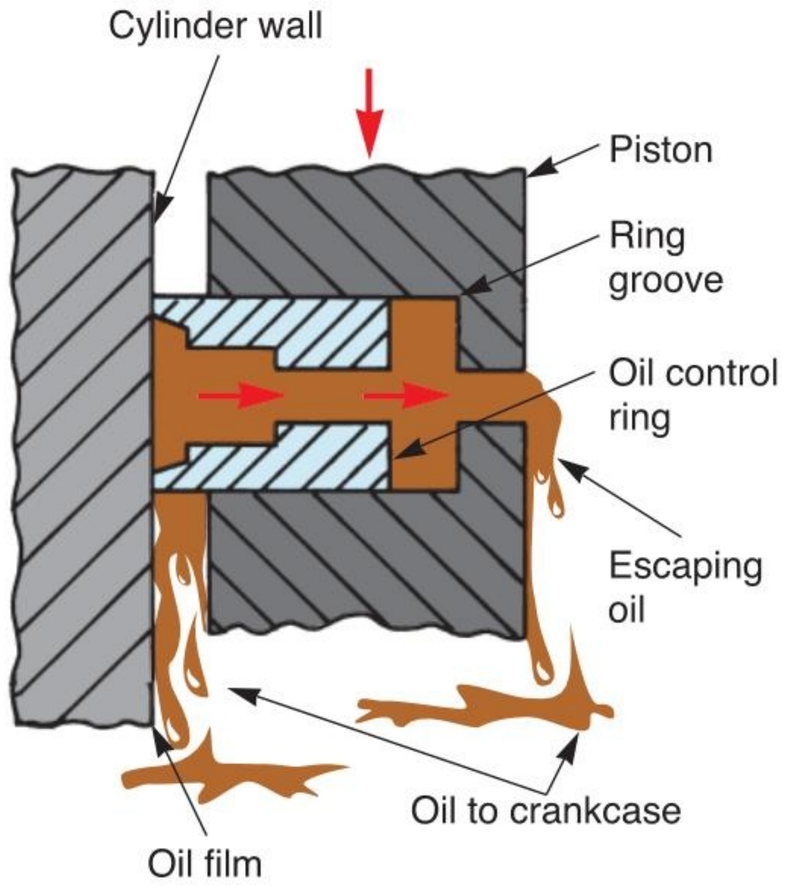
cylinder. When squeezed together and installed in the cylinder, the ring spreads outward and presses on the cylinder wall. This aids ring sealing.



Goodheart-Willcox Publisher

Figure 11-12. The oil control ring scrapes excess oil off the cylinder wall. If this oil entered the combustion chamber, the engine would emit blue smoke.

Engine Top End

The term ***engine top end*** generally refers to the cylinder heads, valves, camshaft, and other related components. These parts work together to control the flow of air and sometimes fuel into the engine cylinders. They also control the flow of exhaust out of the engine. See **Figure 11-13**.

Cylinder Head

The ***cylinder head*** bolts to the deck of the cylinder block. It covers and encloses the top of the cylinders. See **Figure 11-14**.

Combustion chambers are small pockets formed in the cylinder heads. The combustion chambers are located directly over the cylinders. Combustion occurs in these areas of the cylinder head. Spark plugs (gasoline engine) and fuel injectors (direct injection engine) are mounted in holes in the cylinder head and protrude into the combustion chambers. See **Figure 11-15**.

Intake and exhaust ports are cast into the cylinder head. The ***intake ports*** route air (direct injection) or air and fuel (port injection) into the combustion chambers. The ***exhaust port*** routes burned gases out of the engine.

Valve guides are small holes machined through the cylinder head for the valves. The valves fit into and slide in these guides.

Nissan

Figure 11-14. Study the basic engine top end components. The cylinder head is the foundation for these parts.

Valve seats are round, machined surfaces in the combustion chamber port openings. When a valve is closed, it seals against the valve seat, **Figure 11-16**.

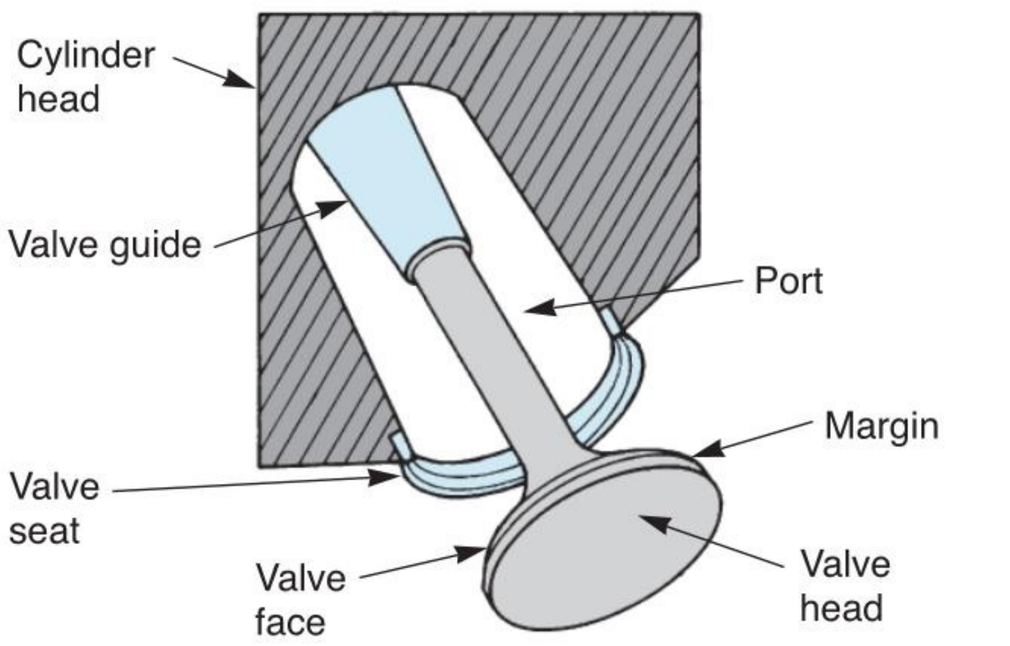
Figure 11-15. The combustion chamber is formed in the cylinder head.



Goodheart-Willcox Publisher

Figure 11-16. A valve slides up and down in the guide during operation. When the valve is closed, it seals against the valve seat to close off the port.

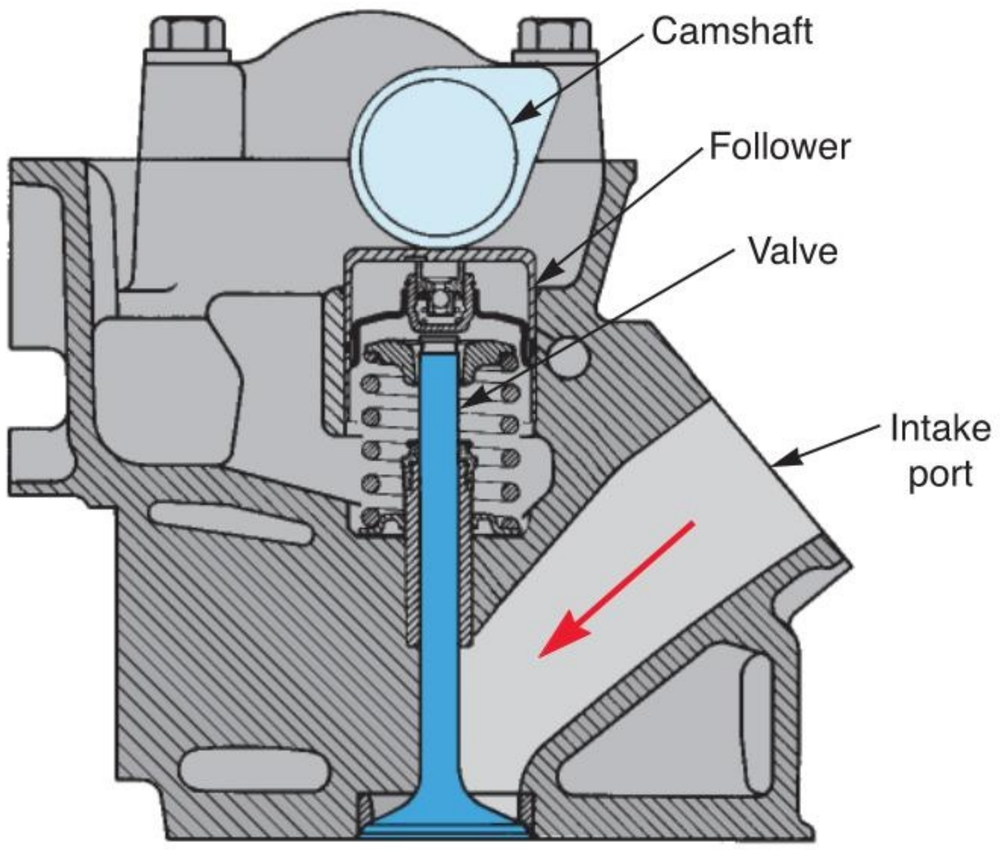
Valve Train

The ***engine valve train*** consists of the valves and the parts that operate them. These include the camshaft, lifters, push rods, rocker arms, valves, and valve spring assemblies. The valve train must open and close the valves at the correct time. Look at **Figure 11-17**. **Figure 11-18** illustrates basic valve train action.

Camshaft

The ***camshaft*** has lobes that open each valve. It can be located in the engine block or in the cylinder head.

Copyright Goodheart-Willcox Co., Inc.



Mercedes-Benz

Figure 11-17. The valve train operates the engine valves. In this particular arrangement, the camshaft is located in the cylinder head, above the valve. As the camshaft lobe turns, it pushes downward on the follower to open the valve.

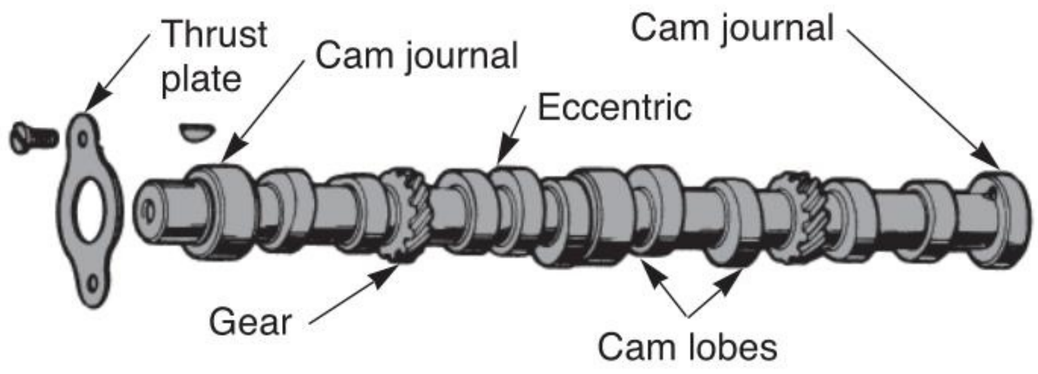
The cam lobes are egg-shaped protrusions (bumps) machined on the camshaft. One cam lobe is provided for each engine valve. Assuming the engine has two valves per cylinder, a 4-cylinder engine camshaft would have 8 cam lobes; a 6-cylinder, twelve lobes; etc.

An eccentric (oval) may be machined on the camshaft to operate a mechanical (engine-driven) fuel pump. This feature can be found on camshafts used in older engines or some diesel engines, as well as many direct gasoline injection engines with a high-pressure mechanical fuel pump. It is similar to a cam lobe but is more round.

Camshaft journals are precisely machined and polished surfaces for the cam bearings. Like the crankshaft, the camshaft rotates on its journals. Oil separates the cam bearings and cam journals. A camshaft is illustrated in **Figure 11-19**.

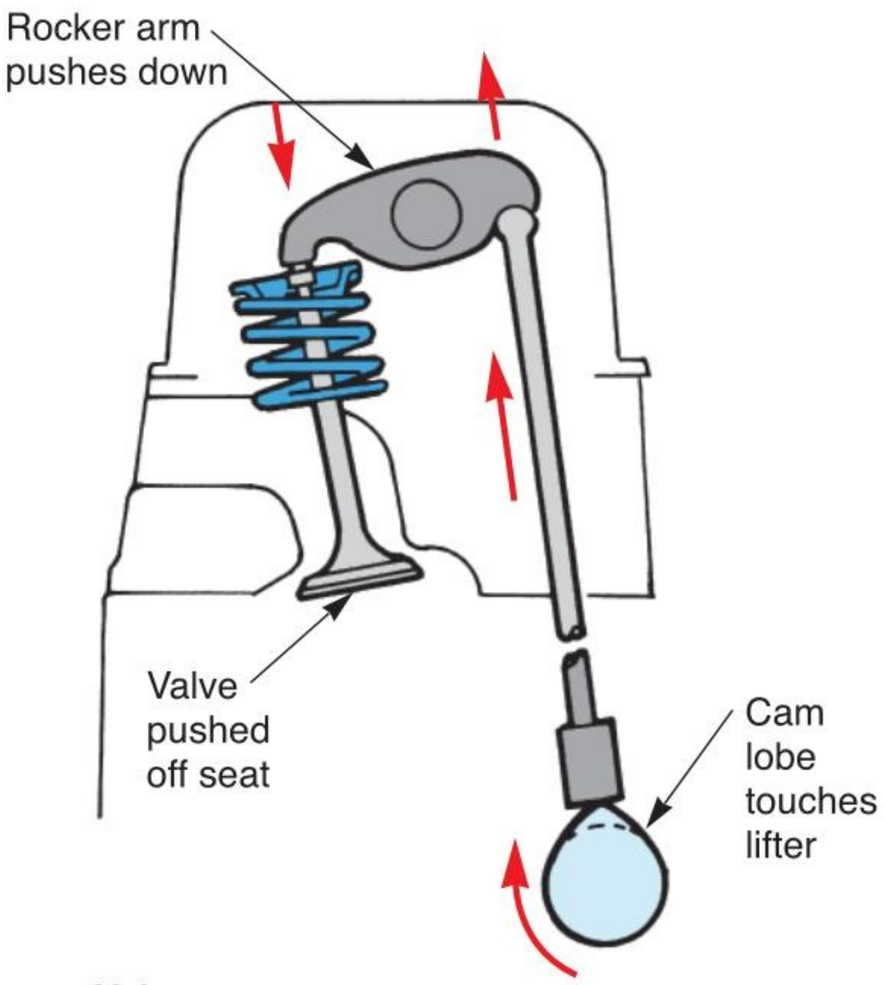
Valve Lifters

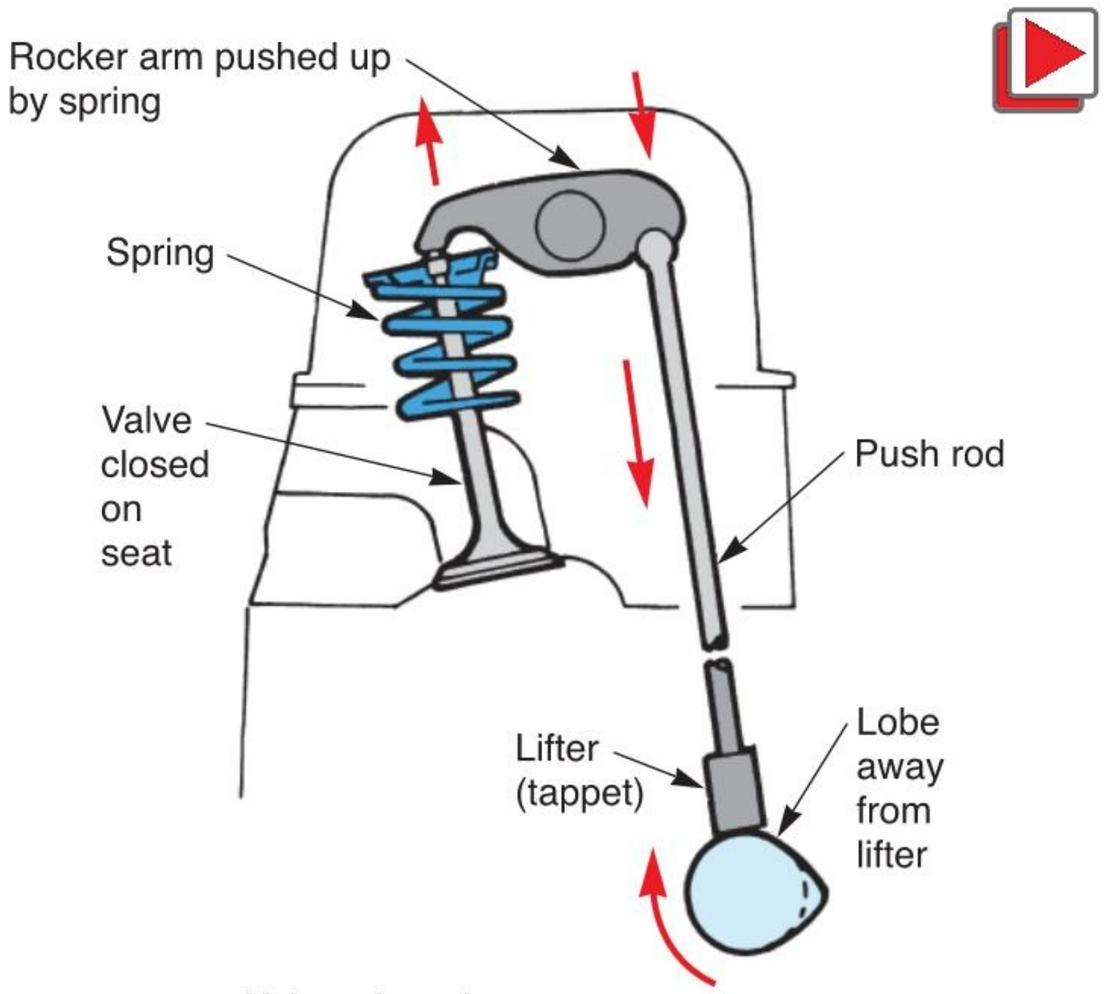
A ***valve lifter***, also called a ***tappet***, usually rides on the cam lobes and transfers motion to the rest of the valve train. The lifters can be located in the engine



Goodheart-Willcox Publisher

Figure 11-19. The camshaft is a long metal shaft with lobes, journals, and sometimes, an eccentric and gears.





Ford

Figure 11-18. In this valve train arrangement, the camshaft is located in the engine block. When the camshaft lobe turns into the lifter, the valve is pushed open. When the lobe rotates away from the lifter, the valve spring pushes the valve closed.

Copyright Goodheart-Willcox Co., Inc.

block or cylinder head. They fit into lifter bores, which are machined holes in the block or head.

When the cam lobe moves toward the lifter, the lifter is pushed up in its bore. This opens the valve. Then, when the lobe rotates away from the lifter, the lifter is pushed down in its bore by the valve spring. This keeps the lifter in constant contact with the camshaft.

Push Rods

Push rods transfer motion between the lifters and the rocker arms. They are needed when the camshaft is located in the cylinder block. They are not needed when the camshaft is in the cylinder head.

A push rod is a hollow metal tube with a ball or socket formed on each end. One end of the push rod fits into the lifter. The other end fits against the rocker arm. In this way, when the lifter slides up, the push rod moves the rocker arm.

Rocker Arms

Rocker arms can be used to transfer motion to the valves. They mount on top of the cylinder head. A pivot mechanism allows the rocker arms to rock back and forth, opening and closing the valves.

Valves

Engine valves open and close the ports in the cylinder head. In the past, only two valves were used per cylinder: one intake valve and one exhaust valve. To improve efficiency, many late-model engines are equipped with four valves per cylinder: two intake valves and two exhaust valves.

The ***intake valve*** is larger than the exhaust valve. It controls the flow of the fuel mixture (gasoline engine) or air (direct injection and diesel) into the combustion chamber. The intake valve fits into the port leading from the intake manifold.

The ***exhaust valve*** controls the flow of exhaust gases out of the cylinder. It is smaller than the intake valve. The exhaust valve fits into the port leading to the exhaust manifold.

The valve head is the large, disc-shaped surface exposed to the combustion chamber. Its outside diameter determines the size of the valve.

The valve face is a machined surface on the back of the valve head. It touches and seals against the seat in the cylinder head.

The valve margin is the flat surface on the outer edge of the valve head. It is located between the valve head and face. The margin is needed to allow the valve to withstand the high temperatures of combustion. Without a margin, the valve head would melt and burn.

The valve stem is a long shaft extending out of the valve head. The stem is machined and polished. It fits into a guide located in the cylinder head.

Keeper grooves, or lock grooves, are machined into the top of the valve stem. They accept small keepers, or locks, that hold the retainer and spring on the valve, **Figure 11-20**.

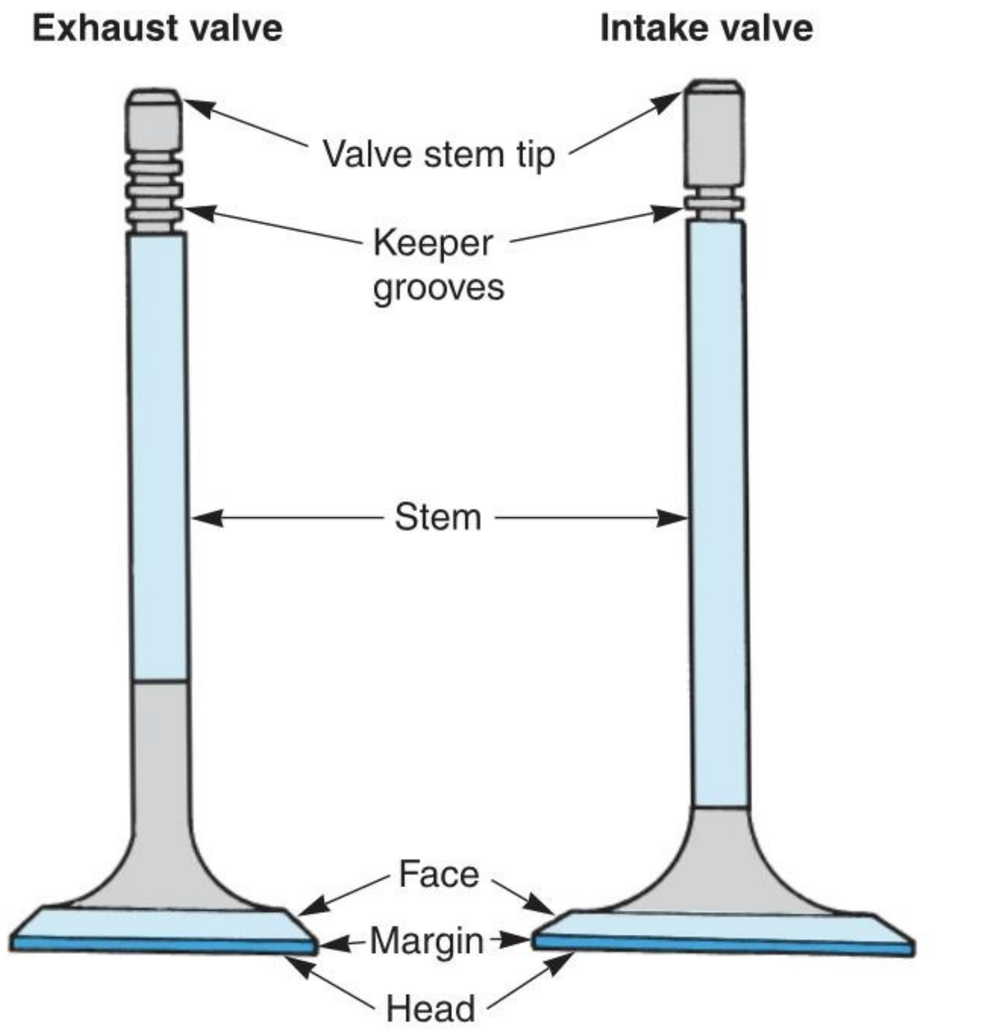
Valve Seals

Valve seals prevent oil from entering the combustion chambers through the valve guides. The valve seals fit over the valve stems and keep oil from entering through the clearance between the stems and guides.

Without valve seals, oil could be drawn into the engine cylinders and burned during combustion. Oil consumption and engine smoking could result. This is illustrated in **Figure 11-21**.

Valve Spring Assembly

The ***valve spring assembly*** is used to close the valve. It basically consists of a valve spring, a retainer, and two keepers. The ***keepers*** fit into the grooves cut in the valve stem. This locks the retainer and spring on the valve. See **Figure 11-22**.



Goodheart-Willcox Publisher

Figure 11-22. The valve spring assembly basically consists of a spring, retainer, keepers, and sometimes, a shield. Note how this type of seal fits on the valve stem.

Intake Manifold

The ***intake manifold*** bolts to the side or top of the cylinder head(s). On modern engines, the intake manifold is often made of plastic or aluminum. The throttle body bolts to the inlet of the intake manifold. A large-volume plenum is formed in the middle of the manifold. Runners connect the plenum to the cylinder head intake ports. Seals fit around each port to seal against the cylinder head to prevent vacuum or pressure leakage. With modern direct gasoline injection or diesel injection, only air passes through the engine's intake manifold because the fuel injector nozzles extend directly into the combustion chambers.

Exhaust Manifold

The ***exhaust manifold*** fastens over the exhaust ports to carry burned gases into the exhaust system. During the exhaust strokes, hot gases blow into this manifold before entering the rest of the exhaust system. An exhaust manifold can be made of heavy cast iron or lightweight aluminum or stainless steel tubing. The trend is toward lighter designs.

Valve Cover

The ***valve cover***, also called the rocker cover, is a thin metal or plastic lid over the top of the cylinder head. It simply keeps valve train oil spray from leaking out of the engine. Look at **Figure 11-23**.

Engine Front End

The ***engine front end*** includes all the parts attached to the front of the engine. It consists of the camshaft drive, a front cover, an oil seal, and a crank damper. It may contain the oil pump, water pump, chain or belt tensioners, auxiliary drives or sprockets, and engine sensors.

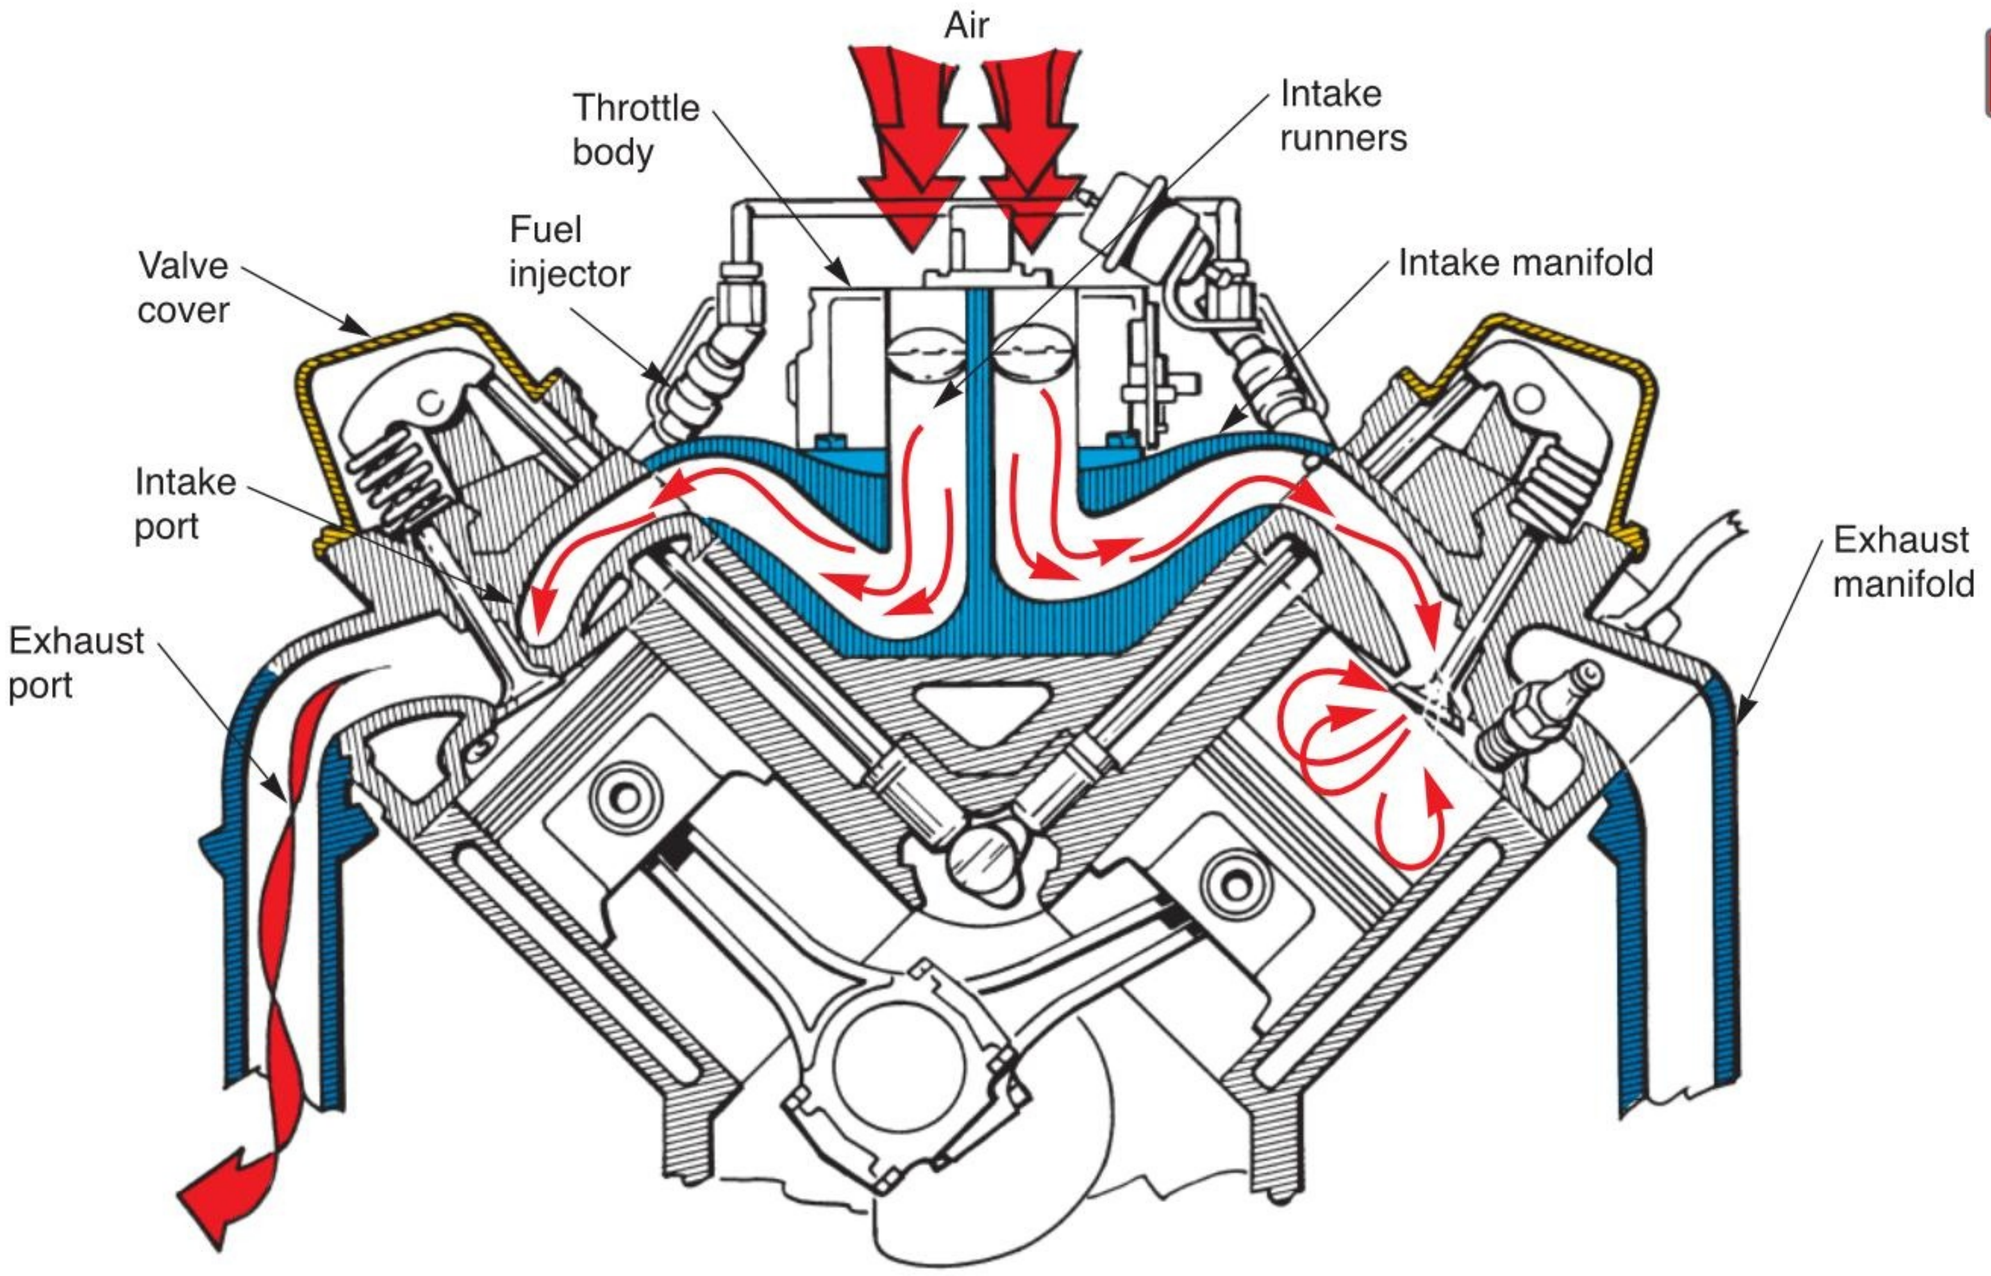
Tech Tip

Engine front end assemblies are much more complicated than in the past. With today's dual overhead cam engines, the cam drive mechanism can be difficult to comprehend. Carefully study all the illustrations in this book to compare front end design differences. This will prepare you to work on various engines.

Camshaft Drive

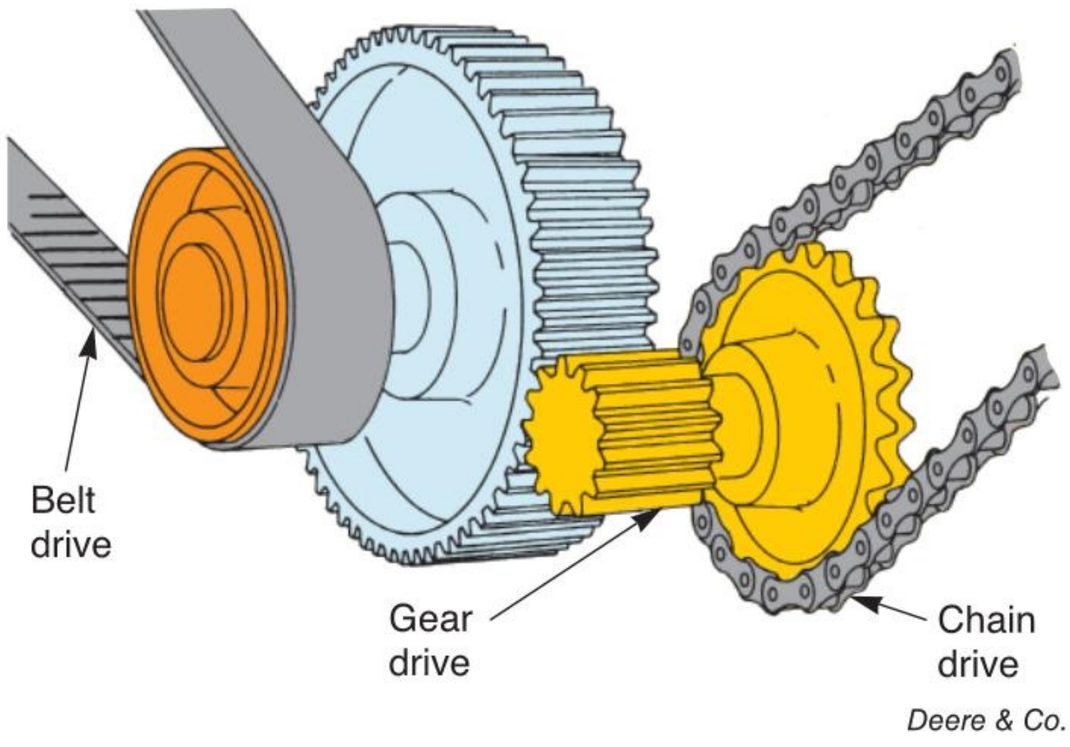
A ***camshaft drive*** is needed to turn the camshaft at one-half engine speed. A belt and sprockets, gears, or a chain and sprockets can be used to turn the camshaft. Look at **Figure 11-24**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 11-23. Intake and exhaust manifolds bolt to the cylinder head. The intake manifold contains runners that route the fuel mixture into the cylinder heads. The exhaust manifolds route burned gases into the exhaust system.



Deere & Co.

Figure 11-24. The camshaft can be turned by one of three drive mechanisms: a belt drive, a gear drive, or a chain drive.

These parts are often called the timing belt, timing gears, or timing chain because they time the camshaft with the crankshaft. The camshaft is designed to turn at one-half engine speed. As a result, each valve will open only once for every two crankshaft revolutions.

For instance, the intake valve must open only on the intake stroke, not the compression, power, or exhaust strokes. To do this, the camshaft gear or sprocket is twice as big as the gear or sprocket on the crankshaft. See **Figure 11-25**.

Front Cover

The ***front cover*** bolts over the crankshaft snout. It holds an oil seal that seals the front of the crankshaft.

When the engine uses a gear- or chain-type camshaft drive, the front cover can also be called the timing cover. With a belt drive, this cover does not enclose the cam drive or timing mechanism. A second cover is installed over the belt. Refer to **Figures 11-26** and **11-27**.

Crank Damper

A ***crank damper*** is a heavy wheel on the crankshaft snout. It is mounted in rubber and helps prevent crankshaft vibration and damage. This damper is also called the harmonic balancer or vibration damper.

Workplace Skills

Teamwork is the key to success in the automotive shop. Smart technicians "talk shop," exchanging information about new tools and repair methods. They also help each other with diagnosis and heavy work.

Working as part of a team will increase your job satisfaction and productivity. You will spend a large portion of your life working. Why not enjoy it?

Summary

- The engine is the source of power for the vehicle. For this reason, it is also called a power plant.
- When the piston is at its highest point in the cylinder, it is at TDC (top dead center). When the piston slides to its lowest point in the cylinder, it is at BDC (bottom dead center).
- The term engine bottom end generally refers to the block, crankshaft, connecting rods, pistons, and related components.
- The crankshaft harnesses the tremendous force produced by the downward thrust of the pistons.
- The engine main bearings are removable inserts that fit between the block main bore and crankshaft main journals.
- Main bearing clearance is the space between the crankshaft main journal and the main bearing insert.
- Crankshaft oil seals keep oil from leaking out the front and rear of the engine.
- The connecting rod fastens the piston to the crankshaft. It transfers piston movement to the crankshaft rod journals.
- The engine piston transfers the pressure of combustion (expanding gas) to the connecting rod and crankshaft.
- Piston clearance is the amount of space between the sides of the piston and the cylinder wall.
- The piston rings seal the clearance between the outside of the piston and the cylinder wall.
- The compression rings prevent blowby (combustion pressure leaking into engine crankcase).
- The main job of oil rings is to prevent engine oil from entering the combustion chamber.
- The term engine top end generally refers to the cylinder heads, valves, camshaft, and related components.
- The camshaft has lobes that open the valves.
- A valve lifter usually rides on the cam lobes and transfers motion to the rest of the valve train.
- Engine valves open and close the ports in the cylinder head.
- The valve spring assembly is used to close the valve.
- The engine front end operates the engine camshaft and, sometimes, the oil pump, water pump, engine sensors, and diesel injection pump.
- A crank damper is a heavy wheel on the crankshaft snout. It is mounted in rubber and helps prevent crankshaft vibration and damage.

Technical Terms

Activities

1. A camshaft changes rotary motion to up-and-down motion. Find and describe or sketch at least three other examples of ways that a mechanical system changes the type, direction, or force of a motion.
2. If possible, obtain from a repair shop a bearing or other engine part that shows severe wear. Clean the part so the wear can be seen easily and pass it around to your classmates. Discuss how the wear was caused.
3. Make a chart showing the position (open or closed) of the intake valve and the exhaust valve during each stroke of the four-stroke cycle.

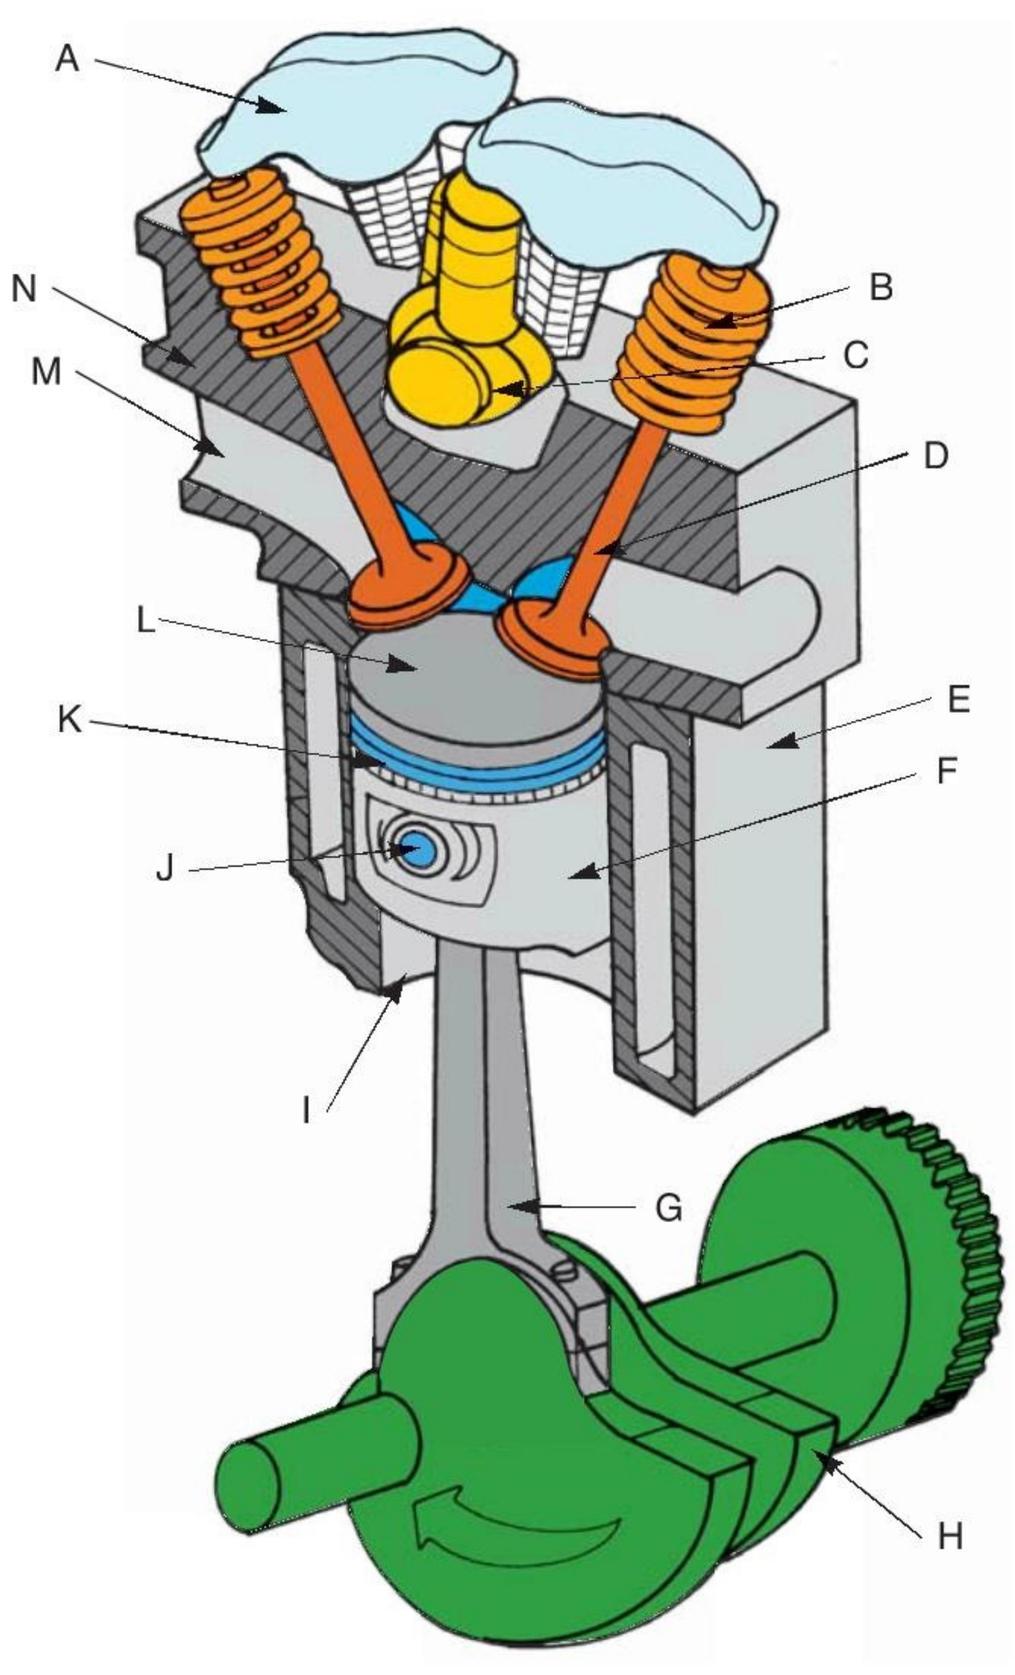
Review Questions

Answer the following questions using the information provided in this chapter.

1. Usually, _____ or _____ is burned inside the engine to produce heat, expansion, and resulting pressure.
2. What do TDC and BDC mean?
3. Every four strokes, the engine produces two power strokes. True or False?
4. Explain the intake stroke.
5. Explain the compression stroke.
6. Explain the power stroke.
7. Explain the exhaust stroke.
8. _____ bolt to the bottom of the block and hold the crankshaft in place.
9. The crankcase is the highest portion in the block. True or False?
10. The crankshaft changes the up-and-down motion of the piston into a useful _____ motion.
11. What is the function of crankshaft counterweights?
12. Describe the function of the main thrust bearing.
13. The _____ transfers piston movement to the crankshaft.
14. The distance from the centerline of the crankshaft to the centerline of a rod journal is 3″ (76 mm). What is the total vertical distance that the piston will travel in the cylinder (from TDC to BDC)?
15. Which of the following is *not* part of a connecting rod?
    (A) I-beam.
    (B) Lobe.
    (C) Cap.
    (D) Bushing.
16. Why is rod bearing clearance needed?
17. Explain the function of compression and oil rings.
18. Which of the following is part of the cylinder head?
    (A) Combustion chambers.
    (B) Intake and exhaust ports.
    (C) Valve guides.
    (D) All of the above.
19. List and explain the basic parts of a camshaft.
20. _____ open and close the ports in the cylinder head.

Copyright Goodheart-Willcox Co., Inc.

21. The intake valves are larger than the exhaust valves. True or False?
22. Describe the five basic parts of an engine valve.
23. What do valve seals do and what would happen without valve seals?
24. Explain the function of the following parts.
    (A) Intake manifold.
    (B) Exhaust manifold.
    (C) Valve cover.
25. Identify the engine parts in the following illustration. Write A through N on your paper. Then write the name of the part next to each letter.



ASE-Type Questions

1. Technician A says the engine camshaft converts reciprocating motion of the piston into rotary motion for power output. Technician B disagrees and says the crankshaft performs this function. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. The distance a piston travels up or down in a cylinder is limited by the:
   (A) flywheel.
   (B) camshaft.
   (C) crankshaft.
   (D) valve train.
3. The air-fuel mixture is actually burned during the:
   (A) power stroke.
   (B) intake stroke.
   (C) exhaust stroke.
   (D) compression stroke.
4. How many crankshaft rotations are needed to complete the four-stroke cycle?
   (A) One.
   (B) Two.
   (C) Three.
   (D) Four.
5. Automobile engines normally have:
   (A) four cylinders.
   (B) six cylinders.
   (C) eight cylinders.
   (D) All of the above.
6. A flywheel performs each of these functions *except:*
   (A) contains a gear used for engine starting.
   (B) smoothes engine operation.
   (C) provides lubrication to parts.
   (D) connects crankshaft to transmission.
7. Which of the following causes piston movement during non-power-producing strokes?
   (A) Flywheel.
   (B) Connecting rod.
   (C) Counterweights.
   (D) Main thrust bearing.

Copyright Goodheart-Willcox Co., Inc.

8. Which of the following components transfers combustion pressure to the crankshaft and connecting rods?
   (A) Piston.
   (B) Camshaft.
   (C) Valve train.
   (D) Thrust bearing.
9. Which of the following keeps a piston from tipping in its cylinder?
   (A) Piston pin.
   (B) Piston boss.
   (C) Piston skirt.
   (D) Piston head.
10. An engine has been diagnosed with blowby. Technician A says the engine could have a cracked flywheel. Technician B says the compression rings could be worn. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
11. Which of the following components is *not* part of the valve train?
   (A) Camshaft.
   (B) Crankshaft.
   (C) Rocker arms.
   (D) Valve springs.
12. While discussing camshaft operation, Technician A states that cam lobes open each valve in the engine. Technician B states that the camshaft journals operate engine valves. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
13. The valve train parts that transfer motion to the rest of the valve train are the:
   (A) lifters.
   (B) tappets.
   (C) Both A and B.
   (D) Neither A nor B.
14. Which of the following is used to turn the camshaft at one-half engine speed?
   (A) Timing belt.
   (B) Timing chain.
   (C) Timing gears.
   (D) All of the above.
15. Which of the following helps prevent crankshaft vibration and damage?
   (A) Crank damper.
   (B) Vibration damper.
   (C) Harmonic balancer.
   (D) All of the above.

Chapter 12
Engine Design Classifications

After studying this chapter, you will be able to:

- Describe basic automotive engine classifications.
- Compare gasoline and diesel engines.
- Contrast combustion chamber designs.
- Discuss alternative engine types.
- Compare two- and four-stroke cycle engines.
- Correctly answer ASE certification test questions that require a knowledge of engine classifications and design differences.

In previous chapters, you learned about the basic parts of an engine. Now you are ready to learn about the various engine types, designs, and classifications used in automobiles and light trucks.

An experienced engine technician can glance into an engine compartment and "rattle off" dozens of engine facts. For example, you might hear a technician say, "This is an inline, 4-cylinder, 16-valve, overhead-cam turbo engine." You must understand these kinds of terms when troubleshooting and repairing engines. Study this chapter carefully. It will help you learn the "language" of an engine service technician.

Engine Classifications

Even though basic engine parts are the same, design differences can change the way engines operate and how they are repaired. For this reason, you must be able to classify engines.

Some common engine classifications include:

- Cylinder arrangement.
- Number of cylinders.
- Cooling system type.
- Valve location.
- Camshaft location.
- Combustion chamber design.
- Type of fuel burned.
- Type of ignition.
- Number of strokes per cycle.
- Number of valves per cylinder.
- Type of aspiration.

Copyright Goodheart-Willcox Co., Inc.

Cylinder Arrangement

Cylinder arrangement refers to the position of the cylinders in relation to the crankshaft. There are four basic cylinder arrangements: inline, V-type, W-type, and opposed. Refer to **Figure 12-1**.

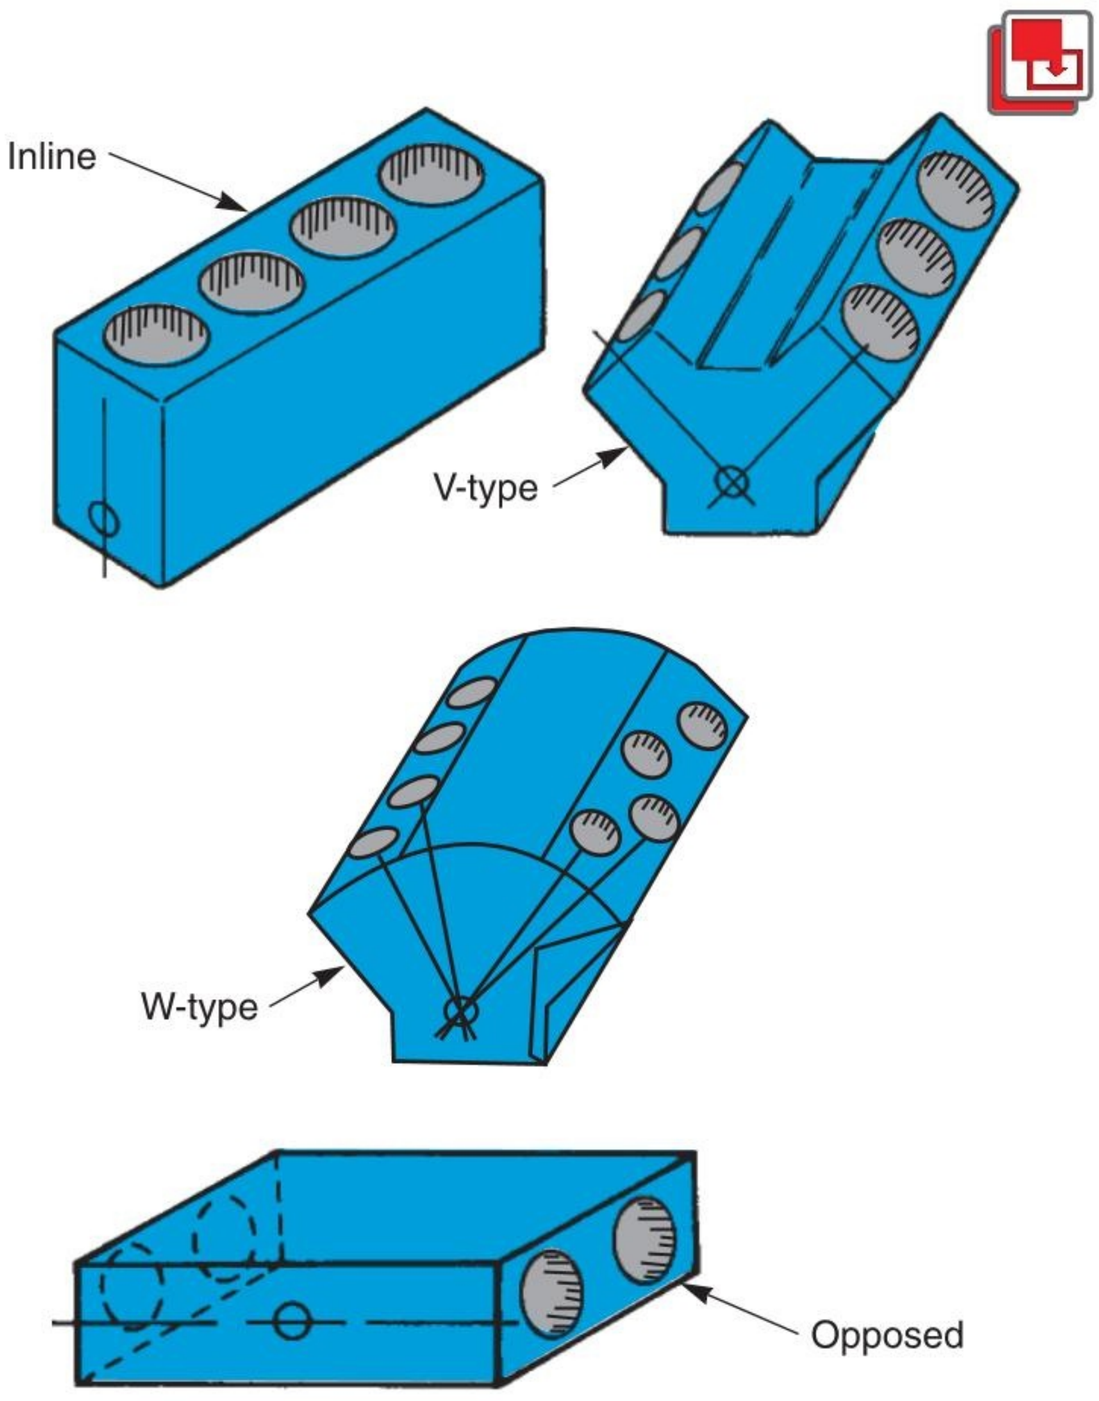
In an ***inline engine***, the cylinders are lined up in a single row. Each cylinder is located in a straight line that is parallel to the crankshaft. Four-, five-, and six-cylinder engines are commonly inline engines.

Viewed from either end, a ***V-type engine*** looks like the letter "V." The two banks of cylinders lie at an angle to each other. This arrangement reduces the length and the height of the engine.

Like a V-type engine, the ***W-type engine*** consists of two cylinder banks that form a "V." However, the cylinders in each bank of the W-type engine are offset, forming a second, very narrow "V" (V+V=W). This compact design allows manufacturers to increase engine displacement without increasing engine size.

Cylinders of an ***opposed engine*** lie flat on either side of the crankshaft. Because of its appearance, this type of engine is sometimes called a "pancake engine" or "boxer engine." An opposed engine may be found in older Volkswagens and a few late-model foreign sports cars (Porsche and Subaru, for example).

One advantage of an "opposed engine" is that it minimizes frictional horsepower loss at the main bearings. Inline and V-type engines produce a downward thrust on the crankshaft that causes a small but unwanted power loss. In an opposed engine, the pistons move right and left against each other to prevent a downward thrust on the main bearings. This type of engine also has a much lower center of gravity than other car and truck engines. This can be an advantage with a sports car or racing car, where a low center of gravity increases cornering ability.



Goodheart-Willcox Publisher

Figure 12-1. Engines can be classified by the way the cylinders are arranged in the block and around the crankshaft. The four basic cylinder arrangements used in automobiles are shown.

Number of Cylinders

Normally, car and truck engines have 4, 6, or 8 cylinders. A few automotive engines have 3, 5, 10, 12, or 16 cylinders.

A greater number of cylinders generally increases engine smoothness and power. For instance, an 8-cylinder engine produces twice as many power strokes per crank revolution as a 4-cylinder engine. This reduces power pulsations and roughness (vibrations) at idle. Four-cylinder engines usually have inline, slant, or opposed cylinder arrangements. Six-cylinder engines can have inline, slant, or V-type arrangements. Five-cylinder engines are normally inline engines. Eight-, 10-, and 12-cylinder engines are commonly V-type engines.

Engine manufacturers number each engine cylinder to help technicians make repairs. The service manual will provide an illustration showing the number of each cylinder.

Cylinder numbers are normally stamped on the connecting rods. Sometimes, they are cast into the intake manifold. Cylinder numbering varies from one manufacturer to another. You should keep this in mind when referring to engine classifications. Two V-6 engines, for example, can have completely different cylinder numbering systems.

Cooling System Type

There are two types of cooling systems: liquid cooling systems and air cooling systems. The liquid cooling system is the most common.

The ***liquid cooling system*** surrounds the cylinder with coolant (water and antifreeze solution). The coolant carries combustion heat out of the cylinder head and engine block to prevent engine damage.

Copyright Goodheart-Willcox Co., Inc.

An ***air cooling system*** circulates air over cooling fins on the cylinders. This removes heat from the cylinders to prevent overheating. Air-cooled or air-oil cooled engines are seldom used in passenger cars. They can be found on motorcycles, lawnmowers, and a few high-performance cars. See **Figure 12-2**.

Fuel Type

An engine is also classified by the type of fuel it burns. A gasoline engine burns gasoline. A diesel engine burns diesel fuel. These are the most common types of fuel for vehicles.

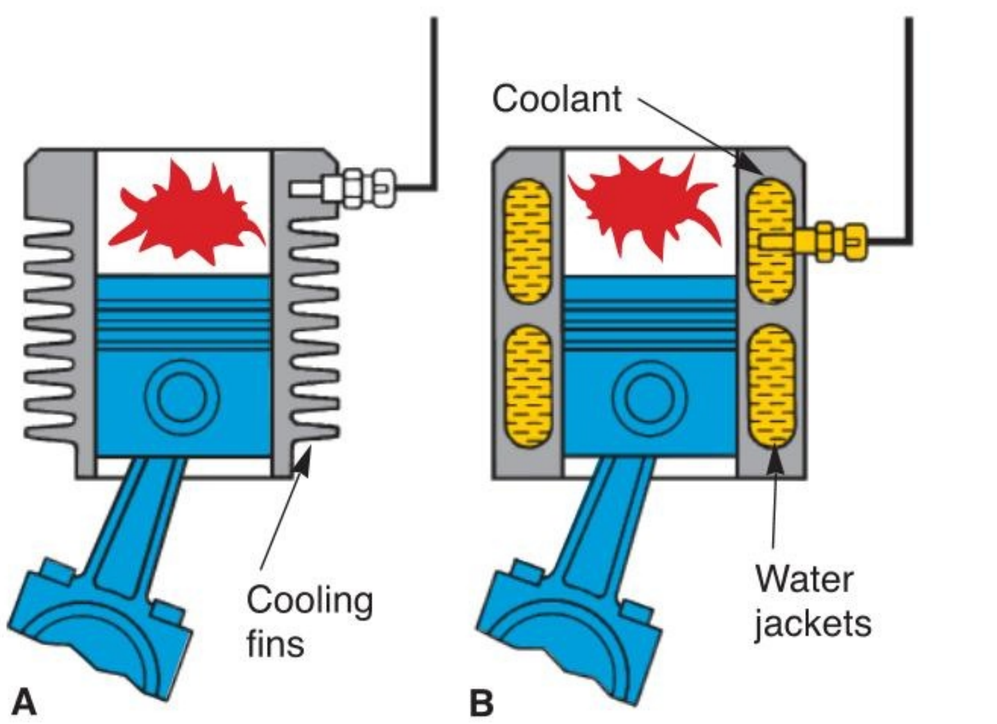
Liquefied petroleum gas (LPG), gasohol (10% alcohol, 90% gasoline), and pure alcohol can also be used to power an engine. These fuels are used in limited quantities.

Ignition Type

Two basic methods are used to ignite the fuel in an engine combustion chamber: spark ignition (spark plug) and compression ignition (compressed air).

A ***spark ignition engine*** uses an electric arc at the spark plug to ignite the fuel. The arc produces enough heat to start the fuel burning. Gasoline engines use spark ignition.

A ***compression ignition engine*** squeezes the air in the combustion chamber until it is hot enough to ignite the fuel. A diesel engine is a compression ignition engine. No spark plugs are used.



Goodheart-Willcox Publisher

Figure 12-2. These are cooling systems. A—Air cooling systems use large fins around the cylinders to remove heat. B—Liquid cooling systems are commonly used in automobiles. Motorcycles and lawnmowers use air cooling systems.

Valve Location

Another engine classification can be made by comparing the location of the valves, given in **Figure 12-3**.

An ***L-head engine*** has both the intake and exhaust valves in the block. Also called a ***flat head engine***, its cylinder head simply forms a cover over the cylinders and valves. The camshaft is in the block and pushes upward to open the valves. Some four-stroke lawnmower engines are L-head types. Automotive engines are no longer L-head types.

An ***I-head engine*** has both valves in the cylinder head. Another name for this design is the ***overhead valve (OHV) engine***. Numerous variations of the overhead valve engine are now in use.

Other valve configurations have been used in the past. However, they are so rare that their mention is not important.

Camshaft Location

There are two basic locations for the engine camshaft: in the block and in the cylinder head. Both locations are common.

A cam-in-block engine uses push rods to transfer motion to the rocker arms and valves. The term overhead valve (OHV) is sometimes used when referring to a cam-in-block engine.

In an ***overhead cam (OHC) engine***, the camshaft is located in the top of the cylinder head. Push rods are not needed to operate the rockers and valves. This type of engine is a refinement of the overhead valve engine.

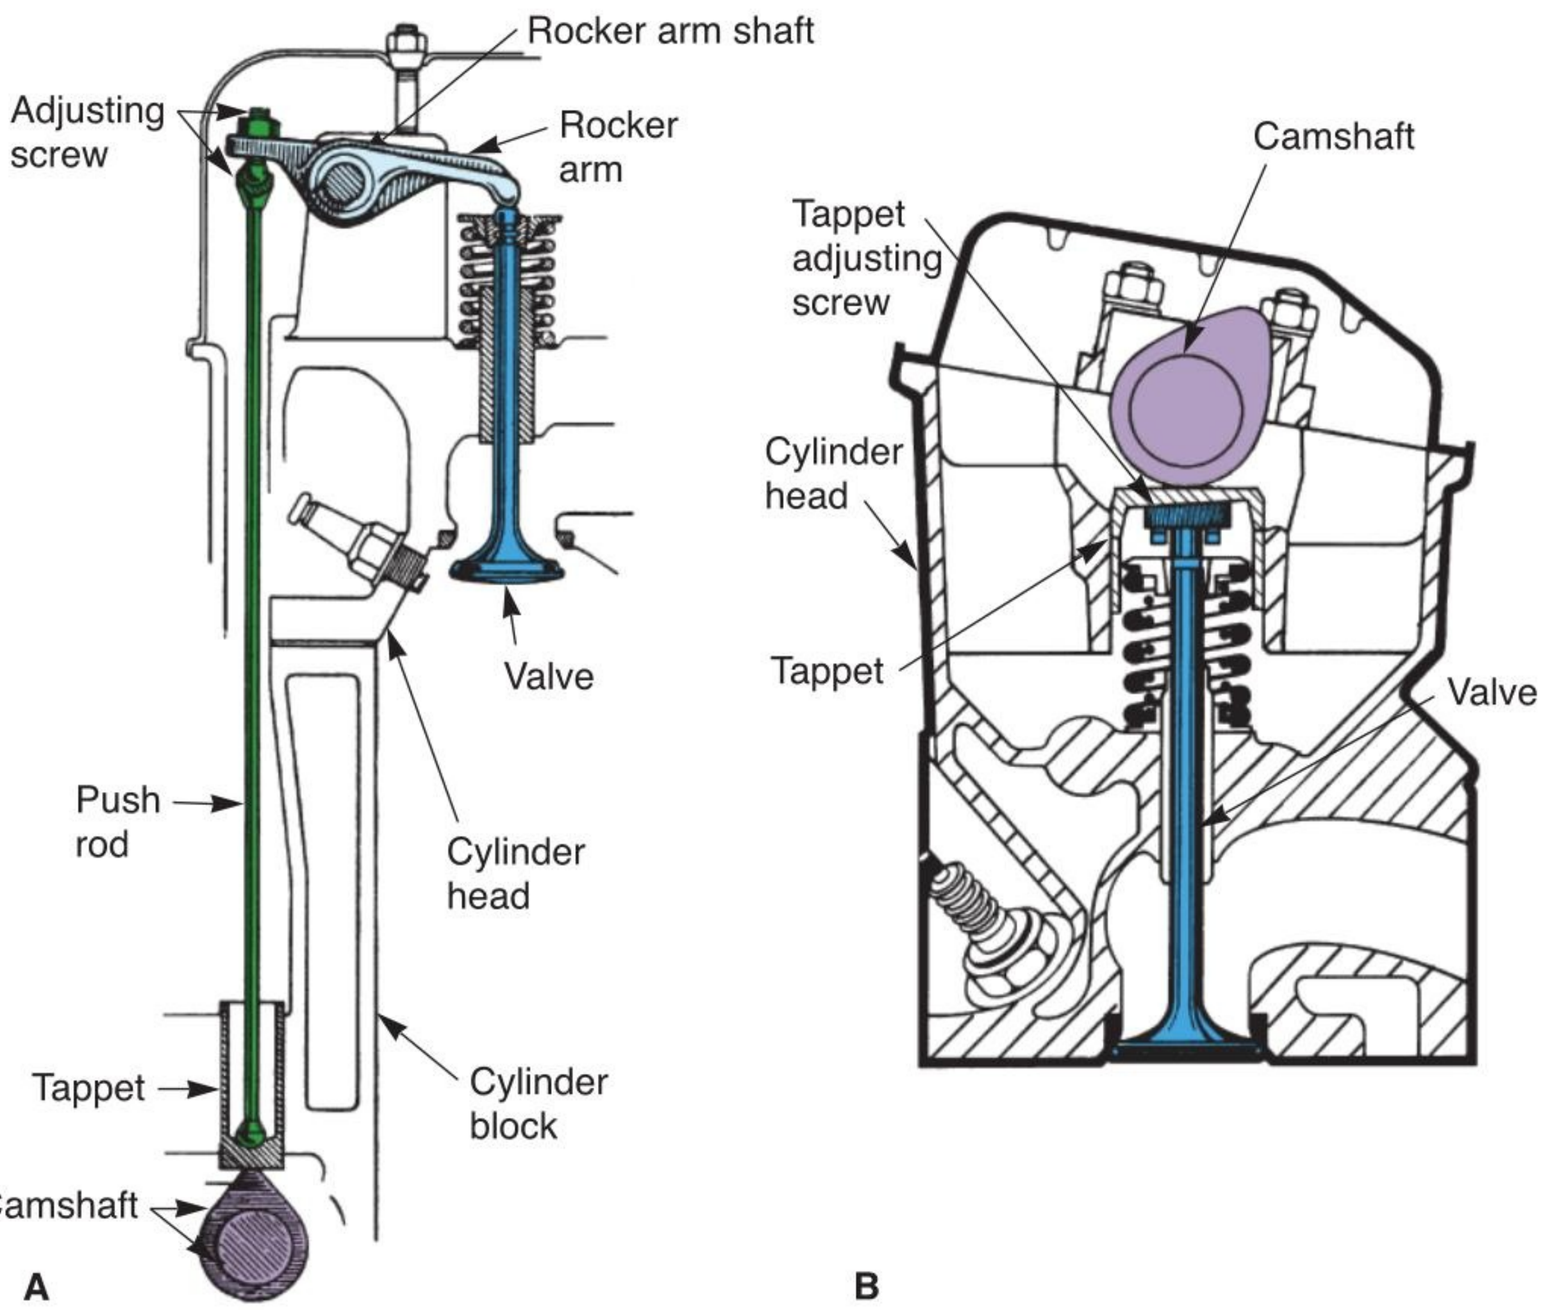
With the camshaft in the head, the number of valve train parts is reduced. This cuts the weight of the valve train. Also, the valves can be placed at an angle to improve breathing (airflow through cylinder head ports).

OHC engines were first used in race cars to improve their high-rpm (revolutions per minute) efficiency. Now all types of engines commonly use this configuration. With lower valve train weight, improved valve positioning, and no push rods to flex, the OHC engine is becoming very popular.

A ***single overhead cam (SOHC) engine*** has only one camshaft per cylinder head. The cam may act directly on the valves, or rocker arms may be used to transfer motion to the valves.

A ***dual overhead cam (DOHC) engine*** has two camshafts per cylinder head. One cam operates the intake valves; the other operates the exhaust valves.

Copyright Goodheart-Willcox Co., Inc.



Black & Decker and Chrysler

Figure 12-3. Study the two common valve-camshaft locations. A—The cam-in-block engine, also called the overhead valve or I-head engine, is common. B—The overhead cam engine is another form of the I-head engine. It is also very common in today's vehicles.

The dual overhead cam arrangement is frequently used in engines equipped with four-valve combustion chambers. A DOHC engine will be shown later in the chapter.

Tech Tip

Subscribe to and read a variety of automotive magazines. They often contain technical information on the latest engine designs. This will give you valuable information when working on new vehicles.

Combustion Chamber Shape

The shape of the combustion chamber provides still another method of classifying an engine. The four basic combustion chamber shapes for gasoline engines are pancake, wedge, hemispherical, and pent-roof.

The ***pancake combustion chamber***, also called the bathtub chamber, has valve heads that are almost parallel to the top of the piston. The chamber forms a flat pocket over the piston head, **Figure 12-4A**.

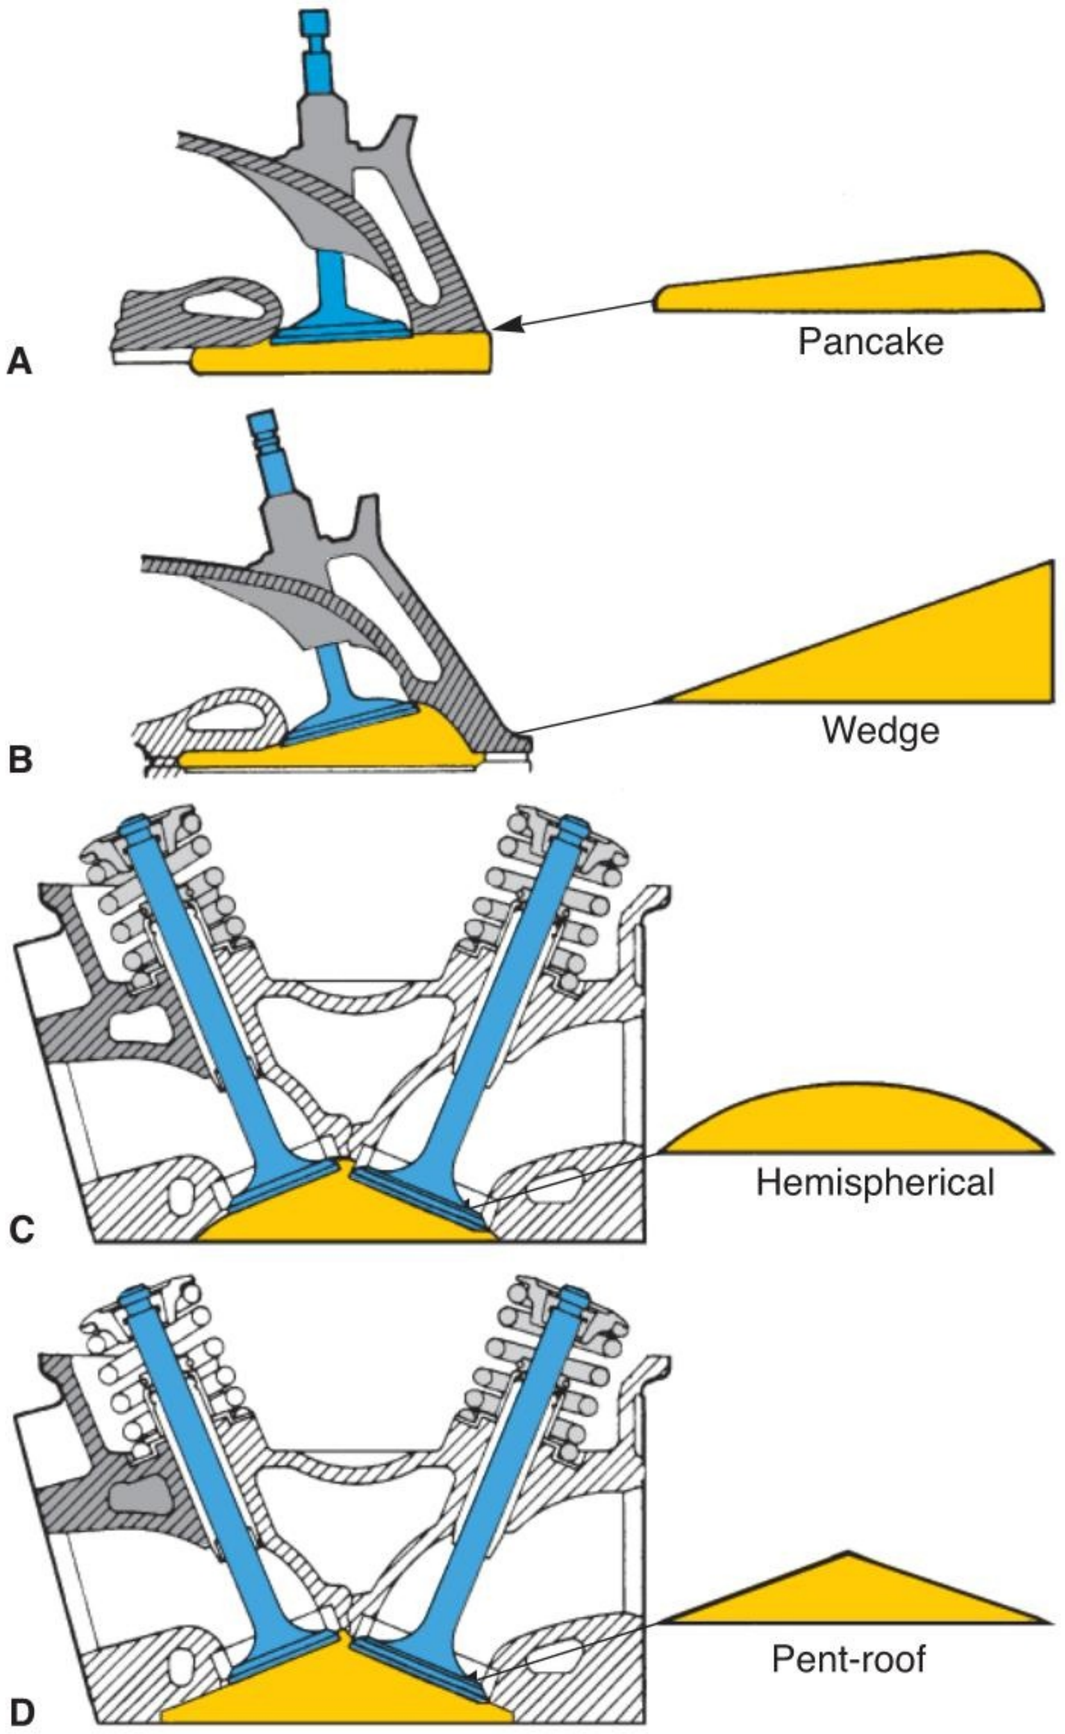
A ***wedge combustion chamber***, or wedge head, is shaped like a triangle, or a wedge, when viewed from the side. Valves are placed side-by-side, and the spark plug is located next to the valves, **Figure 12-4B**.

A ***squish area*** is commonly formed inside a wedge combustion chamber. When the piston reaches TDC, it comes very close to the bottom of the cylinder head. This squeezes the air-fuel mixture in that area and causes it to squirt, or squish, out into the main part of the chamber. A squish area can be used to improve air-fuel mixing at low engine speeds.

A ***hemispherical combustion chamber***, nicknamed hemi-head, is shaped like a dome. The valves are canted (tilted) on each side of the combustion chamber. The spark plug is located near the center of the chamber. A hemi-head is shown in **Figure 12-4C**.

A hemispherical combustion chamber is extremely efficient. There are no hidden pockets, minimizing the chances of incomplete combustion. The surface area is very small, reducing heat loss from the chamber.

Copyright Goodheart-Willcox Co., Inc.



Chrysler

Figure 12-4. There are four basic combustion chamber shapes. A—In a pancake combustion chamber, the valves are almost parallel with the top of the piston. B—In the wedge combustion chamber, the valves are at an angle to the top of the piston. C—The valves are at an angle to each other in a hemispherical combustion chamber. D—In a pent-roof combustion chamber, the valves are located on flat, angled surfaces.

The centrally located spark plug produces a very short flame path for combustion. The canted valves help increase breathing ability.

The hemi-head was first used in high-horsepower racing engines. It is now used in many OHC passenger car engines. It allows the engine to operate at high rpm and makes it very fuel efficient. It also produces complete burning of the fuel to reduce emissions.

The ***pent-roof combustion chamber*** is similar to the hemispherical chamber, but it has flat, angled surfaces rather than a domed surface. This design improves volumetric efficiency and reduces emissions. See **Figure 12-4D**.

Combustion Chamber Types

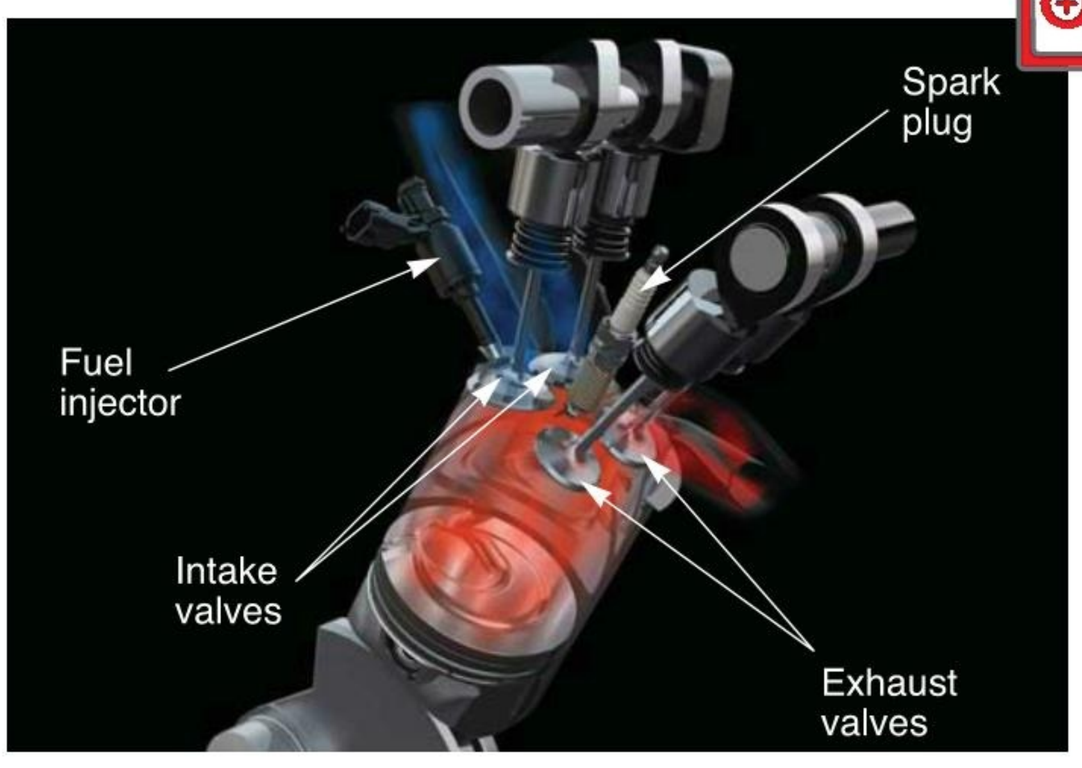
Besides the four shapes just covered, there are several other combustion chamber classifications. Each type is designed to increase combustion efficiency, gas mileage, and power while reducing exhaust pollution.

A ***swirl combustion chamber*** is designed to cause the air-fuel mixture to swirl, or spin, as it enters from the intake port. This causes the air and fuel to mix into a finer mist that burns better.

A ***four-valve combustion chamber*** uses two exhaust valves and two intake valves. The extra valves increase flow in and out of the combustion chamber. This setup is now used on many modern passenger car engines. This is illustrated in **Figure 12-5**.

In some four-valve combustion chambers, one of the intake valves is opened farther than the other. This produces a swirling action on the air-fuel mixture entering the combustion chamber. The swirling action helps reduce low-speed emissions.

A ***three-valve combustion chamber*** has two intake valves and one exhaust valve. The two intake valves allow ample airflow into the combustion chamber on the intake stroke. The single exhaust valve provides enough surface area to handle exhaust flow. This is a relatively new design and is used by only a couple manufacturers. The three-valve combustion chamber provides almost as much performance gain as a four-valve chamber, but it has fewer moving parts. This reduces cost and increases reliability.



Goodheart-Willcox Publisher

Figure 12-5. Two exhaust valves and two intake valves increases flow in and out of the combustion chamber.

Copyright Goodheart-Willcox Co., Inc.

A ***stratified charge combustion chamber*** uses a small combustion chamber flame to ignite and burn the fuel in the main, large combustion chamber. A very lean mixture (high ratio of air to fuel) is admitted into the main combustion chamber. The mixture is so lean that it will not ignite and burn easily. A richer mixture (higher ratio of fuel to air) is admitted into the small chamber by an extra valve. When the fuel mixture in the small chamber is ignited, flames blow into the main chamber and ignite the lean mixture.

The stratified charge chamber allows the engine to operate on a lean, high-efficiency air-fuel ratio. Fuel economy is increased, and exhaust emission output is reduced.

An ***air jet combustion chamber*** has a single combustion chamber fitted with an extra air valve. During the intake stroke, the engine camshaft opens both the conventional intake valve and the jet valve. This allows the fuel mixture to flow past the conventional intake valve and into the cylinder. At the same time, a stream of air flows into the cylinder through the jet valve.

The jet valve action causes the fuel mixture in the cylinder to swirl and mix. This increases combustion efficiency by causing more of the fuel to burn during the power stroke.

The jet valve only works at idle and low engine speeds. At higher rpm, normal air-fuel mixing is adequate for efficient combustion.

A ***precombustion chamber*** is commonly used in automotive diesel engines. It is similar in shape to the stratified charge chamber used in gasoline engines. Also called a ***diesel prechamber***, the precombustion chamber is used to quiet engine operation and to allow the use of a glow plug (heating element) to aid cold weather starting.

During combustion, diesel fuel is injected into the prechamber. If the engine is cold, the glow plug heats the air in the prechamber. This heat, along with the heat produced by compression, causes the fuel to ignite and burn. As the fuel burns, the flame expands and moves into the main chamber to burn the remaining diesel fuel to produce a power stroke.

Alternative Engines

As you have learned, vehicles generally use internal combustion, 4-stroke cycle, reciprocating piston engines. However, there are several alternative engine designs in production or development. Some of these designs are variations of the 4-stroke cycle, piston engine. Other designs have a completely different operational design. This section describes several alternative engine designs.

Variable Displacement Engine

A ***variable displacement engine*** can deactivate cylinders so the engine conserves fuel and reduces emissions. During acceleration, all the cylinders function normally. However, when cruising speed is reached and there is a reduced demand for power, the computer disables cylinders to improve efficiency.

Most variable displacement engines shut off the fuel injectors in certain cylinders. Some also disable the valve train of the deactivated cylinders.

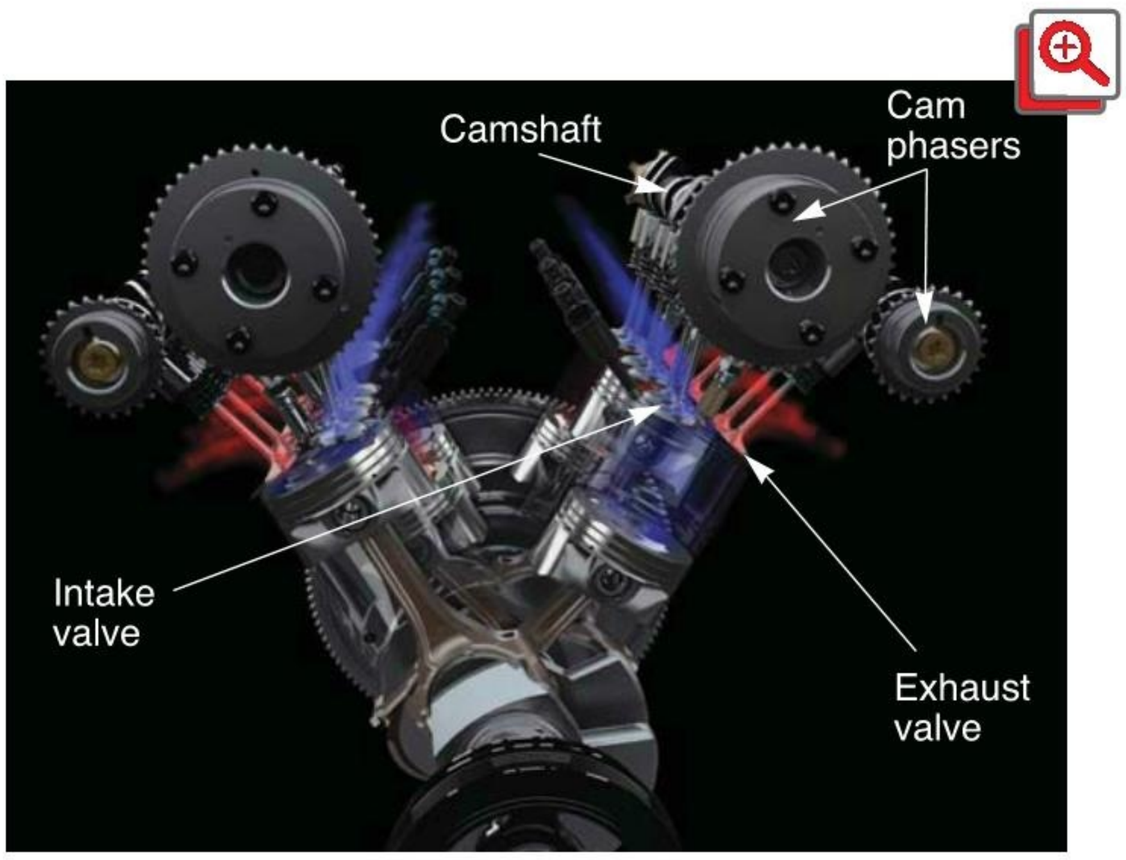
Tech Tip

In most systems, the spark plugs continue to fire in deactivated cylinders. This helps prevent spark plug temperature loss and minimizes fouling caused by incomplete combustion during cylinder reactivation.

Variable Valve Timing Engine

A ***variable valve timing engine*** can alter valve opening and closing independent of crankshaft rotation. This also improves engine efficiency compared to conventional engines that fix valve action with each degree of crankshaft rotation.

In some systems, a rotating camshaft gear called a cam phaser is used to change valve timing. See **Figure 12-6**. However, other variable valve timing designs rely on electro-hydraulically operated rocker arms to alter valve operation. An advantage of this

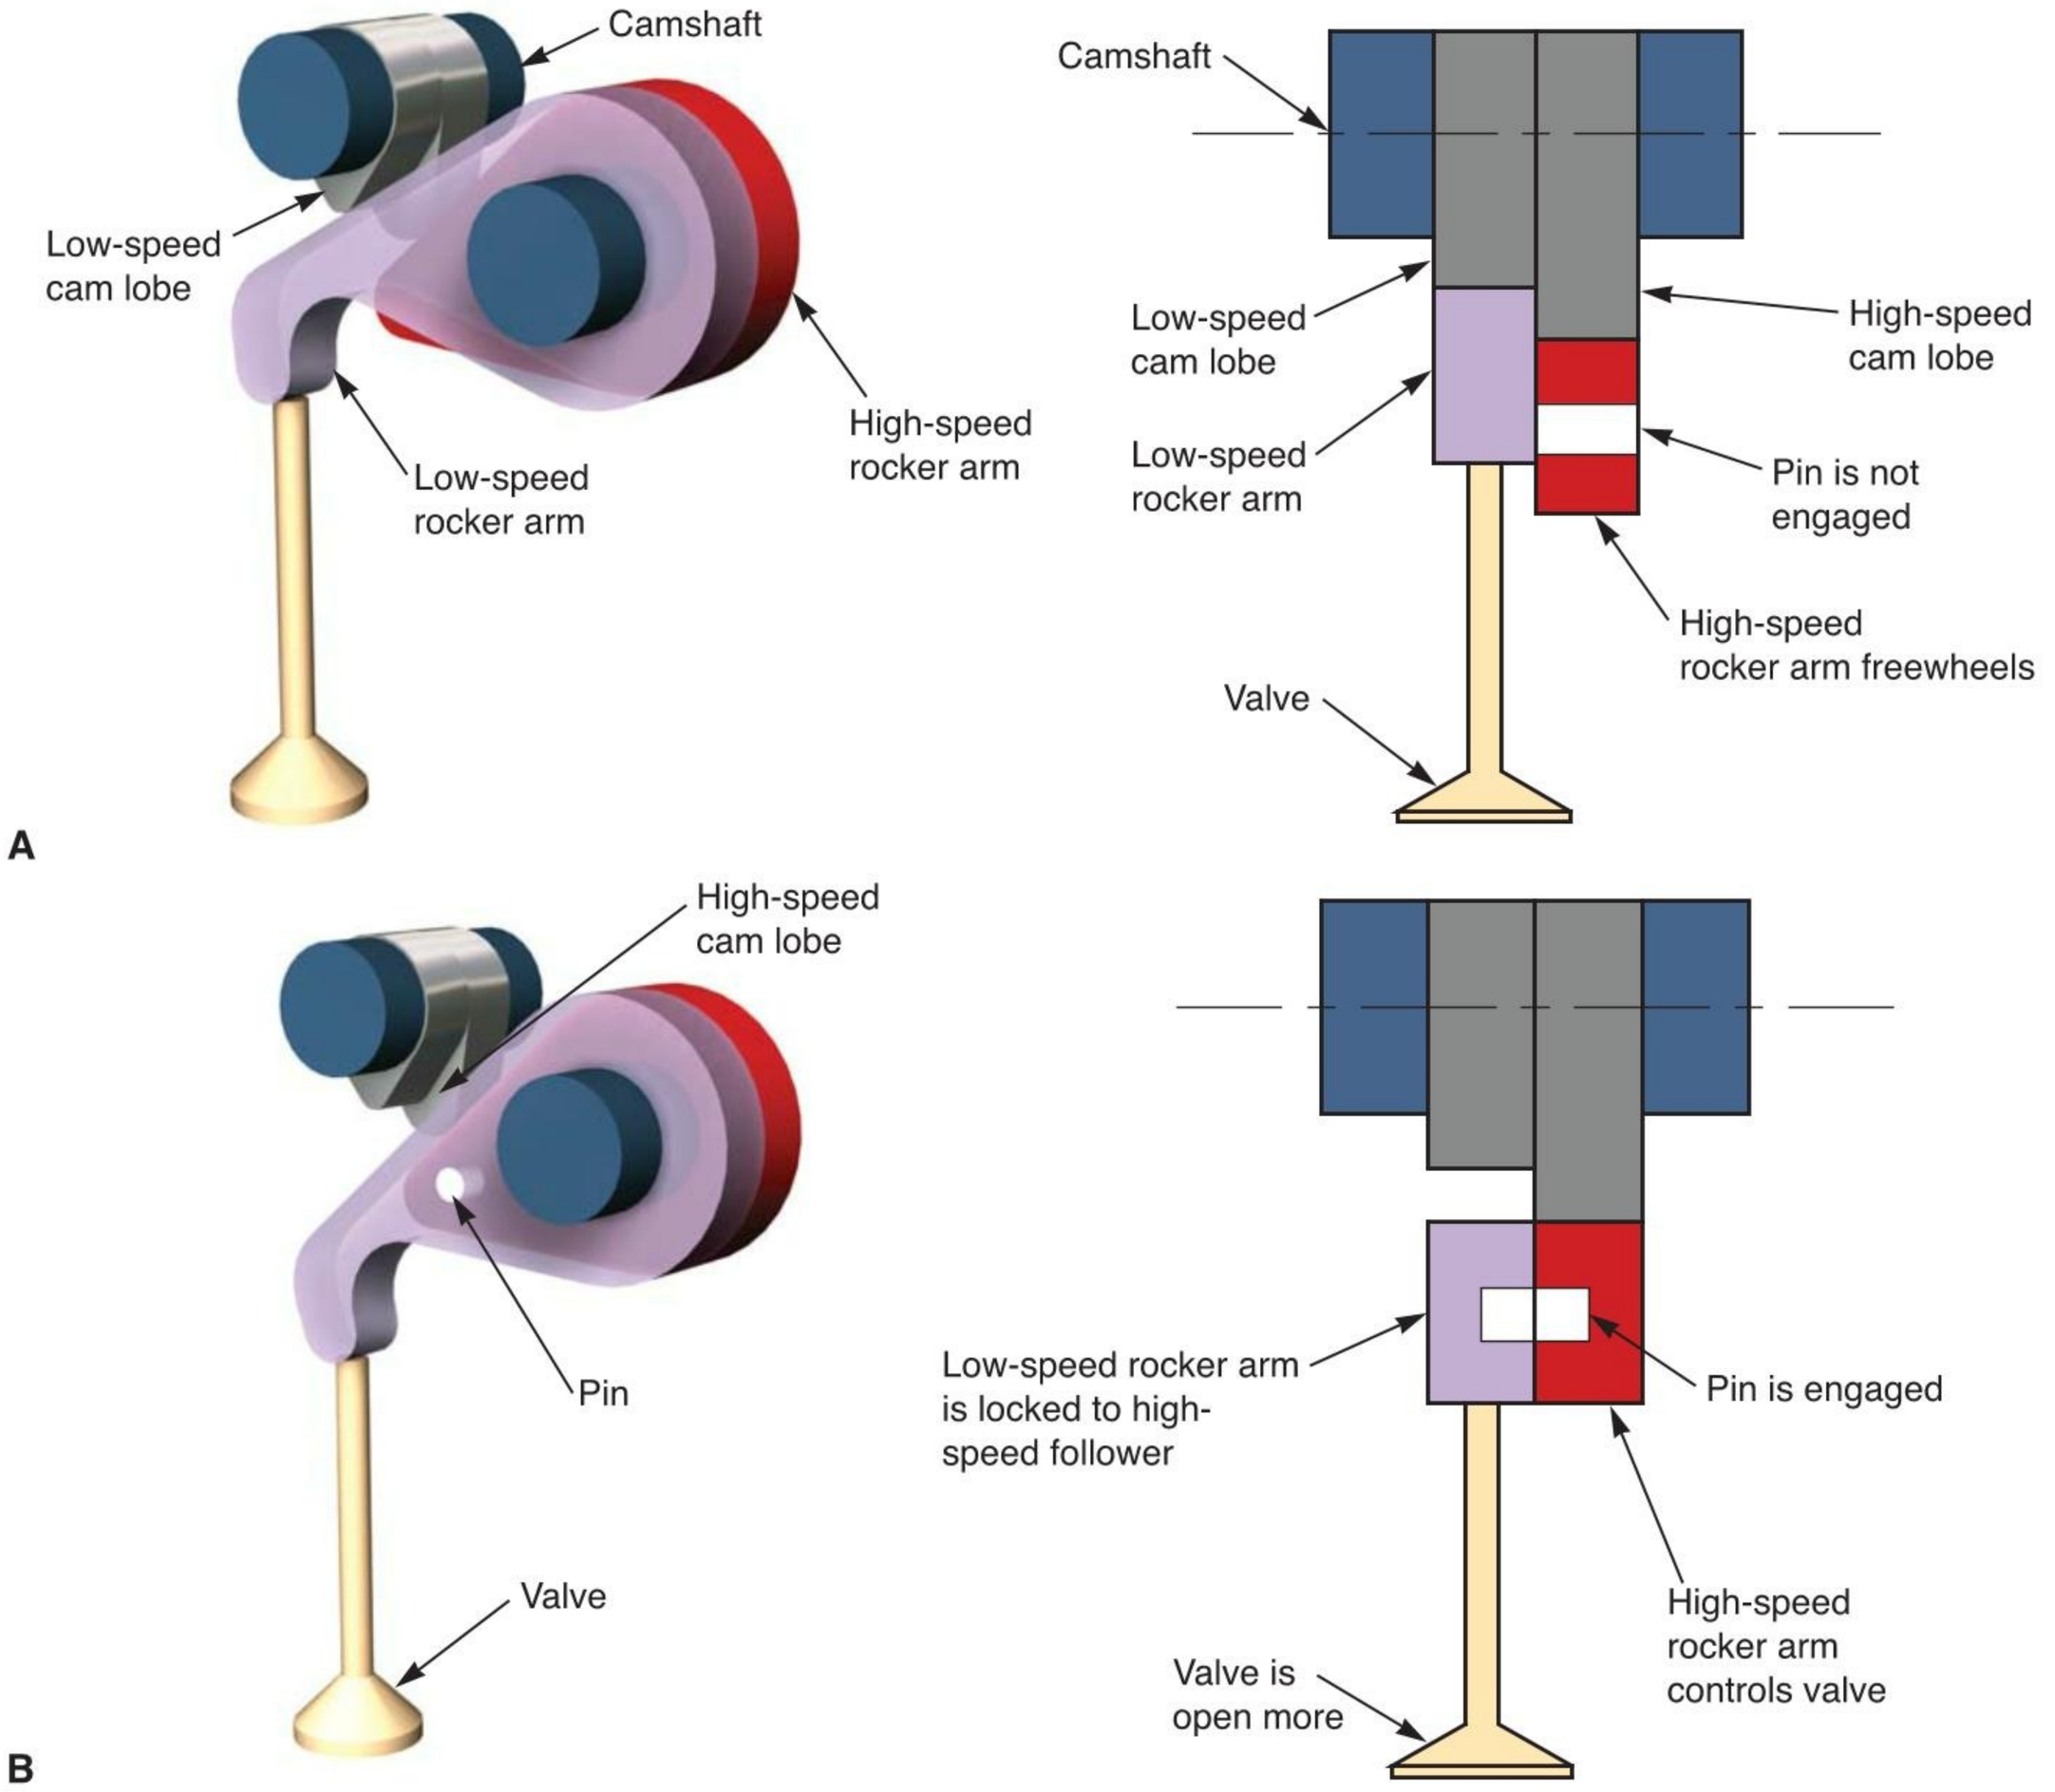


Goodheart-Willcox Publisher

Figure 12-6. This high efficiency engine uses electro-hydraulic cam phasers to advance or retard valve timing with engine speed and load.

Copyright Goodheart-Willcox Co., Inc.

design is that in addition to altering valve timing, it can match valve lift (distance the valve opens) and duration (amount of time valve remains open) to engine speed and load for improved power and lower exhaust emissions. These systems use two different camshaft lobes and two rocker arms for each valve. One lobe is designed for optimal performance at low engine speeds. The second lobe is designed for optimal performance at high engine speeds. At low engine speeds, the low-speed cam lobe acts on the low-speed rocker arm to open the valve. The high-speed cam lobe acts on the high-speed rocker arm, but the rocker arm "freewheels" and does not act on any other component. However, once the engine reaches a certain speed, the computer opens a valve to allow oil pressure to push a pin through both the low- and high-speed rocker arms. Since the rocker arms are now locked together, the high-speed cam lobe controls the opening of the valve. See **Figure 12-7**.



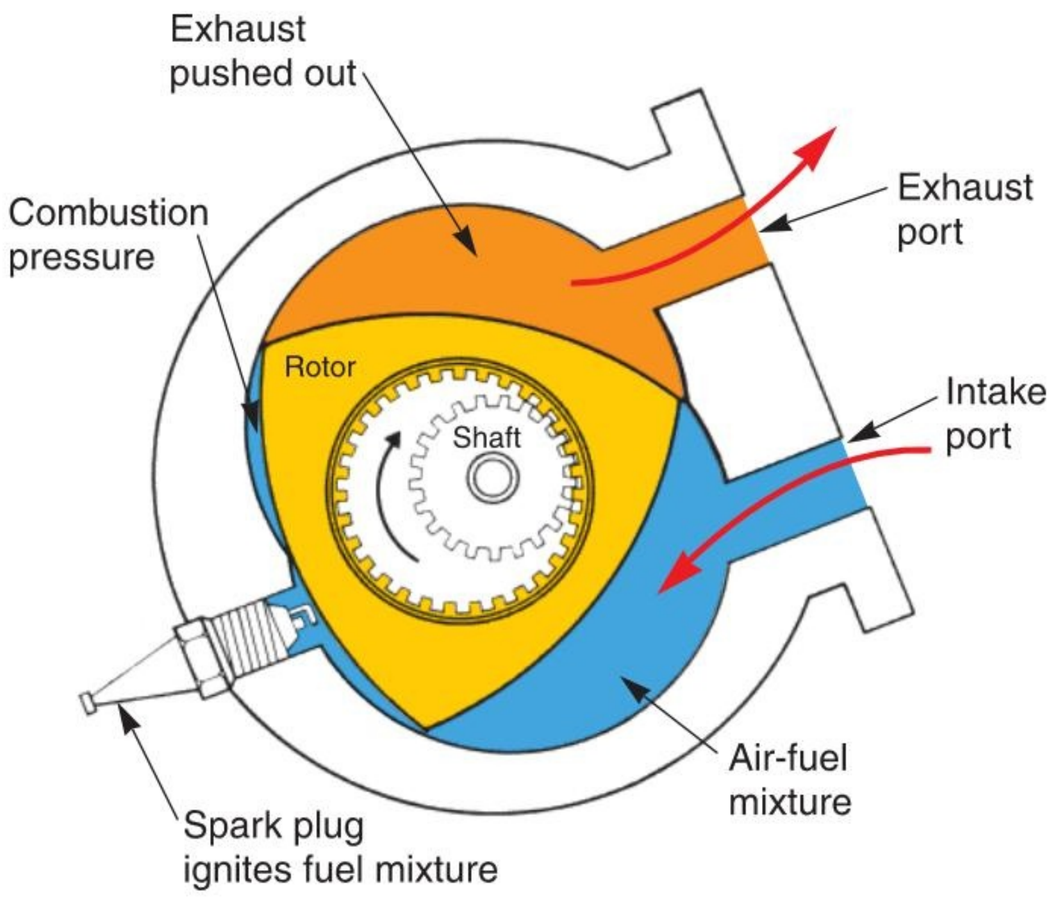
Goodheart-Willcox Publisher

Figure 12-7. This variable valve timing engine uses two camshaft lobes per cylinder to alter valve timing. A—At low engine speeds, the low-speed cam lobe and rocker arm control the valve action. B—At high engine speeds, the pin locks the low- and high-speed rocker arms together and the high-speed cam lobe controls valve action.

Copyright Goodheart-Willcox Co., Inc.

Rotary Engine

A ***rotary engine***, also known as a Wankel engine, uses a spinning triangular rotor instead of conventional pistons. The rotor turns inside a specially shaped chamber, as shown in **Figure 12-8**.



Goodheart-Willcox Publisher

Figure 12-8. Study the parts of a rotary automotive engine. The rotor spins inside the housing for smooth operation. There are no reciprocating pistons in this design.

While turning in the chamber, the rotor orbits around a mainshaft. This eliminates the reciprocating (up-and-down) motion found in piston engines.

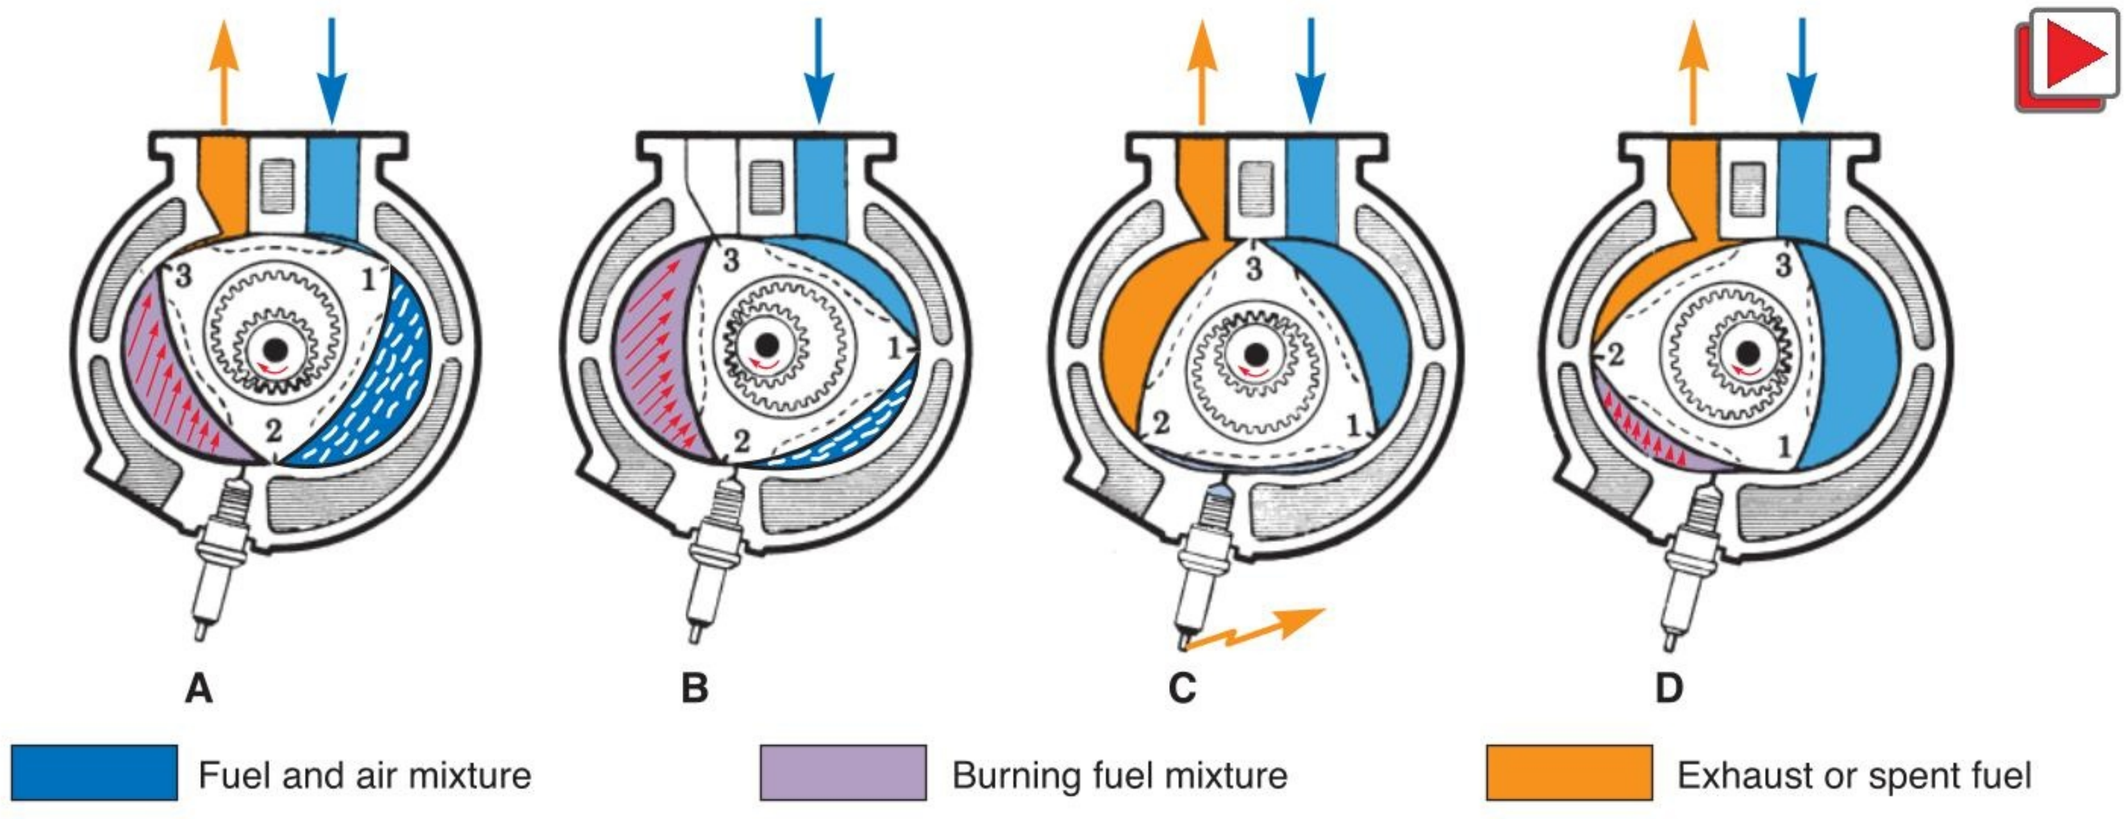
Three complete power-producing cycles take place during every revolution of the rotor: three rotor faces produce three intake, compression, power, and exhaust events per revolution, as shown in **Figure 12-9**.

A rotary engine is very powerful for its size. Also, because it spins—rather than moving up and down—engine operation is very smooth and vibration free.

In the past, a complicated emission control system was needed to make the rotary engine pass emissions standards. This has limited the use of the traditional rotary engine. The newest rotary engine, called the Renesis design, has intake and exhaust ports in the engine endplates and to the side of the rotor housing. The ports are no longer in the periphery of the rotor housing. This helps reduce exhaust emissions because it eliminates the intake/exhaust port overlap of the older design, which contributed to higher emissions. See **Figure 12-10**.

Two-Stroke-Cycle Engine

A ***two-stroke-cycle engine*** is similar to a four-stroke-cycle engine, but it requires only one revolution of the crankshaft for a complete power-producing cycle. Two piston strokes (one upward and one



Goodheart-Willcox Publisher

Figure 12-9. The sequence of events in a rotary engine. A—Intake is starting between points 1 and 3, compression is occurring between points 1 and 2, power is being produced between points 2 and 3, and exhaust is finishing between points 3 and 1. B—Intake continues between points 1 and 3, compression continues between points 1 and 2, and power is finishing between points 2 and 3. C—Intake continues between points 1 and 3, spark occurs between points 1 and 2 (power begins), and exhaust begins between points 2 and 3. D—Intake is finished between points 1 and 3, power is being produced between points 1 and 2, and exhaust is continuing between points 2 and 3.

Figure 12-10. In this rotary engine design, the intake and exhaust ports are located in the endplates. This reduces emissions considerably.

downward) complete the intake, compression, power, and exhaust events. Look at **Figure 12-11**.

As the piston moves up, it compresses the air-fuel mixture in the combustion chamber. At the same time, the vacuum created in the crankcase by the piston movement draws fuel and oil into the crankcase. Either a ***reed valve*** (flexible metal flap valve) or a ***rotary valve*** (spinning disc-shaped valve) can be used to control flow into the crankcase.

When the piston reaches the top of the cylinder, ignition occurs and the burning gases force the piston downward while spinning in the crankshaft.

As the piston moves down in the cylinder, it uncovers an exhaust port in the cylinder wall. Burned gases leave the engine through the exhaust port.

As the piston continues downward, it uncovers the transfer port. Pressure in the crankcase causes a fresh fuel charge to flow through the transfer port and into the cylinder. Upward movement of the piston again covers the transfer and exhaust ports, compression begins, and the cycle is repeated.

Since the crankcase is used as a storage chamber for each successive fuel charge, the fuel and lubricating oil are pre-mixed and introduced into the engine through the carburetor.

Inside the crankcase, some of the oil separates from the gasoline. The oil mist lubricates and protects the moving parts inside the engine.

Generally speaking, two-stroke-cycle engines are not used in vehicles because they:

- Produce too much exhaust pollution.
- Have poor power output at low speeds.
- Require more service than a four-stroke engine.
- Must have motor oil mixed into the fuel.
- Are not as fuel efficient as a four-stroke engine.

Miller-Cycle Engine

A ***Miller-cycle engine*** uses a modified four-stroke cycle. This engine is designed with a shorter compression stroke and a longer power stroke to increase efficiency. The intake valve remains open longer to delay compression. Because the intake valve remains open for a relatively long time, the air-fuel charge wants to

Mazda

Figure 12-12. Cutaway view of a Miller-cycle engine. It is similar to a conventional four-stroke piston engine. However, the opening and closing of the intake valves is modified to increase the duration of power stroke. Note the supercharger, which is needed to prevent backflow of the fuel charge into the intake manifold.

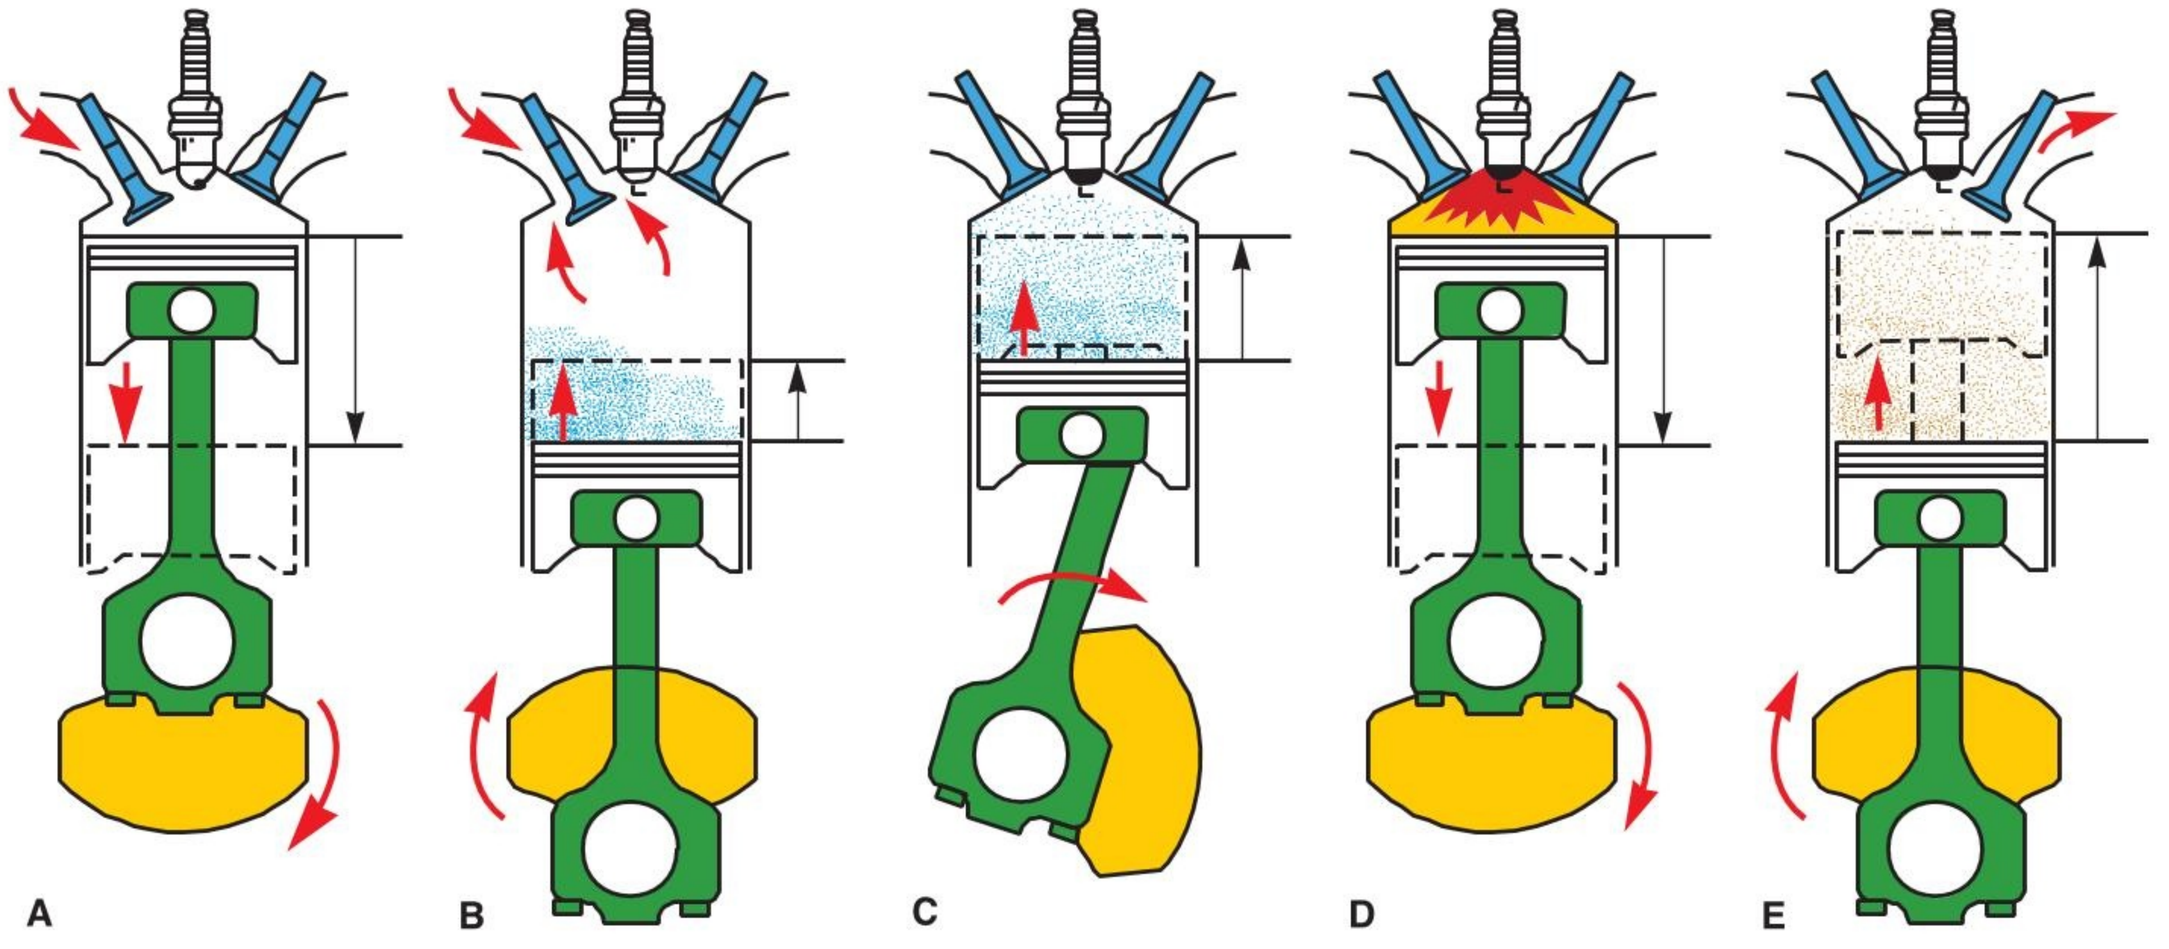
be pushed back out the intake port. To compensate for this reverse flow, a supercharger is normally used to pressurize the intake manifold and block or reverse airflow, **Figures 12-12** and **12-13**.

Today, an Atkinson cycle engine modifies the four-stroke-cycle engine to have a short intake stroke and a very long power stroke. This allows the engine to pull more heat energy out of the burning fuel. Variable cam and valve timing can cause the compression stroke to occur more quickly and power stroke to take more time in degrees of crankshaft rotation. A small cylinder bore and long stroke will also help thermal efficiency.

Theoretically, a Miller-cycle engine can produce more power and is more economical than a conventional four-stroke-cycle engine of equal size. However, the engine is more complex to produce and maintain because of the supercharger. One auto manufacturer is now successfully using a Miller-cycle engine in its passenger cars.

Workplace Skills

An apprentice technician gave a customer a quote for a valve job on a passenger car engine. The apprentice failed to recognize that the customer's vehicle was equipped with a four-valve engine. When the bill came back from the machine shop for grinding the valves and cylinder head seats, it was twice as much as estimated. Instead of 16 valves, the heads had 32 valves and 32 seats, doubling the parts and labor needed to recondition the heads.



Goodheart-Willcox Publisher

Figure 12-13. Illustrations show Miller-cycle engine operation. A—The piston slides down with the intake valve open. B—The intake valve remains open as the piston slides up. Supercharger pressure prevents backflow into the intake port. C—Piston travels with both valves closed. D—Power stroke. E—Exhaust stroke.

Copyright Goodheart-Willcox Co., Inc.

The apprentice tried to explain to the customer why the final bill for the repair was higher than originally estimated. The customer paid the bill, but he left the shop angry, taking his business elsewhere after that.

If the apprentice had taken the time to learn about various engine classifications, he would not have given the low quote and the customer would have been satisfied with the repair. If you are not sure about something, research it.

Summary

- Although basic engine parts are the same, design differences can change how engines operate and how they are repaired.
- Cylinder arrangement refers to the position of the cylinders in relation to the crankshaft.
- The liquid cooling system surrounds the cylinder with coolant (water and antifreeze solution).
- A spark ignition engine uses an electric arc at the spark plug to ignite the fuel.
- A compression ignition engine squeezes the air in the combustion chamber until it is hot enough to ignite the fuel.
- A cam-in-block engine uses push rods to transfer motion to the rocker arms and valves.
- In an overhead cam (OHC) engine, the camshaft is located in the top of the cylinder head.
- A four-valve combustion chamber uses two exhaust valves and two intake valves per cylinder.
- A stratified charge combustion chamber uses a small combustion chamber flame to ignite and burn the fuel in the main combustion chamber.
- A precombustion chamber is commonly used in automotive diesel engines.
- A variable displacement engine can deactivate cylinders so the engine conserves fuel and produces fewer emissions.
- A variable valve timing engine can alter valve opening and closing independent of crankshaft rotation.
- A two-stroke-cycle engine is similar to a four-stroke-cycle engine, but it requires only one revolution of the crankshaft for a complete power-producing cycle.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

air cooling system
air jet combustion chamber
compression ignition engine
cylinder arrangement
cylinder numbers
diesel prechamber
dual overhead cam (DOHC) engine
flat head engine
four-valve combustion chamber
hemispherical combustion chamber
I-head engine
inline engine
L-head engine
liquid cooling system
Miller-cycle engine
opposed engine
overhead cam (OHC) engine
overhead valve (OHV) engine
pancake combustion chamber
pent-roof combustion chamber
precombustion chamber
reed valve
rotary engine
rotary valve
single overhead cam (SOHC) engine
spark ignition engine
squish area
stratified charge combustion chamber
swirl combustion chamber
three-valve combustion chamber
two-stroke-cycle engine
variable displacement engine
variable valve timing engine
V-type engine
wedge combustion chamber
W-type engine

Activities

1. Make a poster that shows the four types of engine cylinder arrangements. Label the arrangements.
2. Visit vehicle manufacturer websites and identify the different engine types offered as standard across the range of automobile models under a single brand name (Ford, Honda, Chrysler, Volvo, etc.). Write a short report on your findings.

Copyright Goodheart-Willcox Co., Inc.

3. Research the Stanley Steamer or another steam-driven automobile on the Internet. Describe to the class how its engine worked. Show a drawing or photograph, if possible.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List ten ways to classify an automotive engine.
2. Normally, car engines have _____, _____, or _____ cylinders.
3. Why are cylinders numbered?
4. Cylinder numbering varies from one manufacturer to another. True or False?
5. Most car engines have air cooling systems. True or False?
6. Explain the difference between spark ignition and compression ignition.
7. Where are the two typical locations for the engine camshaft?
8. Which of the following does not refer to camshaft location and design?
   (A) OHC.
   (B) SOHC.
   (C) DOHC.
   (D) UHC.
9. A hemi-head combustion chamber is flat. True or False?
10. Explain the operation of a diesel precombustion chamber.
11. A(n) _____ engine does *not* use pistons that slide up and down.
12. Some variable valve timing engines use electro-hydraulically controlled _____ to alter valve operation.
13. Three complete power-producing cycles occur during every revolution of a rotary engine's rotor. If an engine has three rotors and each completes one revolution, how many complete cycles are produced?
   (A) 4.
   (B) 3.
   (C) 6.
   (D) 9.
14. Which of the following refers to a two-stroke-cycle engine?
   (A) One crankshaft revolution completes a power-producing cycle.
   (B) Two strokes complete all four events.
   (C) Uses reed valves or rotary valves.
   (D) All of the above.
15. In a Miller-cycle engine, a supercharger is used to _____ the intake manifold.

ASE-Type Questions

1. Vehicle engine classifications include each of the following *except:*
   (A) valve location.
   (B) type of ignition.
   (C) number of cylinders.
   (D) type of drive mechanism.
2. Which of the following is *not* a basic cylinder arrangement?
   (A) Opposed.
   (B) Inline.
   (C) U-type.
   (D) V-type.
3. Technician A says gasoline engines are compression ignition engines. Technician B says compression ignition engines use spark plugs to ignite the fuel. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. The type of engine that has both an intake and exhaust valve in its cylinder head is called a(n):
   (A) I-head engine.
   (B) L-head engine.
   (C) flat head engine.
   (D) All of the above.
5. In cam-in-block engine, push rods are needed to operate the:
   (A) rockers and valves.
   (B) camshaft and valves.
   (C) camshaft and rockers.
   (D) All of the above.

Copyright Goodheart-Willcox Co., Inc.

6. The combustion chamber shape in which the valve heads are almost parallel with the top of the piston is called the:
   (A) swirl chamber.
   (B) wedge chamber.
   (C) pancake chamber.
   (D) stratified chamber.
7. Which of the following combustion chambers allows the use of a glow plug in automotive diesel engines?
   (A) Precombustion chamber.
   (B) Swirl chamber.
   (C) Air jet chamber.
   (D) Stratified charge chamber.
8. The engine type that uses a triangular rotor instead of conventional pistons is called a(n):
   (A) rotary engine.
   (B) opposed engine.
   (C) cam-in-block engine.
   (D) spark ignition engine.
9. A two-stroke-cycle engine requires how many crankshaft revolutions per power cycle?
   (A) One.
   (B) Two.
   (C) Four.
   (D) None of the above.
10. While discussing engines, Technician A says two-stroke-cycle engines are not used in vehicles because they have poor power output at low speeds. Technician B says two-stroke engines are not used in vehicles because they produce too much exhaust pollution. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Chapter 13

Engine Top End Construction

After studying this chapter, you will be able to:

- Describe the design and construction of an engine cylinder head.
- Explain umbrella and O-ring valve seals.
- Explain the purpose of valve spring shims, rotators, stem caps, and spring shields.
- Describe the construction and operation of a camshaft.
- Explain hydraulic and mechanical lifters.
- Describe different types of rocker arm assemblies.
- Explain the construction and design of intake and exhaust manifolds.
- Describe safety practices used when working on engine top end components.
- Answer ASE certification test questions that require a knowledge of engine top end construction.

An ***engine top end*** basically includes the cylinder head assembly, valve train, valve cover, and intake and exhaust manifolds. Understanding the construction of an engine top end helps improve your ability to troubleshoot and repair an engine. This chapter explains the engine top end and each of its components, **Figure 13-1**.

Cylinder Head Construction

A ***bare cylinder head*** is a complex metal casting with all of its parts removed. These parts include the valves, keepers, retainers, springs, seals, and rocker arms. A bare cylinder head is commonly made of cast iron or aluminum.

If a cylinder head becomes badly damaged, the technician may need to install a new bare head. All the old, reusable parts (valves, keepers, retainers, etc.) can be removed and installed in the new head.

The construction of a cylinder head varies with engine design and type. It is critical that you understand the most important cylinder head variations. See **Figures 13-2** and **13-3**.

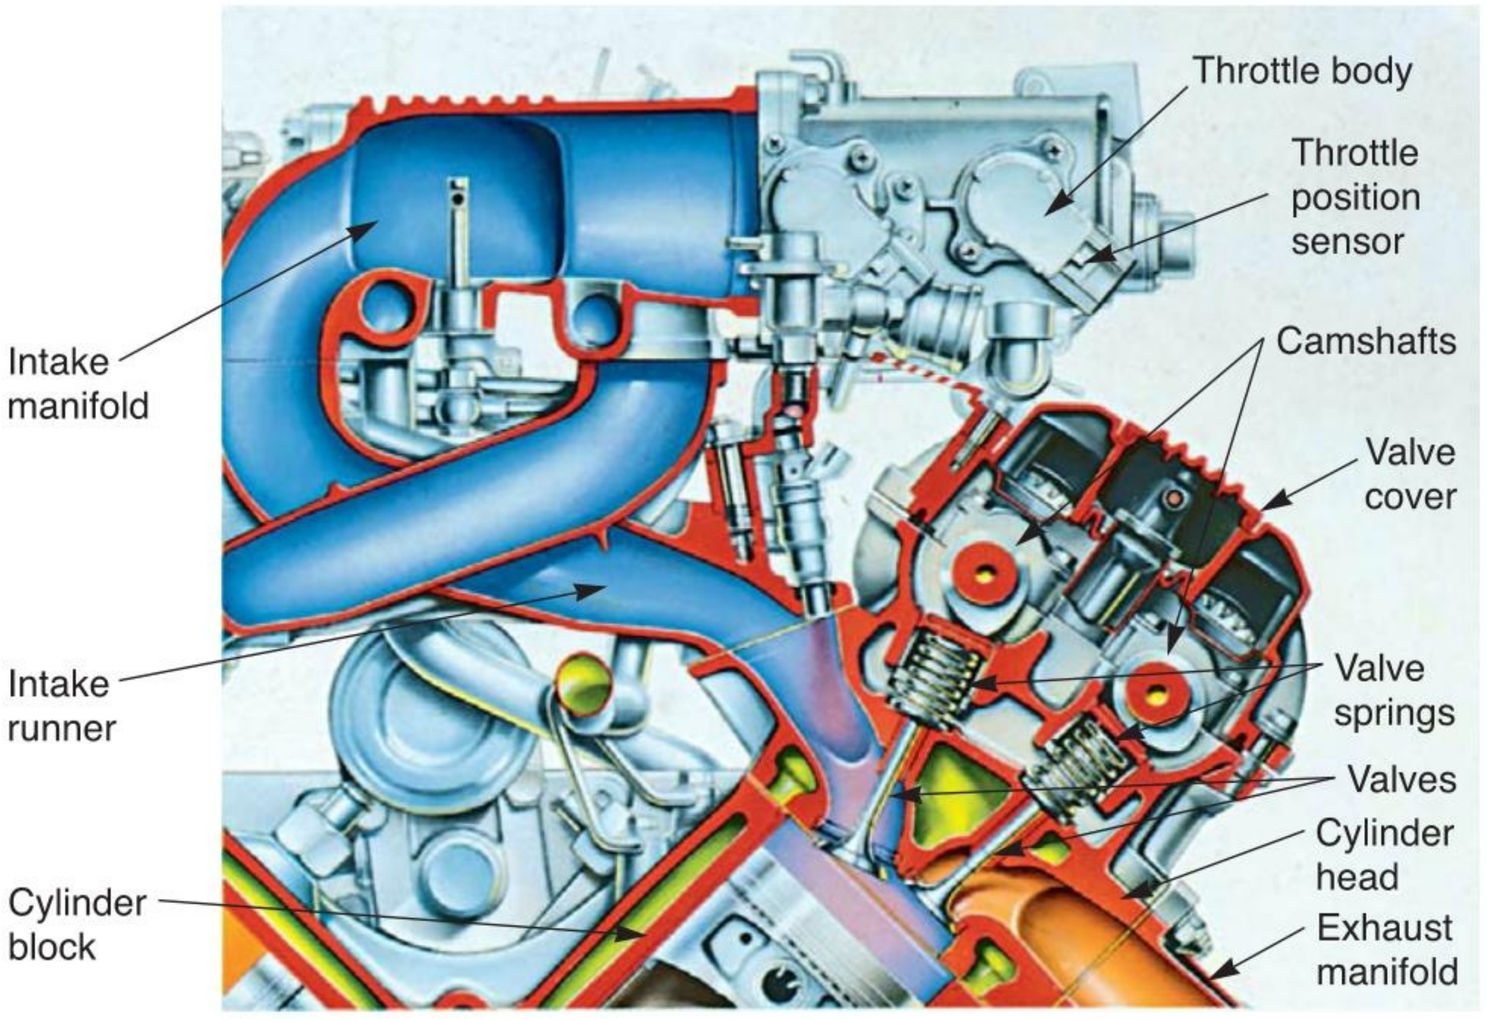
For example, some engines have a drain hole at the rear of the cylinder head. This allows the oil from the valve train to flow back down through the engine and into the sump. With this design, the engine may be mounted in the vehicle at a slight angle.

Valve Guide Construction

There are two basic types of valve guides: integral guides and pressed-in guides. Both types are used in modern engines.

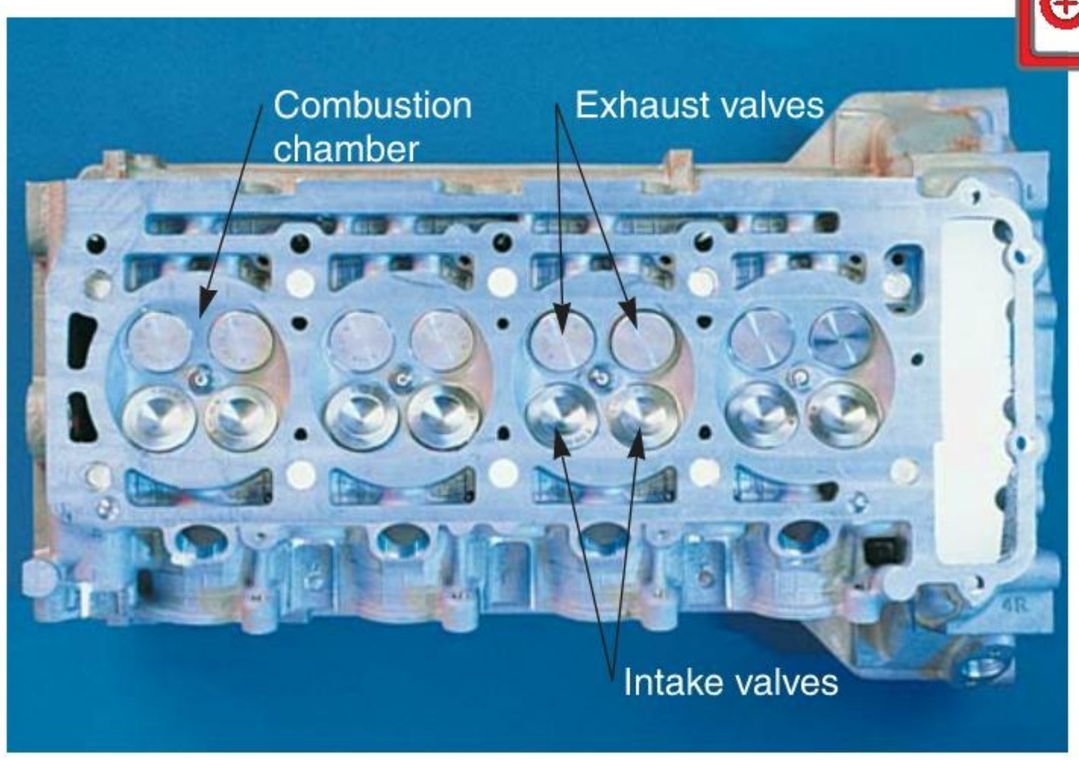
An ***integral valve guide*** is part of the cylinder head casting. An integral guide is simply a hole machined

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 13-1. Generally, an engine top end includes parts that fasten to the top of the cylinder block. These include the head, valve train, intake manifold, exhaust manifold, and valve cover.



Chrysler

Figure 13-2. The cylinder head assembly has the valves and springs still installed. This cast aluminum cylinder head has four-valve combustion chambers.

through the cylinder head. This type of guide is very common because of its low production cost.

A ***pressed-in valve guide*** is a separate sleeve forced into a hole machined in the cylinder head. It can be made of cast iron or bronze. Friction from the press fit holds the valve guide in the cylinder head. A pressed-in valve guide simplifies guide repair. See **Figure 13-4**.

A worn guide can be pressed out and a new guide can be quickly pressed in. This eliminates some of the machining needed when replacing a badly worn integral valve guide.

Valve Seat Construction

Like valve guides, valve seats can be integral or pressed-in. Both are commonly used in modern engines.

An ***integral valve seat*** is simply a machined portion of the cylinder head casting. Different cutters are used to machine a precise face on the valve port opening.

A ***pressed-in valve seat***, also called a seat insert, is a separate part that is forced into a recess cut into the head. Steel pressed-in valve seats are commonly used in aluminum cylinder heads. Steel is needed to withstand the extreme heat produced during engine operation. A pressed-in valve seat is shown in **Figure 13-4**.

The ***valve seat angle*** is the angle formed by the face of the seat. A 45° angle is commonly used on passenger car engines. However, some high-performance engines have seat angles of 30°.

An ***interference angle*** is a 1/2°–1° difference between the valve seat face angle and the angle of the valve face. The interference angle reduces

TRW

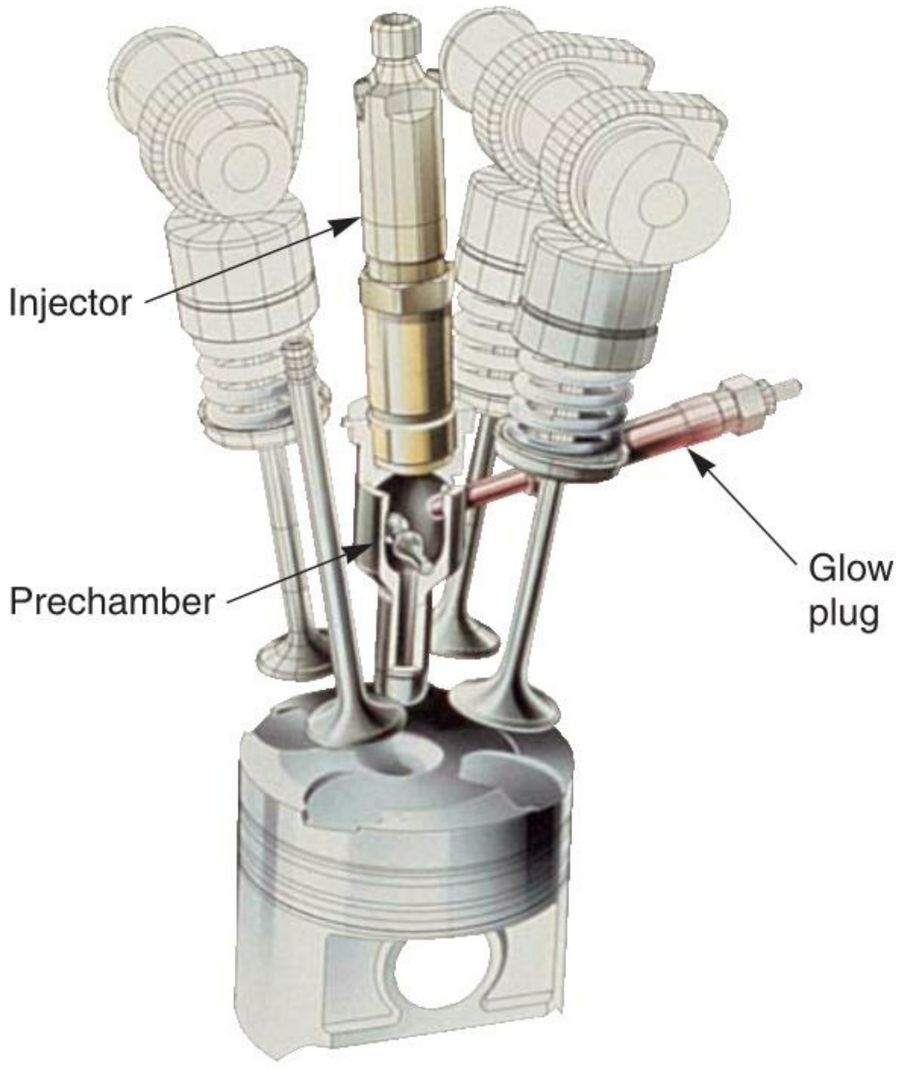
Figure 13-5. Common valve and seat angles are 30° and 45°. The interference angle is the 1° difference between the valve and seat angles to increase sealing pressure and to speed seating, or break-in.

the contact area between the seat and valve. This increases pressure between the two and speeds valve seating (sealing) during engine operation, **Figure 13-5**.

Prechamber Cup

A ***prechamber cup*** is pressed into the cylinder head of some diesel engines. Holes are precisely machined into the cylinder head deck surface. The prechamber cups are force-fit into these holes. Each prechamber cup forms an enclosure around the tip of an injector and glow plug. This area is heated by the glow plug for better cold starting. Refer to **Figure 13-6**.

Copyright Goodheart-Willcox Co., Inc.

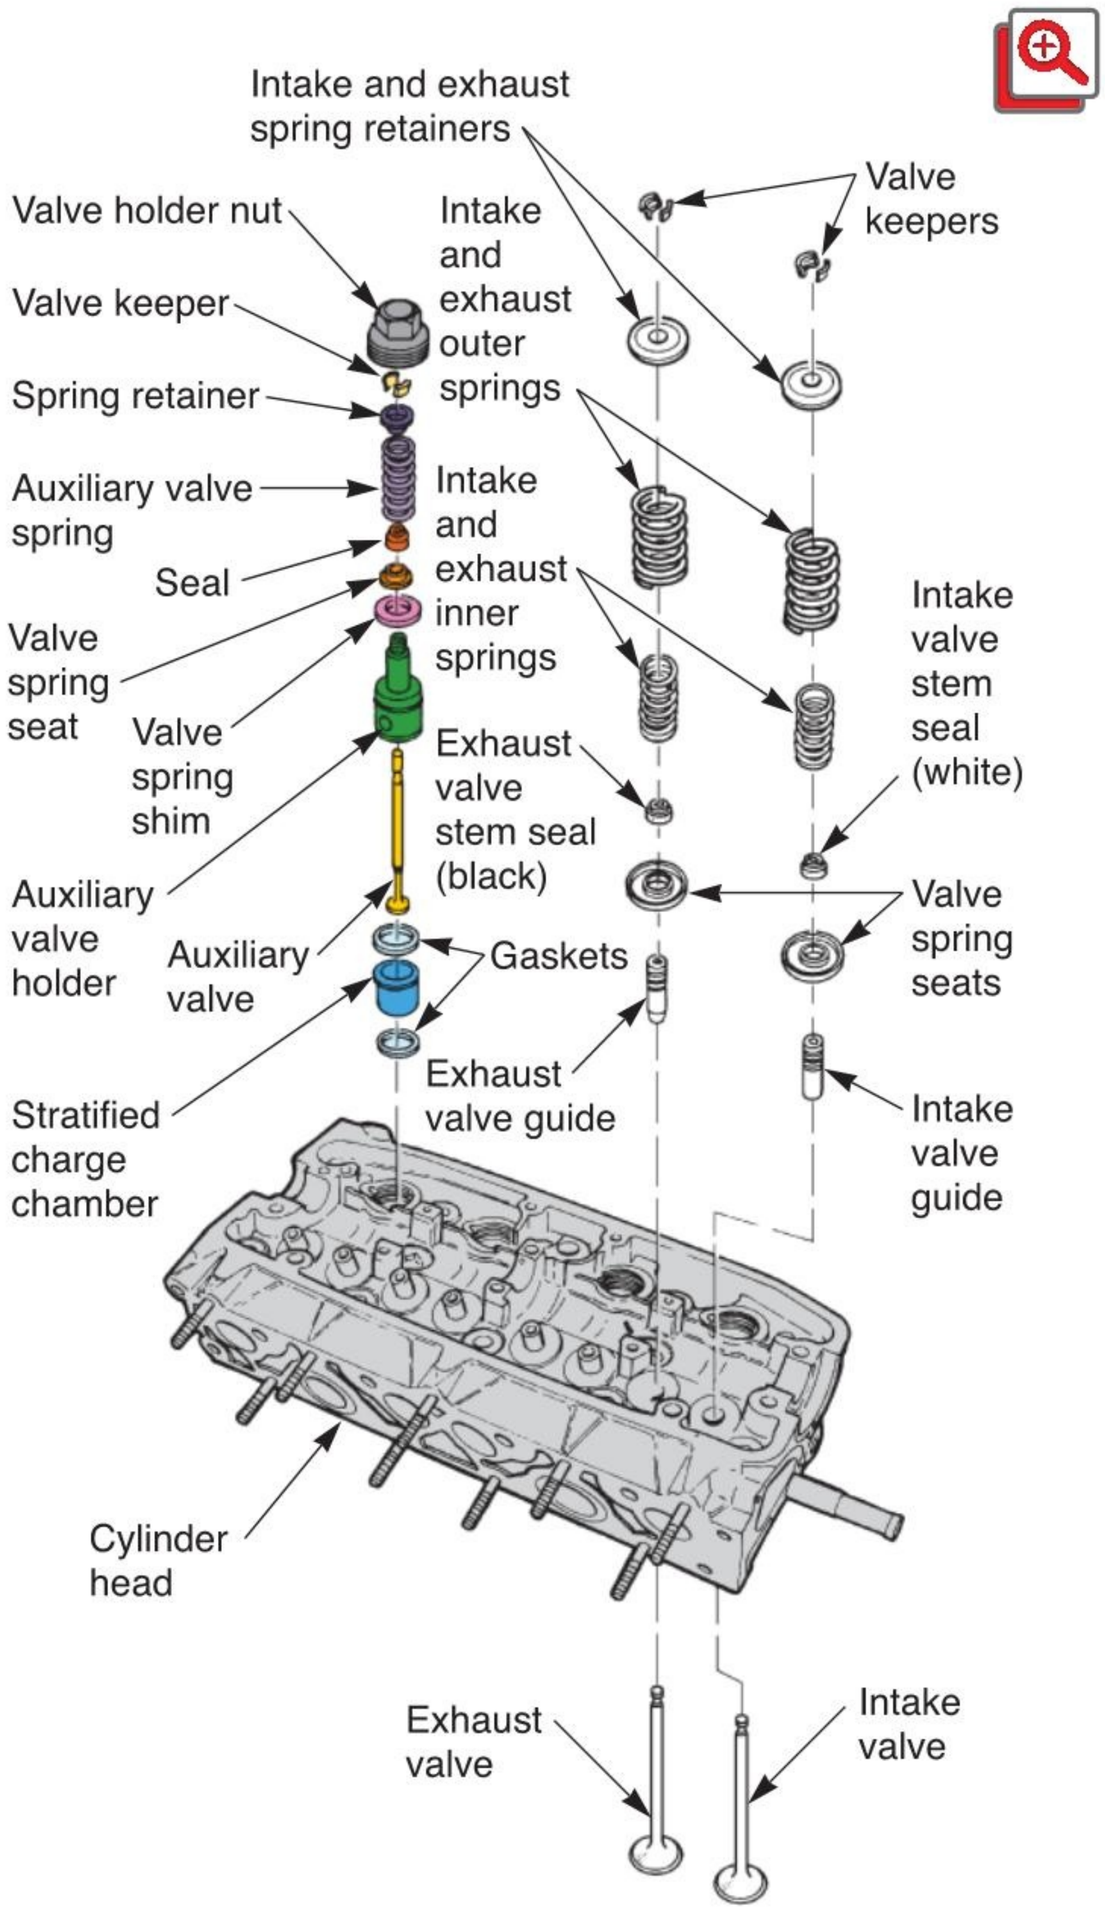


General Motors

Figure 13-6. A diesel cylinder head normally has pressed-in prechamber cups. They form the precombustion chambers for the tips of glow plugs and injectors.

Stratified Charge Chamber

A stratified charge chamber also fits into the cylinder head casting. It is found in gasoline engines that are designed to use a rich fuel mixture in the auxiliary chamber to ignite a lean mixture in the main combustion chamber. **Figure 13-7** shows how the stratified charge chamber and related components are assembled in the cylinder head. Study it closely.



Honda

Figure 13-7. This is a gasoline engine cylinder head with stratified charge auxiliary chambers. Note how the chamber and extra intake valve are assembled.

Valve Train Construction

The valve train controls the opening and closing of the cylinder head ports. Although the basic function of all valve trains is the same, valve train construction will vary with engine design. To be able to work on any type of valve train, you must understand these differences.

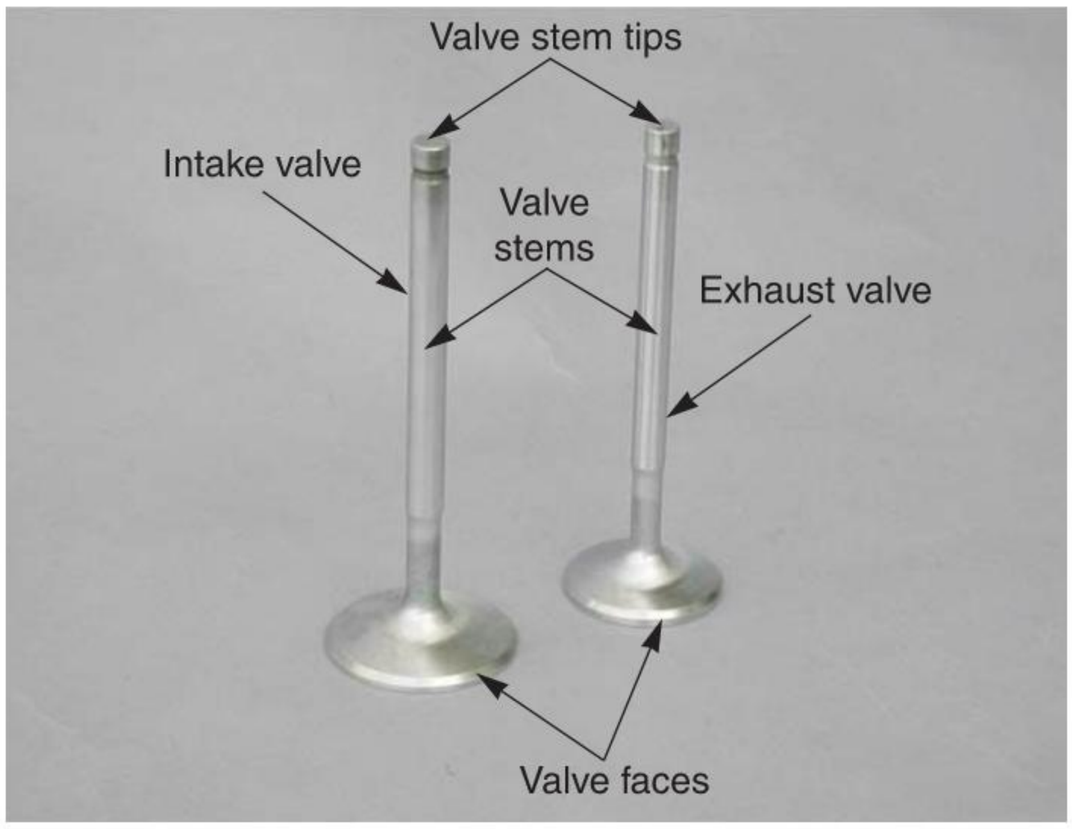
Valve Construction

Automotive engines commonly use ***poppet valves***, or ***mushroom valves***. These terms come from the valve's shape and action. The valve is shaped something like a mushroom and it "pops" open. Actual engine valves are shown in **Figure 13-8**.

Almost every surface of a valve is machined. The stem must accurately fit the guide. Some engine valve stems are chrome plated to better resist wear. The face must contact the seat perfectly. The margin must be thick enough to prevent valve burning. Grooves are cut into the valve stem tops for the keepers.

The ***valve face angle*** is the angle formed between the valve face and valve head. Normal valve face angles are 45° and 30°. The exhaust valve is exposed to higher temperatures than the intake valve—the intake valve has cooler outside air flowing

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 13-8. Typical poppet, or mushroom, valves. The intake valve is normally larger than the exhaust valve.

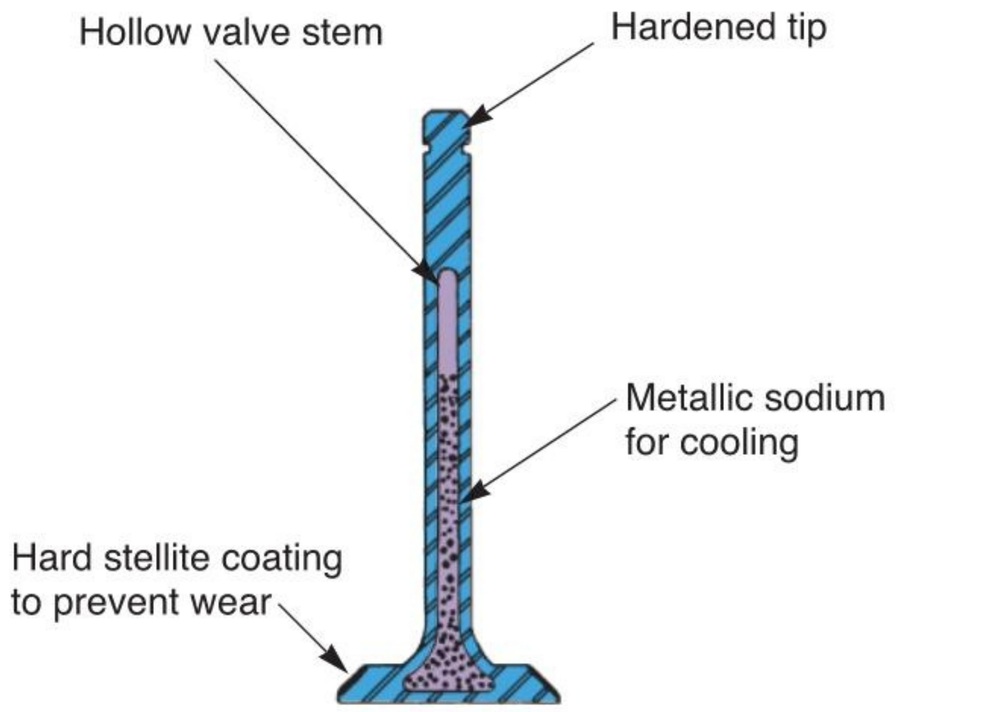
over it, while hot combustion gases flow over the exhaust valve. If the exhaust valve does not transfer heat into the cylinder head, it will burn.

Hollow-stem, sodium-filled valves are used when extra valve cooling action is needed. During engine operation, the sodium inside the hollow valve melts. When the valve is pressed down, or opened, the sodium splashes down into the valve head and collects heat. Then, when the valve is released, or closed, the sodium splashes up into the valve stem. Heat transfers out of the sodium and into the stem, valve guide, and engine coolant. In this way, the valve is cooled.

Warning

Sodium-filled valves are used in a few high-performance engines. They are very light and allow high engine rpm for prolonged periods. However, they can explode if placed in a fire and, therefore, must be disposed of properly.

A stellite valve has a stellite (very hard metal alloy) coating on its face. A stellite coating is often used in engines designed to burn unleaded fuel. Older engines did not require the use of stellite valves, because leaded fuel (now phased out) helped lubricate the valve and seat faces. Look at **Figure 13-9**.



Goodheart-Willcox Publisher

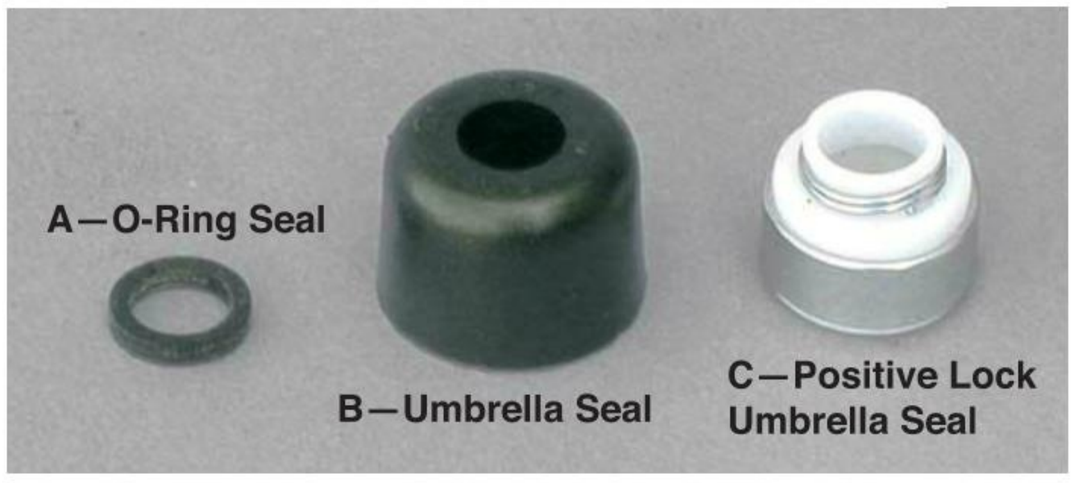
Figure 13-9. Stellite coating on the valve face retards wear and allows the use of unleaded fuel.

Valve Seal Construction

Valve seals come in two basic types. These types are umbrella and O-ring. Both are common on modern engines. See **Figure 13-10**.

An ***umbrella valve seal*** is shaped like a cup and can be made of neoprene rubber or plastic. An umbrella valve seal slides down over the valve stem before the spring and retainer. It covers the small clearance between the valve stem and guide. This keeps oil from being drawn into the cylinder head port and combustion chamber.

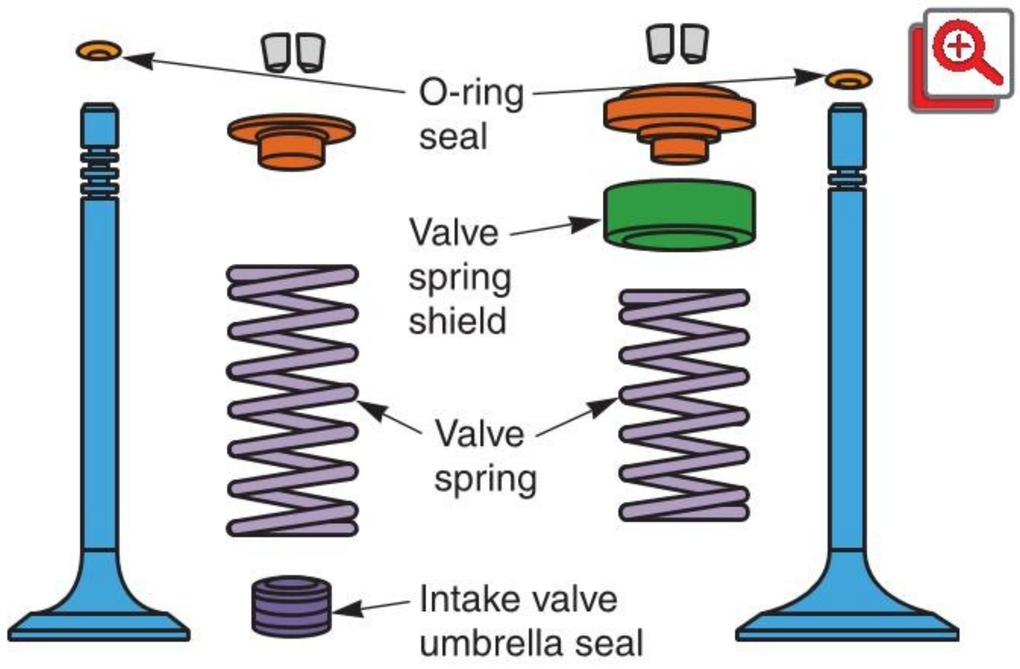
An ***O-ring valve seal*** is a small round seal that fits into an extra groove cut in the valve stem. Unlike the umbrella type, it seals the gap between the retainer and valve stem, not the guide and stem. It stops oil from flowing through the retainer, down the stem, and into the guide. An O-ring valve seal fits onto the valve stem after the spring and retainer. It is made of soft synthetic rubber that allows it to be stretched over the valve stem and into place. Look at **Figure 13-11**.



Goodheart-Willcox Publisher

Figure 13-10. Three types of valve seals are shown.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

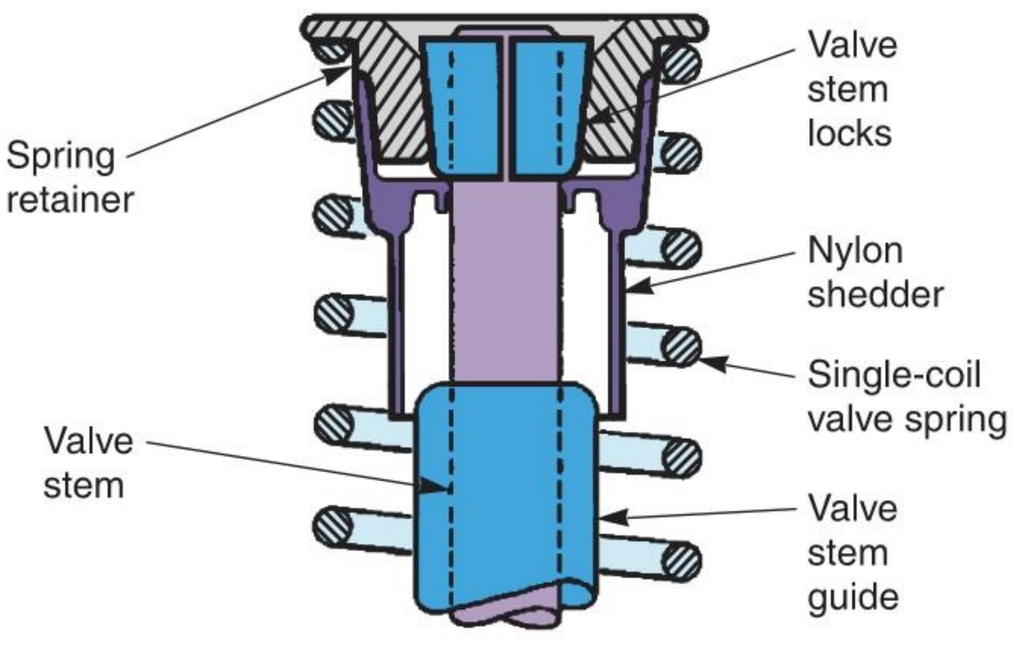
Figure 13-11. An O-ring valve seal fits into an extra groove cut in the valve stem. To prevent seal damage, the spring and retainer must be installed before the seal. This valve spring assembly uses both an O-ring seal and an umbrella seal on the intake valve.

A ***valve spring shield*** is normally used with an O-ring valve seal. The shield surrounds the top and upper sides of the spring and helps keep oil off the valve stem.

A nylon shedder can also be used to limit the amount of oil that splashes on the valve stem and guide opening. The shedder is a cross between a conventional oil seal and a valve spring shield. It seals against the valve stem like a seal and encircles the upper spring like a shield. One is illustrated in **Figure 13-12**.

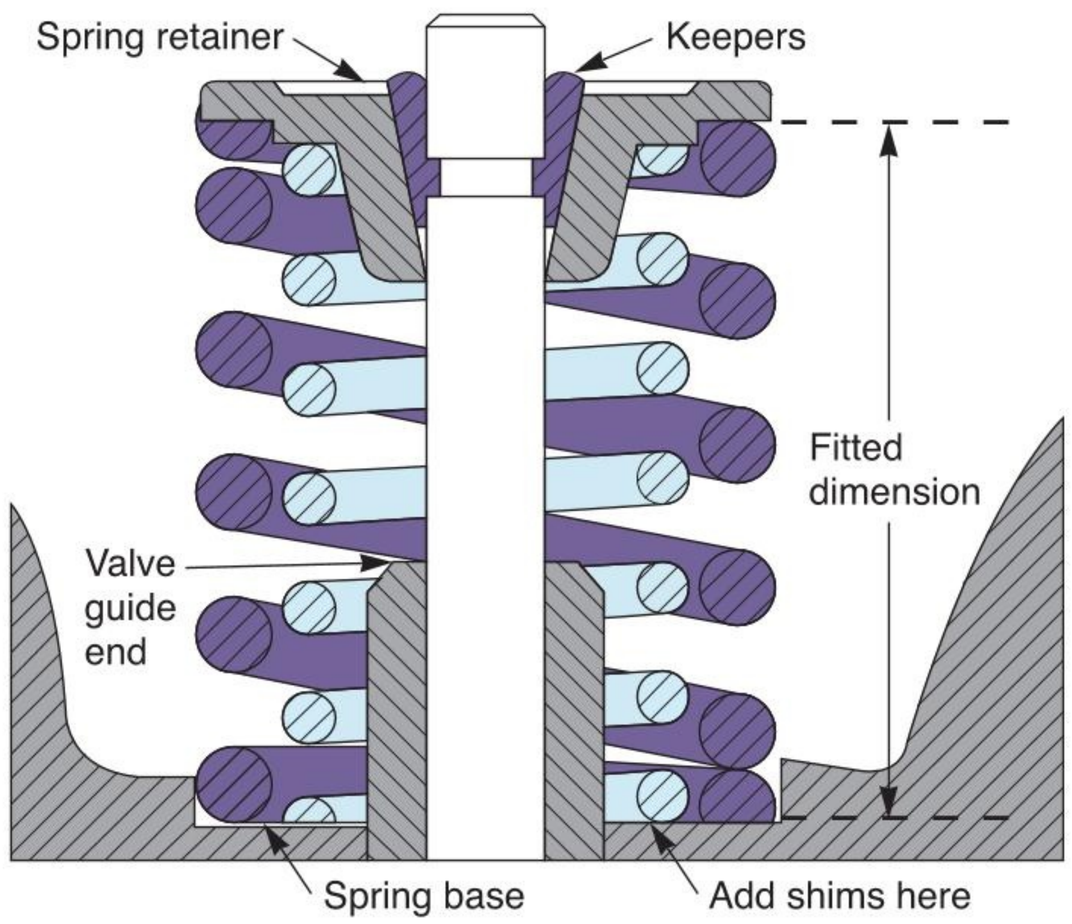
Valve Spring Construction

Valve spring construction is basically the same for all engines. However, the number and type of coils can vary. See **Figures 13-13** and **13-14**.



Goodheart-Willcox Publisher

Figure 13-12. A nylon shedder functions as both an O-ring seal and a shield to keep oil out of the valve guide.

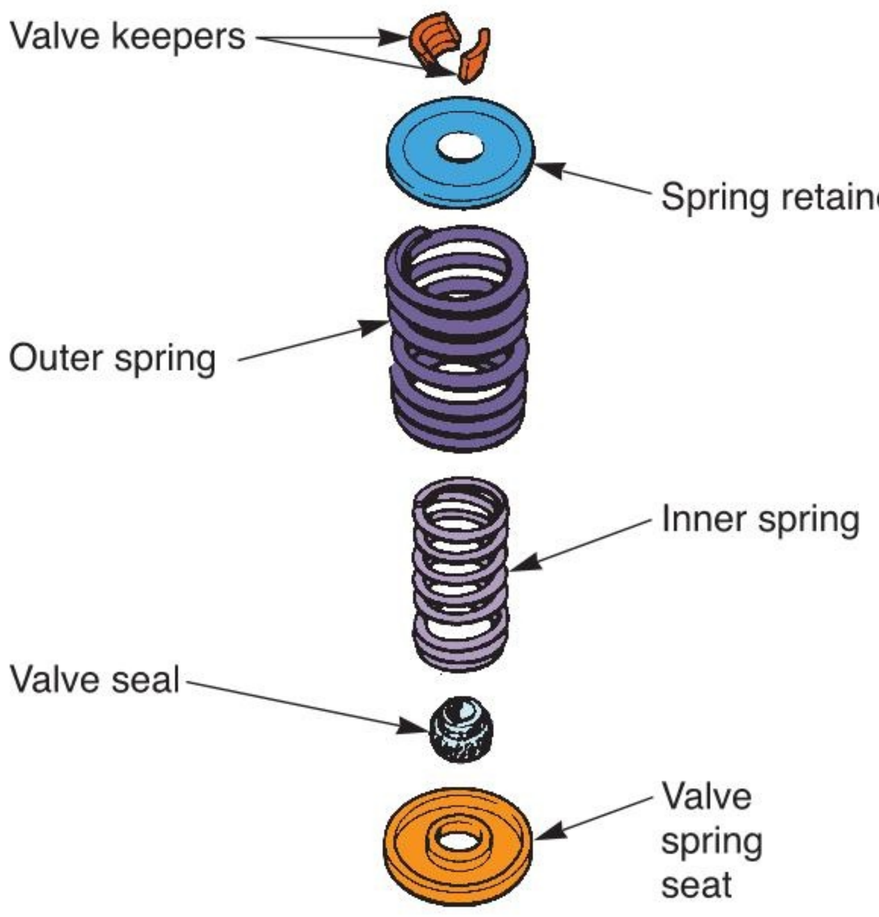


Ford

Figure 13-13. A dual-coil valve spring increases the valve closing pressure. Also notice the other parts.

Spring tension refers to the stiffness of a valve spring measured in pounds or kilograms. Spring tension is usually stated for both opened and closed valve positions. The service manual will give the tension specifications for specific compressed lengths.

Spring free length is the length of the valve spring when removed from the engine. ***Spring open length*** is the spring's length when installed on the



Honda

Figure 13-14. A valve spring assembly using a spring seat. The seat keeps the bottom of the spring in alignment with the stem.

Copyright Goodheart-Willcox Co., Inc.

engine with the valve fully open. ***Spring closed length*** is the length of the valve spring when installed on the engine with the valve closed. Both open length and closed length are measured from the bottom of the spring to the bottom of the spring retainer.

Spring specifications are important. They affect valve action. Low spring tension can cause valve float. ***Valve float*** occurs when the valve fails to close entirely at high rpms because the spring is too weak.

Valve Spring Shim

A ***valve spring shim*** is a very thin, accurately machined washer used to increase spring tension. When a shim is placed under a spring, the open and closed lengths of the valve spring are reduced. This compresses the spring to increase closing pressure. A used valve spring may weaken and lose some of its tension. Valve spring shims provide a means of restoring full spring tension and pressure without spring replacement.

Valve Retainers and Keepers

Valve retainers and ***keepers*** lock the valve spring onto the valve. The retainer is a specially-shaped washer that fits over the top of the valve spring. The keepers fit into the valve stem grooves. This holds the retainer and spring in place.

Valve Spring Seat

A ***valve spring seat*** is a cup-shaped washer installed between the cylinder head and the bottom of the valve spring. It provides a smooth, machined surface or pocket to hold the bottom of the valve spring.

Valve Rotators

A ***valve rotator*** turns the valve to prevent carbon buildup and hot spots on the valve face. A valve rotator may be located under or on top of the valve spring. If under the seat, it is called a seat-type rotator. If on top of the valve spring, it is called a retainer-type rotator. Rotators are commonly used on engine exhaust valves, which are exposed to more heat than intake valves.

Valve Stem Cap

A ***valve stem cap*** may be placed over the end of the valve stem. It helps prevent stem and rocker arm wear. A valve stem cap is free to turn on the valve stem. This serves as a bearing that reduces friction. Some valve stem caps are used to adjust the clearance in the valve train. Different cap thicknesses are available. Caps can be changed to alter the clearance between the rocker arm and the valve stem.

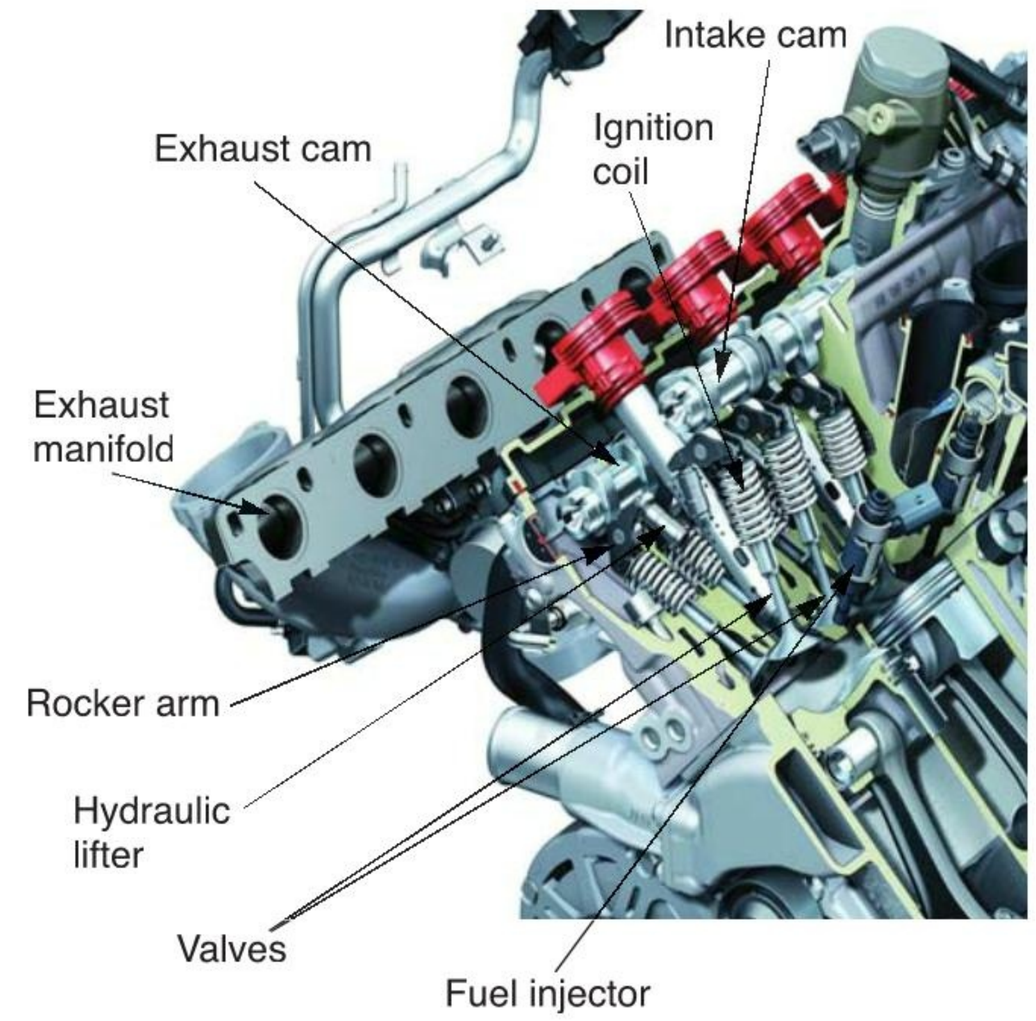
Camshaft Construction

A ***camshaft*** controls when the valves open and close. It can be driven by gears, a chain, or a belt. The number of lobes on a camshaft depends on the number of valves in the combustion chambers and the number of cylinders in the engine. Many engines only use one camshaft. However, others use two or more, **Figure 13-15**.

With dual overhead cam engines, there are two camshafts per cylinder head. One is the intake camshaft and the other is the exhaust camshaft. The intake camshaft operates all the intake valves in the cylinder head. The exhaust camshaft operates all the exhaust valves.

Cam Lobes

The ***cam lobes*** are precision-machined and polished surfaces on the camshaft. Each cam lobe consists of a nose, flank, heel, and base diameter.



Audi

Figure 13-15. In a dual overhead cam engine, separate camshafts control the intake and exhaust valves. The shape of the cam lobes determines when the valves open, how far they open, and how long they remain open.

Copyright Goodheart-Willcox Co., Inc.

Variations in lobe shape control:

- When each valve opens in relation to piston position.
- How long each valve stays open.
- How far each valve opens.

Camshaft lift is the distance the valve opens. Camshaft lift is found by subtracting the cam base diameter from the height of the cam lobe.

Camshaft duration determines how long the valve stays open. The shape of the cam lobe nose and flank regulates camshaft duration. For instance, a pointed cam lobe has a shorter duration than a rounded lobe. See **Figure 13-16**.

Valve timing refers to valve opening and closing in relation to the position of the pistons in the cylinders. Valve timing is designed into the camshaft and drive sprockets or gears by the manufacturer.

Valve overlap is the time when both the intake and exhaust valves in the same cylinder are open. Valve overlap is used to help draw burned gases out of the cylinder. It also helps pull a fresh fuel charge into the cylinder. With both the intake and exhaust valves open, there is more flow into and out of the combustion chamber. The added flow of air-fuel mixture and exhaust gases increases engine power. Valve overlap helps engine breathing, especially at higher engine speeds. Look at **Figure 13-17**.

Some camshafts are machined with dual cam lobes that have two different profile shapes. One cam lobe is designed for good low-speed efficiency. The other is a high-speed profile for high engine rpm power. The driveline control module operates a solenoid valve that controls oil flow to shift the rocker arms from one lobe profile to the other.

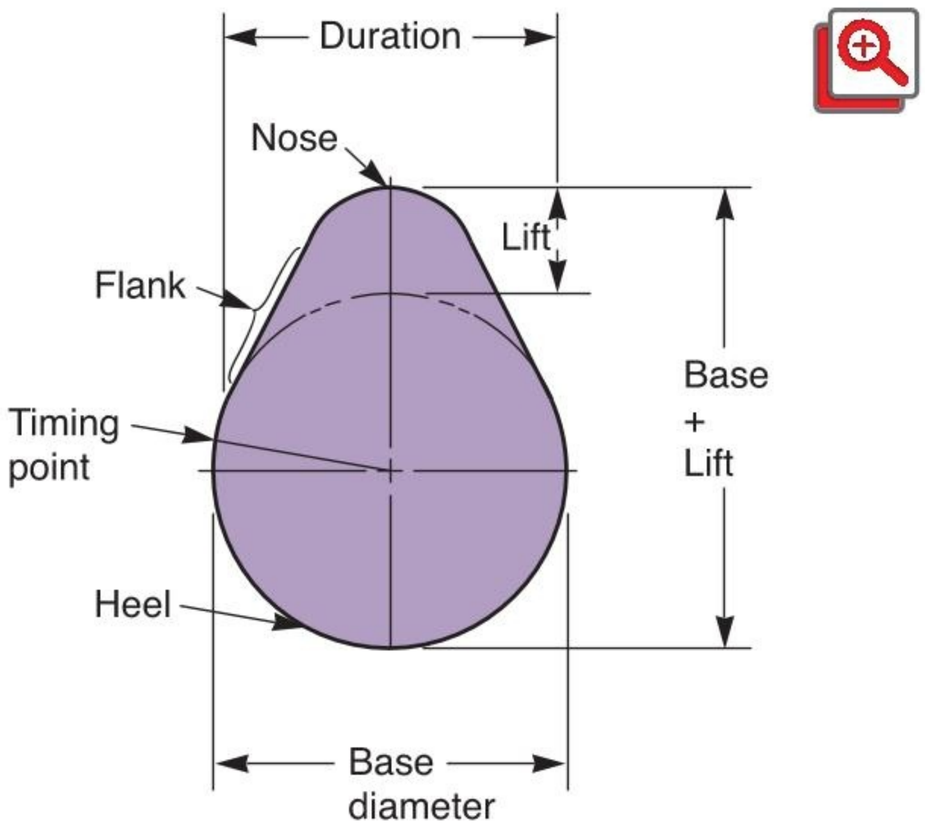
Hollow camshafts can have their lobes pressed onto the shaft. To lock the splined lobes in place, an oversize steel ball is forced down through the center of the hollow shaft. Some new engines use hollow composite camshafts to lighten the valve train for quicker engine acceleration.

Camshaft Thrust Plate

A ***camshaft thrust plate*** is used to limit camshaft end play. End play is the front-to-rear movement. The thrust plate bolts to the front of the block or cylinder head. When the drive gear or sprocket is bolted in place, the thrust plate sets up a predetermined camshaft end play.

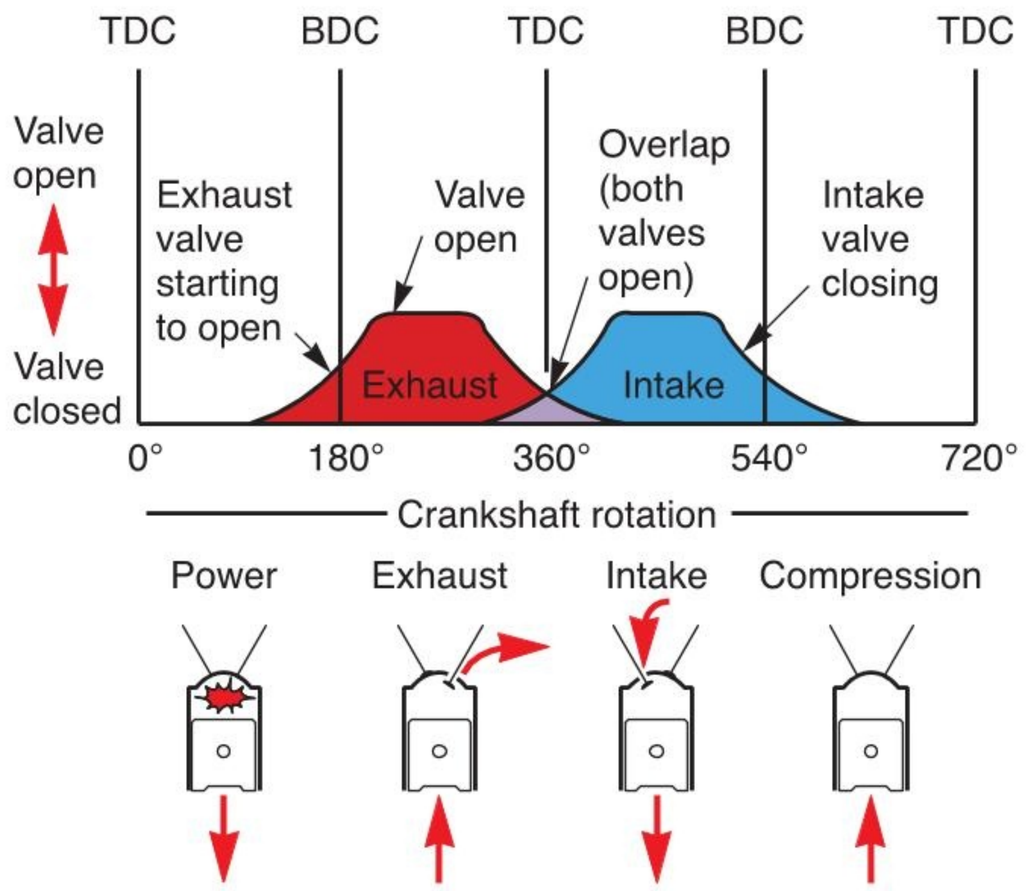
Cam Bearings

Cam bearings are usually one-piece inserts pressed into the block or cylinder head. See **Figure 13-18**. Two-piece inserts are sometimes used when the camshaft is mounted in the head. The camshaft journals ride in the cam bearings. Cam bearings are usually constructed like engine main and connecting rod bearings.



TRW

Figure 13-16. The basic parts and shape of a cam lobe. The height of the nose compared to base circle determines the amount of valve opening. The width or roundness of the nose determines how long the valve stays open.



VW

Federal Mogul

Figure 13-18. Camshaft journals ride in cam bearings. Cam bearings may be pressed into the block or cylinder head bore.

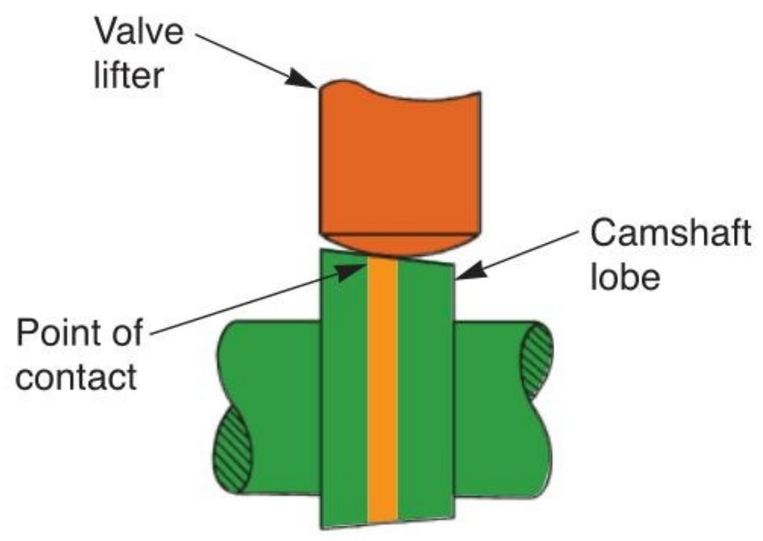
Cam Housing and Cam Cover

Some cam or valve covers are acoustically dampened by making them out of two sheets of steel formed around a center layer of sound-dampening material. A ***cam housing*** is a casting that bolts to the top of the cylinder head to hold the engine camshaft. It is used in some overhead cam engine designs. A ***cam cover*** is a lid over the top of the cam housing. It serves the same purpose as a valve cover on an overhead valve engine. Acoustically dampened construction means the part is designed to help reduce the transmission of sound.

Valve Lifters

Valve lifters, or tappets, ride on the camshaft lobes and transfer motion to the other parts of the valve train. Look at **Figure 13-19**. The bottom of a lifter is crowned, or slightly curved. The camshaft lobe is also not perfectly square with the lifter base. As a result, one side of the lifter touches the cam lobe. This tends to rotate the lifter in its bore to reduce wear. There are four basic types of lifters. These are hydraulic, mechanical, roller, and OHC follower.

Hydraulic valve lifters are common because they operate *quietly* by maintaining zero valve clearance. Zero valve clearance means that there is no space

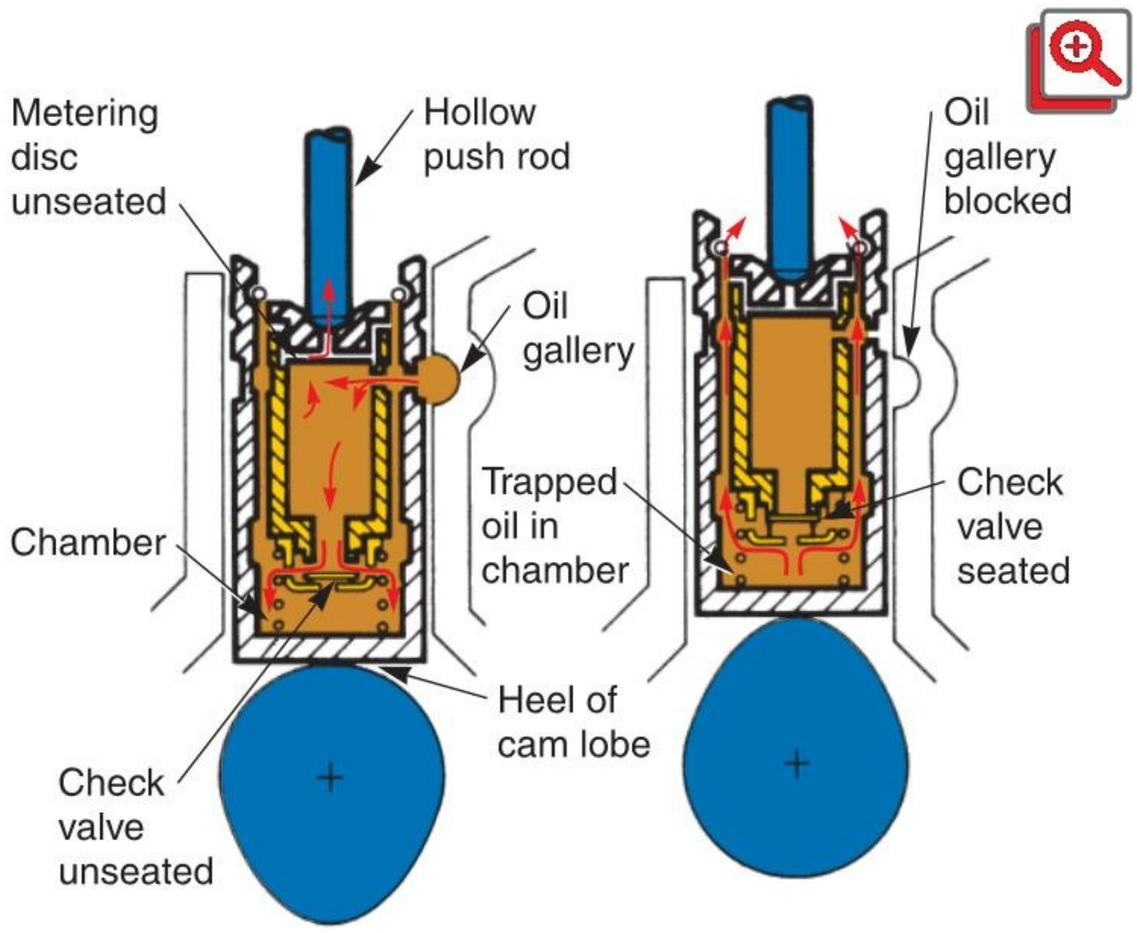


Dana

Figure 13-19. The bottom of a lifter is crowned and the cam lobe is tapered. This causes the rotating cam lobe to turn the lifter in its bore, reducing wear.

between valve train parts. With zero clearance, the valve train does not clatter when the engine is running. The hydraulic lifter adjusts automatically with temperature changes and part wear.

During engine operation, oil pressure fills the inside of the hydraulic lifter with motor oil. The pressure pushes the lifter plunger up in its bore until all the play is out of the valve train. As the camshaft pushes on the lifter, the lifter check valve closes to seal oil inside the lifter. Since oil is not compressible, the lifter acts as a solid unit to open the valve, **Figure 13-20**.



Chrysler

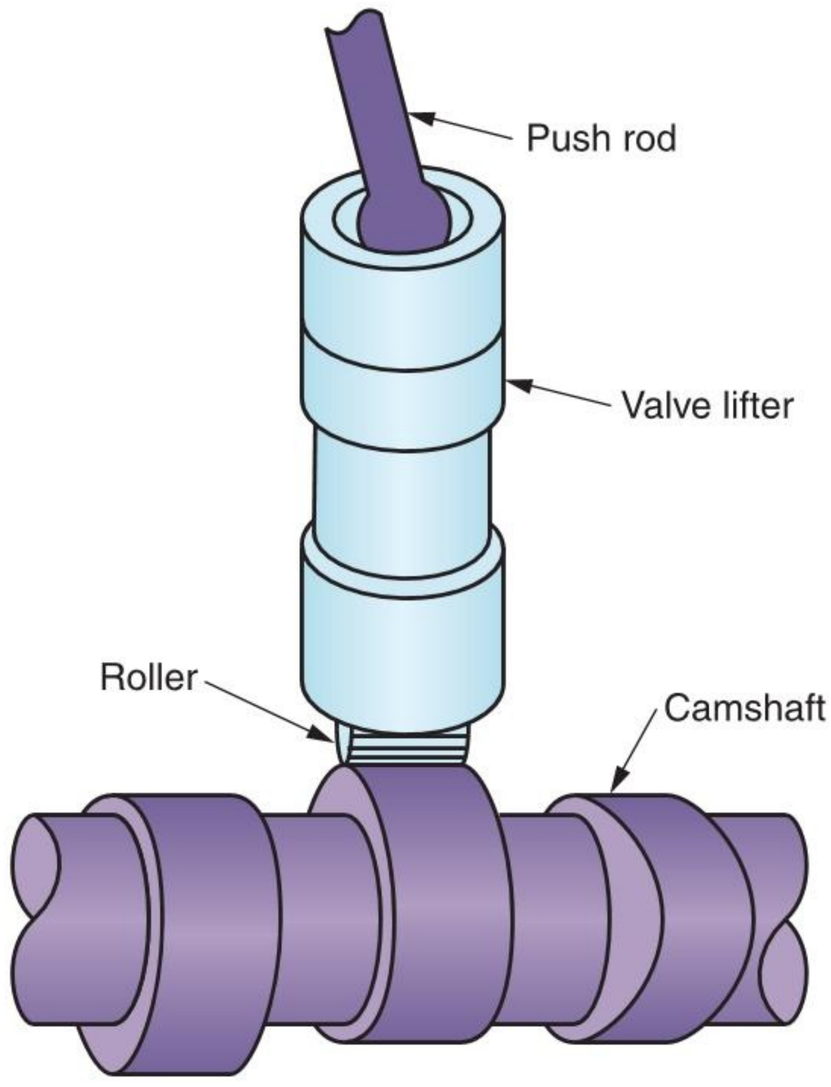
Figure 13-20. Note lifter action. A—When the valve closes, oil rushes into the lifter, pushing up on the disc or plunger to maintain zero clearance. B—When the cam acts on the lifter, oil is trapped in the lifter by a check valve. The lifter acts as a solid unit to push the valve open.

Copyright Goodheart-Willcox Co., Inc.

Mechanical lifters, also called solid lifters, do not contain oil. They simply transfer cam lobe action to the push rod. Mechanical lifters are not self-adjusting and require periodic adjustment. An adjustment screw is normally provided at the rocker arm when solid lifters are used. Turning the adjustment screw down reduces any "play" in the valve train. Unscrewing, or backing off, the rocker arm adjustment increases clearance. The small clearance needed with solid lifters causes valve train noise. A clattering or clicking noise is produced as the valves open and close.

A ***roller lifter*** has a small roller that rides on the camshaft lobe, **Figure 13-21**. This type of lifter can be either mechanical or hydraulic. The point where the lifter touches the camshaft is one of the highest friction points in the engine. The roller helps reduce this friction and wear. A roller lifter is also used to reduce frictional losses of power.

An ***OHC follower*** fits between the camshaft and valve. The follower slides up and down in a bore machined in the head. Either an adjusting screw in the follower or shims of different thicknesses can be used to adjust valve clearance, **Figure 13-22**.



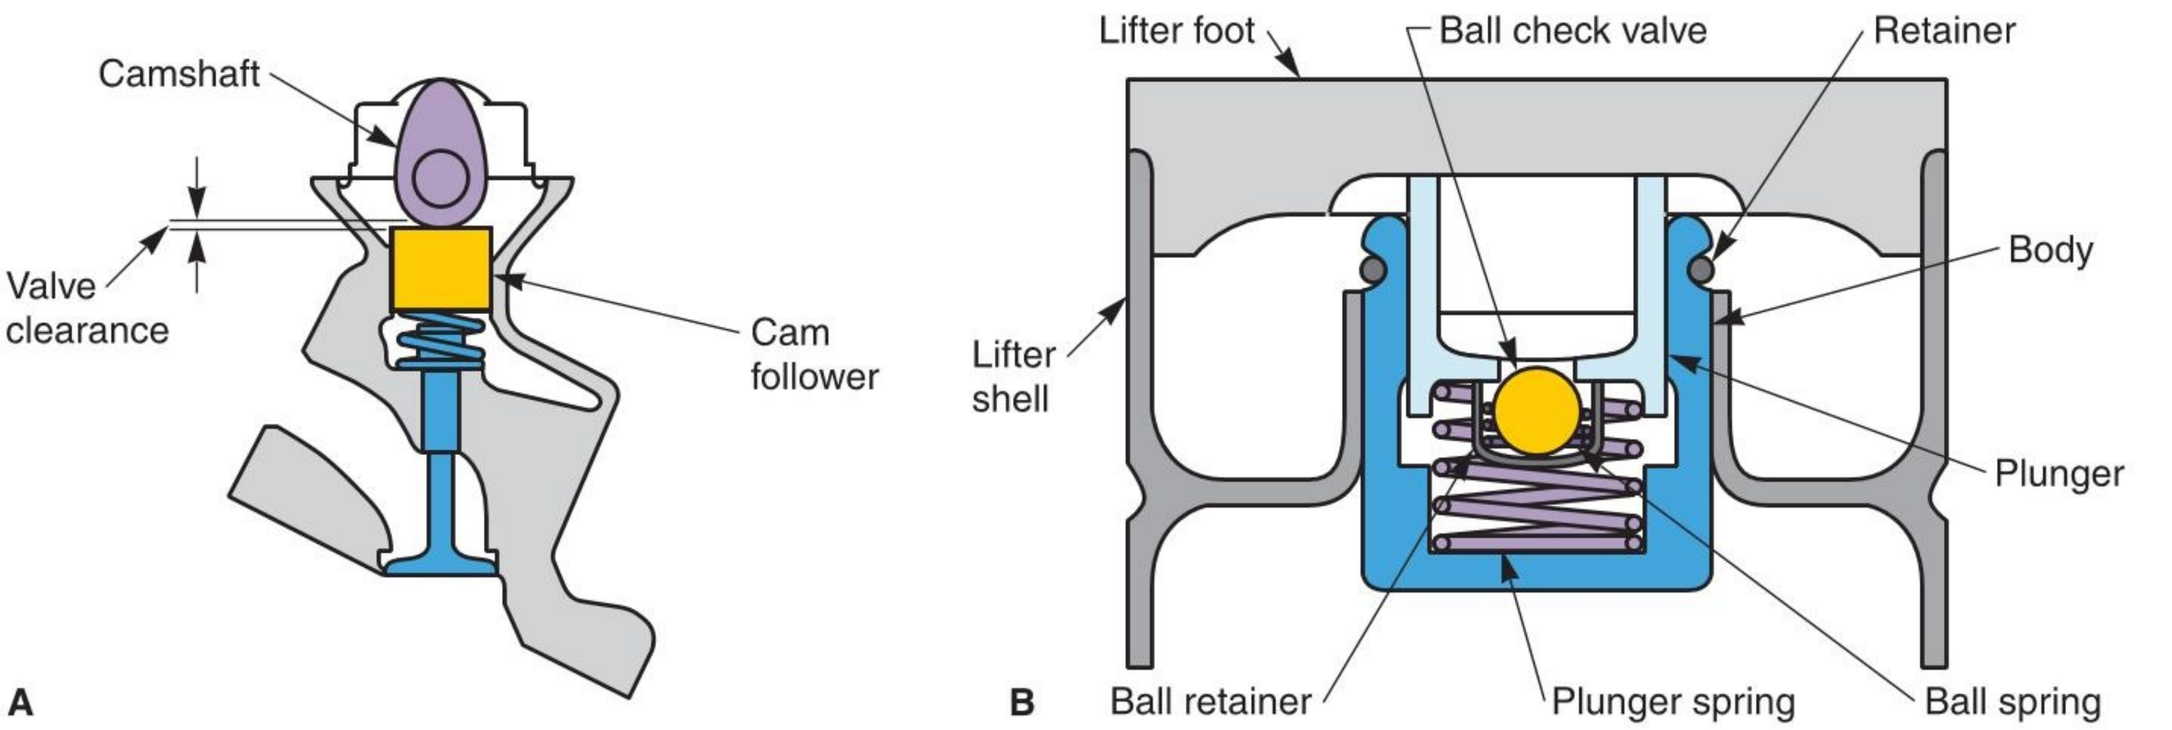
Goodheart-Willcox Publisher

Figure 13-21. A roller lifter is commonly used in diesel engines to reduce friction. The roller spins as the camshaft rotates.

Push Rod Construction

Push rods are metal tubes or rods with specially formed ends. They are used in cam-in-block engines to transfer motion from the lifters to the rocker arms. Some push rods have a ball on each end. Others have a ball on one end and a female socket on the other end. Some hollow push rods have holes in the ends to feed oil from the lifter to the rocker arms. This prevents wear on the tip of the push rod and on the rocker arm.

In some engines, ***push rod guide plates*** are used to limit side movement of the push rods. The guides hold the push rods in alignment with the rocker arms. When the push rods pass through holes in the cylinder head or intake manifold, guide plates are not needed.



Goodheart-Willcox Publisher

Copyright Goodheart-Willcox Co., Inc.

Rocker Arm Construction

Rocker arms transfer valve train motion to the valve stem tips. In OHC engines, the camshaft may act directly on the rocker arm. Then, the rocker acts on the valve. Some rocker arms are forked so that they can actuate two valves at once. In a push rod engine, the push rod acts on the rocker. Then, the rocker transfers the motion to the valve. See **Figure 13-23**. Rocker arms are usually made of either cast iron or steel.

Various methods are used to support the rocker arms on the cylinder head. Individual pivot balls or stands can be used to hold the rocker arm in place over the valve. **Figure 13-24** shows one such arrangement.

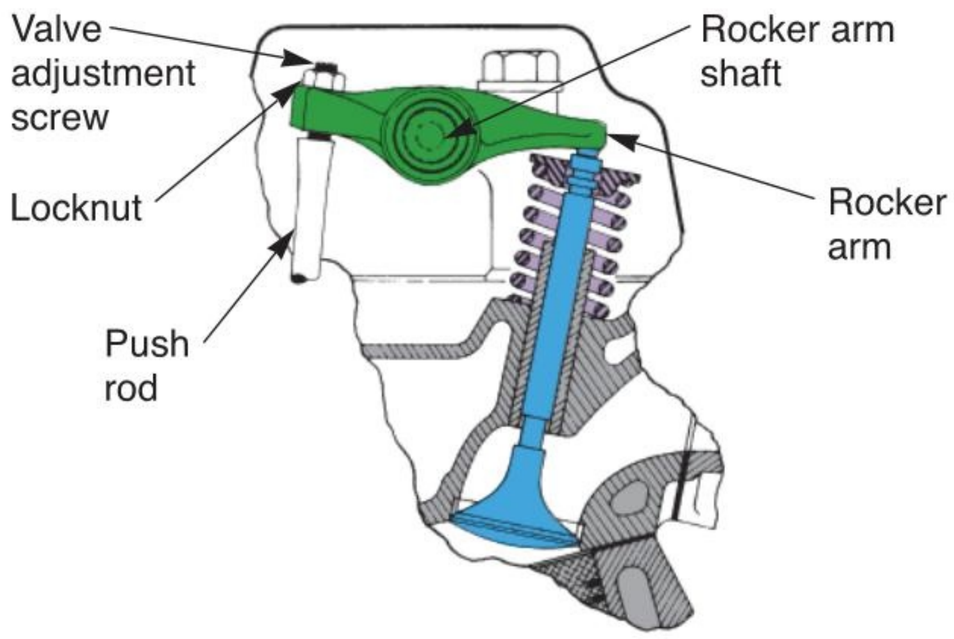
Adjustable rocker arms are used to change the valve train clearance. Either a screw is provided on the rocker arm or the rocker arm pivot point can be changed. Adjustable rocker arms must be used with mechanical lifters. Nonadjustable rocker arms have no means of changing the valve clearance. They are used only with some hydraulic lifters. The rocker arm assembly is tightened to a specific torque. This presets the lifter plunger halfway in its travel. Then, during engine operation, the hydraulic lifter automatically maintains zero clearance. Push rod length can be changed for clearance adjustments when using nonadjustable rocker arms.

Variable Valve Timing System

A ***variable valve timing system*** alters valve timing as engine speed changes. This is done to optimize engine power and efficiency at all operating speeds. Generally, the valves in these systems function with a normal duration at low engine speeds. As speed increases, however, the variable timing mechanism engages to hold the valves open longer, increasing volumetric efficiency.

There are several ways of creating variable valve timing that have been explored. However, there are basically two common methods used in late-model engines. One method has electro-hydraulically operated rocker arms and two different camshaft profiles for each valve. The second method uses a camshaft gear that can rotate on the camshaft.

The system shown in **Figure 13-25** contains two intake valves and two exhaust valves per cylinder. A small hydraulic piston in the rocker arm shaft is used to engage and disengage the rocker arm assembly components. At low engine speeds, only one intake valve is fully opened per cylinder. The other intake rocker arm for that cylinder only slightly opens its intake valve. This slight opening is needed to prevent fuel accumulation behind the valve face. By fully opening only one of the two intake valves, air velocity through the intake port is increased. This, in turn, improves atomization and mixing of the fuel charge for improved combustion efficiency at low engine speeds.



Federal Mogul

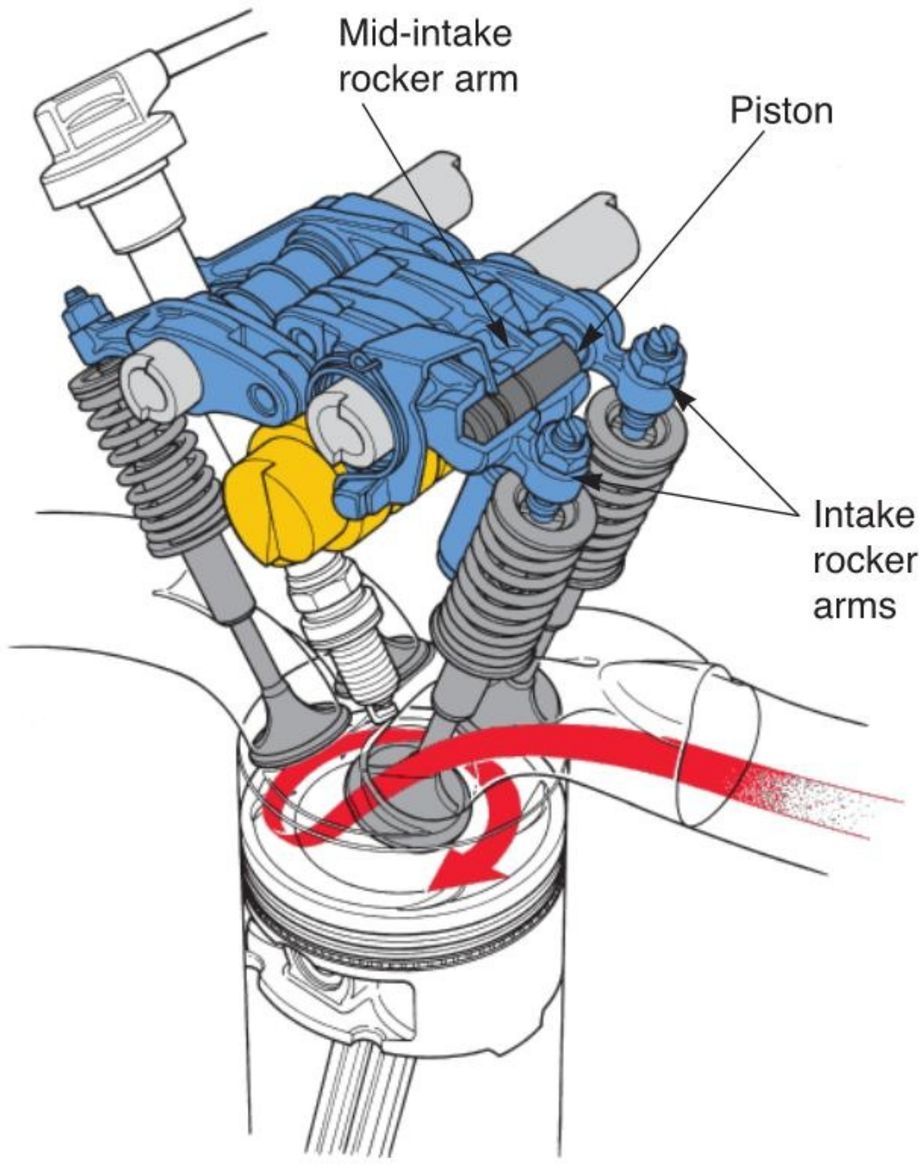
Chrysler

Figure 13-24. This engine uses rectangular rocker arm pivots. A bridge helps hold the rockers in position over the valve stems. These rockers are made of stamped steel.

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 13-25. This engine uses small hydraulic pistons acting on the rocker arm assembly to alter valve lift and duration.

At high engine speeds, the two intake rocker arms are locked to a mid-intake rocker arm, which provides very high valve lift and longer duration. The mid-rocker arm rides on a high-speed camshaft lobe. This allows a larger, more powerful air-fuel charge to enter the combustion chambers.

The system that uses a rotating camshaft gear cannot alter lift or duration, only timing. However, the system has the advantage of being somewhat less complex. The camshaft gear consists of two halves with a rotor contained inside. One-half of the camshaft gear is attached to the rotor and the camshaft. The other half is driven by the crankshaft.

Tech Tip

In some dual overhead cam designs, the outer half of the gear is driven by the adjacent camshaft rather than the crankshaft.

Oil pressure inside the camshaft gear locks the two halves together. The computer controls the oil pressure inside the gear based on engine operating conditions. By shifting oil pressure from one side of the rotor to the other, the two halves of the gear move in relation to each other and valve timing is advanced or retarded. A variation of this system uses a shaft with helical splines instead of a rotor. As the camshaft gear slides along the splined shaft, the valve timing is adjusted.

Tech Tip

Some variable valve timing systems that have a rotating camshaft gear also have an additional system that allows the lift and duration to be altered.

Intake Manifold Construction

An ***intake manifold*** holds the throttle body and has passages, called runners, going to each cylinder head port. The manifold usually contains water jackets for cooling. It can be cast of iron, aluminum, or plastic.

Manifold runners are internal passages formed in the intake manifold to carry either the air-fuel mixture or air to the cylinder head ports. See **Figure 13-26**.

Intake manifolds can also be made of glass-filled nylon or plastic. These can weigh half as much as aluminum and several times less than iron. The inside of the plastic runners is also smoother than metal to improve airflow into the engine for more power. With plastic manifolds, brass thread inserts are pressed into the plastic. This allows additional parts, such as sensors and vacuum fittings, to be bolted to the plastic part without thread damage.

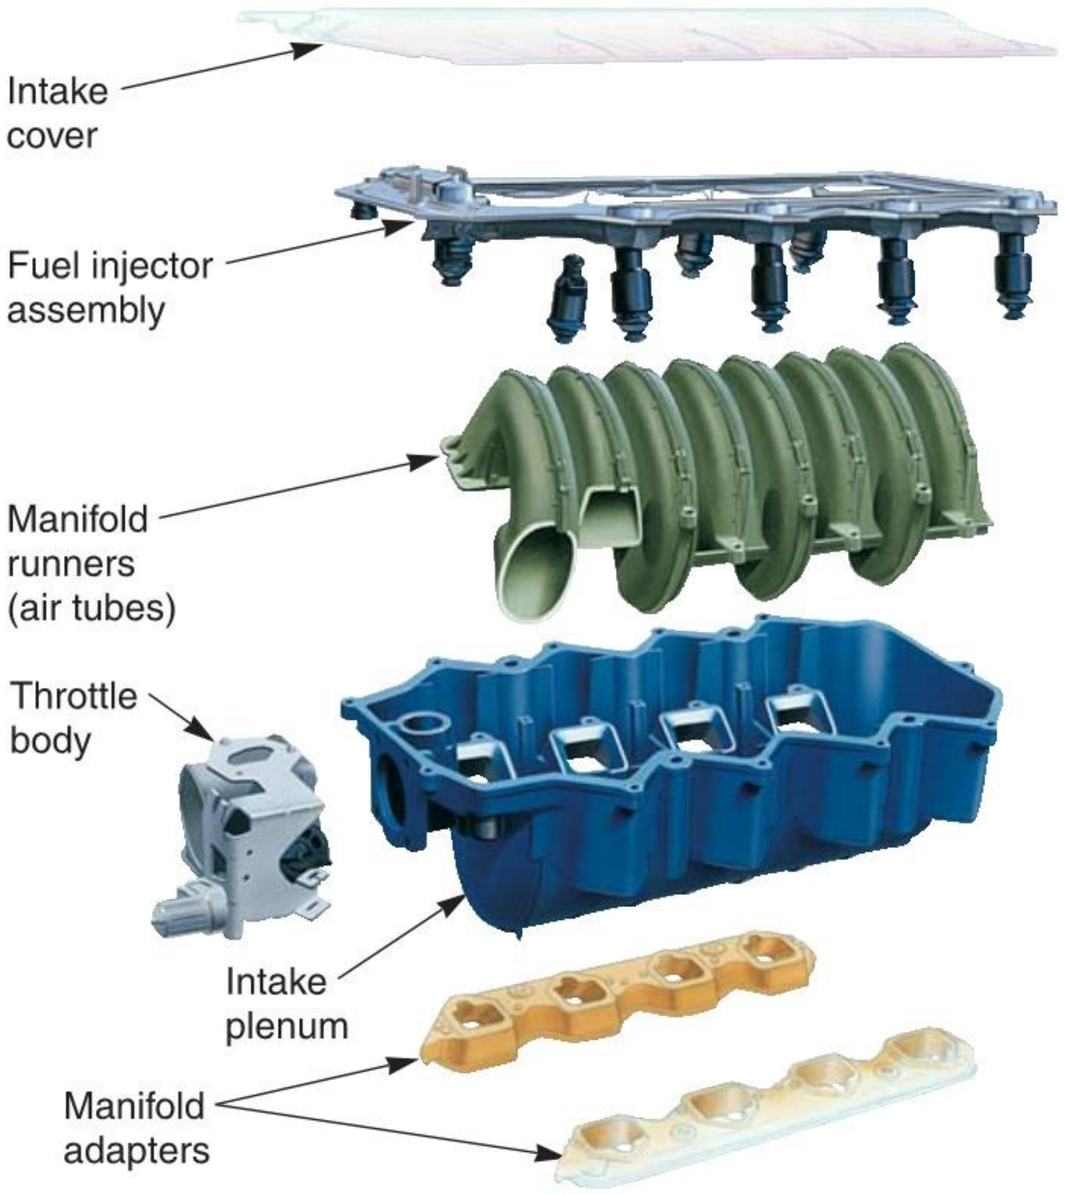
Compression limiters are metal inserts that limit the deformation around bolt holes in plastic parts. They allow enough bolt torque to provide good sealing without cracking or deforming the soft plastic.

A ***flame arrester*** is sometimes located before the engine intake manifold to prevent backfire damage to the air filter. It is made of metal mesh to prevent the flame of an engine backfire from entering the air filter housing. It should periodically be removed and cleaned in solvent for best engine performance.

Variable Induction System

A ***variable induction system*** has two sets of intake runners controlled by butterfly valves to aid engine efficiency and performance. A variable

Copyright Goodheart-Willcox Co., Inc.



Cadillac

Figure 13-26. A multi-piece "ram manifold" assembly takes the place of a traditional intake manifold on some high-performance engines. Individual tubes supply air to each cylinder.

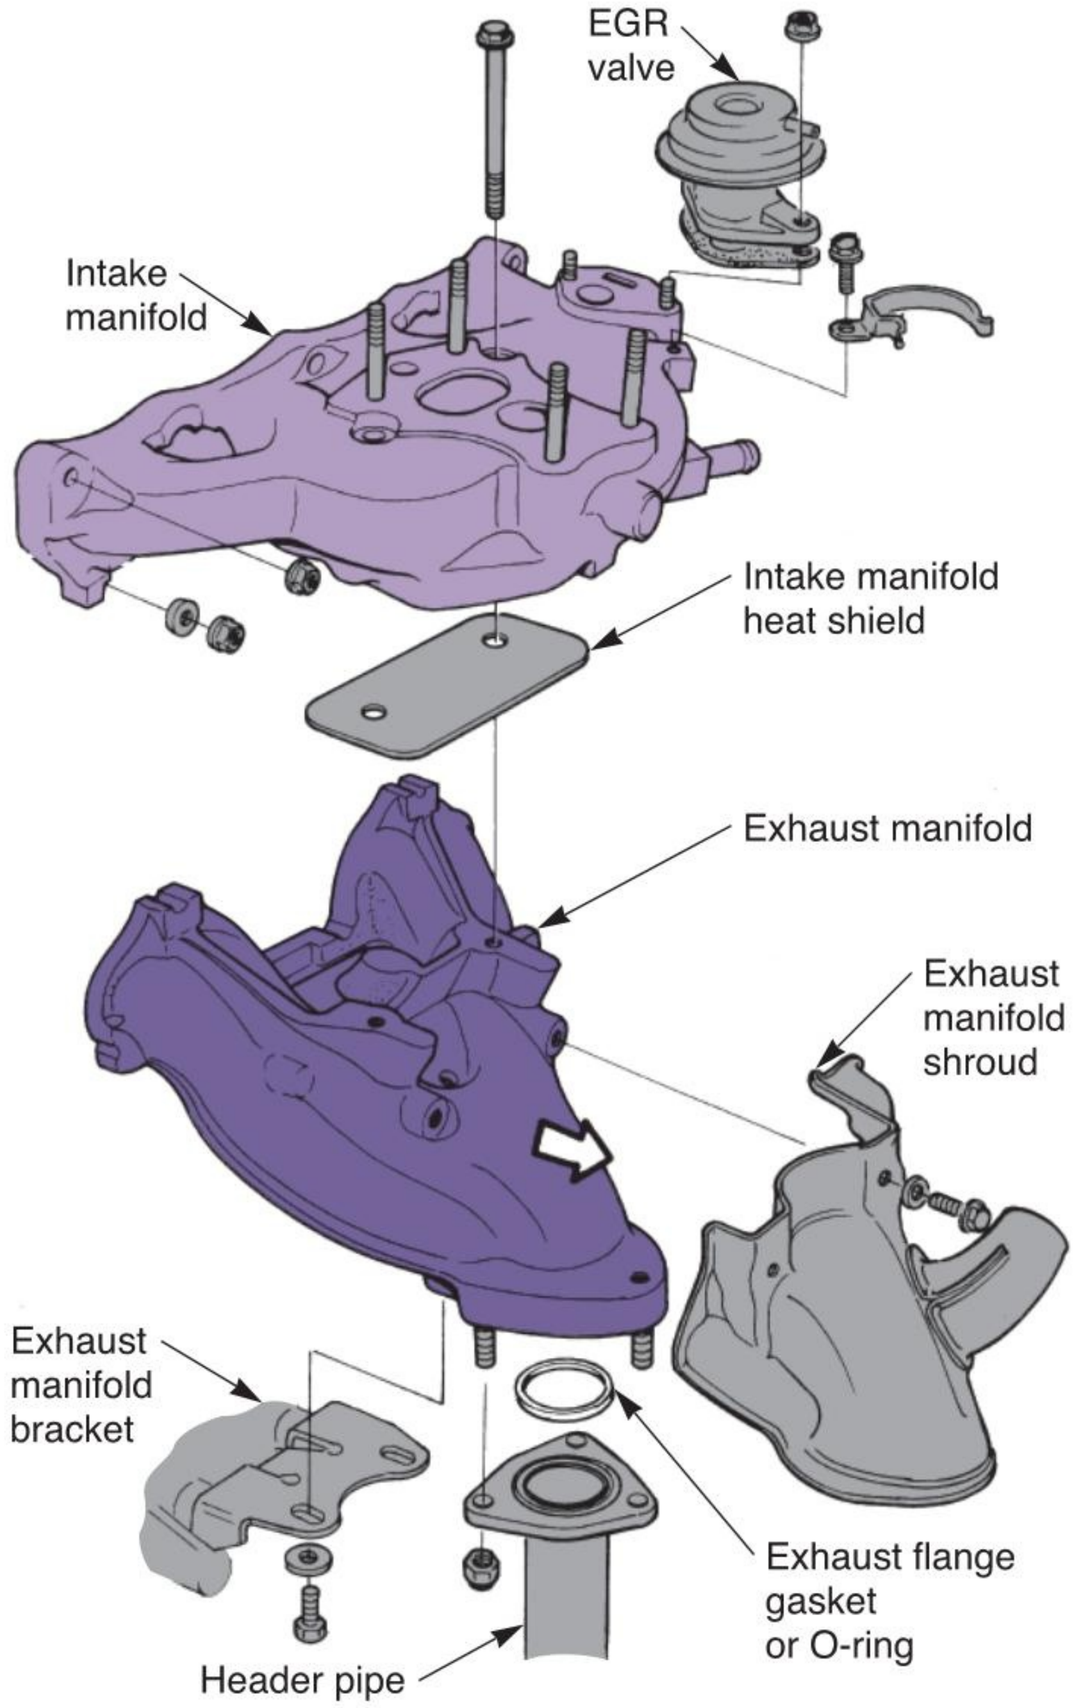
induction system is like having two intake manifolds in one—one is for low-speed torque and another for high-speed power.

At low engine speeds, the system uses long intake runners to "ram" more air and fuel into the cylinders for increased torque. Then, when a specific engine speed is reached, the computer opens the butterfly valves over shorter intake runners. The short runners increase airflow at high rpm for added power.

Exhaust Manifold Construction

An ***exhaust manifold*** routes burned exhaust gases from the cylinder head exhaust port to the exhaust pipe. Because of the high operating temperatures, the exhaust manifold is usually made of cast iron.

A few high-performance or sports car engines use lightweight, free-flowing steel tubing exhaust manifolds called headers. **Figure 13-27** shows both intake and exhaust manifolds for one particular engine.



Honda

Figure 13-27. Intake and exhaust manifolds shown with their related components.

Workplace Skills

Today's thin cast aluminum heads are less tolerant of overheating than older, thicker cast iron heads. If you experience engine overheating, do not keep driving the vehicle. Shut the engine off as soon as possible and allow it to cool. Repair the causes of the overheating problem right away. If the problem is not repaired soon enough, the aluminum head may be warped and cracked from the engine overheating.

Summary

- An engine top end basically includes the cylinder head, valve train, valve cover, and the intake and exhaust manifolds.
- A bare cylinder head is a head with all its parts removed.
- An integral valve guide is part of the cylinder head casting. A pressed-in valve guide is a separate sleeve forced into a hole machined in the head.
- The valve seat angle is the angle formed by the face of the seat.
- An interference angle is a 1/2° to 1° difference between the valve seat face angle and the angle of the valve face.
- The valve face angle is the angle formed between the valve face and valve head.
- An umbrella valve seal is shaped like a cup and can be made of neoprene rubber or plastic.
- An O-ring valve seal is a small round seal that fits into an extra groove cut in the valve stem.
- Spring tension refers to the stiffness of a valve spring.
- A valve spring shim is a very thin and accurately machined washer used to increase spring tension.
- Valve retainers and keepers lock the valve spring on the valve.
- A valve rotator turns the valve to prevent carbon buildup and hot spots on the valve face.
- With dual overhead cam engines, there are two camshafts—the intake camshaft and the exhaust camshaft. The intake camshaft operates all the intake valves in the cylinder head. The exhaust camshaft operates all the exhaust valves.
- Camshaft lift is the amount of valve lift produced by the cam lobe.
- Camshaft duration determines how long the valve stays open.
- Valve timing refers to valve opening and closing in relation to the position of the pistons in the cylinders.
- Valve overlap is the time when both of the intake and exhaust valves in the same cylinder are open.
- Valve lifters, or tappets, ride on the camshaft lobes and transfer motion to the other parts of the valve train.
- Push rods are metal tubes with specially formed ends.
- Rocker arms transfer valve train motion to the valve stem tips.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

bare cylinder head
cam bearing
cam cover
cam housing
cam lobe
camshaft
camshaft duration
camshaft lift
camshaft thrust plate
compression limiter
engine top end
exhaust manifold
flame arrester
hydraulic valve lifter
intake manifold
integral valve guide
integral valve seat
interference angle
keeper
manifold runner
mechanical lifter
mushroom valve
OHC follower
O-ring valve seal
poppet valve
prechamber cup
pressed-in valve guide
pressed-in valve seat
push rod
push rod guide plate
rocker arm
roller lifter
spring closed length
spring free length
spring open length
spring tension
umbrella valve seal
valve face angle
valve float
valve lifter
valve overlap
valve retainer
valve rotator
valve seat angle
valve spring seat
valve spring shield
valve spring shim
valve stem cap
valve timing
variable induction system
variable valve timing system

Activities

1. The rocker arm is a form of lever. Do research to find out what class of lever it is. Construct simple models of the three classes of levers and describe for the class how they work.
2. Make a sketch of a cam lobe, like the one shown in **Figure 13-16**. Assume that TDC is 0°. Use a protractor to mark points for a 90°, 180°, and 270° rotation. Using pencils or pens of different colors, draw the cam lobe in each of these positions.
3. If a disassembled engine is available, examine the head to determine whether integral or pressed-in valve guides and valve seats are used.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What is a bare cylinder head?
2. A(n) _____ type valve guide is part of the cylinder head.
3. A(n) _____ valve guide is a separate sleeve forced into a hole in the cylinder head.
4. Cylinder heads use _____ or _____ valve seats.
5. What is the function of an interference angle on the valve face and seat?
6. This part is pressed into the cylinder head on some diesel engines.
   (A) Stratified charge chamber.
   (B) Glow plug.
   (C) Injector nozzle.
   (D) Prechamber cup.
7. Engines use poppet valves, which are also called _____ valves.
8. Define the term “valve face angle.”
9. Why are some valves filled with sodium?
10. Stellite valves are used in engines designed to burn _____.
11. Describe the two basic types of valve seals.
12. Which of the following does *not* pertain to valve springs?
    (A) Free length.
    (B) Tension.
    (C) Tensile strength.
    (D) Closed length.
13. What is the function of a valve spring shim?
14. What is used to lock the valve spring on the valve?
15. A(n) _____ can be used to turn the valve and prevent hot spots on the valve face.
16. Variations in camshaft lobe shape control _____.
    (A) when each valve opens
    (B) how long each valve stays open
    (C) how far or wide each valve opens
    (D) All of the above.
17. Explain the term *camshaft lift*.
18. Why are hydraulic valve lifters used more than solid or mechanical lifters?
19. _____ lifters reduce friction and are frequently used in diesel or high-performance applications.
20. The cam base circle diameter of a camshaft is 3/4″. The camshaft’s cam lobe height is 1 1/2″. What is the approximate camshaft lift of this engine?
    (A) 3/8″.
    (B) 1/4″.
    (C) 1/2″.
    (D) None of the above.

ASE-Type Questions

1. An engine top end typically consists of each of these *except:*
   (A) valve train.
   (B) connecting rod.
   (C) cylinder head.
   (D) intake manifold.
2. Which of the following is a hole machined through the cylinder head?
   (A) Stellite face.
   (B) Valve seat insert.
   (C) Integral valve guide.
   (D) Pressed-in valve guide.

Copyright Goodheart-Willcox Co., Inc.

3. Common passenger car engines have a valve seat angle of:
   (A) 10°.
   (B) 20°.
   (C) 25°.
   (D) 45°.
4. Which of the following is a cross between an oil seal and a valve spring shield?
   (A) Nylon shedder.
   (B) O-ring valve seal.
   (C) Valve spring shim.
   (D) Umbrella valve seal.
5. Low valve spring tension can cause:
   (A) valve float.
   (B) valve rotation.
   (C) valve spring shim.
   (D) mushroomed valves.
6. Which of the following is used to lock a valve spring on a valve?
   (A) Retainer.
   (B) Keeper.
   (C) Seal.
   (D) Both A and B.
7. Which of the following is *not* a method by which a camshaft can be driven?
   (A) Belt.
   (B) Chain.
   (C) Gears.
   (D) Rotator.
8. A cam lobe consists of each of these *except:*
   (A) heel.
   (B) nose.
   (C) head.
   (D) flank.
9. The device used to limit camshaft endplay is the:
   (A) cam cover.
   (B) thrust plate.
   (C) cam bearings.
   (D) valve overlap.
10. Which type of valve lifter is filled with oil?
    (A) Solid.
    (B) Hydraulic.
    (C) Mechanical.
    (D) All of the above.

Chapter 14
Engine Bottom End Construction

After studying this chapter, you will be able to:

- Compare the construction of different types of cylinder blocks.
- Explain how piston construction affects engine operation.
- Describe piston ring variations.
- Explain the construction of engine bearings.
- Compare design variations of different engine bottom end components.
- Explain safe practices when working with engine bottom end components.
- Correctly answer ASE certification test questions on engine bottom end construction.

As you have learned, the major parts of an ***engine bottom end*** are the cylinder block, crankshaft, connecting rods, rod bearings, main bearings, piston pins, piston rings, and pistons.

This chapter details the various designs and construction methods used by major auto manufacturers. This information will help you understand how to properly repair any make or model engine bottom end assembly. Refer to **Figure 14-1**.

Cylinder Block Construction

Engine cylinder blocks are normally made of cast iron or aluminum. A ***cast iron cylinder block*** is very heavy and strong. Nickel is sometimes added to the iron to improve strength and wear resistance. They are stronger than aluminum and withstand high loads found in turbo-boost applications in gas and diesel engines designed for higher horsepower.

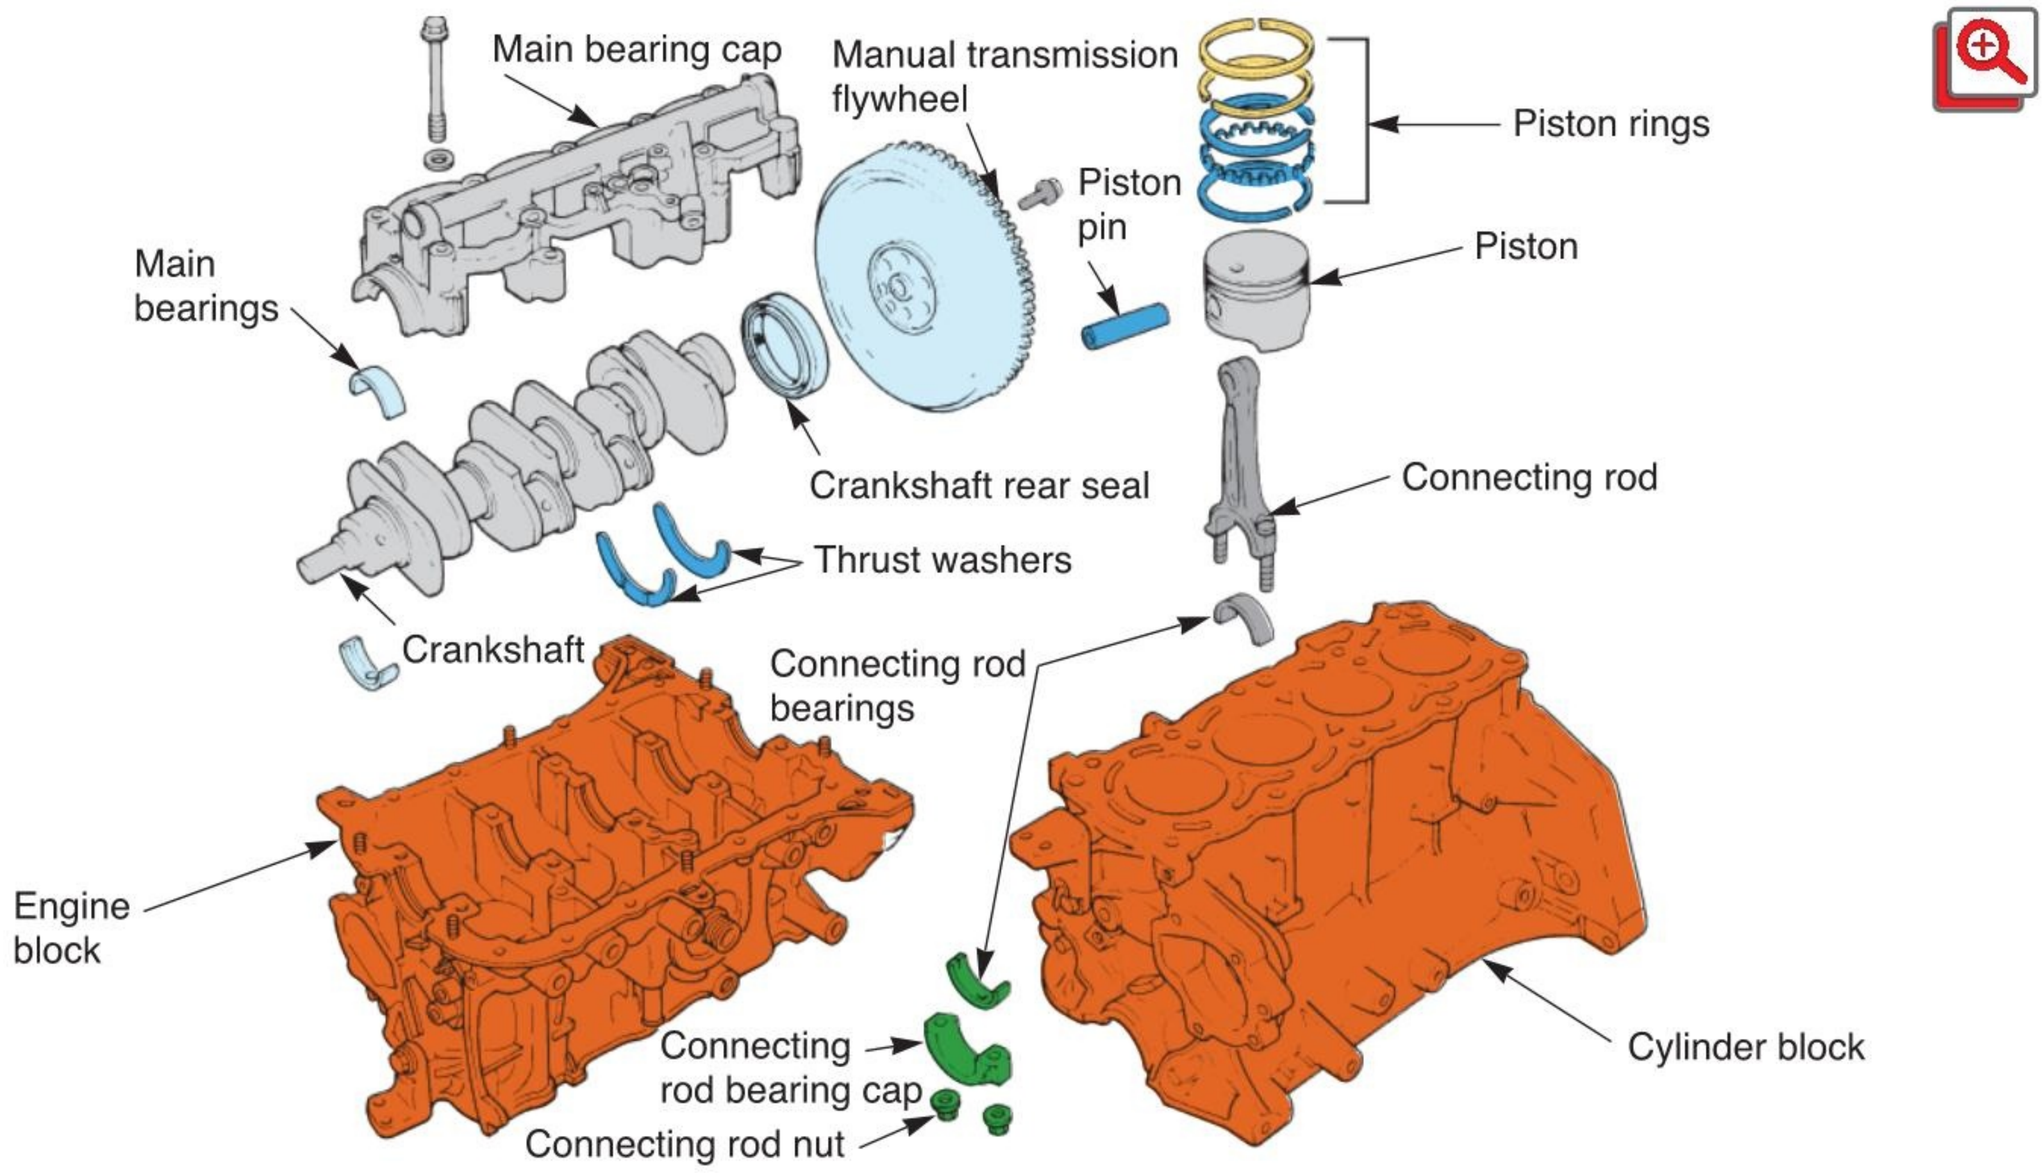
An ***aluminum cylinder block*** is much lighter than cast iron, yet almost as strong. See **Figure 14-2**. An aluminum block also dissipates heat better than a cast iron block. Many late-model vehicles use aluminum blocks to reduce weight and increase fuel economy.

Cylinder Sleeves

Cylinder sleeves, or liners, are metal, pipe-shaped inserts that fit into the cylinder block. They act as cylinder walls for the piston to slide up-and-down on without cylinder block wear.

Cast iron sleeves are commonly used in aluminum cylinder blocks. Sleeves can also be installed to repair badly damaged cylinder walls in cast iron blocks. There are two basic types of cylinder sleeves—dry sleeves and wet sleeves. Look at **Figure 14-3**.

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 14-1. The engine bottom end assembly consists of the block, crank, rods, pistons, and rings. Understanding the construction of these components is very important to service and repair operations.

A ***dry sleeve*** is pressed into a cylinder that has been bored, or machined, oversize. Look at **Figure 14-4A**. A dry sleeve is relatively thin and is not exposed to engine coolant. The outside of a dry sleeve touches the walls of the cylinder block. This provides support for the sleeve.

When a cylinder becomes badly worn or is damaged, a dry sleeve can be installed. The original cylinder must be bored almost as large as the outside diameter of the sleeve. Then, the sleeve is pressed into the oversized hole. Next, the inside of the sleeve is machined to the original bore diameter. This allows the use of the original piston size.

A ***wet sleeve*** is exposed to the engine coolant. It must withstand combustion pressure and heat without the added support of the cylinder block. Therefore, it must be thicker than a dry sleeve. Refer to **Figure 14-4B**.

A wet sleeve will generally have a flange at the top. When the cylinder head is installed, the clamping action pushes down on the sleeve and holds it in position. The cylinder head gasket keeps the top of the sleeve from leaking. A rubber or copper O-ring is used at the bottom of a wet sleeve to prevent coolant leakage into the crankcase. The O-ring seal is pinched between the block and the sleeve to form a leakproof joint.

Many vehicles use aluminum cylinder blocks with cast iron, wet sleeves. The light aluminum block reduces weight for increased fuel economy. The cast iron sleeves wear very well, increasing engine service life. Refer to **Figure 14-5**.

Line Boring

The term ***line boring*** refers to a machining operation that cuts a series of holes through the block for the crankshaft main bearings. A block may also be line bored for the camshaft bearings. The holes must be in perfect alignment for the crankshaft or camshaft to turn freely. Line boring can also be done to an OHC cylinder head.

Two- and Four-Bolt Mains

A ***two-bolt main block*** uses two cap screws to secure each main bearing cap to the cylinder block. A ***four-bolt main block*** has four cap screws holding each main cap. Four-bolt mains are used on high-performance engines. A few engines use six-bolt main blocks. With extra bolts, the block can withstand more crankshaft downward pressure without part failure.

Mazda

Figure 14-5. Modern cylinder blocks are frequently made of aluminum with pressed-in, cast iron wet sleeves.

A ***crossbolted block*** has extra cap screws going in through the sides of the block and main caps for added strength. This design is often used on high-performance engines.

Block Girdle

A ***block girdle***, or main bearing bedplate, is a large one-piece cap that fits over the entire bottom of the block. Also called a unit main cap, it secures the main bearings. All the main caps are formed as one piece to increase strength and block stiffness. The bedplate can also hold any balancer shafts. Gears on the crankshaft are used to drive the balancer shafts.

Tech Tip

Avoid using rings with hard coatings when rebuilding a passenger car engine. The hard rings are more difficult to seat than softer rings. Soft rings are more forgiving of cylinder wall imperfections. Engine smoking problems are more common in rebuilt engines when rings with hard coatings are used, because the rings take much longer to seat.

Piston Construction

Engine pistons are normally cast or forged from an aluminum alloy. Cast pistons are relatively soft and are used in slow-speed, low-performance engines. Forged pistons are commonly used in today's fuel-injected, turbocharged, and diesel engines. These engines expose the pistons to much higher stress loads, which could break cast aluminum pistons.

Since aluminum is very light and relatively strong, it is an excellent material for engine pistons. When an engine is running at highway speeds, the piston must withstand tremendous loads. A piston may accelerate from zero to 60 mph and then back to zero, all in about four inches of piston travel. A heavy piston could break the connecting rod. A weak piston could fall apart under these loads.

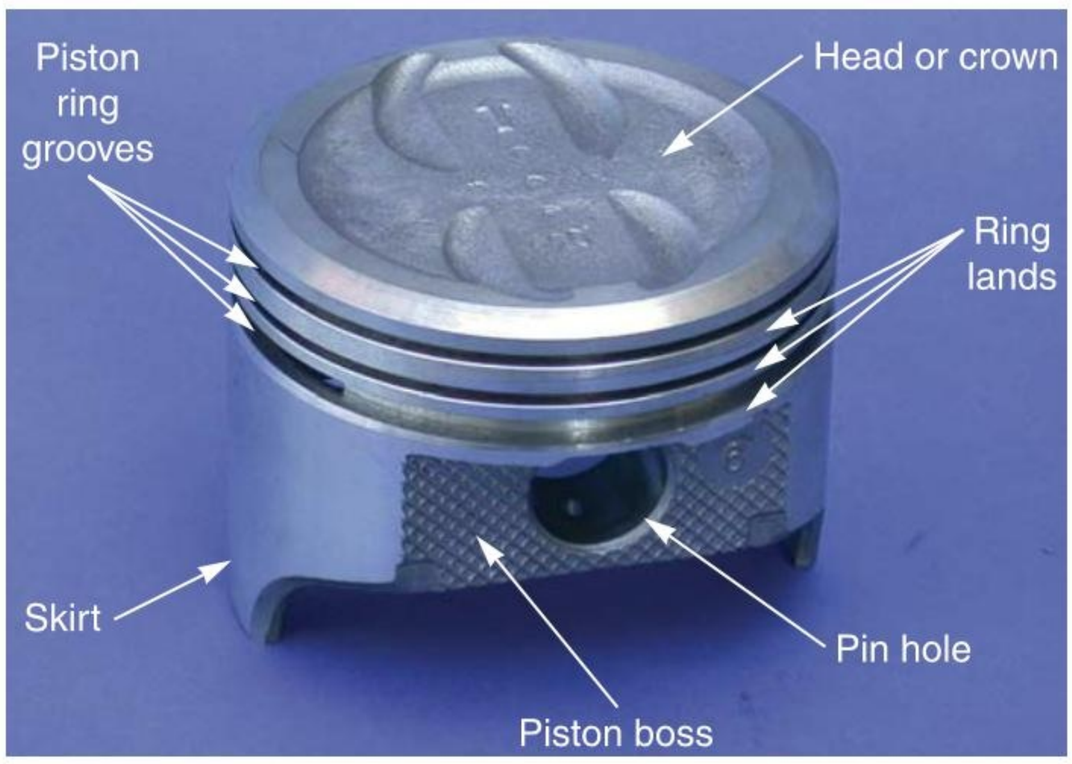
The design of a piston must provide maximum strength and minimum weight. The piston is thicker at stress points. The top of the piston is exposed to combustion and tremendous heat. It can reach operating temperatures as high as 650°F (345°C). Several design methods are used to provide dependable, quiet piston operation.

Piston Parts

The ***piston head***, or crown, is the top of the piston. It is exposed to the heat and pressure of combustion and must be thick enough to withstand these forces. The head must also be shaped to match and work with the shape of the combustion chamber for complete combustion.

Piston ring grooves are three slots machined in the piston for the piston rings. The upper two grooves hold the compression rings. The lower piston groove holds the oil ring. Oil holes in the lower groove allow the oil to pass through the piston. The oil then drains back into the crankcase.

The ***ring lands*** are the areas between and above the ring grooves. They separate and support the piston rings as they slide on the cylinder. See **Figure 14-6**.



Goodheart-Willcox Publisher

Figure 14-6. Study the major parts of a piston.

Copyright Goodheart-Willcox Co., Inc.

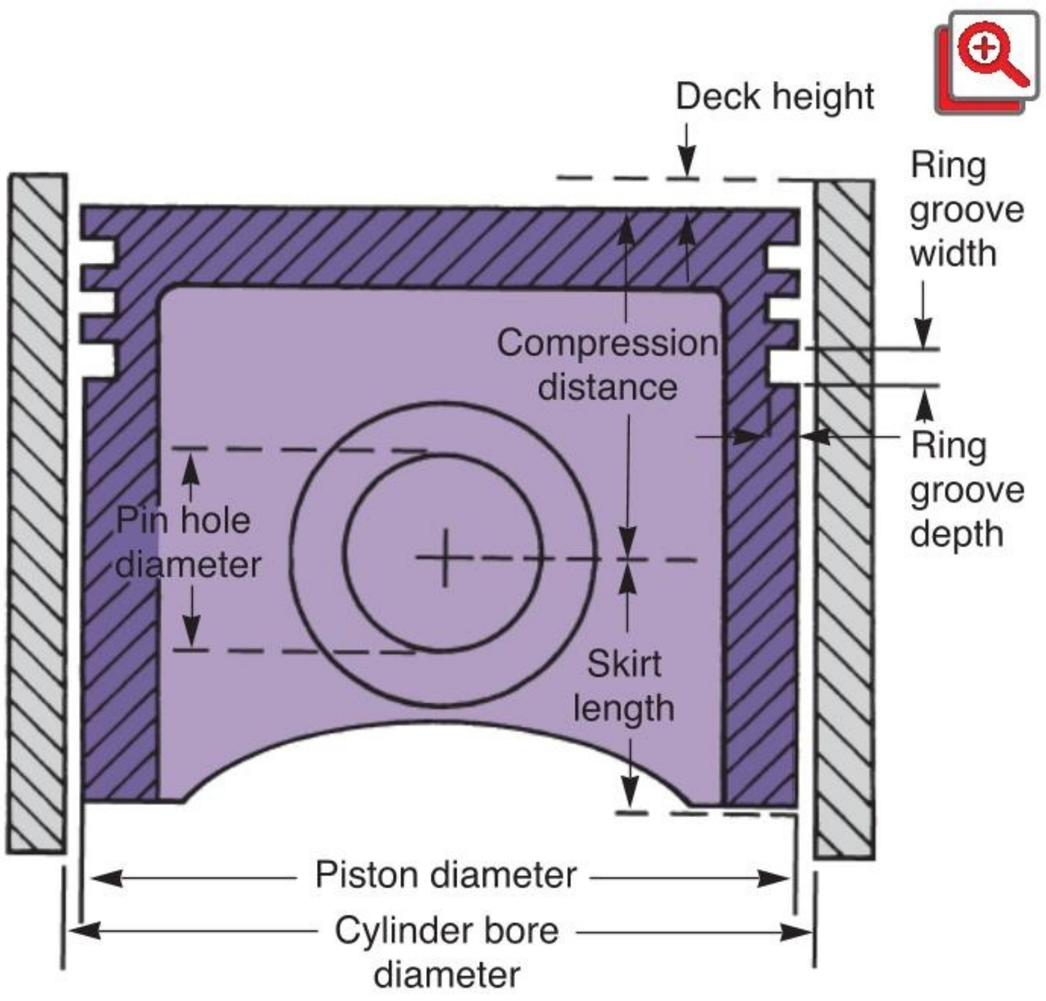
A ***piston skirt*** is the side of the piston below the last ring. It keeps the piston from tipping in its cylinder. Without a skirt, the piston could cock and jam in the cylinder. A slipper skirt is produced when portions of the piston skirt below the piston pin ends are removed. The slipper skirt provides clearance between the piston and the crankshaft counterweights. This allows the piston to slide farther down in the cylinder without hitting the crankshaft. A straight skirt is flat across the bottom. This style is no longer common in automotive engines.

A ***piston pin hole*** is machined through the piston to accept the piston pin. It is slightly larger than the pin. The ***piston boss*** is a reinforced area around the piston pin hole. It must be strong enough to support the piston pin under severe loads.

Piston Dimensions

Figure 14-7 illustrates several piston dimensions. These dimensions affect how the piston functions in the cylinder. These dimensions are explained as follows.

- ***Piston diameter***—The distance measured across the sides of the piston is piston diameter.
- ***Pin hole diameter***—Pin hole diameter is the distance measured across the inside of the piston pin hole.
- ***Ring groove width***—The distance measured from the top to the bottom of the ring groove is ring groove width.
- ***Ring groove depth***—Ring groove depth is the distance measured from the ring land to the back of the ring groove.
- ***Skirt length***—Skirt length is the distance from the bottom of the skirt to the centerline of the piston pin hole.
- ***Compression distance***—The distance from the centerline of the piston pin hole to the top of the piston is compression distance.



Goodheart-Willcox Publisher

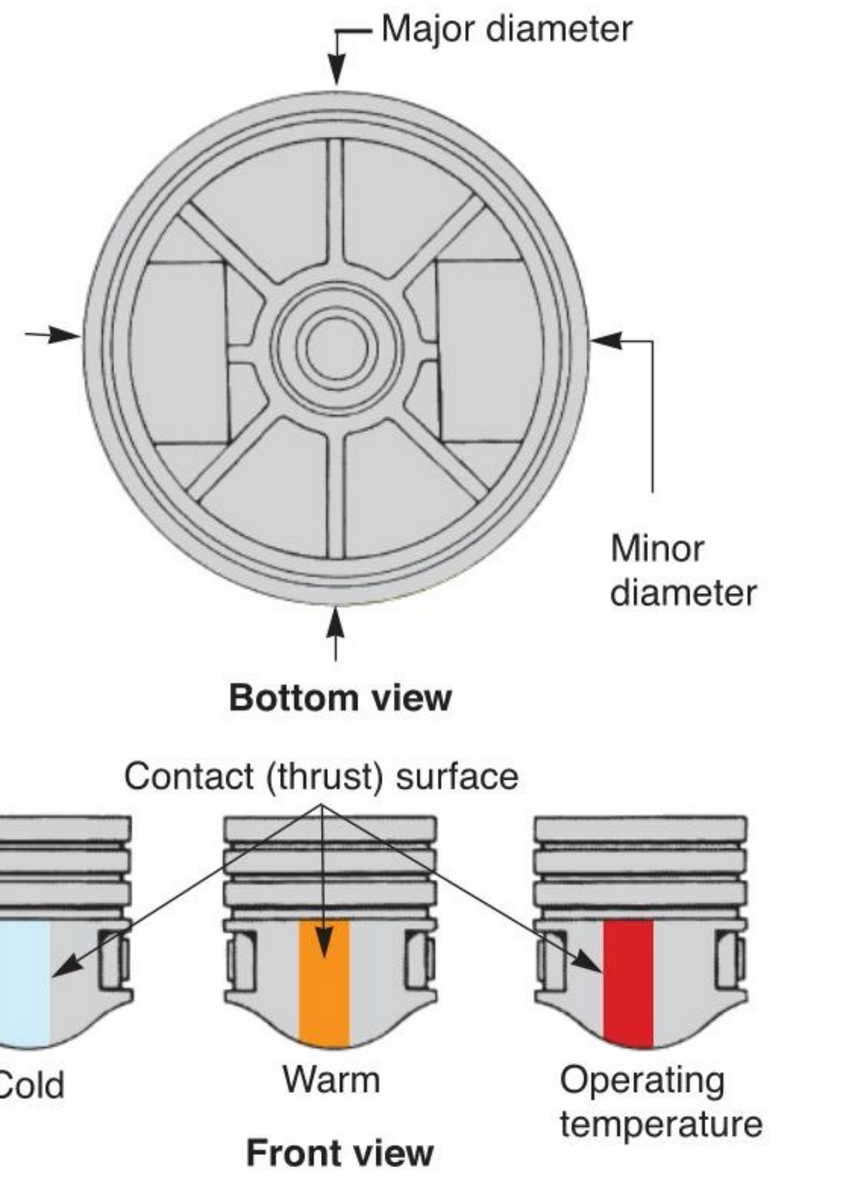
Figure 14-7. Note the basic dimensions of a piston.

Cam-Ground Piston

A ***cam-ground piston*** is slightly out of round when viewed from the top. The piston is machined a few thousandths of an inch larger in diameter perpendicular to the piston pin centerline.

Cam grinding is done to compensate for different rates of piston expansion due to differences in metal wall thickness. As the piston is heated by combustion, the thicker area around the pin boss causes the piston to expand more parallel to the piston pin. The oval-shaped piston becomes round when hot, and there is still enough clearance parallel to the piston pin. See **Figure 14-8**.

A cold cam-ground piston has acceptable piston-to-cylinder clearance. The unexpanded piston will not



Ford

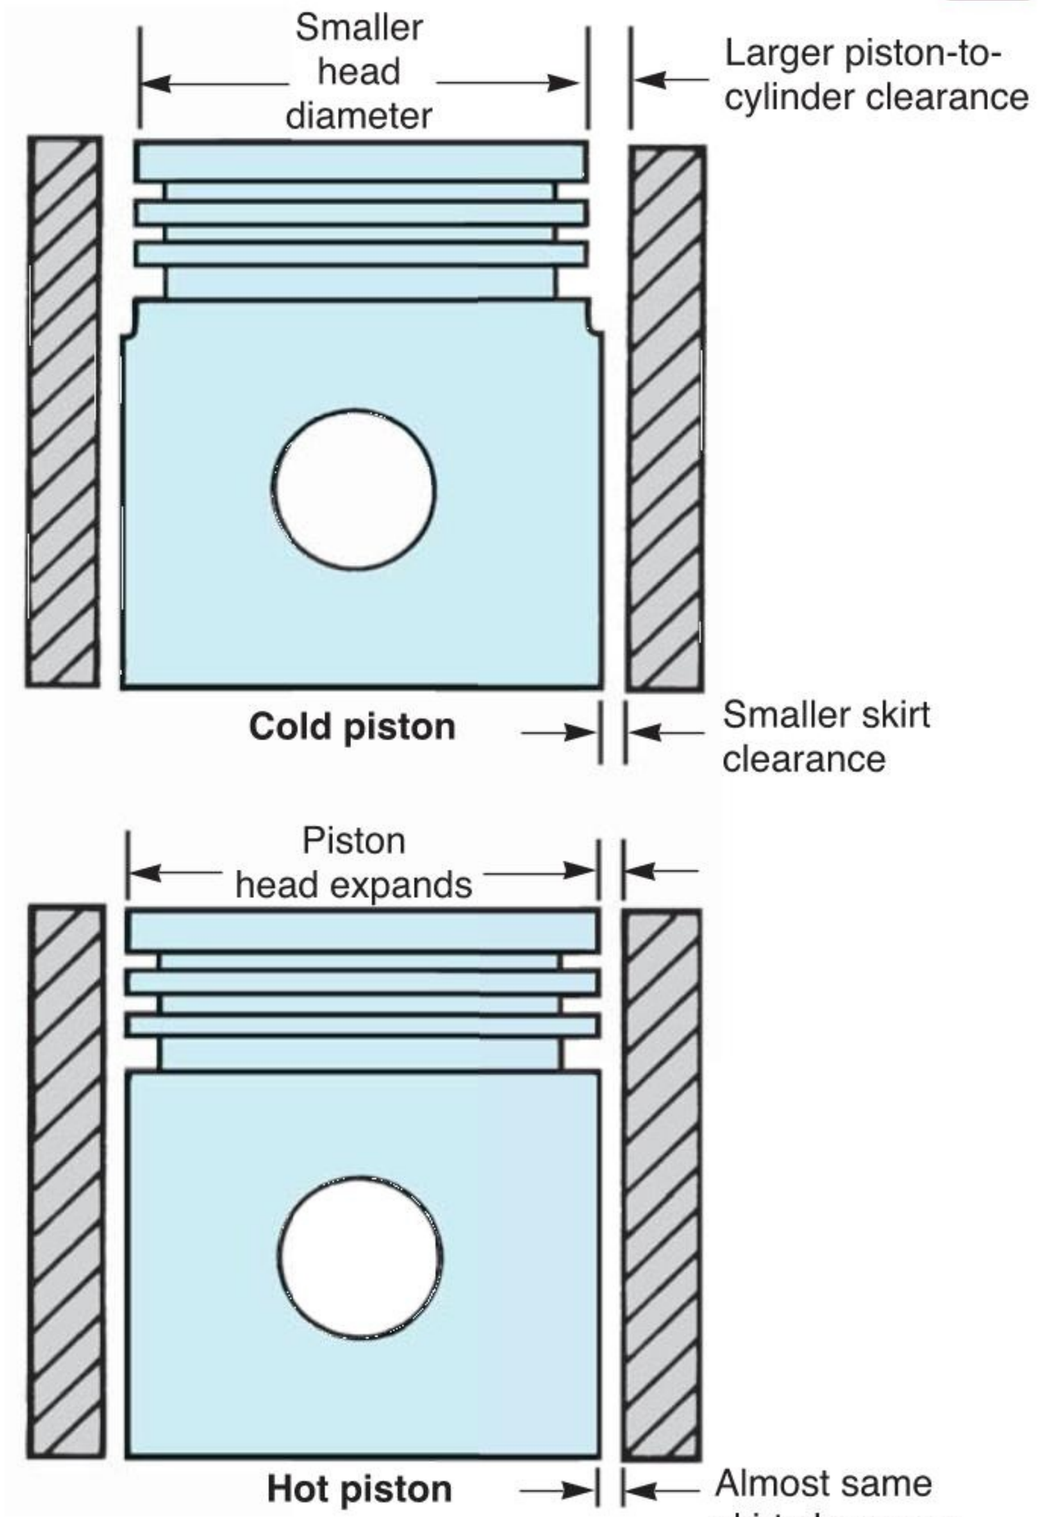
Figure 14-8. A cam-ground piston compensates for different rates of expansion. The piston is larger across the major diameter. The piston expands more across the minor diameter when heated. This causes the piston to become round when at full operating temperature.

Copyright Goodheart-Willcox Co., Inc.

slap, flop sideways, and knock in the cylinder because of too much clearance. When heated to full operating temperature, the cam-ground piston expands for optimal piston-to-cylinder clearance. It will not become too tight in the cylinder.

Piston Taper

Piston taper is also used to maintain the correct piston-to-cylinder clearance. The top of the piston is machined slightly smaller than the bottom, **Figure 14-9**. Since the piston head gets hotter than the skirt, it expands more. The piston taper makes the piston almost equal in size at the top and bottom at operating temperature.



Goodheart-Willcox Publisher

Figure 14-9. Piston taper compensates for more expansion around the piston head. The head becomes hotter than the skirt and expands more. By machining the head smaller, the piston diameter becomes almost equal at the top and bottom when hot.

Piston Head Shape

Piston head shape generally refers to the contour of the piston top. Usually, a piston head is shaped to match and work with the shape of the cylinder head combustion chamber. See **Figure 14-10**.

A—Flat-top piston

B—Dished piston

C—Domed piston

Goodheart-Willcox Publisher

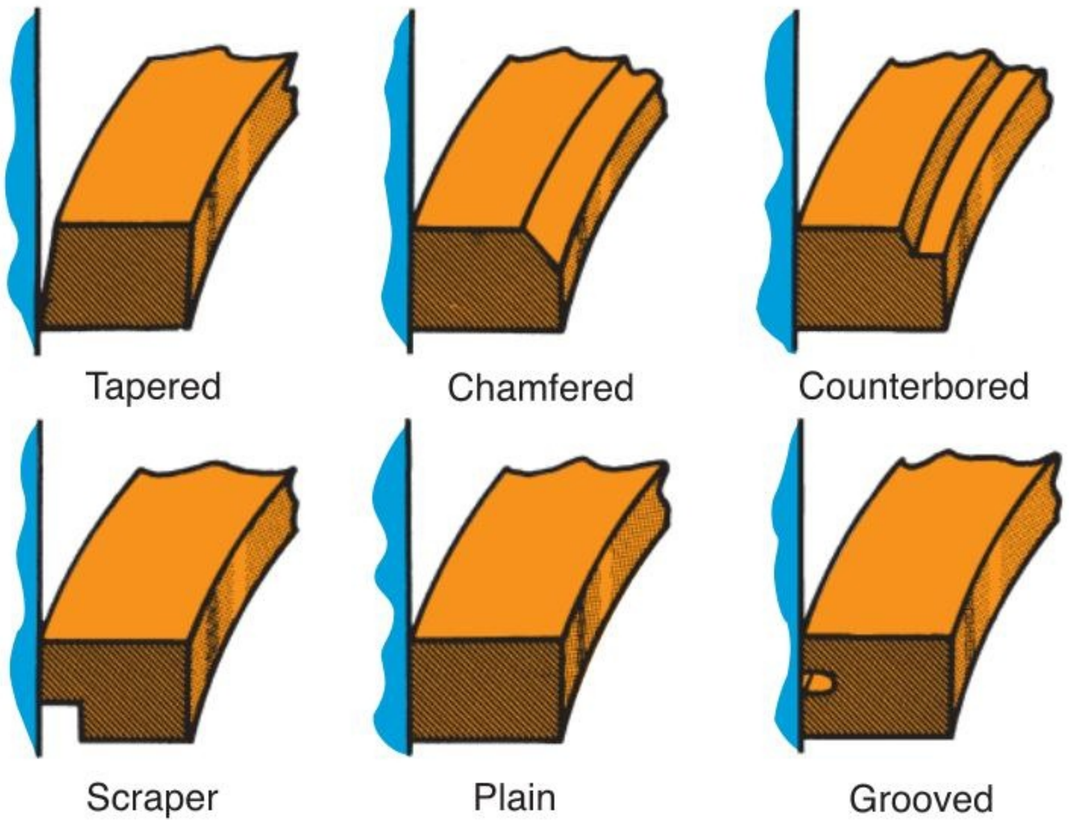
Figure 14-10. Compare common piston shapes.

Copyright Goodheart-Willcox Co., Inc.

As its name implies, a flat-top piston, **Figure 14-10A**, has a flat head that is parallel to the block's deck surface. This type of piston is often used in engines with wedge- or pancake-type cylinder heads. Valve reliefs are cut into the head of this type of piston. Valve reliefs are small indentations either cast or machined into the piston crown to provide ample piston-to-valve clearance. Without valve reliefs, the valve heads could strike the piston.

A dished piston, **Figure 14-10B**, has a head that is sunken, or recessed. This type of piston can be used to lower compression pressure in a turbocharged or supercharged engine.

A domed piston, or pop-up piston, has a head that is convex, or curved upward. See **Figure 14-10C**. This type is normally used with a hemi-type cylinder head and some four-valve heads. The piston head fills the domed combustion chamber and produces enough compression pressure.



Ford

Figure 14-12. Various compression ring shapes are available. Each type is designed to help the ring prevent combustion pressure from leaking into the crankcase.

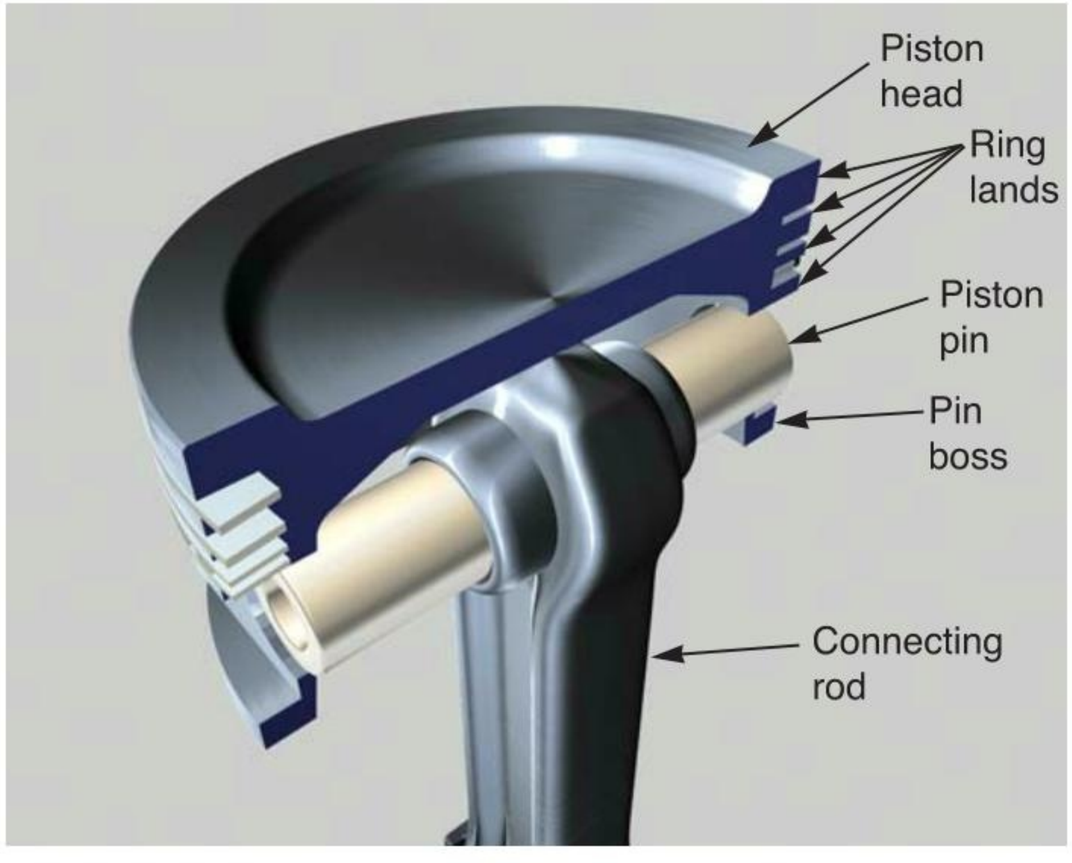
Piston Ring Construction

Automotive pistons normally use three rings—two compression rings and one oil ring. Refer to **Figure 14-11**. It is important for you to understand how variations in ring construction provide different operating characteristics.

The ***compression rings*** prevent pressure leakage into the crankcase. They also wipe some of the oil from the cylinder walls. To accomplish these functions, ring shapes vary, as shown in **Figure 14-12**. These shapes help seal combustion pressure and remove oil from the cylinder wall so oil is not burned with the fuel.

Compression rings are usually made of cast iron. An outer layer of chrome or other metal may be used to increase wear resistance. The face of compression rings may also be grooved to speed ring seating. ***Ring seating*** is the initial ring wear that makes the ring perfectly match the surface of the cylinder.

Oil rings are available in two basic designs: rail-spacer type and one-piece type, **Figure 14-13**. The primary function of oil rings is to keep crankcase oil out of the combustion chambers. A three-piece oil ring consisting of two rails, or scrapers, and an expander-spacer is the most common. The ***ring expander-spacer*** holds the two steel oil ring rails apart and helps push them outward, **Figure 14-13A**. A ***ring expander*** can be placed behind a one-piece oil ring to increase ring tension, **Figure 14-13B**. It can also be used behind the second compression ring. The expander helps push the ring out against the cylinder wall, increasing the ring's sealing action.



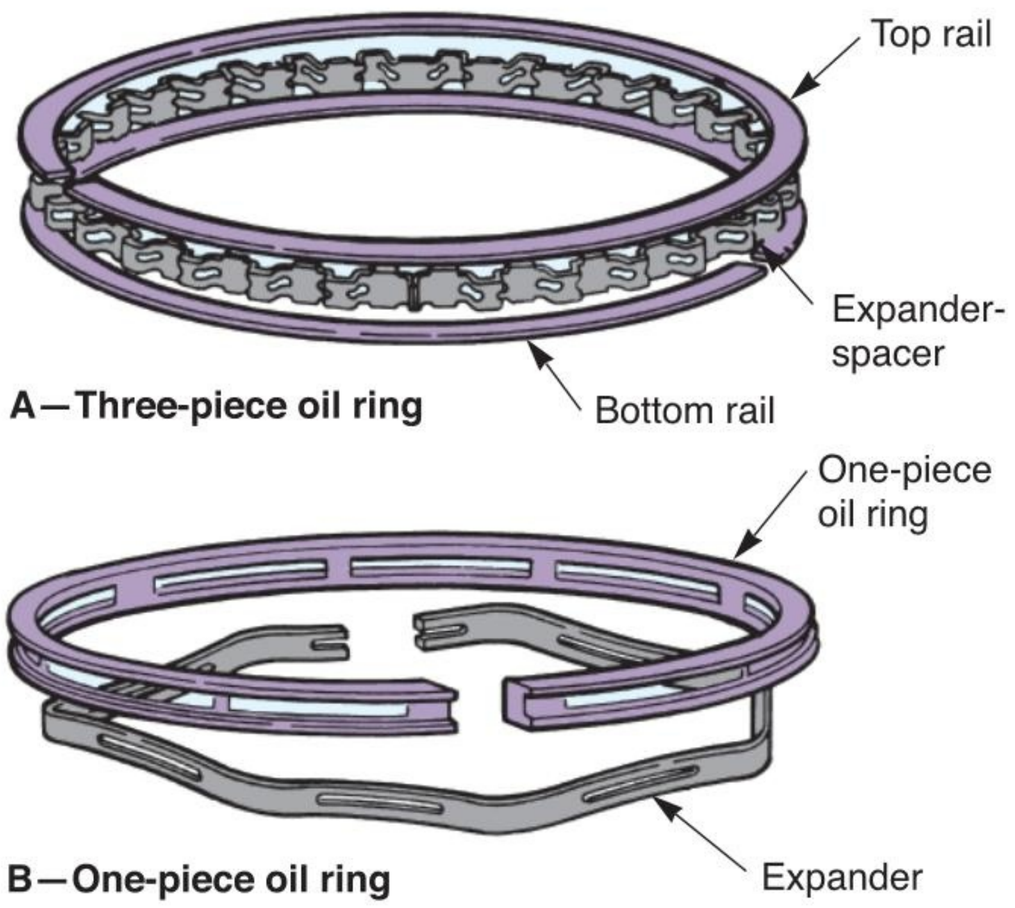
Goodheart-Willcox Publisher

Figure 14-11. Study the basic parts of a typical piston and rod assembly. This piston pin is press fit in the connecting rod.

Piston Ring Dimensions

Basic piston ring dimensions include the width, radial wall thickness, and gap. Refer to **Figure 14-14**. These dimensions affect the operation of the engine. Ring side and back clearances are also very important. They must be within factory specifications or poor engine performance could result.

Copyright Goodheart-Willcox Co., Inc.

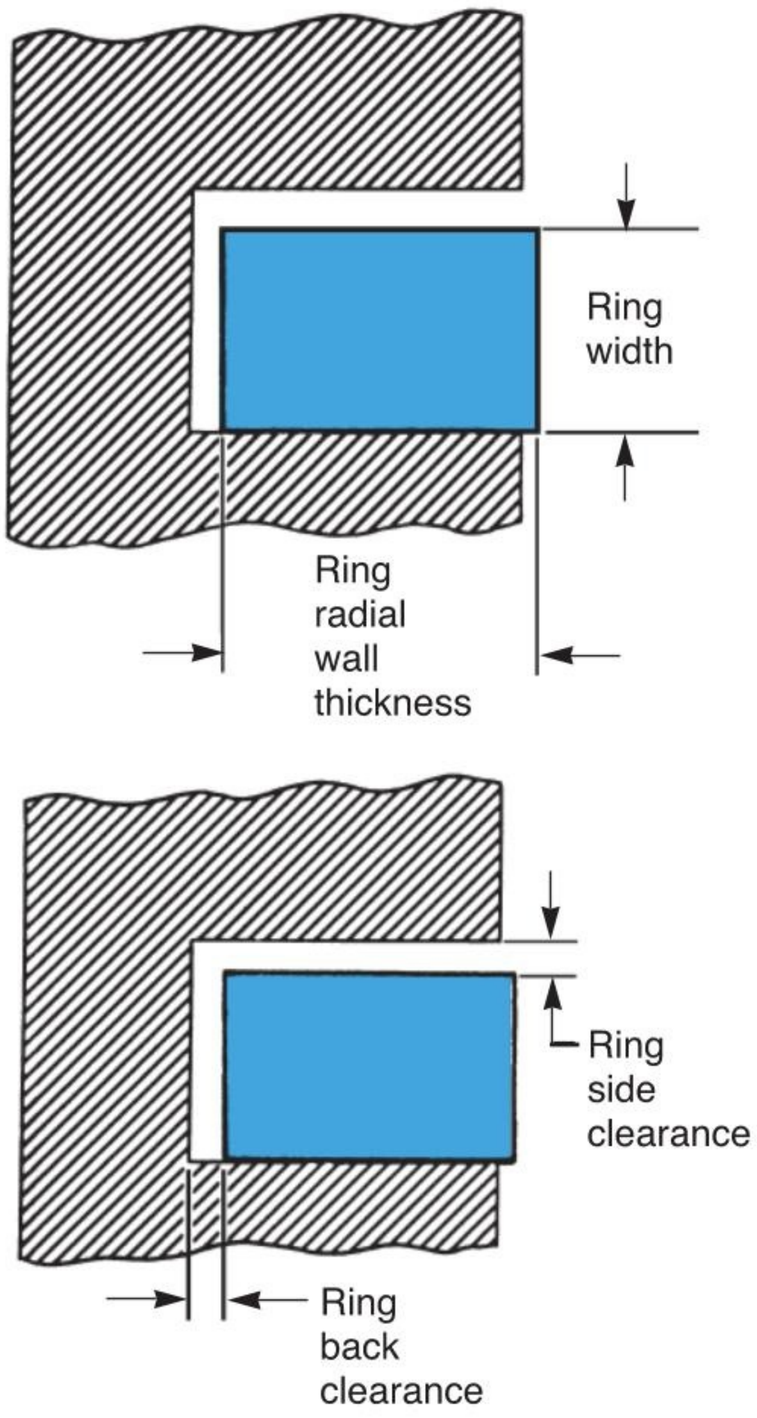


A—Three-piece oil ring

B—One-piece oil ring

Ford

Figure 14-13. An oil ring must wipe excess oil off the cylinder wall.



Perfect Circle

Figure 14-14. Ring width, ring groove depth, ring radial wall thickness, and ring groove height determine the ring back and side clearances.

The ***piston ring width*** is the distance from the top of the ring to the bottom of the ring. The difference between the ring width and the width of the piston ring groove determines the ***ring side clearance***.

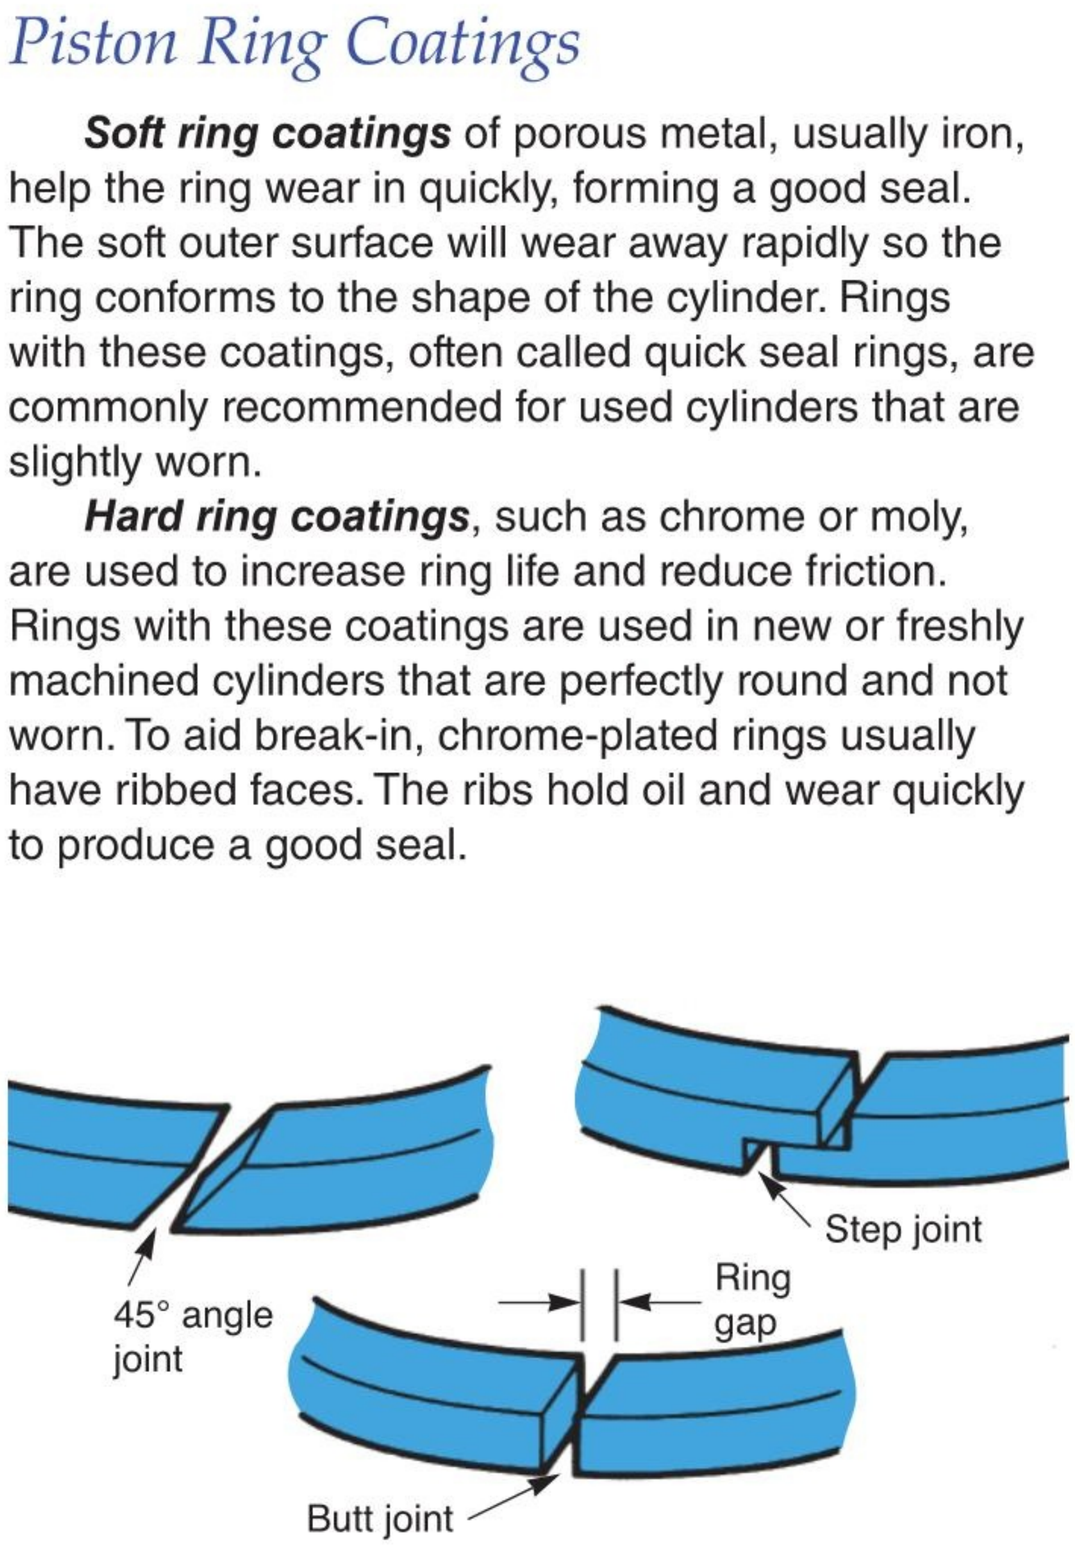
The ***piston ring radial wall thickness*** is the distance from the face of the ring to its inner wall. The difference between the piston ring radial wall thickness and ring groove depth determines the ***ring back clearance***.

The ***piston ring gap*** is the distance between the ends of the ring when the ring is installed in the cylinder. This is pictured in **Figure 14-15**. The ring gap allows the ring to be installed on the piston and to "spring outward" in its cylinder. The gap also allows the ring to conform to any variation in the cylinder diameter due to wear.

Piston Ring Coatings

Soft ring coatings of porous metal, usually iron, help the ring wear in quickly, forming a good seal. The soft outer surface will wear away rapidly so the ring conforms to the shape of the cylinder. Rings with these coatings, often called quick seal rings, are commonly recommended for used cylinders that are slightly worn.

Hard ring coatings, such as chrome or moly, are used to increase ring life and reduce friction. Rings with these coatings are used in new or freshly machined cylinders that are perfectly round and not worn. To aid break-in, chrome-plated rings usually have ribbed faces. The ribs hold oil and wear quickly to produce a good seal.



Ford

Figure 14-15. The ring gap is the small space between the ends of the ring when it is installed on the piston and the piston is in the cylinder. Most modern piston rings use a butt joint.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

Avoid using rings with hard coatings when rebuilding a passenger car engine. The hard rings are more difficult to seat than softer rings. Soft rings are more forgiving of cylinder wall imperfections. Engine smoking problems are more common in rebuilt engines when rings with hard coatings are used, because the rings take much longer to seat.

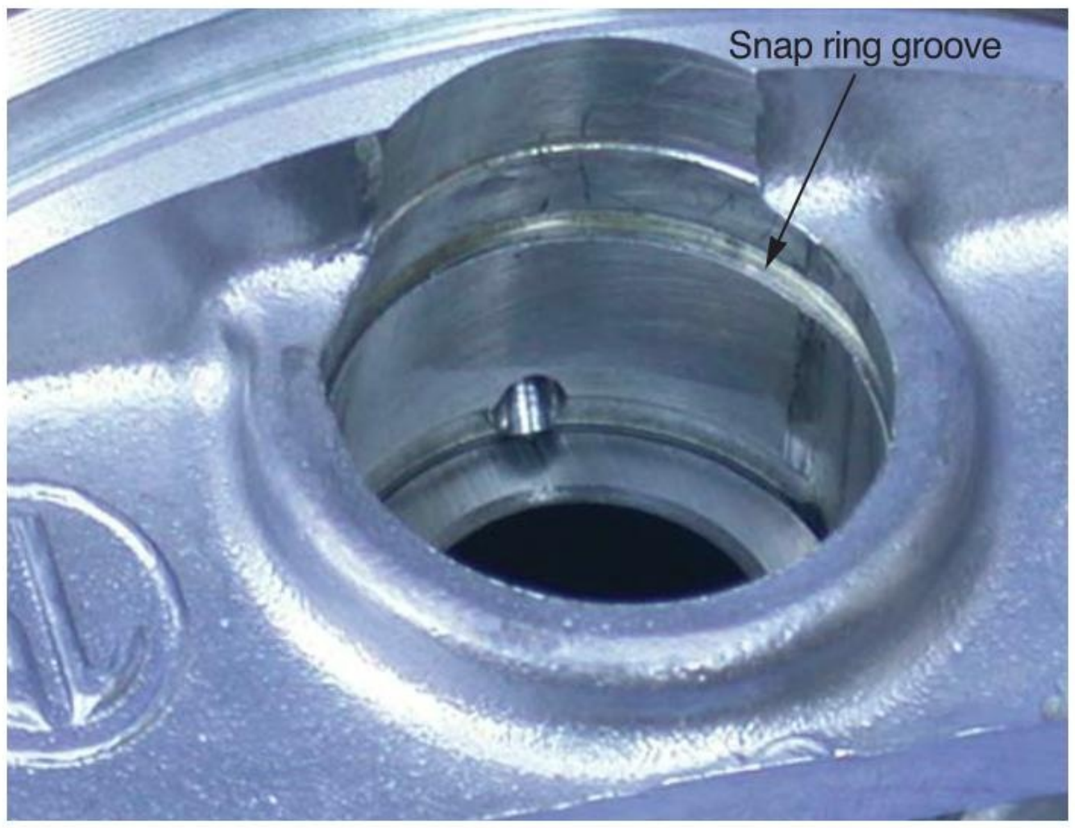
Piston Pin Construction

Piston pins are normally made of case-hardened steel. Case-hardening is a heating and cooling process that increases the wear resistance of the piston pin. It hardens the outer layer of metal on the pin. The inner metal remains unhardened so the pin is not too brittle. The hollow piston pin is also machined and polished to a very precise finish. Piston pins are held in the piston by one of two means—a press-fit or snap rings.

A ***press-fit piston pin*** is forced tightly into the connecting rod's small end. It can rotate freely in the piston pin hole. However, the pin is not free to move in the connecting rod, **Figure 14-16A**. This holds the pin inside the piston and prevents it from sliding out and rubbing on the cylinder wall. The press-fit is a very dependable piston pin design. It is also inexpensive to manufacture.

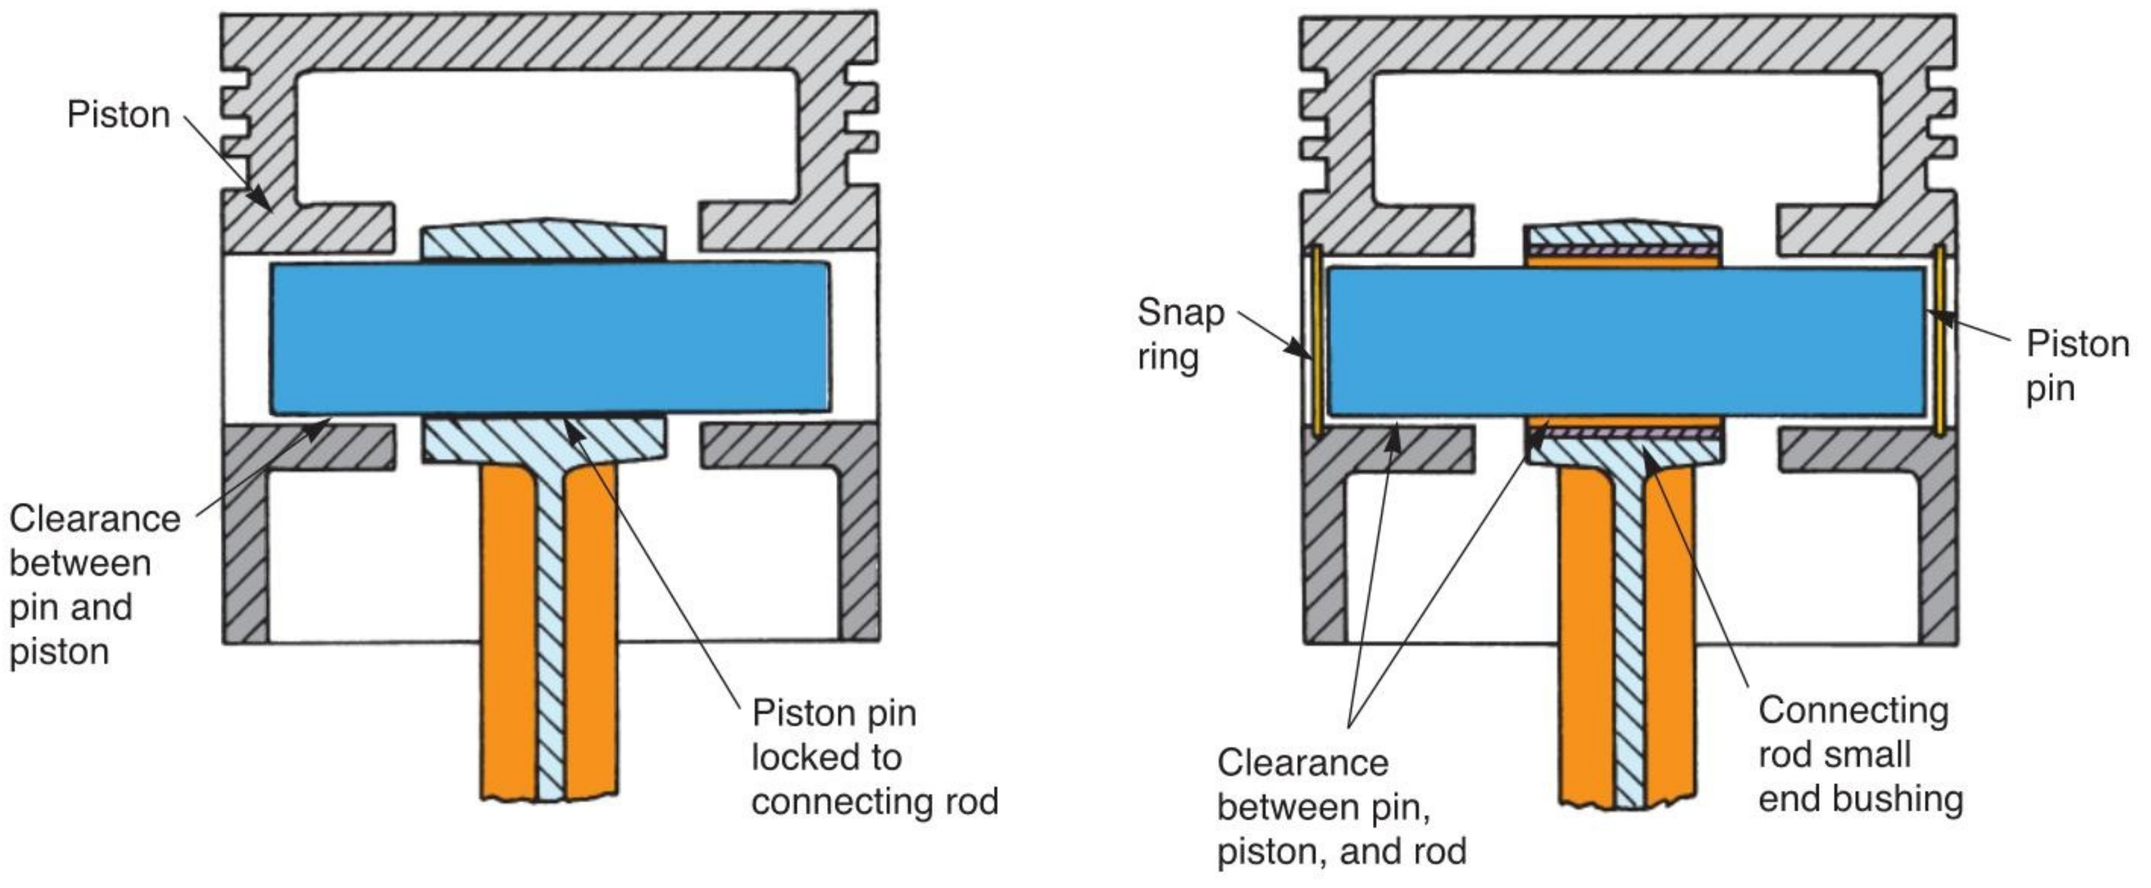
A ***full-floating piston pin*** is secured by snap rings and is free to rotate in both the rod and piston. Look at **Figure 14-16B**. The pin is free to "float" in both the piston pin bore and the connecting rod small end.

Full-floating piston pins are better than press-fit pins because they reduce friction and wear. A bronze bushing is usually used in the connecting rod. The piston pin hole serves as the other bearing surface for the pin. The snap rings fit into grooves machined inside the piston pin hole. See **Figure 14-17**.



Goodheart-Willcox Publisher

Figure 14-17. A full-floating piston pin is held in place by snap rings that fit into grooves in the piston.



A—Press-fit piston pin

B—Full-floating piston pin

Goodheart-Willcox Publisher

Figure 14-16. Compare piston pin and piston boss designs.

Copyright Goodheart-Willcox Co., Inc.

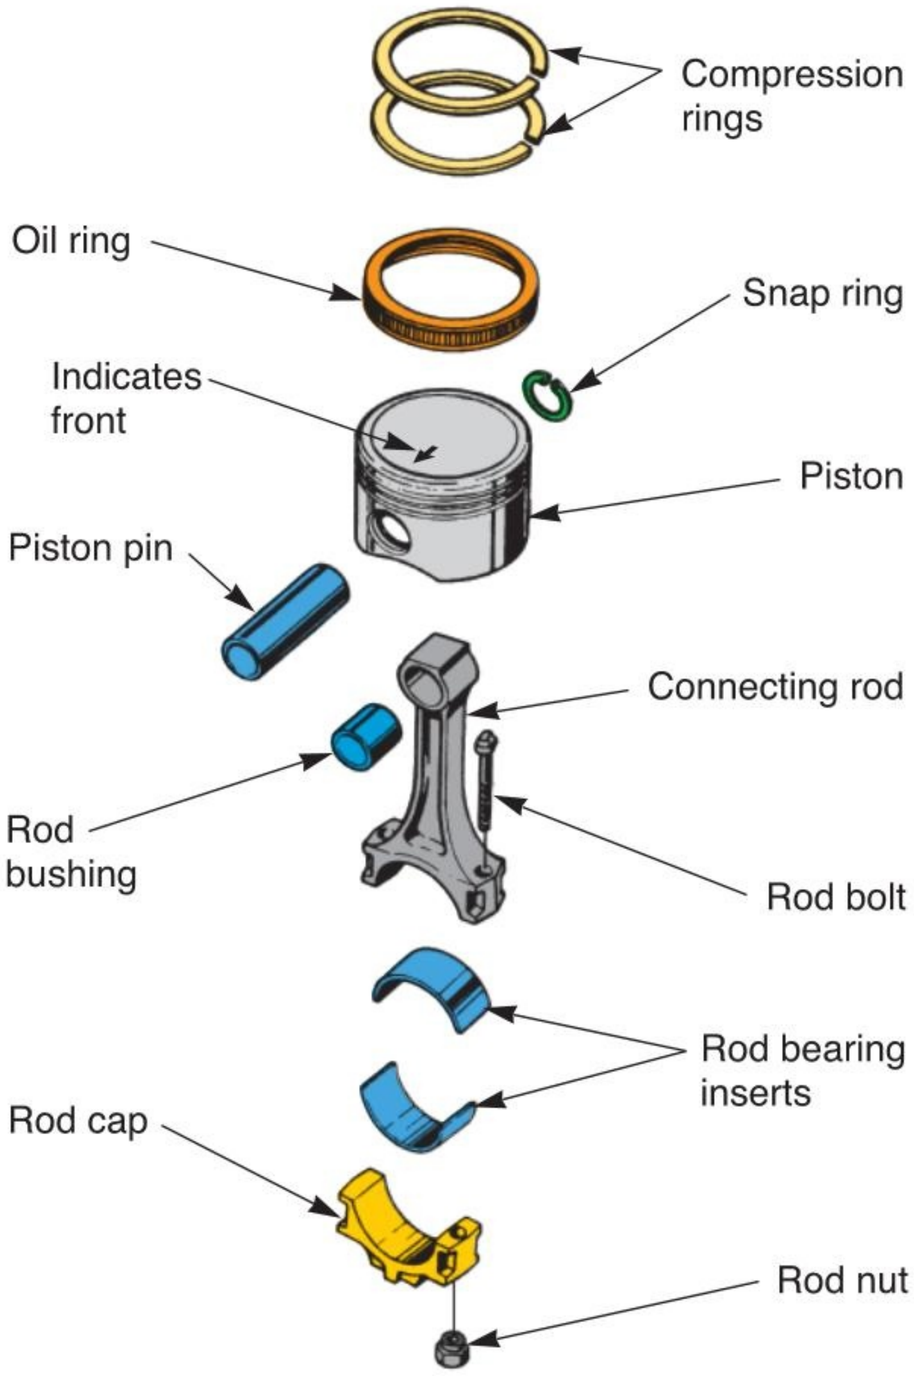
Piston Pin Offset

A ***piston pin offset*** locates the piston pin hole slightly to one side of the piston centerline. This helps quiet the piston during use. The piston pin hole is moved toward the piston's major thrust surface. This is the surface of the piston that is pushed tightly against the cylinder wall during the power stroke.

If the piston pin hole were centered in the piston, the piston could slap or knock in the cylinder. As the piston moves up in the cylinder, it could be positioned opposite the major thrust surface. Then, during combustion, the piston could be rapidly pushed to the opposite side of the cylinder, producing a knocking sound. With the piston pin offset, the piston tends to be pushed against its major thrust surface. This reduces its tendency to slap sideways in the cylinder.

A piston notch or other marking on the head of the piston is frequently used to indicate piston pin offset and the front of the piston. The piston may also have the word "front" or an arrow stamped on it. This information lets you know how to position the piston in the block for correct location of the piston pin offset.

Figure 14-18 shows an exploded view of a piston and connecting rod assembly. Note how the parts are assembled.



Goodheart-Willcox Publisher

Figure 14-18. An exploded view of a piston and rod assembly. This piston has a full-floating piston pin.

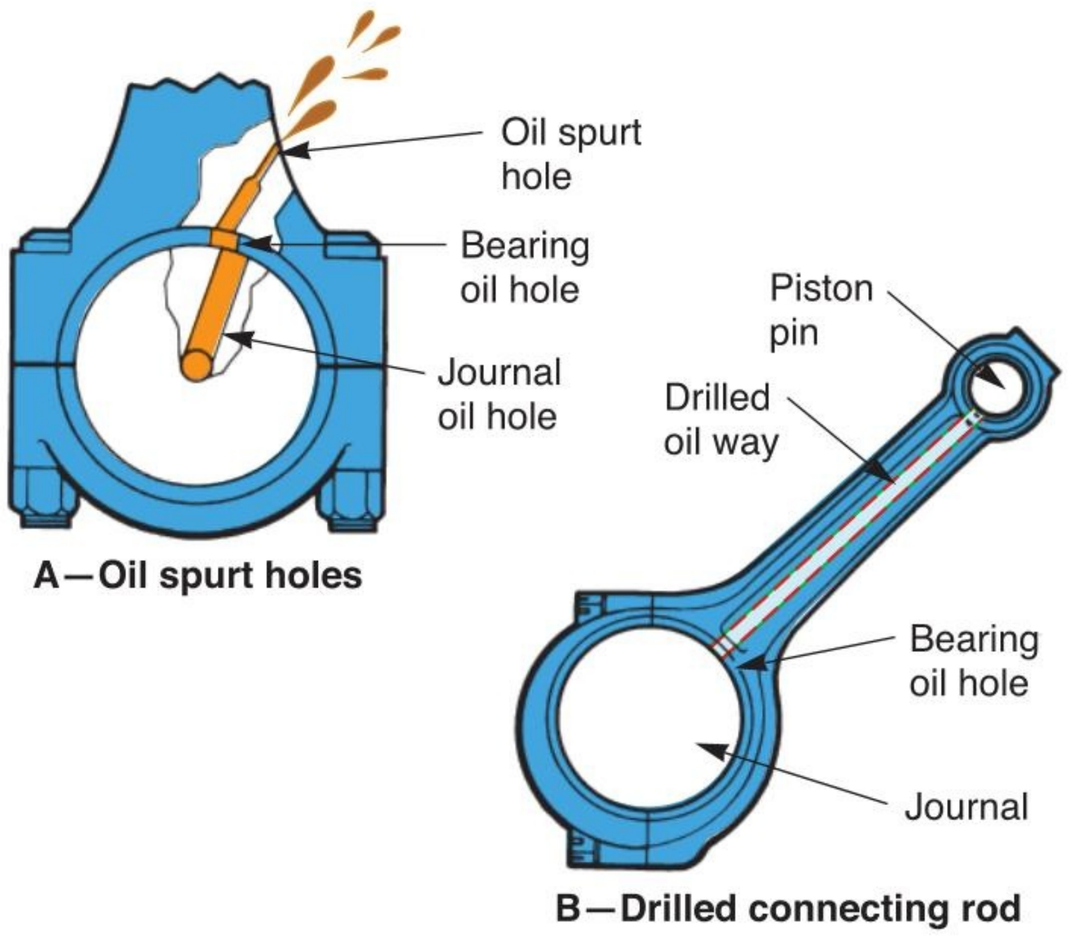
Connecting Rod Construction

Most connecting rods are made of steel. The rod must withstand tons of force as the piston moves up and down in the cylinder. Connecting rods normally have an I-beam shape. This shape has a high strength-to-weight ratio.

Connecting rods must be very strong, but as light as possible for low inertia forces from their changes in direction at top dead center (TDC) and bottom dead center (BDC). Low-inertia parts are light parts that will accelerate quickly.

Some connecting rods have an ***oil spurt hole*** that provides added lubrication for the cylinder walls, piston pin, and other surrounding parts. See **Figure 14-19**. Oil pressure forces oil out when the holes in the crankshaft journal and bearing align with the spurt hole. A ***drilled connecting rod*** has a machined hole through its entire length. The purpose of this hole is to supply oil to the piston pin.

Connecting rod numbers are used to ensure proper location of each connecting rod in the engine. They also ensure that the rod cap is installed on the rod body correctly.



Federal Mogul

Figure 14-19. Oil passages are machined through the crankshaft to lubricate rod bearings. Some connecting rods are drilled to also feed the oil up to the piston pin.

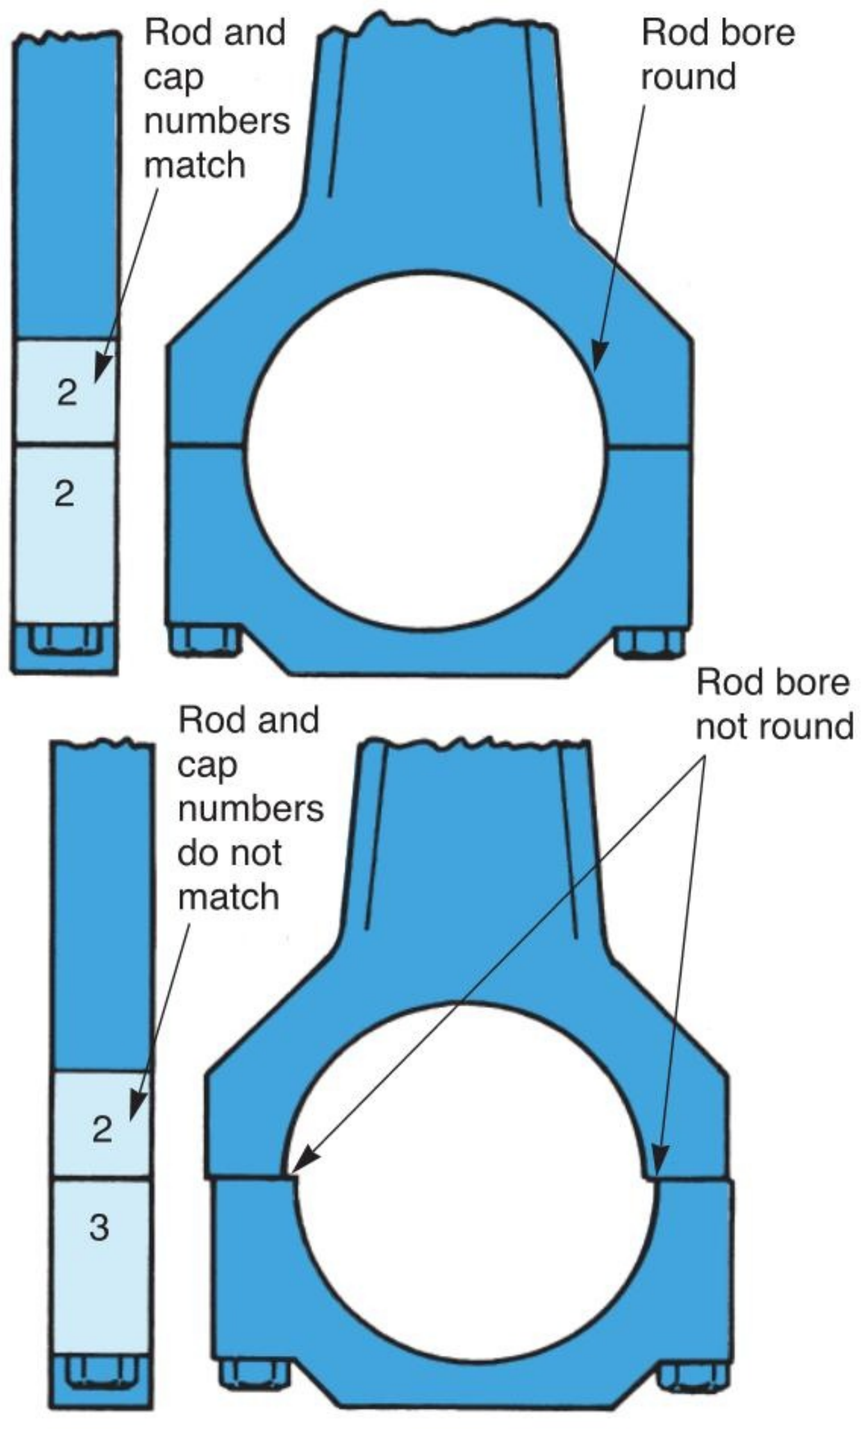
Copyright Goodheart-Willcox Co., Inc.

During manufacture, connecting rod caps are bolted to the connecting rods. Then, the crank holes are machined in the rods. Since these holes may not be perfectly centered, rod caps must not be mixed up or turned around. If the cap is installed without the rod numbers in alignment, the bore will not be perfectly round. Severe rod, crankshaft, and bearing damage will result. Look at **Figure 14-20**.

A ***broken-surface rod*** is scribed and broken off when manufactured to produce a rough, irregular mating surface between the rod body and cap. This is done to help lock the rod and cap into alignment. The broken, irregular surfaces match perfectly to prevent the rod and cap from shifting during engine operation. This type of rod cannot be rebuilt. However, oversize rod bearings can still be installed during an engine rebuild.

Powdered metal forging refers to a process that forms the rough shape of a part out of metal powder before final shaping in a powerful forge. Some connecting rods are powdered metal forged to help control the shape and weight while reducing machining.

Machined block forging involves initial turning in a lathe to bring the blank of metal to size before forming it in a drop or press forge. This process helps eliminate flashing. Flashing is the small lip of rough metal produced when the two halves of the forge come together to "smash" the metal into shape. By reducing flashing, a step is removed from the manufacturing process.



Goodheart-Willcox Publisher

Figure 14-20. A rod cap must be installed on the rod correctly. If rod caps are mixed up or turned, the bore for the bearing may not be round. The bearing could be crushed into the crankshaft journal, damaging both.

Crankshaft Construction

Engine crankshafts are usually made of cast iron or forged steel. Forged steel crankshafts are needed for heavy-duty applications, such as turbocharged or diesel engines. A forged steel crankshaft is stiffer and stronger than a cast iron crankshaft. It will withstand greater forces without flexing, twisting, or breaking.

Oil passages leading to the rod and main bearings are either cast or drilled in the crankshaft, **Figure 14-21**. Oil enters the crankshaft at the main bearings and passes through holes in the main bearing journals. It then flows through passages in the crankshaft and out to the connecting rod bearings.

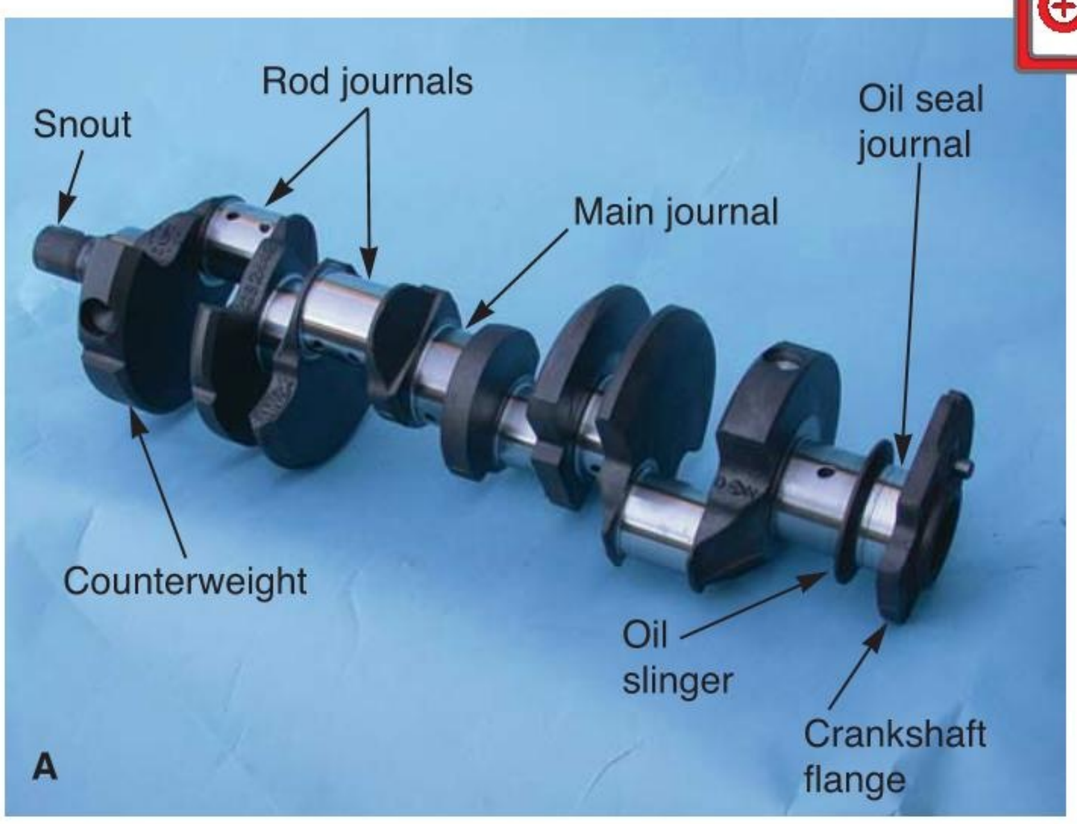
With an inline engine, only one connecting rod fastens to each rod journal, or ***crankpin***. With a V-type engine, two connecting rods bolt to each rod journal. The amount of rod journal offset controls the stroke of the piston. The journal surfaces are precision machined and polished to very accurate tolerances.

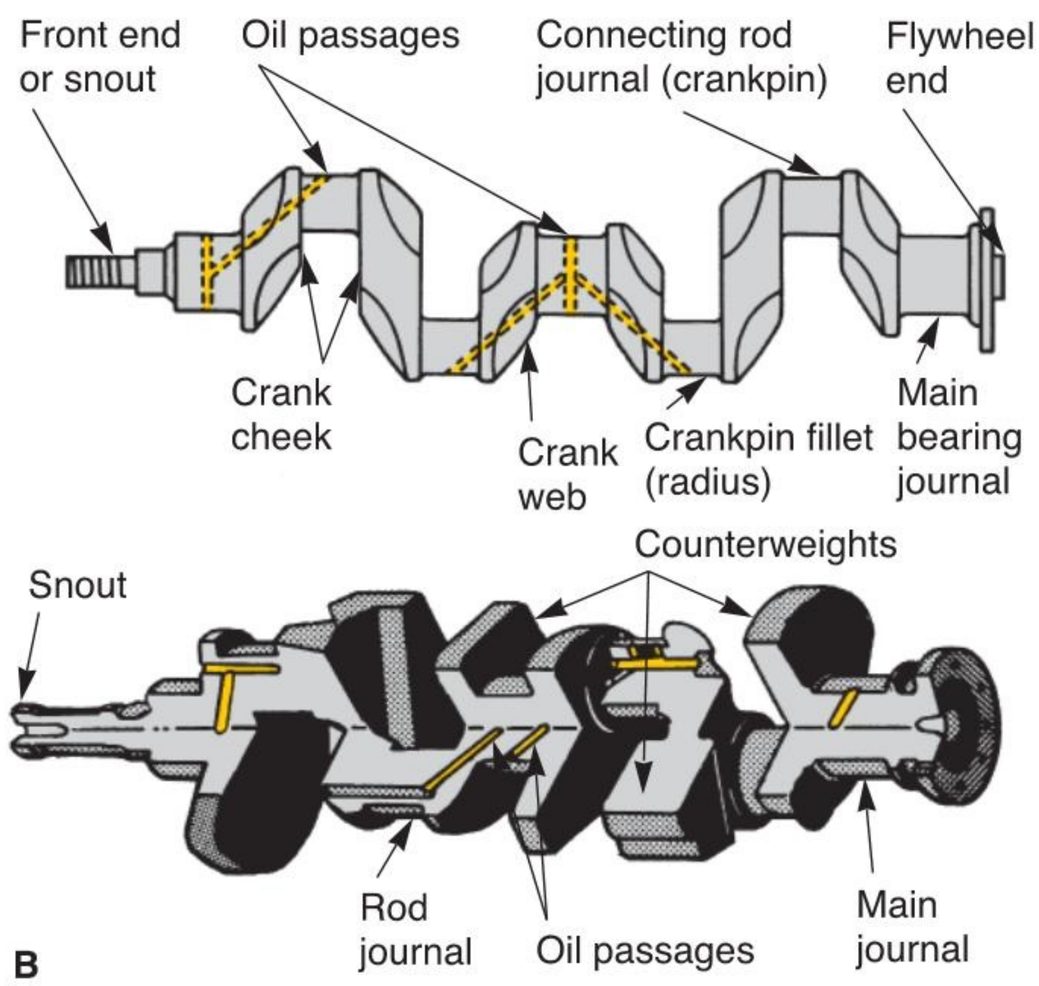
A ***fully counterweighted crankshaft*** has weights formed opposite every rod journal. A ***partially counterweighted crankshaft*** has weights formed opposite the journals in the center portion of the shaft only. A fully counterweighted crankshaft will operate with less vibration than a partially counterweighted crankshaft.

Engine Bearing Construction

There are two types of engine bearings: sleeve-type bearings and split-type bearings. ***Sleeve-type bearings***, or one-piece bearings, are press fit into the block or head. If the bearing has an oil hole, it must be aligned with the corresponding oil hole in the block or head. ***Split-type bearings*** are often called two-piece bearings because they consist of two halves. One half fits into the block or head, and the other half fits into a removable cap. Engine bearings include connecting rod bearings, crankshaft main bearings, and camshaft bearings. See **Figure 14-22**.

Copyright Goodheart-Willcox Co., Inc.



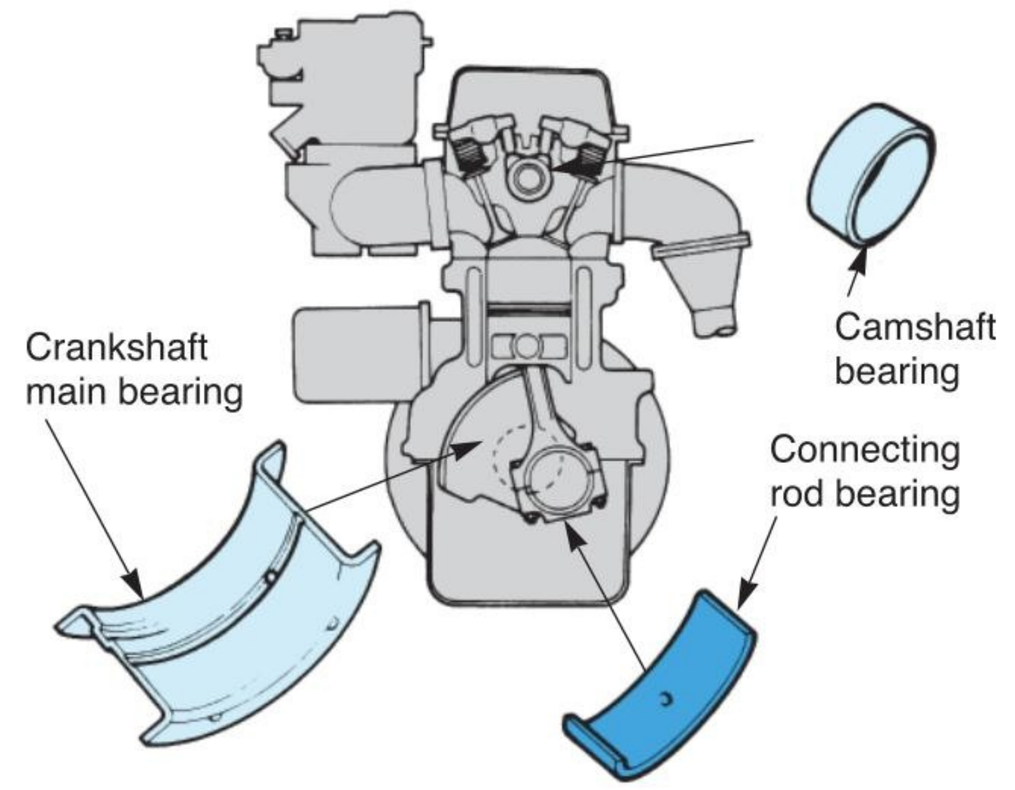


Ford

Figure 14-21. Study crankshaft construction. A—The crankshaft is often made of steel and is precision-balanced to prevent vibration damage. B—A crankshaft has internal passages to supply oil to the connecting rod bearings.

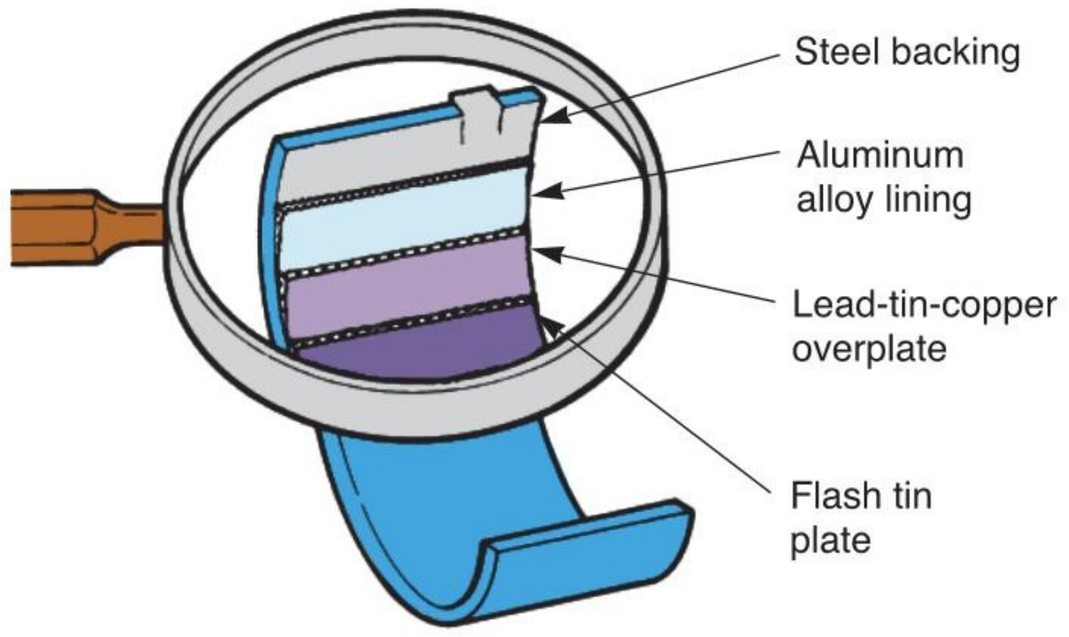
Steel is normally used for the bearing body, or backing, which contacts the stationary part of the engine. Softer alloys are bonded over this backing to form the bearing surface.

Any one of three metal alloys can be plated over the steel backing. These are babbitt (a lead-tin alloy), copper, or aluminum. These three metals may be used in different combinations to design bearings for use in light-, medium-, heavy-, or extra-heavy-duty applications. See **Figure 14-23**.



Federal Mogul

Figure 14-22. The three basic types of engine bearings are crankshaft main bearings, connecting rod bearings, and camshaft bearings.



Federal Mogul

Figure 14-23. Note the typical construction of an engine bearing. Steel backing forms the body of the bearing. Other alloys are plated over the backing to provide better operating characteristics.

Bearing Characteristics

Engine bearings must operate under tremendous loads, severe temperature variations, abrasive conditions, and corrosive surroundings. Essential bearing characteristics are described in this section. It is important to understand each of these.

Bearing load strength is the bearing's ability to withstand pounding and crushing during engine operation. The piston and rod can produce several tons of force. The bearing must not fail under these loads. If bearing load resistance is too low, the bearing can smash, spin, or split. This can ruin the bore or journal.

Copyright Goodheart-Willcox Co., Inc.

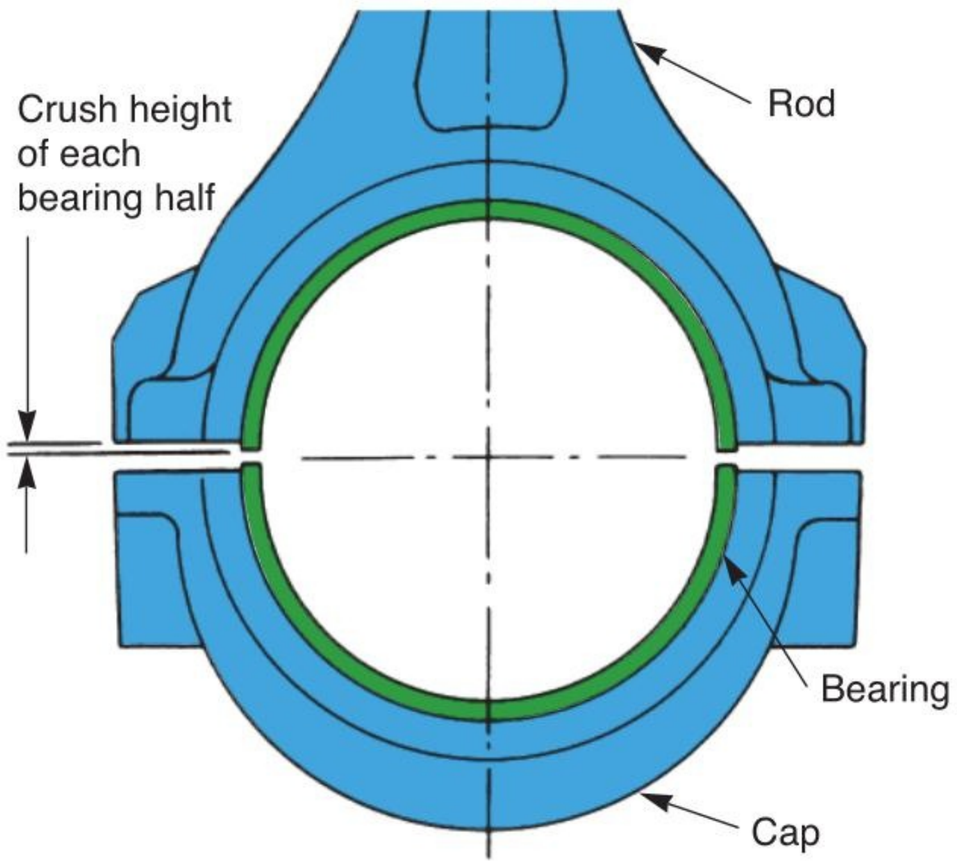
Bearing conformability is the bearing's ability to adjust to imperfections in the journal surface. Usually, a soft metal is plated over a hard steel backing. This lets the bearing conform to any defects in the journal.

Bearing embedability refers to the bearing's ability to absorb dirt, metal, or other hard particles. Dirt or metal is sometimes carried into the bearings. The bearing should allow the particles to sink into the bearing material. This prevents the particles from scratching, wearing, and damaging the surface of the crankshaft or camshaft journal.

Bearing corrosion resistance is the bearing's ability to withstand being acted on by acids, water, and other impurities in the engine oil. Combustion blowby gases cause oil contamination that can also corrode the engine bearings. Aluminum-lead and other alloys are commonly used because of their excellent corrosion resistance.

Bearing Crush

Bearing crush is used to help prevent a split-type bearing from spinning inside its bore during engine operation. Each bearing is made slightly larger than the bearing bore. The ends of the bearing extend slightly above the bore. When the rod or main cap is tightened, the bearing ends press against each other. This jams the back sides of the bearing inserts tightly against the bore, locking them in place. Bearing crush is illustrated in **Figure 14-24**.



Deere & Co.

Figure 14-24. Bearing crush is produced when bearings are made slightly larger than the bearing bore. When the cap is bolted down, the bearing is forced into the bore. This keeps the bearing from turning with the crankshaft.

Bearing Spread

Bearing spread is used on a split-type engine bearing to hold the bearing in place during assembly. The distance across the parting line of the bearing is slightly wider than the bearing bore. This causes the bearing insert to stick in its bore when pushed into place with your fingers. Tension from bearing spread keeps the bearing from falling out of its bore as you assemble the engine.

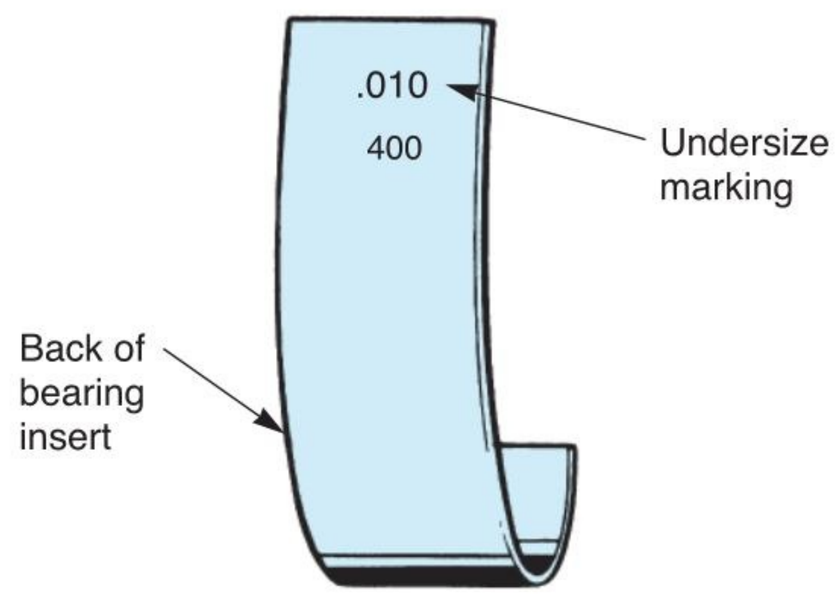
Standard and Undersize Bearings

A ***standard bearing*** has the original dimensions specified by the engine manufacturer for a new, unworn, or unmachined crankshaft. A standard bearing may have the abbreviation "STD" stamped on its back.

An ***undersize bearing*** is designed to be used on a crankshaft journal that has been machined to a smaller diameter. If the crankshaft journals have been worn or damaged, they can be ground undersize by a machine shop. Then, undersize bearings are needed. Connecting rod and main bearings are available in undersizes of 0.010″, 0.020″, 0.030″, and sometimes 0.040″. The undersize is normally stamped on the back of the bearing. The crankshaft may also have an undersize number stamped on it by the machine shop. Undersize bearings are illustrated in **Figure 14-25**.

Bearing Locating Lugs and Dowels

Bearing locating lugs and ***dowels*** position split bearings in their bores. Look at **Figure 14-26**. The bearing usually has a lug that fits into a recess



Buick

Figure 14-25. The bearing undersize is stamped on the back of the bearing. An undersize marking of 0.010″, for example, means that crankshaft journal has been ground 0.010″ smaller in diameter. Undersize bearings are needed to maintain correct bearing clearance.

Federal Mogul

Figure 14-26. Bearing locating lugs or dowels can be used to position engine bearings in their bore.

machined in the bearing bore or cap. Sometimes a dowel in the cap or bore fits in a hole in the bearing insert. Either method helps keep the insert from shifting or turning during crankshaft rotation.

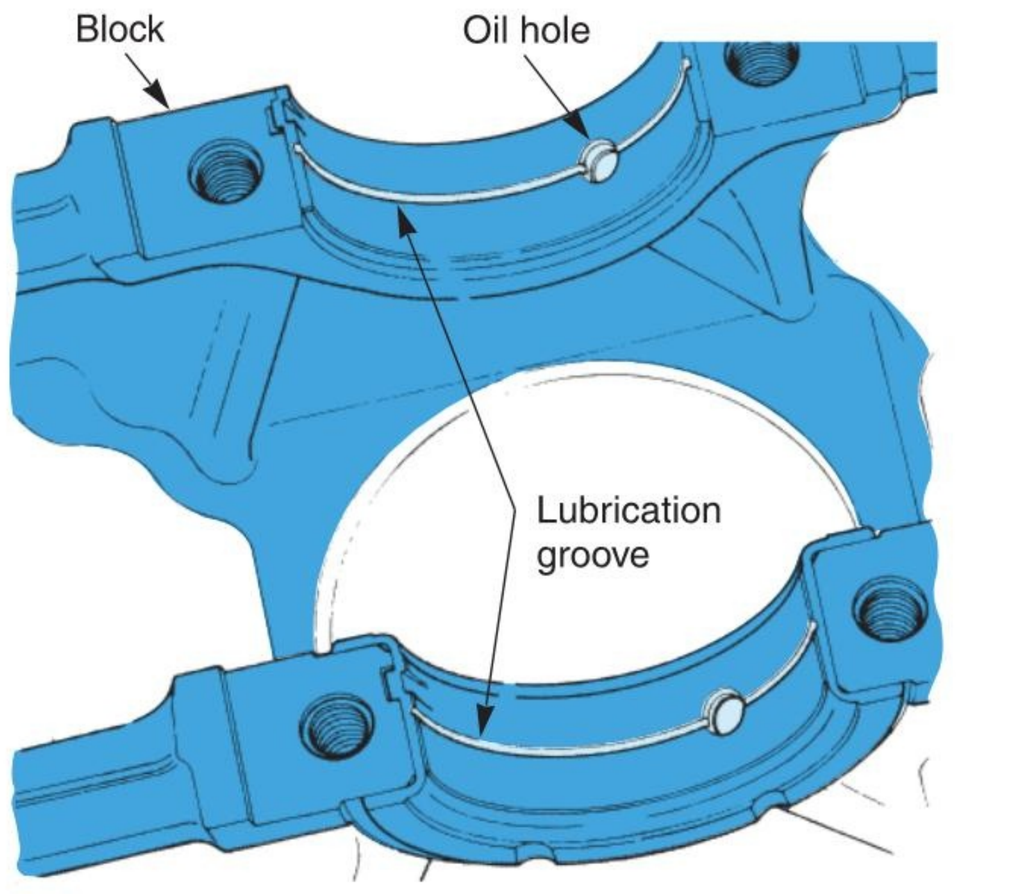
Bearing Oil Holes and Grooves

Bearing oil holes and ***grooves*** in the engine bearings permit bearing lubrication. The holes allow oil to flow through the block and into the clearance between the bearing and the journal. The grooves provide a channel so oil can completely encircle the bearing before flowing over and out of it. See **Figure 14-27**.

Main Thrust Bearings, Thrust Washers

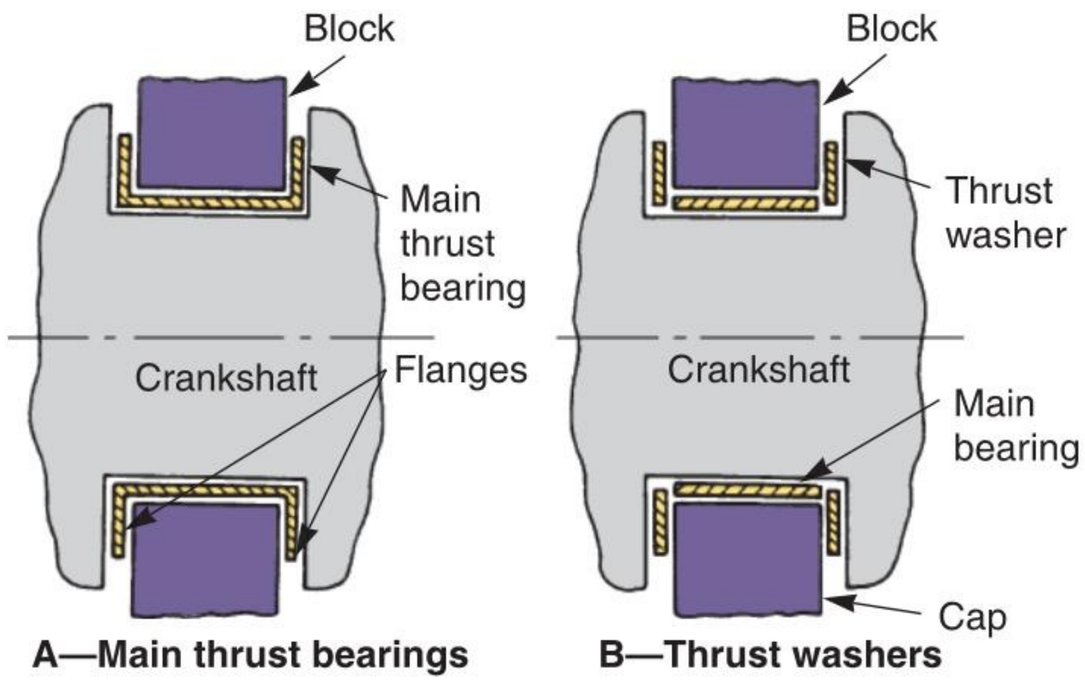
A ***main thrust bearing*** limits crankshaft end play. ***Crankshaft end play*** is the forward and rearward movement of the crankshaft. Thrust flanges are formed on the main bearing sides. These flanges almost touch the thrust surfaces machined on the crankshaft. Shown in **Figure 14-28A**, this keeps the crankshaft from sliding back and forth in the block.

Thrust washers are sometimes used instead of thrust bearings to limit crank end play. The thrust washers are separate parts from the main bearing. They slide down into the space between the crankshaft and block, as pictured in **Figure 14-28B**.



Chrysler

Figure 14-27. Main bearings have holes that let oil enter the bearing clearance. Grooves allow oil to circle the bearing to evenly distribute lubricating oil.



Deere & Co.

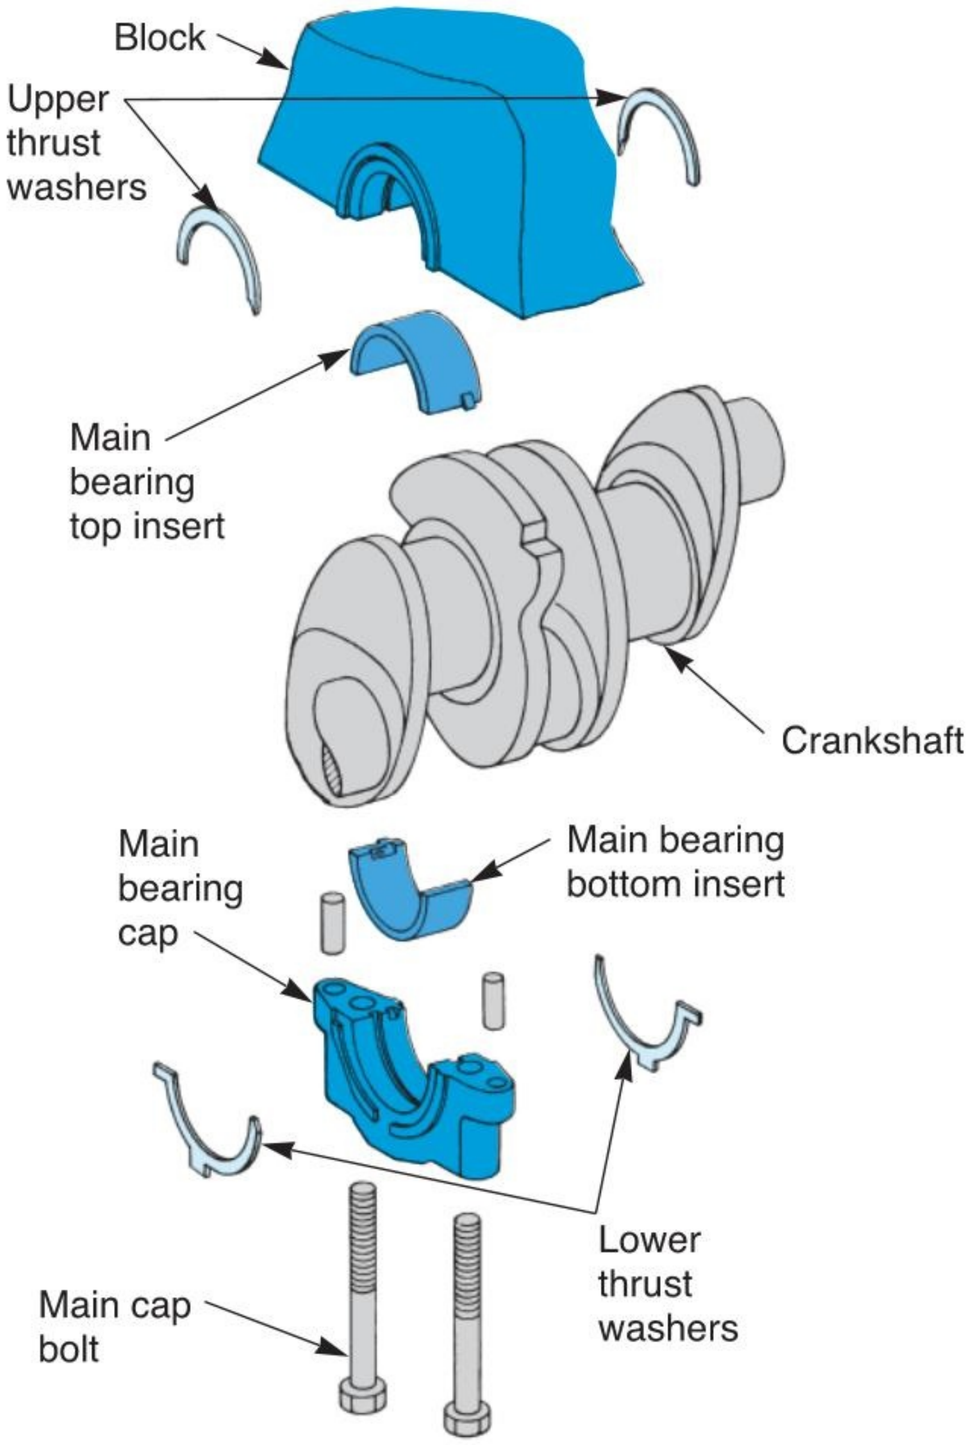
Figure 14-28. Thrust bearings or washers limit crankshaft end play.

Figure 14-29 shows how a main bearing, thrust washers, main cap, and related components assemble to the block.

Rear Main Bearing Oil Seal Construction

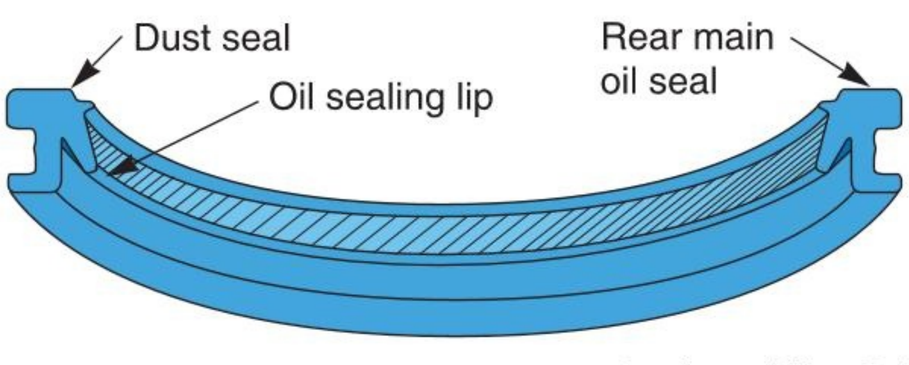
The engine ***rear main bearing oil seal*** prevents oil leakage around the back of the crankshaft. There are several different types of rear oil seals. These include a two-piece neoprene seal, a one-piece neoprene seal, and a wick or rope seal. Refer to **Figure 14-30**.

Copyright Goodheart-Willcox Co., Inc.



Chrysler

Figure 14-29. Note how the main bearing, thrust washers, crankshaft, and cap fit together.

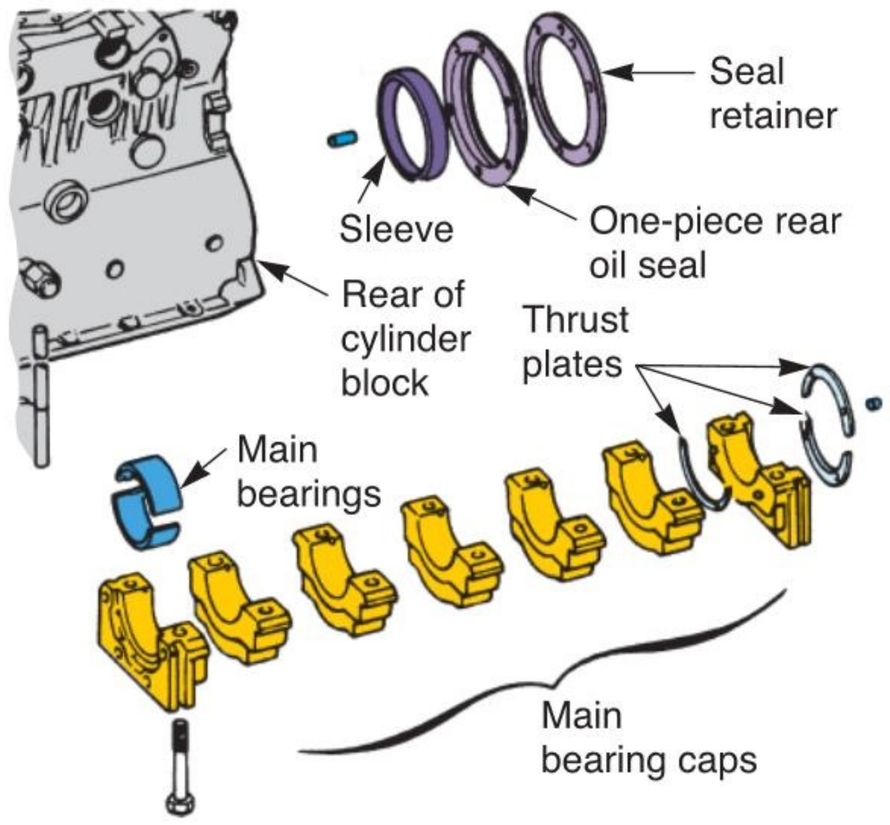


Goodheart-Willcox Publisher

Figure 14-30. A rear main oil seal has a sealing lip that must face the inside of the engine. The dust seal faces the outside of the engine.

A two-piece neoprene rear oil seal usually fits into a groove cut into the block and rear main cap. The seal has a lip that traps oil and another lip that keeps dust and dirt out of the engine. The sealing lips ride on a machined surface of the crankshaft. Spiral grooves may be used on the crank surface to help throw oil inward, preventing leakage.

A one-piece neoprene rear oil seal fits around the rear flange on the crankshaft. **Figure 14-31** shows how a retainer may be used to hold the seal on the rear of the engine. The one piece rear seal has sealing lips that are similar to those on a two-piece neoprene seal.



Chrysler

Figure 14-31. Some rear oil seals are one piece. They assemble into the rear of the block around the crankshaft flange.

A rope, or wick, rear oil seal is simply a woven rope filled with graphite. One piece of the rope seal fits into a groove in the block. Another piece fits in a groove in the main cap. This type seal was used on antique cars and trucks.

Select-Fit Parts

Select-fit means that some engine parts are selected and installed in a certain position to improve the fit or clearance between parts. For example, pistons are commonly selected to fit precisely into their cylinders. To do so, the engine manufacturer measures the diameter of the cylinders. If one cylinder is machined slightly larger than another, a slightly larger piston is installed. Because of select-fit parts, it is important that you reinstall parts in their original locations whenever possible.

Balancer Shafts

Balancer shafts are used in some engines to cancel the vibrating forces produced by crankshaft, piston, and rod movement. They are usually found on 4- and 6-cylinder engines. **Figure 14-32** shows the balancer shafts used in one particular engine.

The balancer shafts, also called silencer shafts, are installed in the right and left sides of the cylinder block on V-type engines. Usually, a chain is used to spin the shafts at twice crankshaft rpm. The shafts are supported on bearings fitted in a bore machined in the block. Oil is pressure-fed to these bearings to provide lubrication.

Workplace Skills

Reliability consists of being at work every day, arriving to work on time, and doing the job right. Reliability is your most important personality trait to an employer. Without it, you will have a difficult time keeping a good job and earning a good living as an auto repair technician.

Summary

- The basic parts of an engine bottom end are the block, crankshaft, connecting rods, and piston assemblies.
- Cylinder sleeves, or liners, are metal, pipe-shaped inserts that fit into the cylinder block.
- Line boring refers to a machining operation that cuts a series of holes through the block for the crankshaft bearings.
- A two-bolt main block only uses two bolts to secure each main bearing cap to the cylinder block. A four-bolt main block has four bolts holding each main cap.
- A main bearing bedplate is a large part that fits over the whole bottom of the block.
- A cam-ground piston is slightly out-of-round when viewed from the top.
- Piston taper is normally used to maintain the correct piston-to-cylinder clearance.
- A slipper skirt is produced when the portions of the piston skirt below the piston pin ends are removed.
- Piston ring width is the distance from the top of the ring to the bottom of the ring.
- Piston ring gap is the distance between the ends of the ring when it is installed in the cylinder.
- Case-hardening is a heating and cooling process that increases the wear resistance of the piston pin.
- A full-floating piston pin is secured by snap rings and is free to rotate in both the rod and piston.
- A press-fit piston pin is forced tightly into the connecting rod's small end.
- Piston pin offset locates the piston pin hole slightly to one side of the piston centerline to quiet piston operation.
- Connecting rod numbers are used to ensure proper location of each connecting rod in the engine.
- A broken surface rod is scribed and broken off when manufactured to produce a rough, irregular mating surface between the rod body and cap.
- A standard bearing has the original dimensions specified by the engine manufacturer and is used for a new, unworn, or unmachined crankshaft.

Copyright Goodheart-Willcox Co., Inc.

- An undersize bearing is designed to be used on a crankshaft journal that has been machined to a smaller diameter.
- A main thrust bearing limits crankshaft end play.
- Select fit means that some engine parts are selected and installed in a certain position to improve the fit between parts.
- Balancer shafts are used in some engines to cancel the vibrating forces produced by crankshaft, piston, and rod movement.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

aluminum cylinder block
balancer shaft
bearing crush
bearing locating lug
bearing oil hole
bearing spread
block girdle
broken-surface rod
cam-ground piston
cast iron cylinder block
compression distance
compression ring
connecting rod number
crankpin
crankshaft end play
crossbolted block
cylinder sleeve
dowel
drilled connecting rod
dry sleeve
engine bottom end
four-bolt main block
full-floating piston pin
fully counterweighted crankshaft
grooves
hard ring coating
line boring
main thrust bearing
oil spurt hole
partially counterweighted crankshaft
pin hole diameter
piston boss
piston diameter
piston head
piston head shape
piston pin hole
piston pin offset
piston ring gap
piston ring groove
piston ring radial wall thickness
piston ring width
piston skirt
piston taper
press-fit piston pin
rear main bearing oil seal
ring back clearance
ring expander
ring expander-spacer
ring groove depth
ring groove width
ring land
ring seating
ring side clearance
select-fit
skirt length
sleeve-type bearings
soft ring coating
split-type bearings
standard bearing
thrust washer
two-bolt main block
undersize bearing
wet sleeve

Activities

1. Use inside and outside micrometers to measure the diameter of a piston and the engine cylinder bore. Then, find the amount of piston clearance by subtracting the piston diameter from the bore measurement.
2. If a number of pistons are available, determine whether any are cam ground. Do this by measuring the diameter parallel to the piston pin, and then measuring the diameter perpendicular (at a 90° angle) to the piston pin. If the piston is cam ground, the measurement perpendicular to the pin will be larger by a few thousandths of an inch.
3. Disassemble a rod cap from its connecting rod, turn it end-for-end so the numbers no longer align, and fit it into place. Can you visually detect an "out-of-round" rod bore? If not, try to think of a way to determine whether the bore is perfectly round. When finished with this activity, reassemble the rod and cap properly.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Cylinder blocks can be made of _____ or _____.
2. Explain the difference between wet sleeves and dry sleeves.
3. Aluminum blocks commonly use _____, _____ sleeves.
4. List and define six piston dimensions.
5. A(n) _____ piston is machined slightly out-of-round to compensate for different rates of piston _____.
6. When the top of the piston outside diameter is machined slightly smaller than the bottom, it is called a _____.
   (A) pop-up piston
   (B) dished piston
   (C) cam-ground piston
   (D) piston taper
7. _____ are small indentations either cast or machined in the piston top.
8. What is a *ring expander-spacer*?

Copyright Goodheart-Willcox Co., Inc.

9. The difference between the ring width and the width of the piston ring groove determines _____.
10. The difference between the ring wall thickness and ring groove depth determines _____.
11. Define *ring gap*.
12. When should you use piston rings with soft coatings?
13. Explain why some parts are case hardened.
14. Which of the following does *not* relate to modern piston assemblies?
    (A) Full-floating pin.
    (B) Press-fit pin.
    (C) Bolted piston pin.
    (D) Offset piston pin.
15. Describe *piston slap* and *piston pin offset*.
16. A(n) _____ on the head of a piston is used to indicate piston pin offset.
17. Name two reasons connecting rod numbers are used.
18. Engine crankshafts are usually made of _____ or _____.
19. How does lubricating oil get to the connecting rod bearings?
20. Which of the following does not pertain to engine bearings?
    (A) Load strength.
    (B) Lubrication absorption.
    (C) Conformability.
    (D) Embedability.
21. Explain *bearing crush*.
22. Explain *bearing spread*.
23. A(n) _____ bearing has the original dimensions specified by the manufacturer for a new, unworn, or unmachined crankshaft.
24. A(n) _____ bearing is designed to be used on a crankshaft journal that has been machined to a smaller diameter.
25. Describe three rear main oil seal variations.

ASE-Type Questions

1. Which of the following is *not* a basic part of an engine bottom end?
   (A) Block.
   (B) Valve train.
   (C) Crankshaft.
   (D) Connecting rods.
2. A piston head can reach operating temperatures as high as:
   (A) 450°F.
   (B) 500°F.
   (C) 650°F.
   (D) 700°F.
3. Which of the following provides clearance between the piston and crankshaft counterweights?
   (A) Slipper skirt.
   (B) Piston taper.
   (C) Valve reliefs.
   (D) Compression rings.
4. The distance from the piston pin hole centerline to the piston top is called:
   (A) skirt length.
   (B) piston diameter.
   (C) pin hole diameter.
   (D) compression distance.
5. The piston type commonly used with a wedge-type cylinder head is:
   (A) concave.
   (B) pop-up.
   (C) flat-top.
   (D) All of the above.
6. The most common oil rings consist of:
   (A) two rails and a spacer.
   (B) ten slots and a spacer.
   (C) three rails and an expander.
   (D) seven slots and an expander.
7. The difference between piston ring width and ring groove width determines:
   (A) ring gap.
   (B) ring side clearance.
   (C) ring wall thickness.
   (D) ring back clearance.
8. The purpose of a drilled connecting rod is to:
   (A) rotate the piston pin.
   (B) create piston pin offset.
   (C) prevent pressure leakage.
   (D) supply oil to the piston pin.
9. How many connecting rods bolt to each crankshaft journal in a V-type engine?
   (A) One.
   (B) Two.
   (C) Three.
   (D) Four.
10. Basic types of engine bearings include each of these *except:*
    (A) piston bearings.
    (B) camshaft bearings.
    (C) crankshaft bearings.
    (D) connecting rod bearings.

Chapter 15
Engine Front End Construction

After studying this chapter, you will be able to:

- Explain the function and construction of a vibration damper.
- Compare the three types of camshaft drives.
- Explain the construction of a timing gear, timing chain, and timing belt assembly.
- Summarize the construction of engine front covers, oil slingers, and other related components.
- Describe safety practices related to working on engine front end components.
- Correctly answer ASE certification test questions on engine front end construction.

The typical engine front end assembly consists of the parts that attach to the front of the engine. These parts include the camshaft drive mechanism, front cover-mounted oil pump, water pump, auxiliary shafts, supercharger, etc.

Tech Tip

As automotive engineers design more compact, lighter, and more powerful engines, many of the auxiliary units that were traditionally mounted on the front of the engine and driven off the front of the camshaft are now mounted elsewhere on the engine and are driven off the rear or even the center of the crankshaft.

This chapter explains the construction and operation of engine front end assemblies. Study it carefully. It will help you understand later chapters on service and repair. Refer to **Figure 15-1**.

Tech Tip

Oil pumps, water pumps, and other front end–related parts are detailed in other textbook chapters. Refer to the index for more information on these components.

Vibration Damper Construction

Harmonic vibration is a high-frequency movement resulting from twisting and untwisting of the crankshaft. Each piston and rod assembly can exert

Figure 15-2. The vibration damper, or harmonic balancer, installs on the front of the crankshaft. A key locks the damper to the crank snout. A large bolt is commonly used to hold the damper in place. Study the construction of a vibration damper. A rubber ring separates the inertia ring and inner sleeve. This acts to deaden, or cancel, crankshaft harmonic vibration.

over a ton of downward force on its journal. This can actually flex, or bend, the crankshaft. If harmonic vibration is not controlled, the crankshaft could vibrate like a musician's tuning fork or a string-type musical instrument. Serious engine damage, usually a broken crankshaft, can result.

A ***vibration damper***, or ***harmonic balancer***, is used to control harmonic vibration. The vibration damper also cuts load variation (changes in torque applied to crank) on the engine timing belt, chain, or high-pressure fuel pump, so these parts last longer.

The vibration damper is a heavy wheel mounted on a rubber ring to control harmonic vibration. The balancer is keyed to the crankshaft snout. This makes the damper spin with the crankshaft.

The rubber ring separates the outer ***inertia ring*** and the inner sleeve. A typical vibration damper is shown in **Figure 15-2**. The inertia ring and the rubber ring set up a damping action on the crankshaft as it tries to twist and untwist. This deadens vibrating action.

A ***dual-mass harmonic balancer*** has one weight mounted on the outside of the crankshaft pulley and another on the inside. The extra rubber-mounted weight helps reduce vibration at high engine speeds.

Crankshaft Pulley

The ***crankshaft pulley*** operates belts for the alternator, water pump, air conditioning compressor, and other units. It is often part of the vibration damper. It may also simply be bolted to the front of the balancer. The pulley has either V or ribbed grooves for the belts. Refer to **Figure 15-2**.

Camshaft Drives

The ***camshaft drive*** transfers the rotational motion of the crankshaft to the camshaft(s). The camshaft drive must rotate the camshaft(s) at one-half of engine speed. It must do this smoothly and dependably. There are three basic types of camshaft drives: timing gears, a timing chain and sprockets, or a timing belt and sprockets.

Copyright Goodheart-Willcox Co., Inc.

Timing Gears

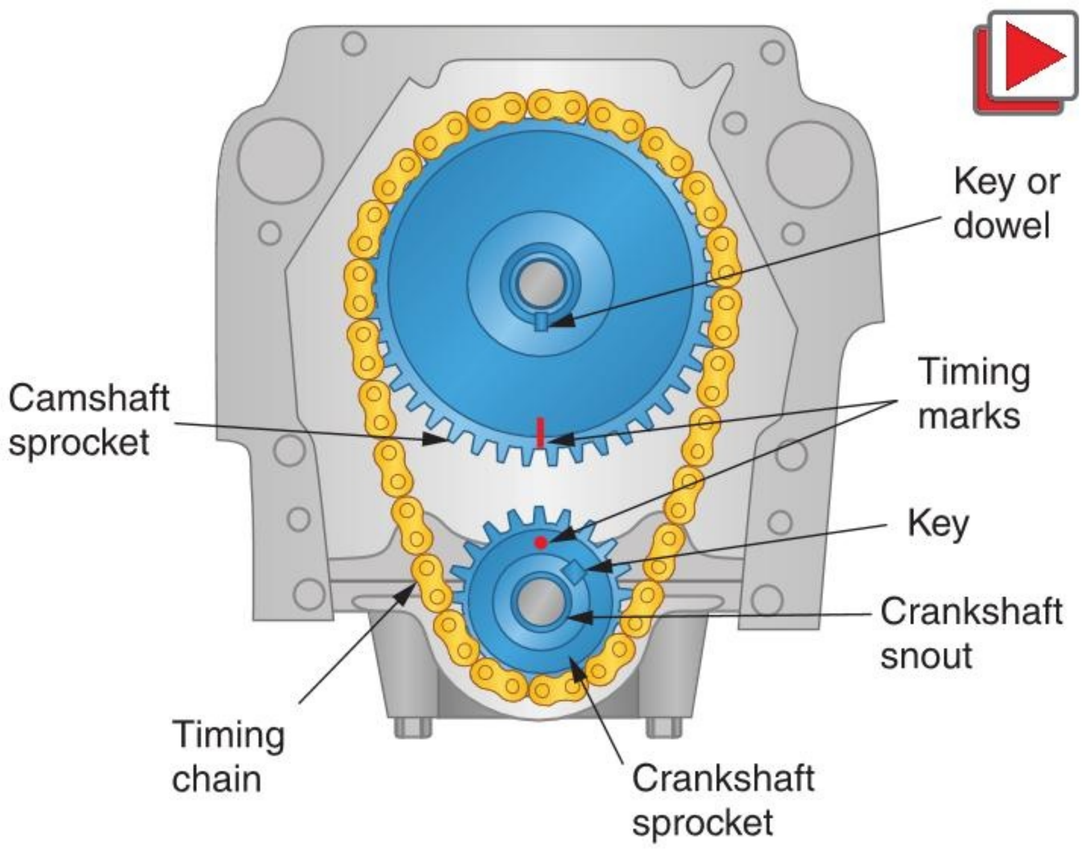
Timing gears are common in engines used for heavy-duty applications, such as taxicabs or trucks. They are very dependable and long lasting. However, they are noisier than a chain or belt drive. Gears are primarily used in cam-in-block engines where the crankshaft is close to the camshaft.

Two ***timing gears*** are used to drive the engine camshaft. A crankshaft gear is keyed to the crankshaft snout. It turns a camshaft gear on the end of the camshaft. The cam gear is twice the size of the crank gear. This results in the desired 2:1 reduction. See **Figure 15-3**.

Timing marks on the two gears show the technician how to install the gears properly. The marks may be circles, indentations, or lines on the gears. The timing marks must line up for the camshaft to be in time with the crankshaft.

Timing Chain and Sprockets

A ***timing chain*** and ***sprockets*** can also be used to turn the camshaft. See **Figure 15-4**. This is the most common type of camshaft drive arrangement on cam-in-block engines. It may also be used in OHC engines.



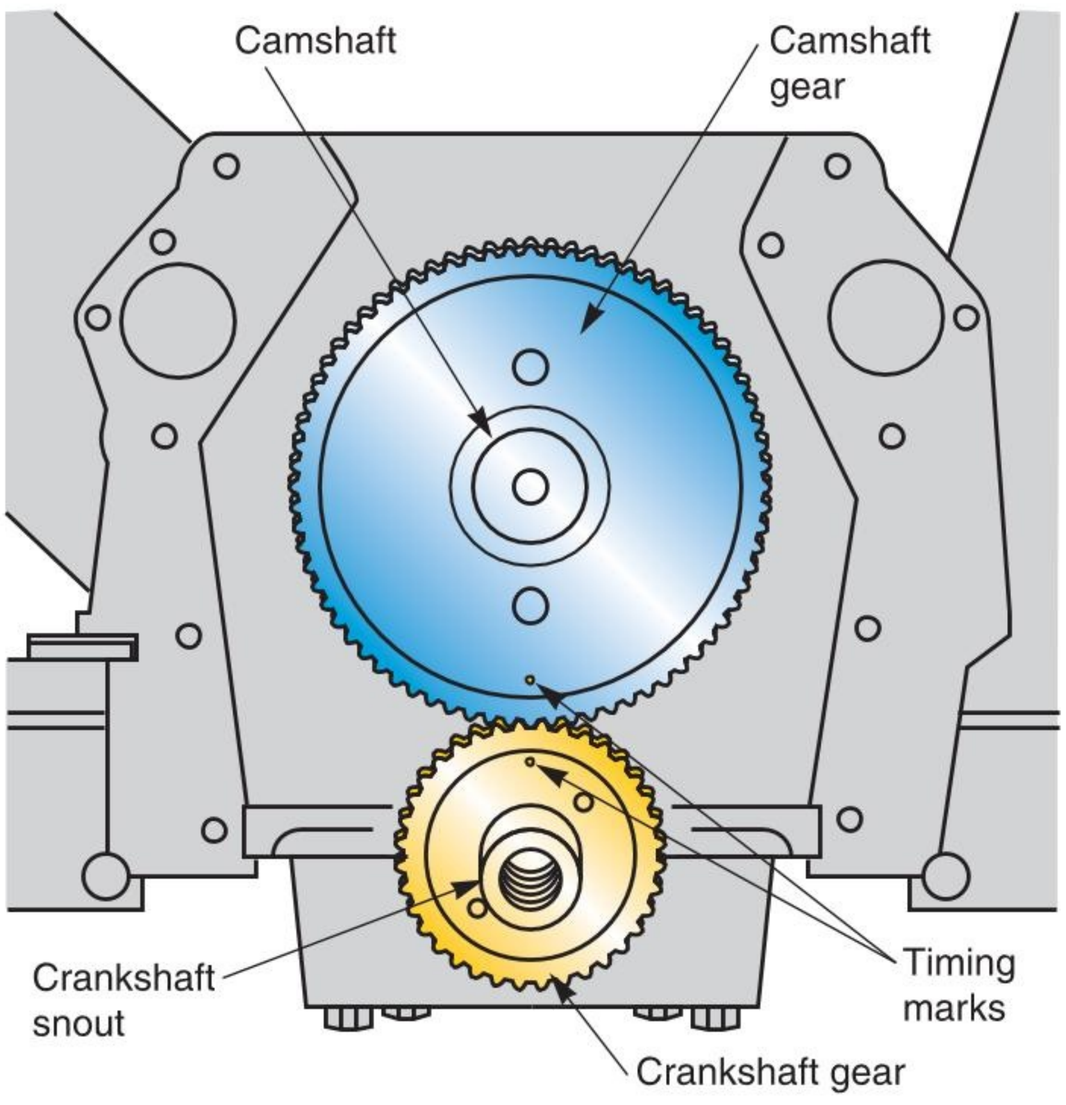
Goodheart-Willcox Publisher

Figure 15-4. A timing chain setup is very common. Study the part names.

A ***crankshaft sprocket*** is keyed to the crankshaft snout. A larger camshaft sprocket, with either metal or plastic teeth, bolts to the camshaft. The timing chain transfers power from the crankshaft sprocket to the camshaft sprocket. Like timing gears, the chain sprockets have timing marks. The marks must line up to properly time the camshaft with the crankshaft.

A ***chain guide*** may be needed to prevent chain slap. ***Chain slap*** occurs when the chain flaps back and forth because of excessive slack in the chain. **Figure 15-5** shows a timing chain using chain guides. The guides have a metal body with either a plastic or Teflon® face. This allows the chain to slide on the guide with minimum friction and wear.

A ***chain tensioner*** may be used to take up the slack in the chain as it and the sprockets wear. It is usually a spring-loaded plastic or fiber block. The spring pushes the block outward, keeping a constant tension on the chain. A chain-type camshaft drive for an OHC engine commonly uses guides and sometimes a tensioner. Refer to **Figure 15-6** for a front view of this setup.



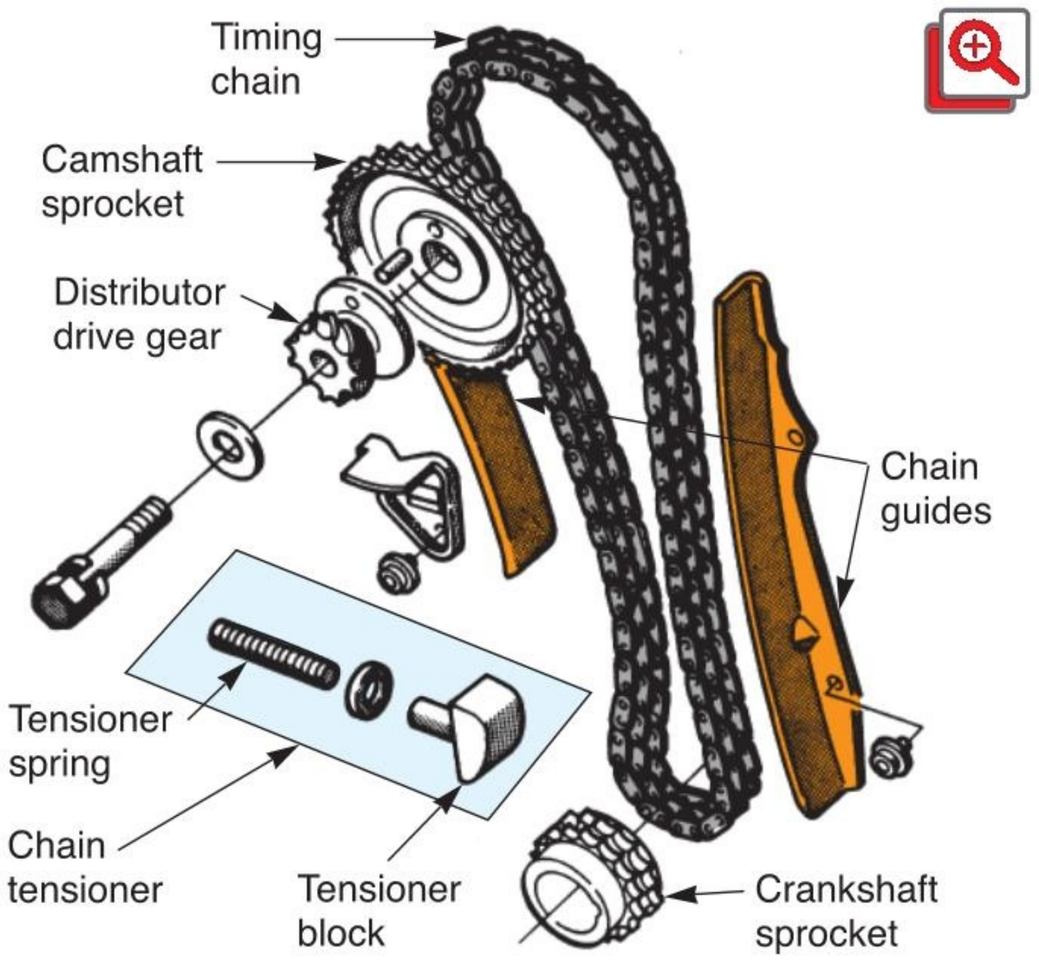
Goodheart-Willcox Publisher

Figure 15-3. A timing gear setup is very dependable. The crankshaft gear turns the camshaft gear at one-half of the crankshaft speed. Timing marks allow for the proper assembly of the gears.

Auxiliary Chain

An ***auxiliary chain*** may be used to drive the engine oil pump, balancer shafts, and other units on the engine. **Figures 15-6** and **15-7** show two examples. An auxiliary chain is driven by an extra

Copyright Goodheart-Willcox Co., Inc.



Chrysler

Figure 15-5. An OHC timing chain assembly normally uses chain guides and sometimes a tensioner.

sprocket, usually placed in front of the crankshaft timing chain sprocket. Do *not* confuse an auxiliary chain with a timing chain.

Engine Front Cover Construction

An ***engine front cover***, also called a ***timing cover***, encloses the timing chain or gear mechanism and prevents oil leakage from the front of the engine. The front cover bolts to the front of the engine block. The cover may hold the front oil seal, timing pointer, crankshaft position sensor, water pump, and other parts.

A ***front oil seal*** prevents oil leakage between the crankshaft and the front cover. The seal is press-fit in the cover. See **Figure 15-8**.

An engine front cover is commonly made of thin, stamped steel or cast aluminum. Sometimes the water pump bolts onto the front cover. Some water pump housings are cast into the front of the engine block. The core of the pump bolts onto the block housing. The oil pump may also be housed in the front cover.

Mazda

Figure 15-8. Note the location of the front cover on this late-model engine. In addition to enclosing the timing chain mechanism, the front cover contains the front oil seal, which prevents oil from leaking between the crankshaft and the cover itself.

Oil Slinger

An ***oil slinger*** is a washer-shaped part that fits in front of the crankshaft sprocket. When the engine is running, oil squirts out of the front main bearing and strikes the spinning slinger. Centrifugal force then throws the oil outward and onto the timing chain or gears. The oil slinger not only helps lubricate the timing mechanism, but it blocks the oil from striking the front seal, preventing leakage.

Timing Belt and Sprockets

A ***timing belt drive mechanism*** basically consists of a crankshaft sprocket, camshaft sprocket, timing belt, and belt tensioner. It is used to drive the camshaft on OHC engines.

A ***timing belt*** provides a very smooth and accurate method of turning the camshaft. The timing belt and the sprockets have cogged, or square, teeth that prevent belt slippage. Some timing belts are made of fiberglass-reinforced nitrile rubber for increased strength and durability. Some are designed for a service life of over 100,000 miles (160,000 km) if not damaged by road debris or oil. Look at **Figure 15-9**.

The ***timing belt sprockets*** are usually made of cast iron or aluminum. The crank sprocket is keyed to the crankshaft snout. The camshaft sprocket normally bolts to the front of the camshaft. A dowel pin may be used to position the camshaft sprocket correctly. Belt sprockets have timing marks, just like timing gears and chain sprockets. The timing marks must be aligned with specific points on the engine. This will properly time the opening of the engine valves.

A ***belt tensioner*** is a spring-loaded wheel that keeps the timing belt firmly seated on its sprockets. The tensioner pushes inward on the back of the belt. This prevents the belt teeth from slipping on the sprocket teeth. The tensioner wheel is mounted on an antifriction bearing. This bearing is filled with grease and permanently sealed at the factory.

Some belt tensioners use both spring tension and hydraulic pressure to maintain belt tightness on its sprockets. The spring tension keeps the belt tight

Honda

Figure 15-9. Study the parts that install on the front of this OHC engine. Cogged sprockets are used with the camshaft timing belt. A V-belt operates in the crankshaft pulley. A belt cover surrounds the timing belt and sprockets.

when the engine is shut off. The hydraulic pressure adjusts the belt tension with engine speed. At higher rpms, belt tension is increased to keep the belt from slipping or flying off.

The timing belt may also be used to drive the oil pump, diesel injection pump, or water pump.

Timing Belt Cover

A timing belt cover simply protects the belt from damage and the technician from injury. It is made from sheet metal or plastic. A gasket may seal the mating surfaces between the timing belt cover and the block. Timing belt covers are tightly sealed at the bottom to keep road debris and water off the rubber belt. If ice forms on the belt sprocket, it can cause the belt to jump off its sprockets, upsetting valve timing. This can lead to severe engine damage.

Tech Tip

A timing belt cover should not be confused with an engine front cover. A timing belt cover does not contain oil or an oil seal.

Diagnostic Case Study

Concern: Mr. Washington brought his 2009 Lexus GS350 into the shop, complaining of a knocking sound that seemed to be coming from the engine.

Cause: After asking Mr. Washington to describe the problem, Duff, the shop owner, asks specific questions about the knocking noise. He asks if the problem is the same at all engine temperatures. Mr. Washington says the knock is the same with engine cold or hot but adds that the engine seems to knock more at idle than at other speeds.

Duff starts the overhead-cam engine and notices a light rattle that seems to be coming from around the front of the engine. He passes this information along to one of the shop's ASE-certified engine repair technicians.

The technician uses a stethoscope to help pinpoint the source of the noise. He touches the tip of the stethoscope to various points on the engine to find the area emitting the loudest noise. The knock seems loudest on the sides of the timing chain cover. The technician suspects that the timing chain is hitting on the inside of the aluminum cover. He disassembles the front of engine for further inspection and discovers that the timing chain guides and the chain itself are badly worn. Marks inside the front cover serve to confirm the technician's suspicions: the worn timing chain is indeed striking the front cover.

Correction: The technician installs a new timing chain and chain guides. He also changes the oil and filter, since the oil looked very dark and dirty. When Mr. Washington returns to the shop to pick up the vehicle, the technician explains the cause of the problem and reminds him to change the oil at the recommended intervals to prevent excess engine wear.

Copyright Goodheart-Willcox Co., Inc.

Summary

- The typical engine front end assembly consists of the parts that attach to the front of the engine.
- Harmonic vibration is a high-frequency movement resulting from twisting and untwisting of the crankshaft.
- A vibration damper, also called a harmonic balancer, is a heavy wheel mounted in rubber to control harmonic vibration.
- The crankshaft pulley operates belts for the alternator, water pump, and other units.
- Timing gears are two gears that operate the engine camshaft.
- A timing chain and sprockets can be used to turn the camshaft.
- A chain guide may be needed to prevent chain slap.
- A chain tensioner may be used to take up slack as the chain and sprockets wear.
- A front oil seal prevents oil leakage between the crankshaft and front cover.
- A timing belt mechanism basically consists of a crankshaft sprocket, camshaft sprocket, timing belt, and belt tensioner.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

auxiliary chain
belt tensioner
camshaft drive
chain guide
chain slap
chain tensioner
crankshaft pulley
crankshaft sprocket
dual-mass harmonic balancer
engine front cover
front oil seal
harmonic balancer
harmonic vibration
inertia ring
oil slinger
sprockets
timing belt
timing belt drive mechanism
timing belt sprockets
timing chain
timing cover
timing gears
timing marks
vibration damper

Activities

1. On an engine with the timing cover removed, locate the timing marks on the crankshaft and camshaft pulleys, gears, or sprockets. If the engine can be rotated by hand, determine whether the timing marks align properly.
2. Sketch a front-end view of an engine with a timing chain or timing belt. Show the belt or chain path and label the sprockets that the chain or belt engages.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Define the term *crankshaft harmonic vibration*.
2. A(n) _____ is a heavy wheel mounted on a rubber ring to control harmonic vibration.
3. The _____ operates belts for the alternator, water pump, and other units.
4. A camshaft drive must turn the camshaft at _____ crankshaft speed.
5. Which of the following does *not* refer to timing gears?
   (A) Used on heavy-duty applications.
   (B) Dependable and long lasting.
   (C) Very quiet.
   (D) All of the above.
6. The most common camshaft drive setup for cam-in-block engines consists of a(n) _____ and a set of _____.
7. Why is a chain guide used?
8. Explain the function of a chain tensioner.
9. What does an auxiliary chain commonly drive?
10. Is an engine front cover the same as a timing belt cover?

Copyright Goodheart-Willcox Co., Inc.

ASE-Type Questions

1. High-frequency movement resulting from the twisting and untwisting of the crankshaft is called:
   (A) engine knock.
   (B) after-running.
   (C) oscillating vibration.
   (D) harmonic vibration.
2. Which of the following is used to control the high-frequency movement that results from crankshaft twisting?
   (A) Vibration damper.
   (B) Crankshaft pulley.
   (C) Harmonic balancer.
   (D) Both A and C.
3. Which of the following normally operates belts for the alternator, water pump, and other units?
   (A) Auxiliary chain.
   (B) Timing sprockets.
   (C) Vibration damper.
   (D) Crankshaft pulley.
4. All of the following are basic types of camshaft drives *except:*
   (A) rod drive.
   (B) belt drive.
   (C) gear drive.
   (D) chain drive.
5. A camshaft drive must turn the camshaft at:
   (A) twice crankshaft speed.
   (B) crankshaft speed.
   (C) one-half crankshaft speed.
   (D) None of the above.
6. The two gears that operate the camshaft are the:
   (A) helical and spur gears.
   (B) crankshaft and camshaft gears.
   (C) countershaft and crankshaft gears.
   (D) camshaft sprocket and pulley gears.
7. Which of the following transfers power from the crankshaft sprocket to the camshaft sprocket?
   (A) Spur gear.
   (B) Timing idler.
   (C) Timing chain.
   (D) Timing gears.
8. Which of the following devices is used to prevent chain slap?
   (A) Chain guide.
   (B) Auxiliary chain.
   (C) Timing sprocket.
   (D) Chain link.
9. A timing belt mechanism contains each of the following *except:*
   (A) timing belt.
   (B) belt damper.
   (C) cam sprocket.
   (D) belt tensioner.
10. The washer-shaped part that fits directly in front of the crankshaft sprocket is the:
    (A) pulley.
    (B) damper.
    (C) retainer.
    (D) oil slinger.

Chapter 16
Engine Size and Performance Measurements

After studying this chapter, you will be able to:

- Describe engine size measurements based on bore, stroke, displacement, and number of cylinders.
- Explain engine compression ratio and how it affects engine performance.
- Explain engine torque and horsepower ratings.
- Describe the different methods used to measure and rate engine performance.
- Explain volumetric efficiency, thermal efficiency, and mechanical efficiency.
- Follow safe practices when making engine performance measurements.
- Correctly answer ASE certification test questions on engine size and performance measurements.

Engine size and performance measurements are important to the technician. Shop manuals list many engine size and performance values for specific engines. You must be able to understand this information to properly communicate with others working in the auto repair industry.

Engine Size Measurement

Engine size is determined by the number of cylinders, the cylinder diameter, and the amount of piston travel per stroke. Any of these variables can be changed to alter engine size. Engine size information is used when ordering parts and when measuring wear during major engine repairs.

Bore and Stroke

Cylinder bore is the diameter of the engine cylinder. See **Figure 16-1**. It is measured across the cylinder, parallel with the top of the block. Cylinder bores vary in size, but they typically range from 3–4″ (75–100 mm).

Piston stroke is the distance the piston moves from top dead center (TDC) to bottom dead center (BDC), **Figure 16-1**. The amount of throw (offset) built into the crankshaft rod journal controls the piston stroke. The stroke also varies from about 3–4″ (75–100 mm) in automotive engines.

A shop manual normally gives bore and stroke specifications. For instance, suppose a specification for bore and stroke is given as 4.00″ × 3.00″. This means that the engine cylinder is 4″ in diameter and the piston stroke is 3″. Bore is always the first value given and stroke is the second.

Generally, a larger bore and a longer stroke make an engine more powerful. It can pull in more fuel and

Copyright Goodheart-Willcox Co., Inc.

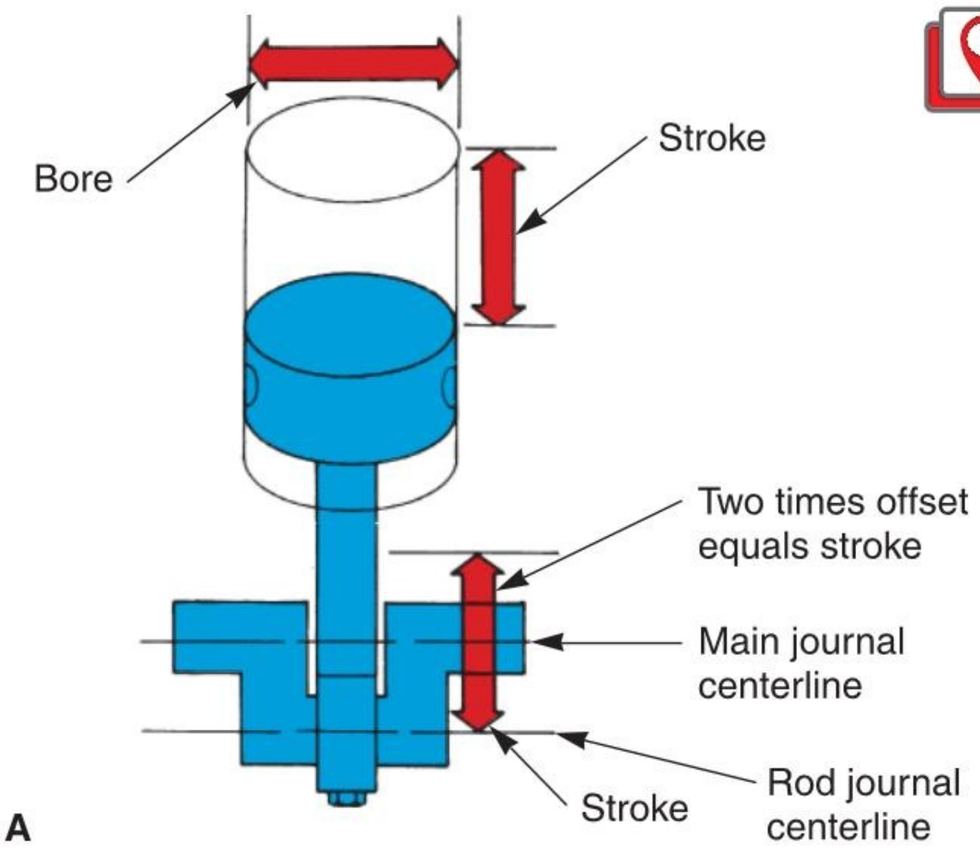

Figure 16-1. Bore and stroke measurements. A—Cylinder bore is measured across the cylinder, parallel with the deck of the engine block. Piston stroke is the distance the piston moves from BDC to TDC. Piston displacement is the amount of volume the piston moves in one upward stroke. B—Engine displacement is the volume displaced by all the pistons combined.

air (port injection) or air (direct injection) on each intake stroke. As a result, more combustion pressure is exerted on the head of the piston during the power stroke. To improve fuel economy and reduce emissions, the trend is toward smaller, more efficient engines.

Piston Displacement

Piston displacement is the volume the piston displaces (moves) as it travels from BDC to TDC. It is found by comparing cylinder diameter and piston stroke. A large cylinder diameter and large piston stroke produce a large piston displacement.

Piston displacement is calculated using a simple formula:

$$\text{piston displacement} = \frac{\text{bore squared} \times 3.14 \times \text{stroke}}{4}$$

Example: If an engine has a bore of 4″ and a stroke of 3″, what is its piston displacement?

Solution: piston displacement $= \frac{(4'')^2 \times 3.14 \times 3''}{4}$

$= 37.68$ cu. in.

Engine Displacement

Engine displacement, or ***engine size***, is the volume displaced by all the pistons in an engine (piston displacement multiplied by the number of engine cylinders). For example, if one piston displaces 25 cu. in. and the engine has four cylinders, the engine displacement would be 100 cu. in. ($25 \times 4 = 100$).

Cubic inch displacement (CID), ***cubic centimeters (cc)***, and ***liters (L)*** are units of engine displacement. For example, a V-8 engine might have a 350 CID. A V-6 could be a 3.3 L engine. A four-cylinder engine might have a displacement of 2300 cc. Since one liter equals 1000 cc, a 2 liter engine would have 2000 cc.

Engine displacement is usually matched to the weight of the vehicle. A heavy car, truck, or van needs a large engine, which produces a great deal of power. A light vehicle only needs a small, low-power engine for adequate acceleration.

Force, Work, and Power

Force is a pushing or pulling action. When a spring is compressed, an outward movement and force is produced. Force is measured in pounds or newtons.

Work is done when force causes movement. If a compressed spring moves another engine part, work has been done. If the spring does not cause movement, no work has been done. Work is measured in foot-pounds or joules. The formula for work is:

work = distance moved × force applied

Example: If you use a hoist to lift a 400 lb engine 3′ in the air, how much work has been done?

Solution: work = 3′ × 400 lb

= 1200 foot pounds (ft lb)

Copyright Goodheart-Willcox Co., Inc.

Power is the rate, or speed, at which work is done. It is measured in foot-pounds per second or per minute. The metric unit for power is the watt (kilowatt).

The formula for power is:

$$\text{power} = \frac{\text{distance (feet)} \times \text{force (pounds)}}{\text{time (minutes)}}$$

Example: If a hydraulic lift raises a 3000 lb car 8' in 30 seconds, how much power is needed?

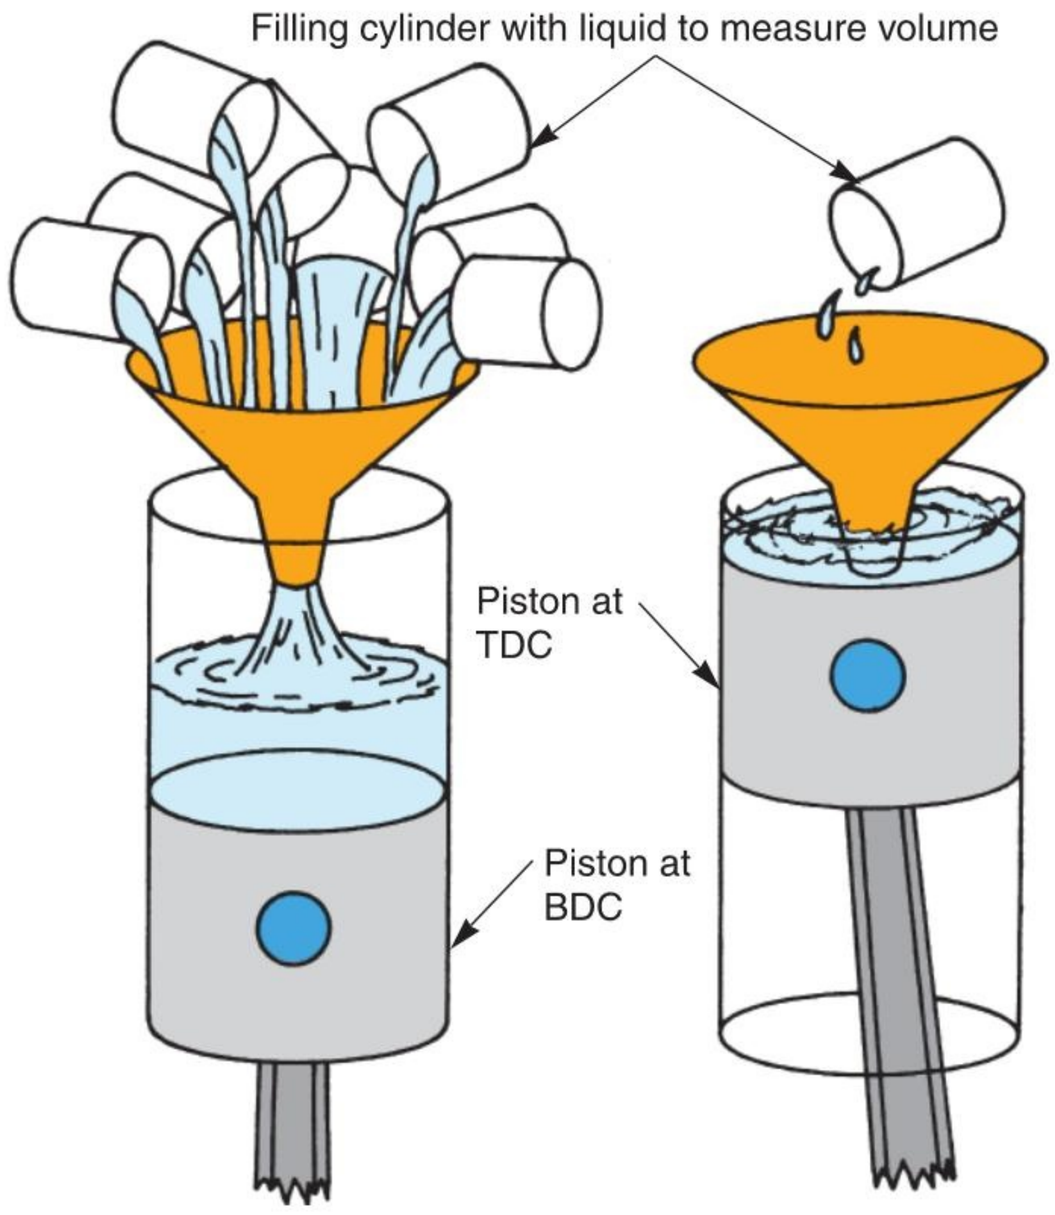
Solution:

$$\text{power} = \frac{8 \times 3000 \text{ lb}}{0.5 \text{ min.}}$$

$$= \frac{48{,}000 \text{ ft lb}}{\text{min.}}$$

Compression Ratio

Engine ***compression ratio*** compares the cylinder volume with the piston at TDC to the cylinder volume with the piston at BDC. An engine's compression ratio partially determines how much the air-fuel mixture is pressurized, or squeezed, on the compression stroke. A compression ratio is given as two numbers. For example, an engine may have a compression ratio of 9:1 (9 to 1). This means the maximum cylinder volume is nine times larger than the minimum cylinder volume. At BDC, a cylinder has maximum volume. Minimum cylinder volume occurs at TDC. Look at **Figure 16-2**.



Goodheart-Willcox Publisher

Figure 16-2. Compression ratio is a comparison of cylinder volumes with the piston at TDC and BDC. This engine has eight times the volume at BDC, producing an 8:1 compression ratio.

Figure 16-3A illustrates an example of a compression ratio for a gasoline engine. When the gasoline engine piston is at BDC, the cylinder volume is 40 cu. in. (0.65 L). When the piston slides to TDC, the volume is reduced to 5 cu. in. (0.08 L). Dividing 40 by 5 (0.65 by 0.08), the compression ratio for this engine would be 8:1.

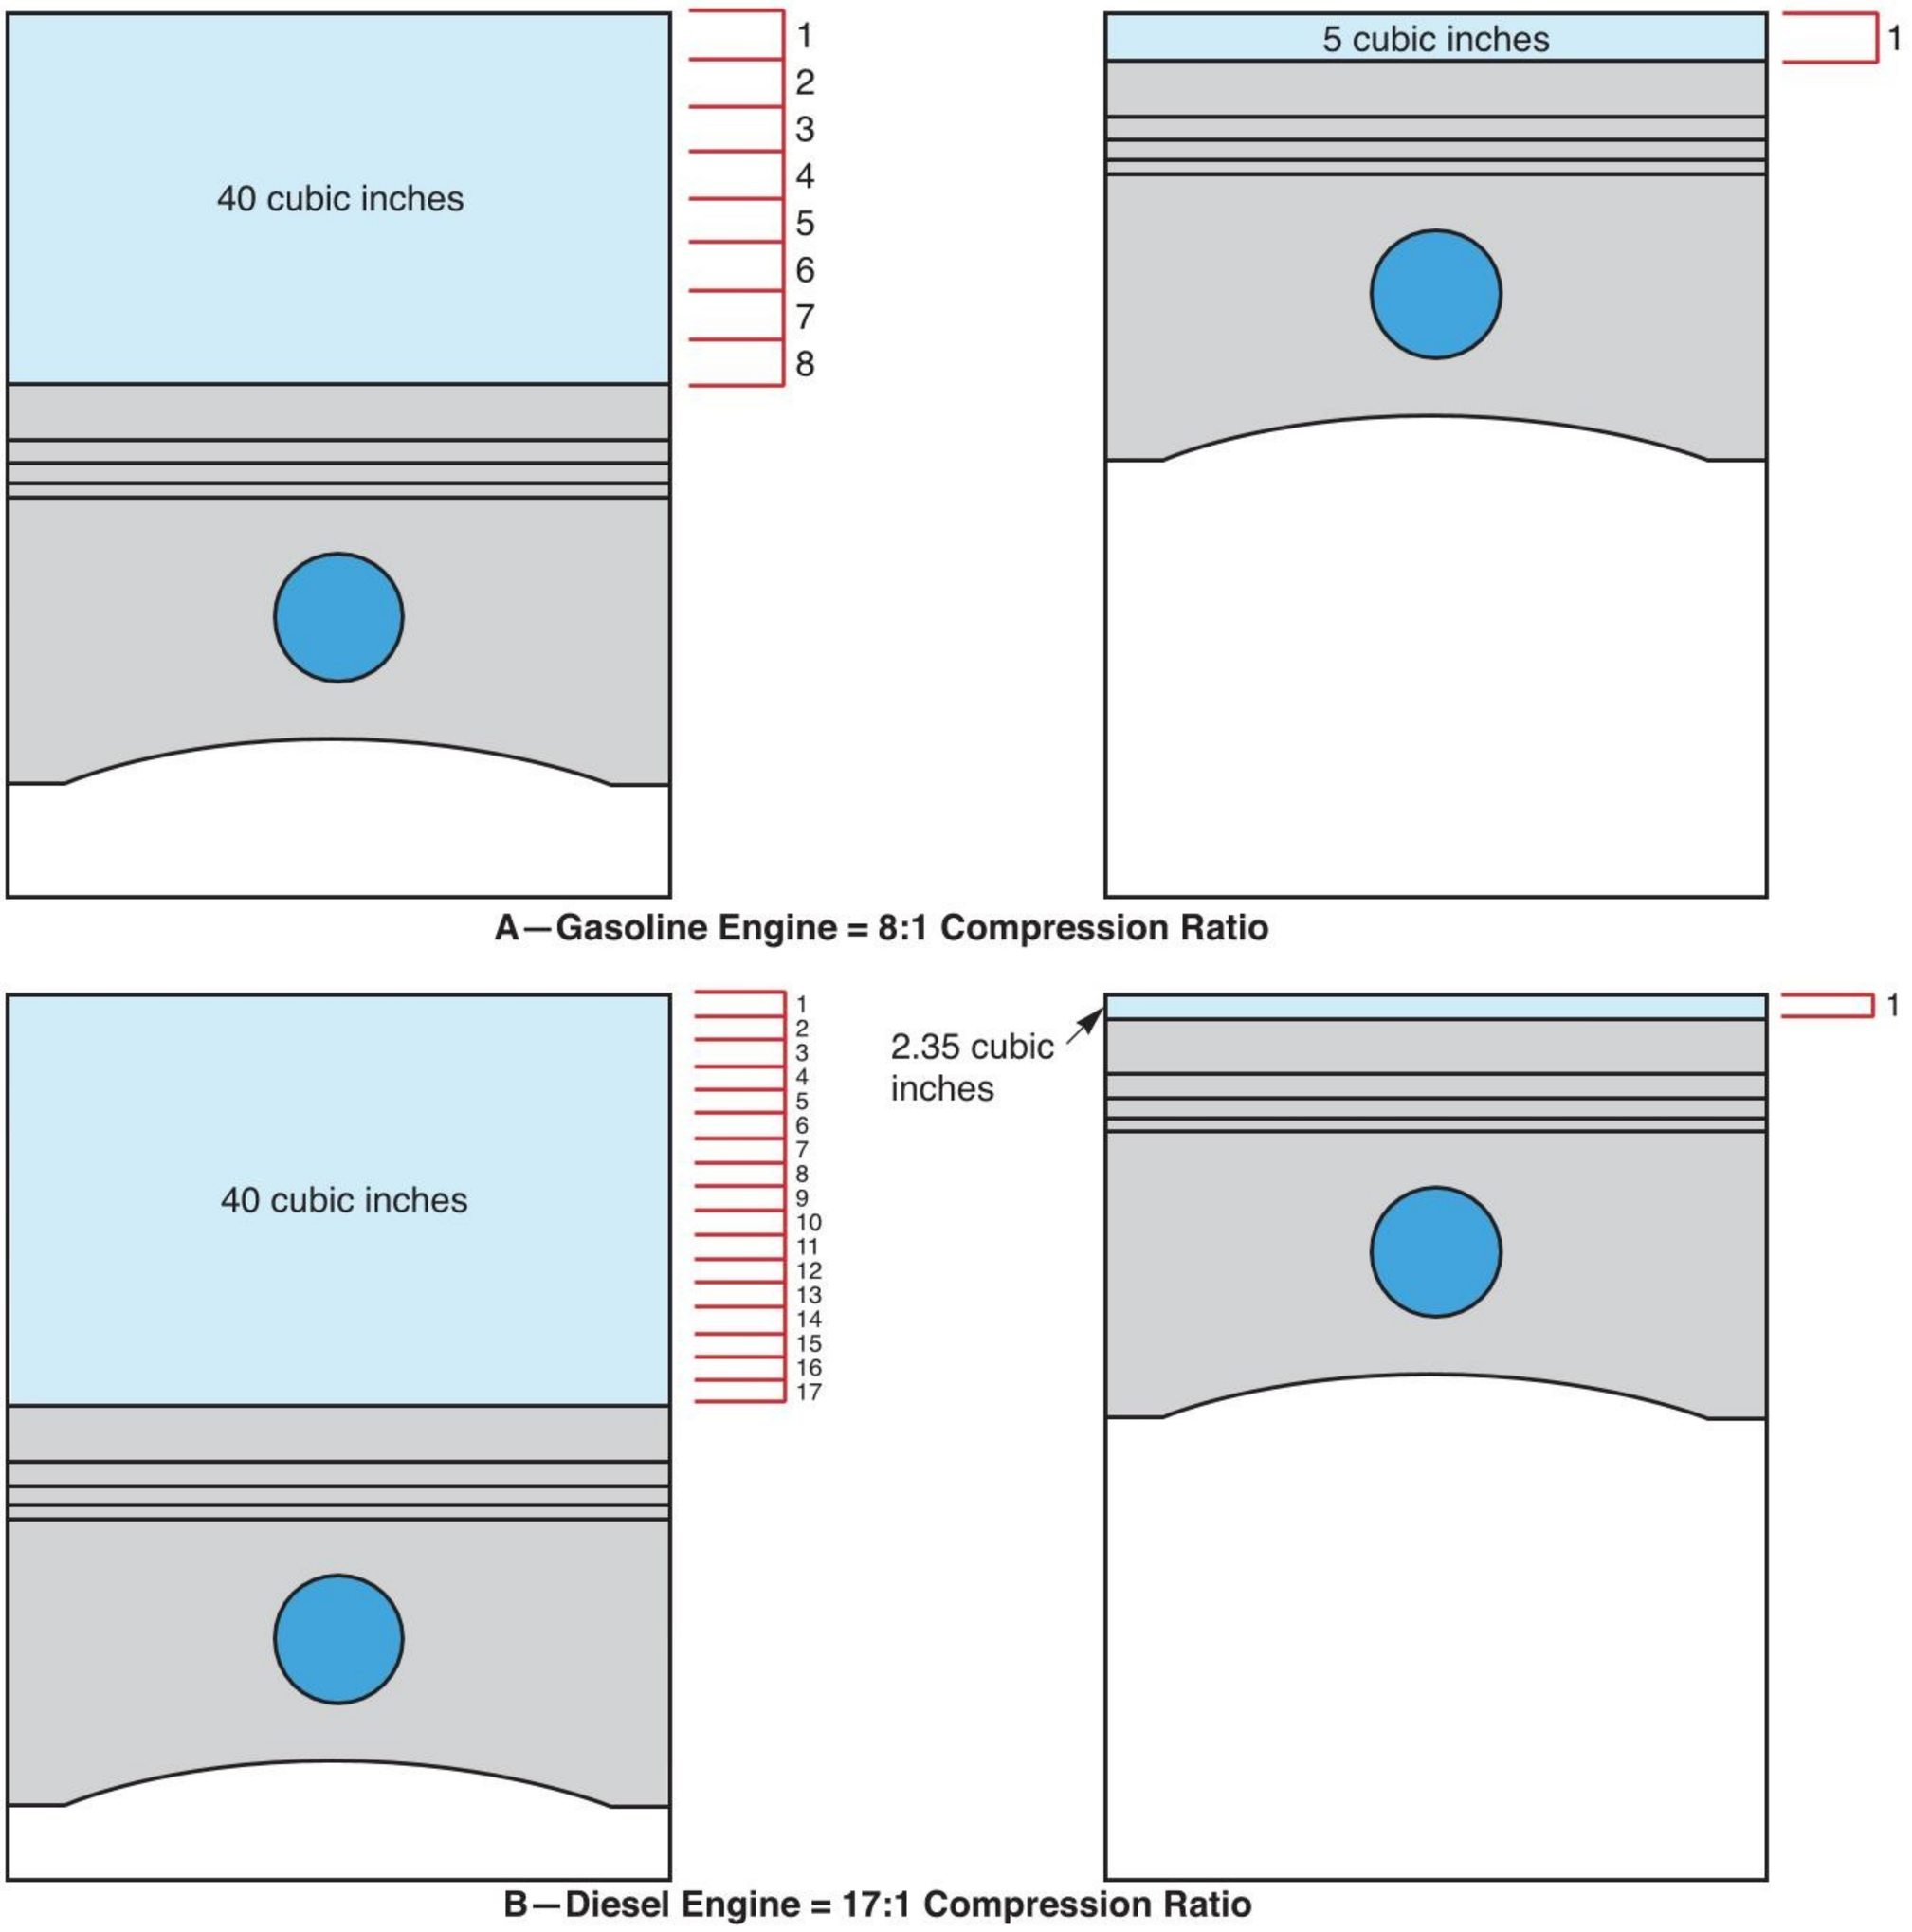
Engines manufactured in the 1960s had very high compression ratios from the factory. They were designed to run on high-octane leaded gasoline. These "muscle car engines" had stock compression ratios as high as 11 or 12:1. When lead was phased out of gasoline for environmental reasons, automakers started reducing compression ratios to improve driveability, but lost power and gas mileage.

Today's high-tech, high-efficiency engines are again being designed with relatively high compression ratios. Late-model, naturally aspirated, high-performance engines can now have compression ratios as high as 11 or 12:1.

Factory supercharged and turbocharged engines have a lower compression ratio (usually about 7 or 8:1) than naturally aspirated engines (only atmospheric pressure pushes air into the engine intake manifold). The supercharger or turbocharger forces the air charge into the engine above atmospheric pressure. The lower compression ratio allows a larger volume of air (oxygen) to be forced into the combustion chambers. In effect, the supercharger or turbocharger raises the compression ratio and pressure in the engine cylinders to provide greater fuel-charge compression, as well as more rapid and complete combustion of the fuel mixture.

Diesel engines have a very high compression ratio compared to engines designed to burn gasoline. Typical compression ratios for diesel engines range from 17:1 for automotive diesel engines to 25:1 for industrial diesels. **Figure 16-3B** illustrates an example of a compression ratio for a diesel engine. Being a compression-ignition engine, the fuel charge must be pressurized until it is hot enough to burn. Unlike a gasoline engine, no spark plug is used to produce an electric arc to start combustion. Compression pressure alone must start combustion of the fuel/air mixture.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 16-3. A diesel engine has a much higher compression ratio than a gasoline engine. A diesel must squeeze the fuel mixture very tight to cause combustion.

Compression Pressure

Compression pressure is the amount of pressure produced in the cylinder during the compression stroke. Compression pressure is normally measured in pounds per square inch (psi) or kilopascals (kPa).

A ***compression gauge*** is used to measure compression pressure. The gauge is screwed into the spark plug, injector nozzle, or glow plug hole. The ignition or injection system (whichever contains the removed part) is disabled. Then, the engine is cranked over. The gauge measures the compression pressure.

A gasoline engine has compression pressure from 130–180 psi (900–1200 kPa). A diesel engine has a much higher compression pressure of about 250–400 psi (1700–2800 kPa). A turbocharged or supercharged engine may develop only 110 to 150 psi compression pressure during a compression test.

Copyright Goodheart-Willcox Co., Inc.

Service specifications will give the exact compression pressure for a new, unworn engine.

Compression pressure is an indicator of engine condition. If it is low, something is allowing air to leak out of the cylinder. The engine may have bad rings, burned valves, or a blown head gasket.

Engine Torque

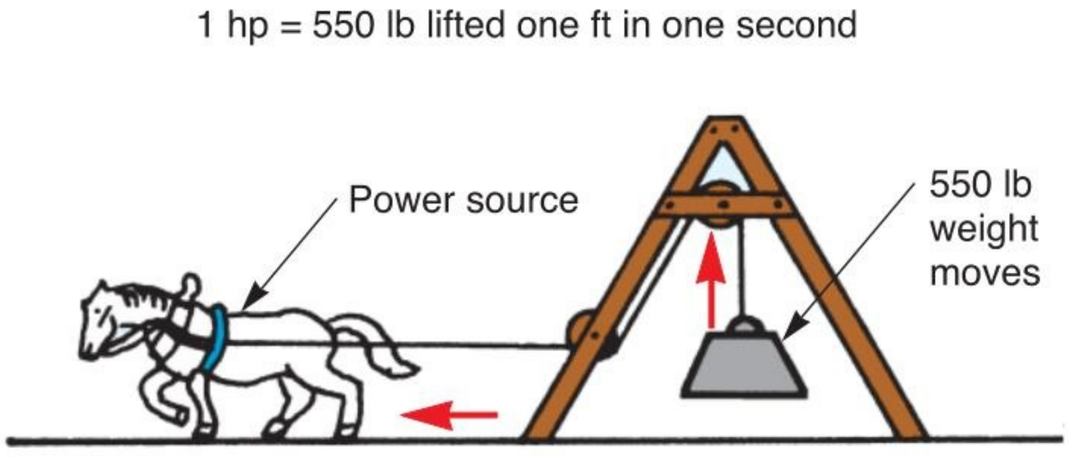
Torque is a turning, or twisting, force. When you turn a steering wheel or tighten a belt, you have applied torque.

Engine torque is a rating of the turning force at the engine crankshaft. When combustion pressure pushes the piston down, a strong rotating force is applied to the crankshaft. This turning force is sent to the transmission or transaxle, and to wheels, propelling the car.

Engine torque specifications are given in a shop manual. An example of a torque specification is 450 ft lb @ 3000 rpm. This high-performance engine would be capable of producing a maximum of 450 ft lb of torque at an operating speed of 3000 revolutions per minute. In metrics, engine torque is often stated in newton-meters (N•m).

Horsepower

Horsepower (hp) is a measure of an engine's ability to perform work (power). The term *horsepower* originated over 200 years ago when James Watt used the term to compare the work done by a steam engine to that done by horses. It was determined that one horsepower would be approximately equal to the amount of work done by a strong horse in one minute. A 300 hp engine could theoretically do the work of 300 horses, **Figure 16-4**.



Goodheart-Willcox Publisher

Figure 16-4. This represents one horsepower. In automotive work, one horsepower equals 33,000 lb moved one foot in one minute.

One horsepower equals 33,000 ft lb of work per minute. To find engine horsepower, use the following formula:

$$hp = \frac{\text{work (ft lb)}}{33{,}000}$$

or

$$hp = \frac{\text{distance (ft)} \times \text{weight (lb)}}{33{,}000}$$

Example: For a small engine to lift 500 lb a distance of 700′ in one minute, about how much horsepower would be needed?

Solution:

$$hp = \frac{700' \times 500 \text{ lb}}{33{,}000}$$

$$= 10.6 \text{ hp}$$

Factory Horsepower Ratings

Automobile makers rate engine horsepower at a specific engine speed. For instance, a high-performance, supercharged engine might be rated at 400 hp @ 5000 rpm. This engine power rating is normally stated in a service manual or sales literature. There are several different methods of calculating engine horsepower.

Brake horsepower (bhp) measures the usable power at the engine crankshaft. A prony brake was first used to measure brake horsepower. The engine turns the prony brake when the braking mechanism is applied, producing a force on the scale. The resulting amount of pointer deflection is then used to find brake horsepower. See **Figure 16-5**.

An ***engine dynamometer (dyno)*** is used to measure the brake horsepower of modern car engines. Refer to **Figure 16-6**. It functions in much the same way as a prony brake. Either an electric motor or a fluid coupling is used to place a drag on the engine crankshaft. Then, brake horsepower output can be determined.

A ***chassis dynamometer*** measures the horsepower delivered to the drive wheels. See **Figure 16-7**. It indicates the amount of horsepower available to propel the car.

Indicated horsepower (ihp) refers to the amount of power formed in the engine combustion chambers. A special pressure-sensing device is placed in the cylinder. The pressure readings are used to determine the indicated horsepower.

Frictional horsepower (fhp) is the power needed to overcome engine friction. It is a measure of the resistance to movement between engine parts, or

MSD Ignition Systems

Figure 16-6. A technician is using an engine dynamometer to measure engine performance. The dynamometer loads the engine to simulate driving conditions while monitoring horsepower output, fuel efficiency, emissions, and many other engine functions.

Ford

Figure 16-8. Net horsepower is the available horsepower with the engine operating all accessories.

power lost to friction. It reduces the amount of power left to propel the car.

Net horsepower, or SAE net horsepower, is the maximum power developed when an engine is loaded by all accessories (alternator, water pump, fuel pump, air injection pump, air conditioning, and power steering pump). Net horsepower indicates the amount of power available to move the car. Look at **Figure 16-8**.

Gross horsepower (ghp) is similar to net horsepower, but it is the engine power available with only basic accessories installed (alternator, fuel pump, and water pump). Gross horsepower does not include the power lost to the power steering pump, air injection pump, air-conditioning compressor, or other extra units. Refer to **Figure 16-9**.

Taxable horsepower is simply a general rating of engine size. In some states, it is used to find the tax placed on a car. The formula for taxable horsepower (thp) is:

$$thp = \text{bore squared} \times \text{number of cylinders} \times 0.4$$

Copyright Goodheart-Willcox Co., Inc.

Mazda

Figure 16-9. Gross horsepower is similar to net horsepower, but it does not include power lost to unneeded accessories.

Volumetric Efficiency

Volumetric efficiency is the ratio of air drawn into the cylinder to the maximum possible amount of air that could enter the cylinder. It is an indication of how well an engine can "breathe" on its intake stroke.

If volumetric efficiency was 100%, the cylinder would completely fill with air on the intake stroke. Engines are capable of only 80–90% volumetric efficiency. Restrictions in the ports and around the valves limit airflow.

High volumetric efficiency increases engine power because more fuel and air can be burned in the combustion chambers. The formula for volumetric efficiency is:

$$\text{volumetric efficiency} = \frac{\text{actual volume of air taken into cylinder}}{\text{volume of cylinder}}$$

Mechanical Efficiency

Mechanical efficiency compares brake horsepower and indicated horsepower. It is a measurement of mechanical friction. Indicated horsepower is the theoretical power produced by combustion. Brake horsepower is the actual power at the engine crankshaft. The difference between the two is due to friction losses.

Mechanical efficiency of 70–80% is normal. This means that 20–30% of the engine's power is lost to friction (frictional hp loss). The friction between the piston rings and cylinder walls accounts for most of this loss.

Thermal Efficiency

Thermal efficiency is found by comparing the horsepower output to the amount of fuel burned. It indicates how well an engine uses the fuel's heat energy. Thermal efficiency measures the amount of heat energy converted into crankshaft rotation.

Generally, engine thermal efficiency is 30–40%. The rest of the heat energy is absorbed by the metal parts of the engine or blown out the exhaust.

Industry Trend

Vehicle design has been greatly refined during the last few years. Sports cars like the Corvette and the Dodge Viper produce over 500 horsepower while producing far less pollution than their counterparts of past. High-performance, "race-bred parts" are found in every major system of today's sports cars.

Summary

- Engine size is determined by cylinder diameter, amount of piston travel on each stroke, and number of cylinders.
- Cylinder bore is the diameter of the engine cylinder.
- Piston stroke is the distance the piston moves from TDC to BDC.
- Piston displacement is the volume the piston displaces (moves) from BDC to TDC.
- Engine displacement, or engine size, equals piston displacement times the number of engine cylinders.
- Force is a pushing or pulling action.
- Work is done when force causes movement.
- Power is the rate, or speed, at which work is done.
- Engine compression ratio compares cylinder volumes with the piston at TDC and BDC.
- Compression pressure is the amount of pressure produced in the engine cylinder on the compression stroke.
- Torque is a turning, or twisting, force.
- Engine torque is a rating of the turning force at the engine crankshaft.

Copyright Goodheart-Willcox Co., Inc.

- Horsepower (hp) is a measure of an engine's ability to perform work.
- Brake horsepower (bhp) measures the usable power at the engine crankshaft.
- An engine dynamometer (dyno) is used to measure brake horsepower.
- A chassis dynamometer measures the horsepower delivered to the drive wheels.
- Volumetric efficiency is the ratio of actual air drawn into the cylinder and the maximum possible amount of air that could enter the cylinder.
- Mechanical efficiency compares brake and indicated horsepowers. It is a measurement of mechanical friction.
- Thermal efficiency is heat efficiency found by comparing fuel burned and horsepower output.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

brake horsepower (bhp)
chassis dynamometer
compression gauge
compression pressure
compression ratio
cubic centimeters (cc)
cubic inch displacement (CID)
cylinder bore
engine displacement
engine dynamometer (dyno)
engine size
engine torque
force
frictional horsepower (fhp)
gross horsepower (ghp)
indicated horsepower (ihp)
liters (L)
mechanical efficiency
net horsepower
piston displacement
piston stroke
power
taxable horsepower
thermal efficiency
torque
volumetric efficiency
work

Activities

1. Use a compression gauge to measure the compression of each cylinder of an engine. Check your findings against the specifications for that engine. Are all the readings "in spec," or do one or more cylinders read high or low?
2. Convert your compression readings from pounds per square inch to kilopascals, or vice versa. Multiply psi readings by 6.895 to find kPa; divide kPa readings by 6.895 to find psi.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What three factors determine engine size?
2. Cylinder bore is measured across the cylinder, parallel with the top of the block. True or False?
3. Piston stroke is the distance the piston moves during a complete four-stroke cycle. True or False?
4. _____ is the volume the piston moves from BDC to TDC.
5. If an engine has a bore of 3.5″ and a stroke of 3″, what is the piston displacement?
6. Define the term *engine displacement*.
7. Explain the difference between force, work, and power.
8. When a gasoline engine's piston is at BDC, the cylinder volume is 45 cu. in. When the piston slides to TDC, the cylinder volume is 9 cu. in. What is the compression ratio for this engine?
   (A) 8:1.
   (B) 5:1.
   (C) 7:1.
   (D) 9:1.
9. Which of the following would *not* be a compression ratio for a car engine?
   (A) 2:1.
   (B) 8:1.
   (C) 17:1.
   (D) 20:1.
10. A gasoline engine may produce a compression pressure of _____ to _____ psi (_____ to _____ kPa).
11. A diesel engine can produce a compression pressure of about _____ to _____ psi (_____ to _____ kPa).

Copyright Goodheart-Willcox Co., Inc.

12. What is engine torque?
13. Explain the term "horsepower."
14. The ratio of actual air drawn into an engine to the maximum possible air that could enter the engine is called _____.
15. A piston engine's thermal efficiency is approximately _____.
    (A) 80–100%
    (B) 70–80%
    (C) 40–50%
    (D) 20–30%

ASE-Type Questions

1. Engine size is determined by:
   (A) cylinder diameter.
   (B) number of cylinders.
   (C) piston travel per stroke.
   (D) All of the above.
2. The distance a piston moves from TDC to BDC is called:
   (A) piston taper.
   (B) piston stroke.
   (C) piston clearance.
   (D) piston displacement.
3. Piston displacement times the number of engine cylinders equals:
   (A) engine size.
   (B) cylinder bore.
   (C) engine torque.
   (D) compression ratio.
4. Work can be measured in:
   (A) watts.
   (B) joules.
   (C) kilograms.
   (D) kilopascals.
5. Modern gasoline engines have a compression ratio of about:
   (A) 8 or 9:1.
   (B) 11 or 12:1.
   (C) 15 or 16:1.
   (D) 20 or 21:1.
6. Compression pressure is measured in:
   (A) kilopascals.
   (B) pounds per square inch.
   (C) Both A and B.
   (D) Neither A nor B.
7. Diesel engines have compression pressure of about:
   (A) 130 to 180 psi.
   (B) 250 to 400 psi.
   (C) 425 to 500 psi.
   (D) 510 to 525 psi.
8. One horsepower equals:
   (A) 28,000 kW of work per minute.
   (B) 25,000 ft lb of work per hour.
   (C) 30,000 in lb of work per second.
   (D) 33,000 ft lb of work per minute.
9. Which of the following is used to measure brake hp of an engine?
   (A) Brake tachometer.
   (B) Compression gauge.
   (C) Engine dynamometer.
   (D) Chassis dynamometer.
10. Which abbreviation indicates the amount of power or pressure formed in engine combustion chambers?
    (A) ihp.
    (B) fhp.
    (C) ghp.
    (D) thp.

Electrical and Electronic Components

Chapter 20
Electrical Tools and Test Equipment

Chapter 21
Wiring Diagrams and Wiring Repairs

Chapter 22
Basic Electrical Tests

If you look under the hood of any late-model vehicle, you will see a maze of wires connecting dozens of devices. In fact, electrical and electronic devices are found in almost every major automotive system, including the suspension, transmission, fuel, ignition, emission control, and braking systems.

Section 3 will introduce you to the basics of automotive electricity and electronics. It contains detailed explanations of electrical principles, describes various circuit types and components, discusses the tools and test equipment used when servicing these systems, outlines techniques for reading wiring diagrams and performing wiring repairs, and provides a thorough explanation of the basic electrical tests.

This section will provide you with a sound background in electricity and electronics, which is necessary to effectively troubleshoot and service today's complex vehicle systems. It will also help you pass ASE Certification Test A6, Electricity and Electronics, as well as several other ASE Certification Tests.

Chapter 17
Electrical Principles

After studying this chapter, you will be able to:

- Describe the parts of the atom.
- Explain the principles of electricity.
- Describe the principles of magnetism and magnetic fields.
- Describe the action of electric circuits.
- Compare voltage, current, and resistance.
- Compare dc and ac electricity.
- Correctly answer ASE certification test questions that require a basic understanding of electricity and electronics.

By understanding the principles of electricity, you will be much better at problem solving or troubleshooting electrical and electronic systems of a car. By knowing what electricity is and how it functions in nature, you will also have a much better grasp of the more complex electronic components covered in later chapters.

Atomic Structure

To fully grasp the concept of electricity, you must first have a basic understanding of atoms and the atomic structure of matter. ***Matter*** is anything in the universe that occupies space and has mass (weight). Matter can be a solid, a liquid, or a gas.

All matter is made up of atoms. An ***atom*** is a microscopic particle that cannot be broken into smaller pieces without losing its properties. This book, air, the sun, and even your body are made of atoms. Atoms are too small to be seen without a highly specialized electron microscope.

An ***element*** is a group of one type of atom. For example, hydrogen is the simplest element in the universe and it contains atoms of hydrogen only. There are over 100 elements in nature. They combine to form all types of matter. The periodic table of elements lists all known elements or atom types.

A ***molecule*** is a group of two or more atoms joined together. Water (H_2O) is a molecule because it contains three atoms. Each water molecule has two hydrogen atoms and one oxygen atom, hence H_2O. A ***compound*** is a substance composed of molecules containing two or more elements.

Copyright Goodheart-Willcox Co., Inc.

Parts of an Atom

An atom consists of three parts:

- ***Electrons***—Electrons are negatively charged particles that circle in specific orbits around the center, or ***nucleus***, of the atom.
- ***Protons***—These positively charged particles are located in the nucleus of the atom.
- ***Neutrons***—Neutrons are particles with no positive or negative charge, but still have mass and occupy space, in the nucleus.

Figure 17-1 shows the relationship of electrons, protons, and neutrons in a simple atom.

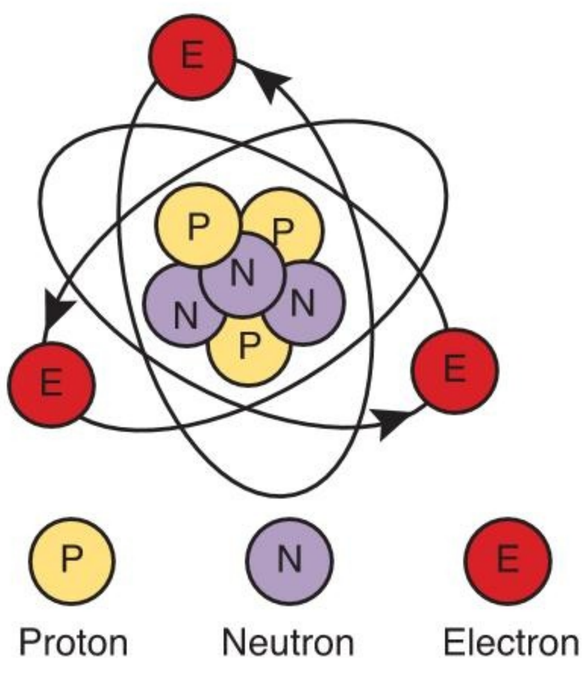
Free Electrons

Normally, an atom has a balance of forces. The number of electrons circling the center of the atom equals the number of protons in the nucleus. This makes the atom stable. However, it is possible for atoms to have extra electrons in their outer orbits. These extra electrons are known as ***free electrons***. Free electrons can be easily dislodged from one atom and made to jump to a neighboring atom, **Figure 17-2**.

Electricity

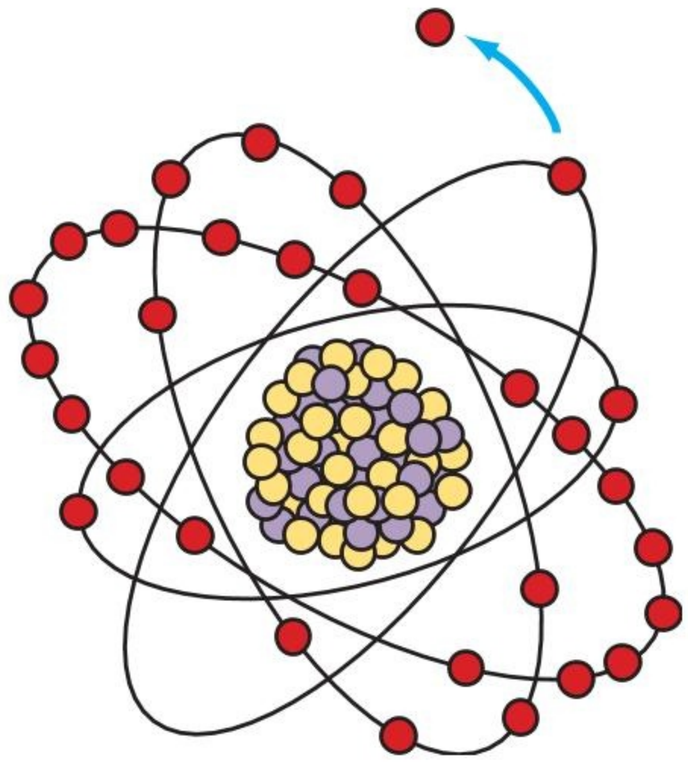
Movement of free electrons is the result of a difference in positive and negative charges between atoms. This difference causes a free electron to jump from one atom and enter the orbit of an adjacent atom. This extra electron will upset the balance of forces in the adjacent atom (adjacent atom becomes negatively charged). As a result, an electron will be forced to jump out of orbit in that atom and enter the orbit in another atom in the conductor. This will cause a chain reaction, and free electrons will continue to jump from atom to atom throughout the circuit. The resulting flow of electrons is electric current, as shown in **Figure 17-3**.

Electricity can be defined as the movement of free electrons from one atom to another. If a wire has a ***negative charge*** (excess electrons) on one end and a ***positive charge*** (excess protons) on the other end, electrical flow, or ***discharge*** will result. Electrical discharge is the flow of electrons through the atoms in a solid, gas, or liquid. The electrons will flow through the wire to balance out the atomic forces.



Goodheart-Willcox Publisher

Figure 17-1. The nucleus of an atom contains protons and neutrons that have no charge. Electrons orbit around the nucleus of the atom.



Goodheart-Willcox Publisher

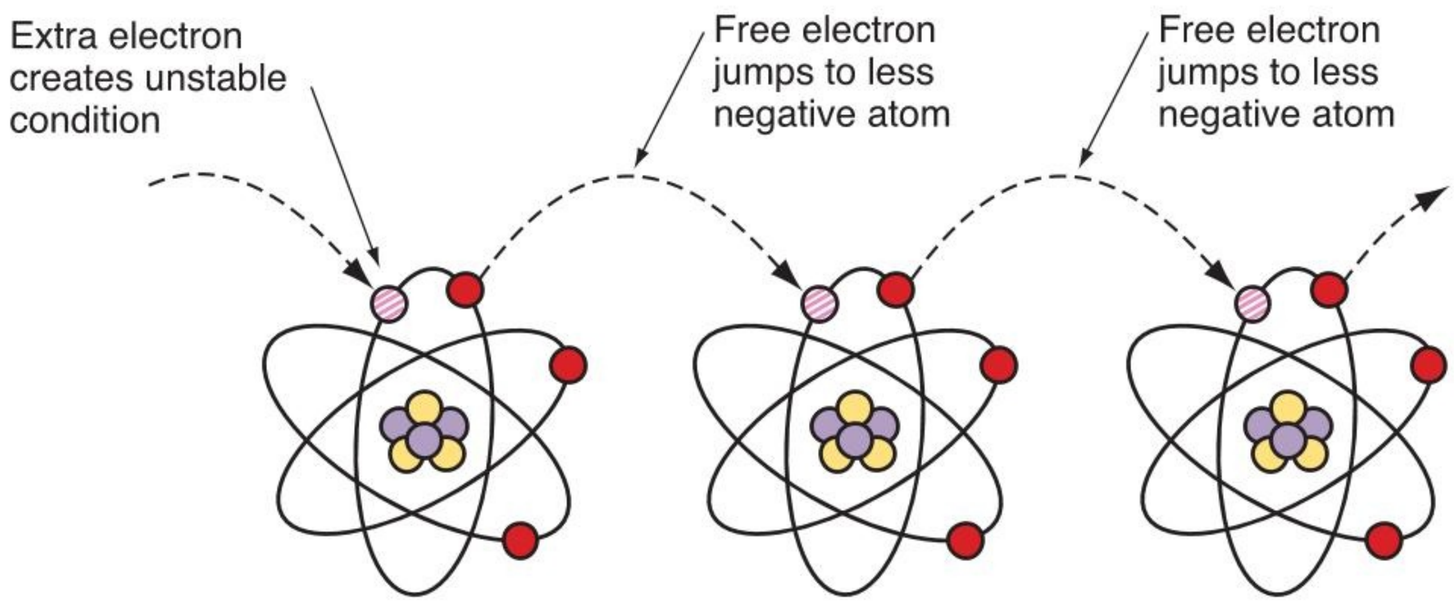
Figure 17-2. This copper atom is a good conductor of electricity because its outer electron is not tightly bonded to the atom. This electron can move from atom to atom to produce current.

Conductors and Insulators

A ***conductor*** is a substance that allows the flow of free electrons. Metal wires make good conductors because metals (gold, silver, copper, aluminum, iron, etc.) have unstable atoms that allow electrical flow from one point to another. Gold is the best conductor of all the elements.

An ***insulator*** is a substance that resists or stops the flow of electrons. The atoms in insulators are very stable and do not allow easy electron movement. For instance, the insulation on wires is designed to prevent electron flow out of the center conductor of the wire. Examples of insulators include air, glass, plastic, rubber, and porcelain.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 17-3. When a free electron jumps to an atom, that atom becomes negatively charged and unstable, forcing an electron to jump from that atom to a less negative atom. The second atom becomes unstable, and an electron jumps to the next less negative atom. This chain reaction is the basis of electricity.

Functions of Electricity

Electricity has three basic functions—to produce light, heat, and motion. For example, electricity can be sent through a lightbulb. The filament in the bulb heats up and glows white hot, producing light.

When free electrons flow through a conductor with high resistance, such as a filament in an incandescent lightbulb, an electrical friction results. Just as rubbing your hands together produces heat, the electrons rubbing against the atoms in the filament produce heat. This is why incandescent lightbulbs grow warm when they are lit.

Electricity is also used to produce movement of parts, as well as magnetism. The magnetism is used inside electric motors, relays, solenoids, and other electric devices to cause motion and to do work.

Mechanical vs. Electrical

In newer automobiles, electrical devices have replaced many mechanical devices. Electrical devices can do the job of mechanical devices more quickly and efficiently.

With electronics, the car can be designed for higher fuel economy and higher performance, but with fewer toxic emissions. The vehicle can be made to be lighter, ride more smoothly, stop more quickly, and provide more comfort and convenience for its driver and passengers. As you will learn, modern vehicles have an advanced computer system that will detect and identify hundreds of problems so they can be repaired quickly and easily.

Electrical vs. Electronic

An ***electrical device*** is a conventional component that uses electricity to do work, such as an electric motor, a mechanical switch, relay, solenoid, lightbulb, etc. While these devices are still used today, the term refers to devices that were used prior to the invention of the transistor, computer, and electronics industry.

An ***electronic device*** is a more modern solid state component that does not use moving parts for operation. Examples include diodes, transistors, sensors, and computers. Electronic devices normally operate off of low voltage (one volt or less) and alter current flow during operation.

Tech Tip

This book will use the term "electrical" or "electronic" as it best describes the situation. There is some overlap and confusion as to when an electrical component or system should be classified as electronic because most automotive devices operate on low voltage (around 12 volts dc, or direct current).

When a component uses less than one or two volts for operation, it is *electronic*. The voltage in a home wall outlet, an appliance, or a hybrid electric drive system is much higher (120 volts or more ac, or alternating current) and would always be classified as *electrical*.

Copyright Goodheart-Willcox Co., Inc.

Magnetism

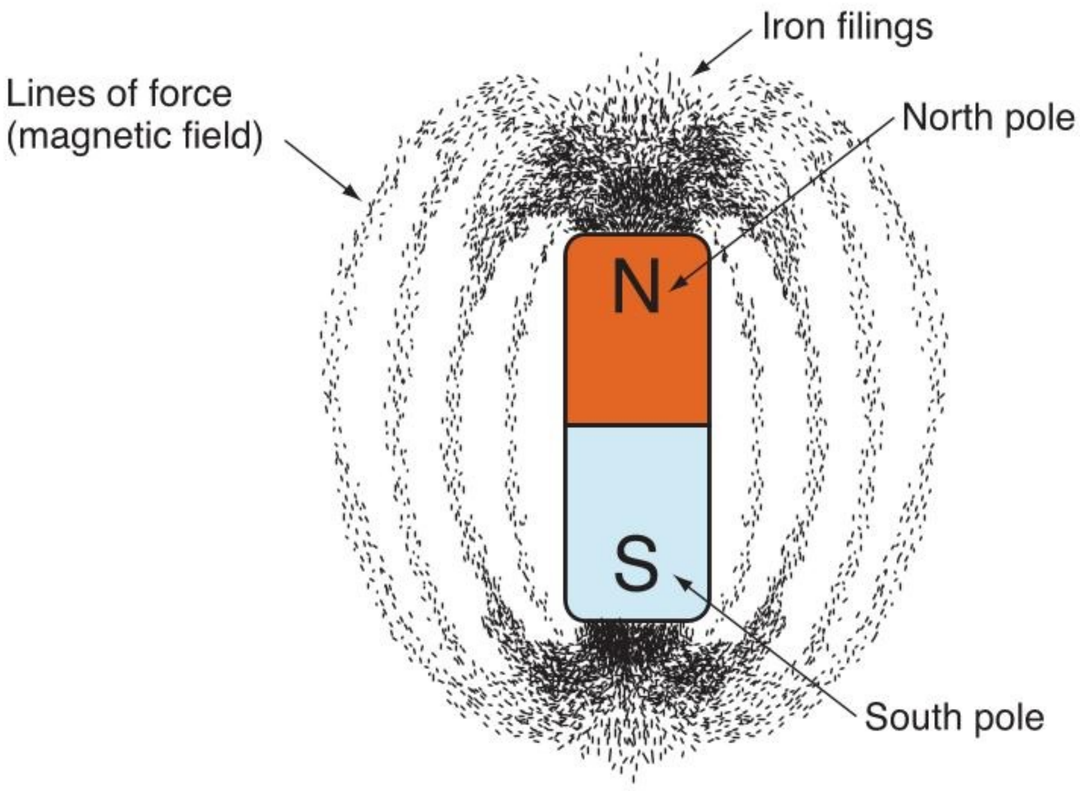
Magnetism plays an important role in the production and use of electrical energy. For the purpose of this text, magnetism is an atomic force that can attract or repel ferrous (iron-containing) substances through space, air, or solid matter.

You are probably familiar with a permanent magnet. As shown in **Figure 17-4**, it has north (positive) and south (negative) poles. An invisible ***magnetic field***, or ***flux***, exists between the poles of a magnet. The magnetic field is caused by the movement of electrons and can be used to act on ferrous (iron) substances. Even though the magnet is not in direct contact with the ferrous object, its magnetic field can affect the object.

When a piece of iron is magnetized, the molecules in the iron are aligned to produce north and south poles. This makes a magnetic field develop around the magnet. **Figure 17-5** illustrates how a permanent magnet acts on a piece of metal. Note how the magnetic field surrounds the magnet and the metal nail. If iron filings are placed on the tip of the nail, they cling to the nail because of the magnetic field.

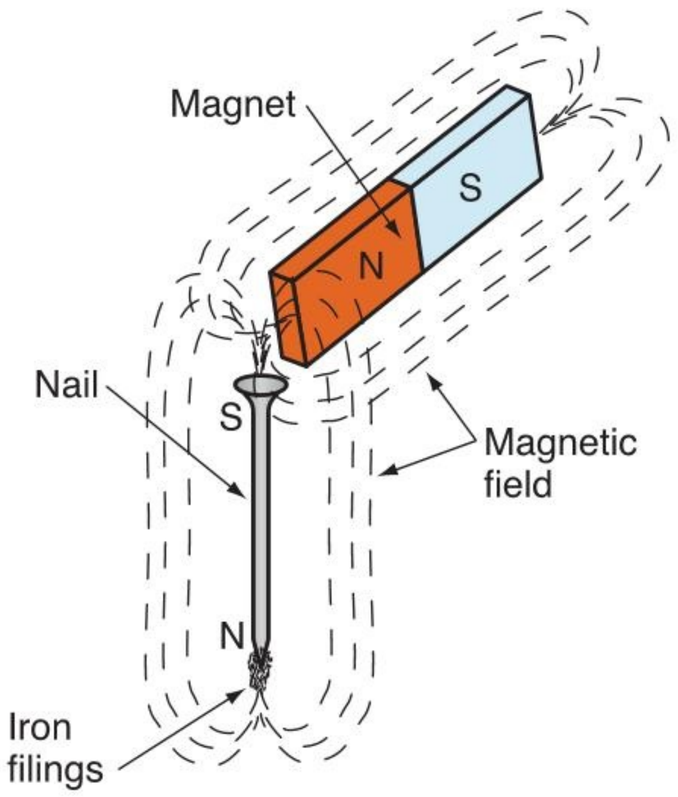
Tech Tip

A magnetic field acts on ferrous substances only. It has no effect on nonferrous substances such as plastic and glass.



Goodheart-Willcox Publisher

Figure 17-4. A permanent magnet has north and south poles. The north pole has a positive charge, and the south pole has a negative charge. If you sprinkle iron particles around a magnet, you can see action of the magnetic field.



Goodheart-Willcox Publisher

Figure 17-5. A magnet acting on a nail shows the effect of a magnetic field. Note how the field surrounds both the magnet and the nail. The magnetic field magnetizes the nail temporarily to hold the iron particles.

Like and Unlike Charges

The interaction of magnetic substances follows two basic rules:

- Like charges repel each other.
- Unlike charges attract each other.

For example, try to touch the south poles (like charges) of two magnets together. The two magnets repel each other. If you push them together on a tabletop, they actually slide apart. On the other hand, if you place a north pole and a south pole (unlike charges) near each other, they will attract. Magnetic force pulls them together with considerable force. See **Figure 17-6**.

As you will learn later, this pushing and pulling force can be used in numerous electric devices, including motors, relays, and solenoids.

Electromagnetism

Electromagnetism is a branch of physics that deals with the interaction of electricity and magnetism. Electricity can be used to produce magnetism, and magnetic fields can be used to produce electricity. As shown in **Figure 17-7**, when electricity flows through a wire, a magnetic field sets up around the wire. The magnetic field is weak, but it can be detected with electronic test equipment.

You can demonstrate the presence of the magnetic field by placing a piece of cardboard around the

wire and then sprinkling iron powder on the cardboard. See **Figure 17-8**. The magnetic field sets up at right angles to the wire. When several electricity-carrying wires are placed next to each other, the magnetic field strengthens, as shown in **Figure 17-9**. Inserting

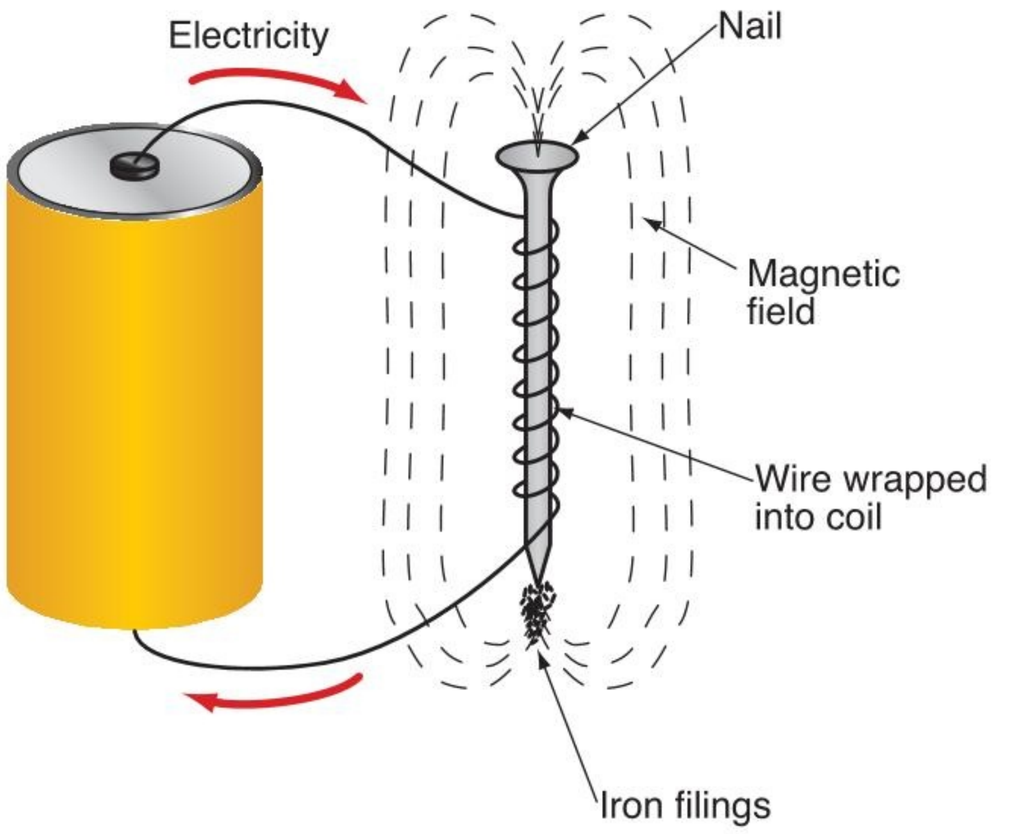
Figure 17-9. Placing several electricity-carrying wires close together strengthens the magnetic field around them.

an iron core through the coils of wire strengthens the magnetic field further, creating an ***electromagnet*** (electrically energized magnet), **Figure 17-10**. This principle is used in numerous electric components.

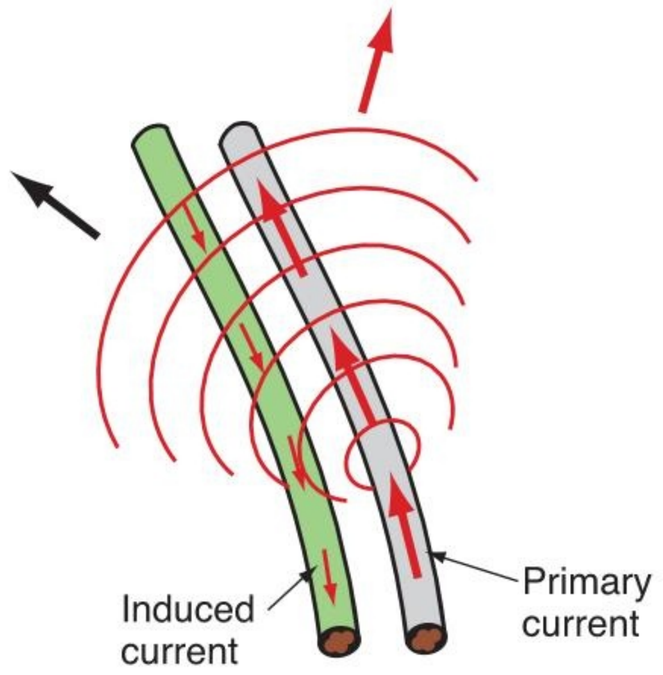
Induction

Induction is the process of creating electricity in a wire by passing the wire through a magnetic field. Electricity can also be induced in a wire if the wire is near an expanding and collapsing magnetic field. The magnetic field acts on the free electronics in the wire to produce electricity. The principle of electrical induction is used in alternators, inductive meters, and other electrical-electronic components. Refer to **Figure 17-11**.



Goodheart-Willcox Publisher

Figure 17-10. An electromagnet can be made by wrapping wire around iron core. Electricity through the wire produces a powerful magnetic field.



Goodheart-Willcox Publisher

Figure 17-11. Electricity can be induced in a wire by moving the wire through a magnetic field. Electricity can also be induced in a wire that is in close proximity to an expanding and a collapsing magnetic field.

Electric Circuits

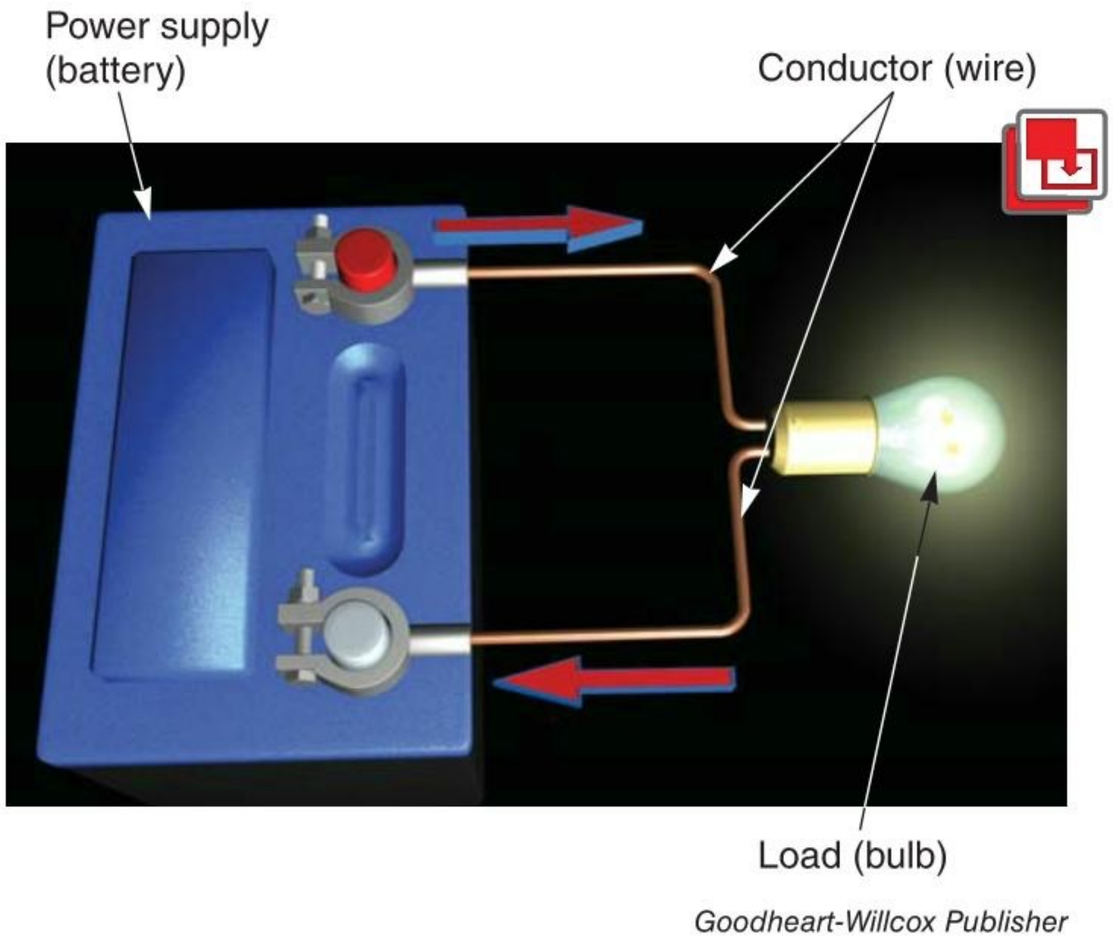
Now that you understand something about electrical principles, you are ready to review a basic electric circuit. An ***electric circuit*** consists of the basic components needed to utilize electrical energy. These components include:

- Power supply—A power supply is a source of electrical energy, such as a battery or an engine-driven generator.
- Load—A device that uses the electrical energy, such as a lightbulb or an electric motor, is a load.
- Conductor—A conductor is a substance (element or alloy) that can carry electrical current through a circuit (wires, metal frame of vehicle, engine block, etc.).

Figure 17-12 shows a simple electric circuit. The battery (power supply) or engine-driven generator (alternator) applies electrical voltage (volts) into the wire (conductor). Electric current (amps) flows through the wire and lightbulb filament (load). The filament heats up and emits light. Electric current continues through the wire and electrons return to the battery through the return conductor, or frame ground. This simple circuit can be expanded to make much more complex electric circuits, but all circuits operate on this basic principle.

A hydraulic circuit can be used to demonstrate the action in an electric circuit. See **Figure 17-13**. The hydraulic pump is comparable to the battery. It produces the pressure for circuit operation. The hydraulic

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 17-12. A simple electric circuit requires these basic parts. The power source feeds electrons into the circuit. Conductors carry electrons to and from the load. The load uses the electrical energy to do work.

hoses represent the conductors or wires in the circuit. They allow flow between the power source and the load device. The hydraulic ram is comparable to an electric load (a lightbulb in this example).

The control valve is comparable to an electric switch or a variable resistor. Both the control valve and the switch or variable resistor control flow through the circuit. If the valve (switch) is closed, the flow stops and the circuit will not function.

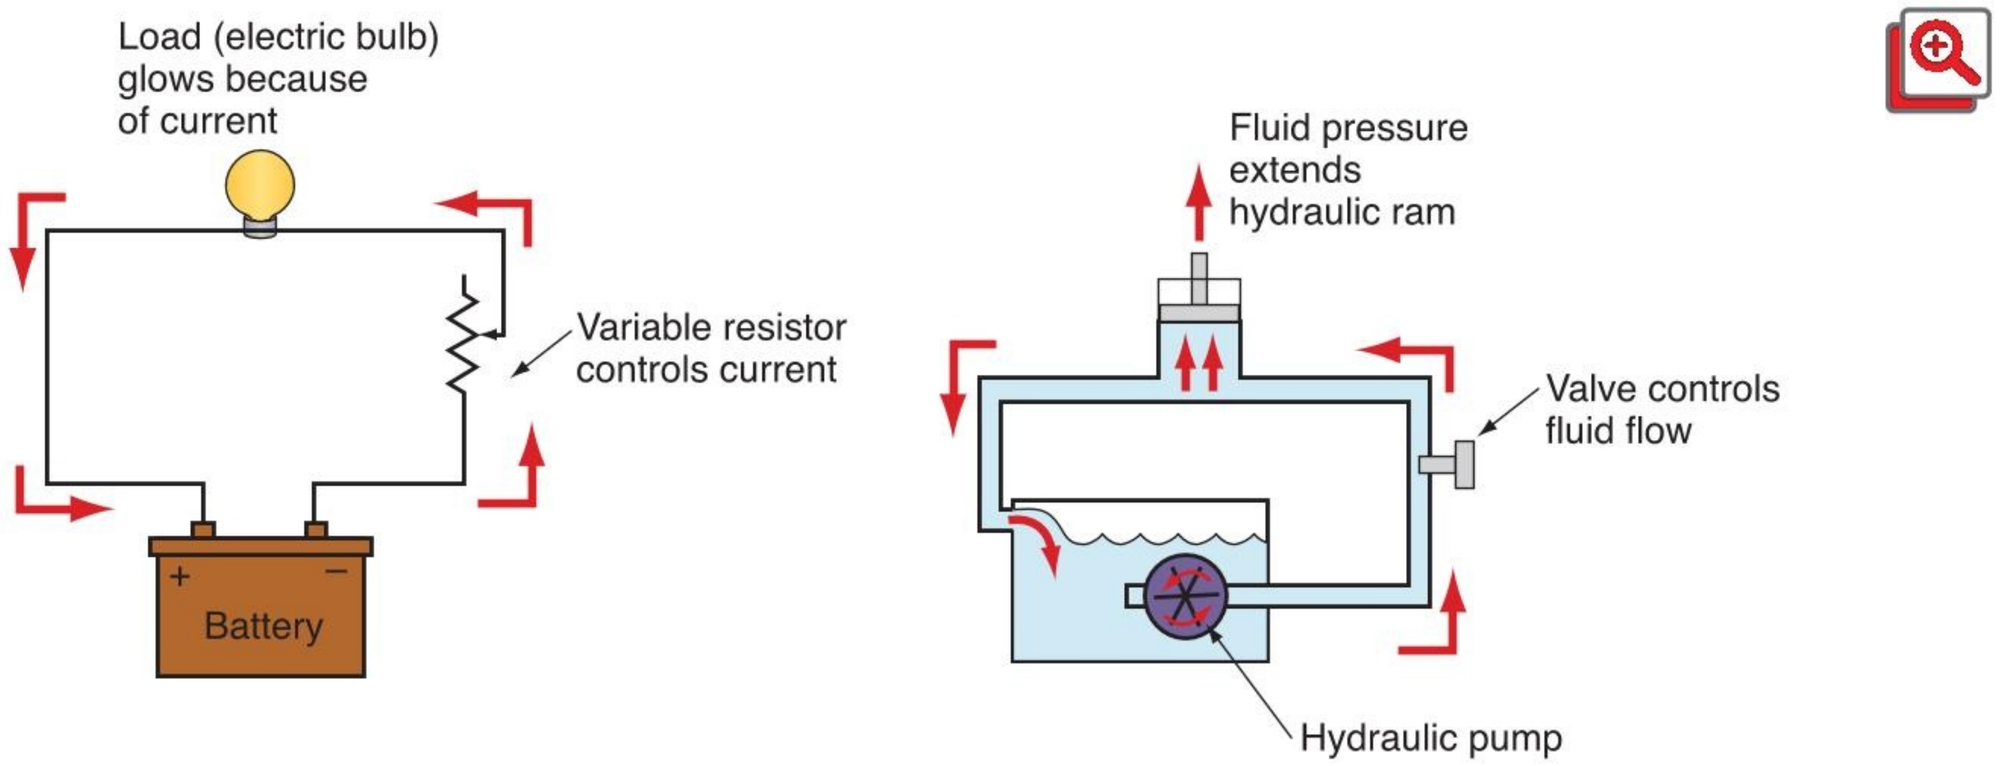
All electric circuits have three fundamental properties: voltage (electrical pressure), current (rate of electron flow), and resistance (opposition to current). These three properties are interrelated; the value of each property depends on the value of the other two, as described in the following paragraphs. A house garden hose demonstrates the principles of voltage (water pressure), current (water flow), and resistance (water valve restriction). See **Figure 17-14**.

Voltage

Voltage is the electrical force, or pressure, that pushes free electrons and causes current. It is also known as ***electromotive force (EMF)*** or ***potential difference***, and refers to how voltage has the power or force to cause electron movement through a conductor.

Voltage is measured in ***volts*** and is represented in formulas and diagrams by the letters *V* or *E*. Increasing voltage increases current because more free electrons flow through the circuit. Reducing voltage reduces current.

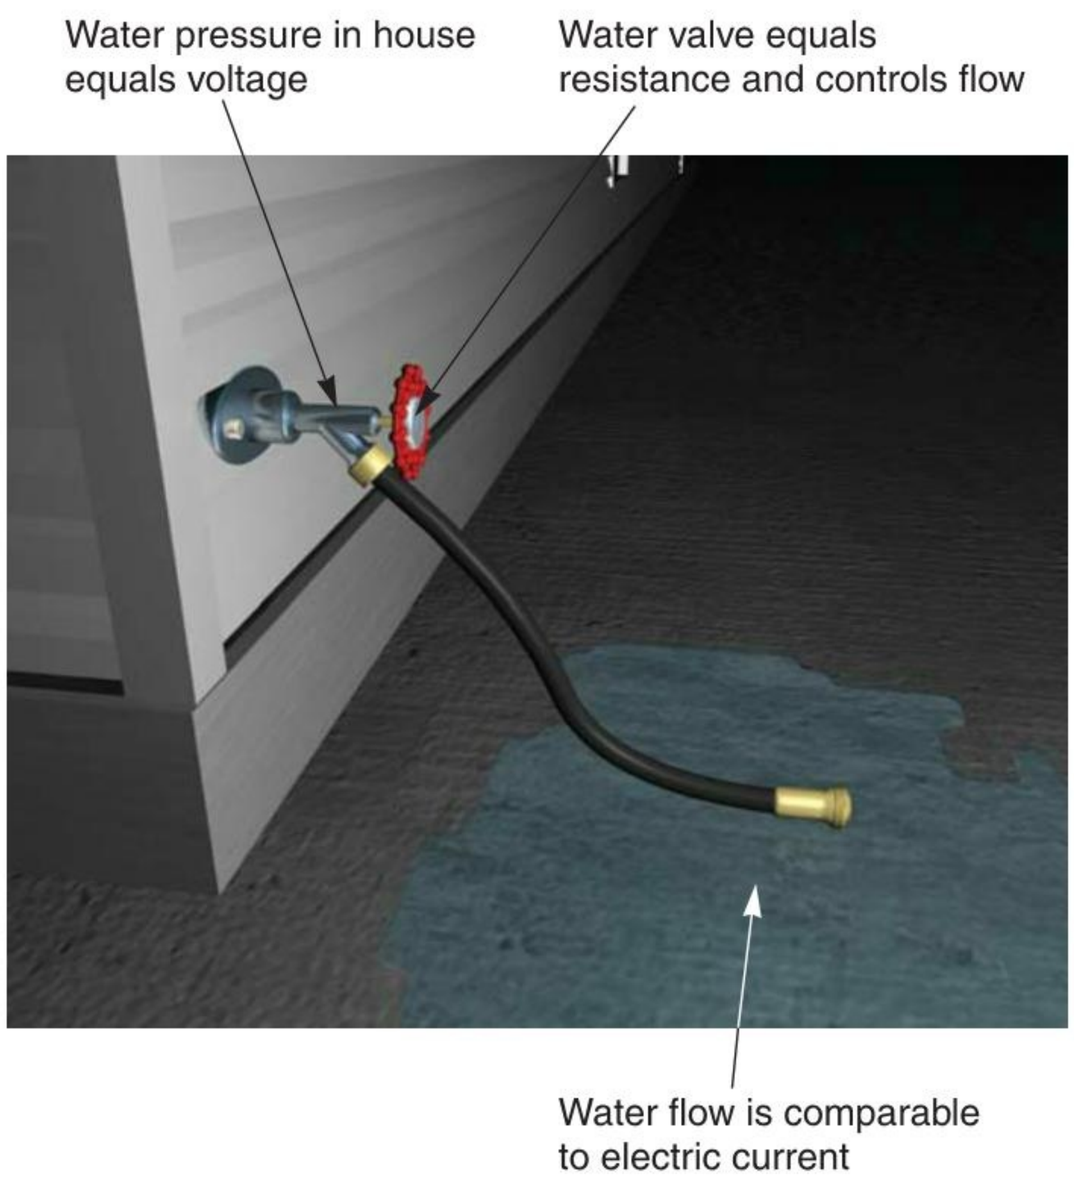
For example, in a simple circuit containing a lightbulb, higher voltage forces more free electrons through the bulb filament and the bulb glows more brightly. If lower voltage is applied, the bulb does not glow as brightly. This applies to other circuits and loads as well.



Goodheart-Willcox Publisher

Figure 17-13. Hydraulic circuit compared to electric circuit. The hydraulic pump is comparable to a power source. The flow control valve is similar to an electric switch or variable resistor. In both circuits, the load (hydraulic ram, electric fan) is the purpose for the circuit.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 17-14. The valve on a garden hose demonstrates resistance in a circuit. The water pressure represents voltage and produces current, or flow. The valve provides resistance and controls flow. When the valve is fully open, resistance is low, so water (current) flow increases, and vice versa.

Current

Current, or amperage, is the rate of electron flow in a circuit. The term *current* is also commonly used to simply mean the flow of electrons in a circuit. Current is measured in electrical units called ***amperes*** (commonly shortened to amps) and is the result of voltage in a complete circuit. Current is represented in formulas and diagrams by the letter *I*.

Current is high if resistance is low or if voltage is high. Current is reduced by high resistance or low voltage.

For current to exist in a circuit, there must be a power source, a complete conducting path, and a load. If the path is not complete, there will be no current.

Resistance

Resistance is the opposition to free electron flow. It is used to limit or control current. Measured in ***ohms*** (Ω), resistance is designed into all electric circuits. The load (a lightbulb, for example) has an internal resistance that uses the energy of the current. Resistance is represented in formulas and diagrams by the letter *R*.

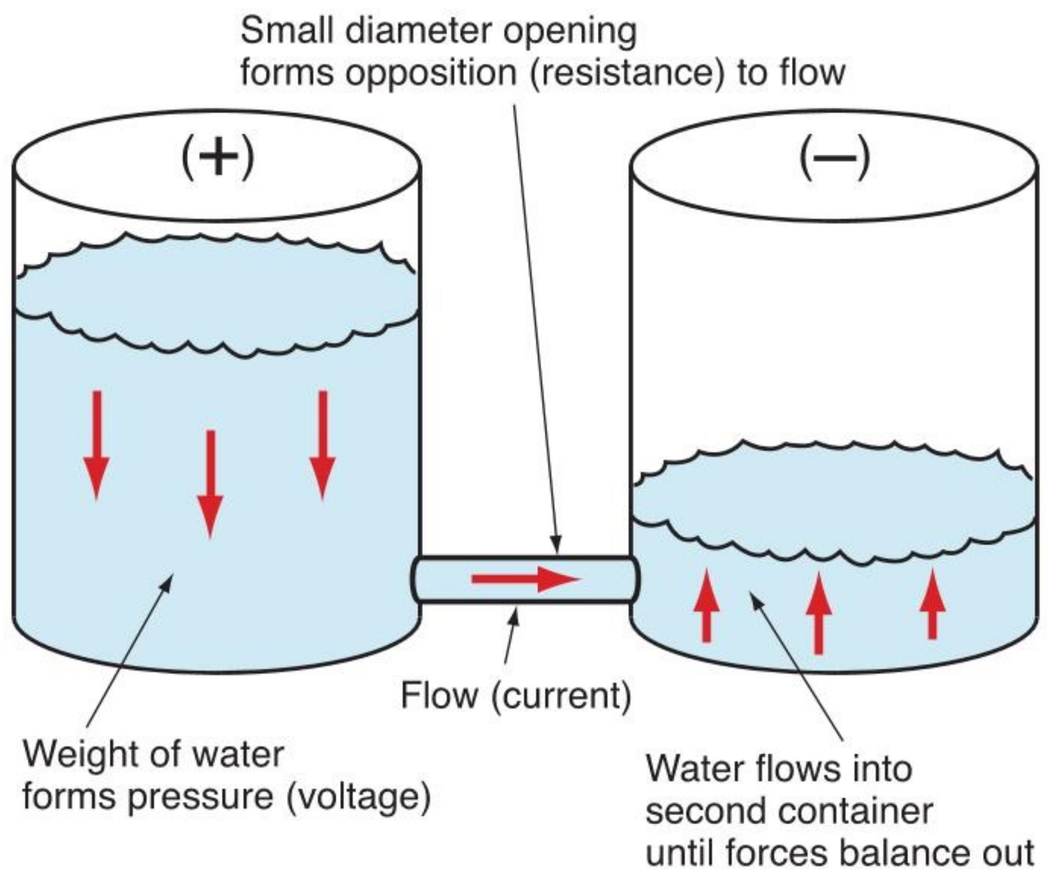
As illustrated in **Figure 17-14**, resistance is comparable to the water valve on a garden hose. If the valve is opened fully, resistance is low and flow is high. If you partially shut the water valve, resistance becomes higher and flow drops off. If you completely close the water valve, resistance is maximum (infinite), and flow stops completely.

Tech Tip

A short circuit results when there is not enough resistance to current flow. Excess electron flow and the resulting heat in a shorted circuit will instantly burn wires and components.

Relationship of Voltage, Current, and Resistance

The water circuit shown in **Figure 17-15** demonstrates the relationships between voltage, current, and resistance. Imagine two containers connected with a piece of tubing. Fill one container with water and



Goodheart-Willcox Publisher

Figure 17-15. Two containers connected by tubing demonstrate electrical action. If the left container is filled with water, water pressure, or potential difference, results. This forces the water to flow through the tube, producing current. The tube acts as resistance to limit the flow. The current stops when the water level (potential difference) is equal in the two containers.

Copyright Goodheart-Willcox Co., Inc.

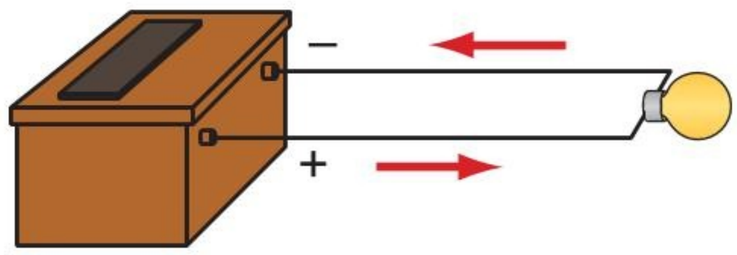
leave the other container empty. Water flows through the tube to equalize the amount of water in the two containers. This is similar to the electrical action of charges in atoms trying to balance out in a circuit.

The difference between the weights of the water in the two containers represents voltage, or the pressure trying to balance out the forces. The flow through the tube represents current. The diameter of the tubing represents the resistance that controls the amount of flow. An electric circuit can be thought of in the same way.

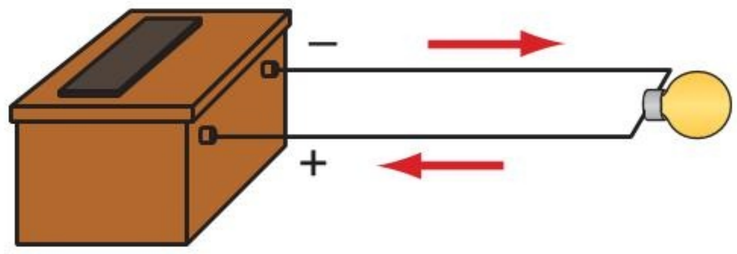
Conventional and Electron Theories

Current through a circuit can be explained by two different theories. The ***conventional current theory*** says that electrons flow through a circuit from positive (+) to negative (–). Electrons leave the positive terminal of the battery, flow through the circuit, and then reenter the battery through the negative terminal.

According to the ***electron flow theory***, electrons leave the negative (–) terminal of the battery, flow through the circuit, and then reenter the positive (+) terminal. The electron flow theory is just the opposite of the conventional current theory. Actually, the electron flow theory is the most accurate. Electrons are naturally attracted to the positive terminal. However, it is more convenient to use the conventional current theory in automotive work. Therefore, conventional current theory is used in all chapters that describe current, except for Chapter 19, which discusses semiconductor components. These components are best described using electron flow theory. See **Figure 17-16**.



Conventional Current Theory
(Positive to Negative)



Electron Flow Theory
(Negative to Positive)

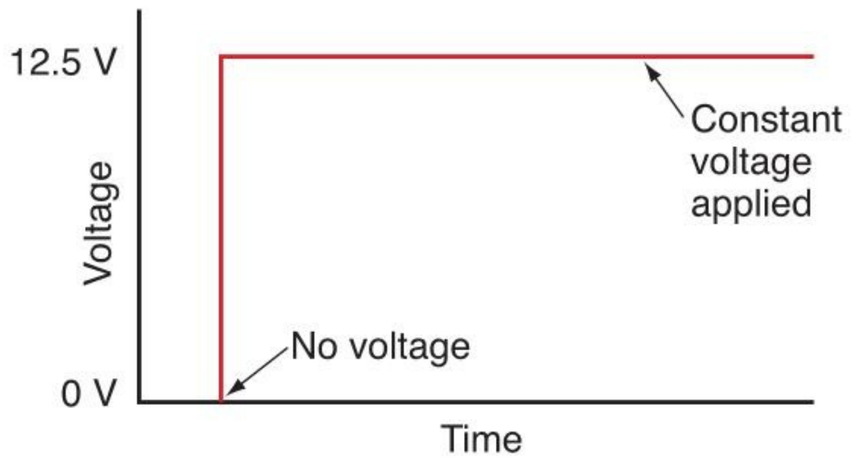
Goodheart-Willcox Publisher

Figure 17-16. In conventional current theory, electrons flow from positive to negative. In electron flow theory, electrons flow from negative to positive.

Direct and Alternating Current

Direct current (dc) is electron flow in one direction only. Most automotive circuits operate on direct current. Current flows through a circuit from positive to negative. See **Figure 17-17**.

Alternating current (ac) is electron flow in alternating directions. This means that electrons flow in one direction, reverse, and then flow in the opposite direction. The polarity (positive or negative state) of ac cycles back and forth in the circuit. Most automotive circuits do not use ac. However, as you will learn in later chapters, a charging system alternator produces an internal ac that is rectified (changed back into dc) before leaving the alternator. Some computer system sensors also produce an ac output.



DC Current

Goodheart-Willcox Publisher

Figure 17-17. Direct current moves in one direction only. This graph shows how dc voltage and direction remain the same over time.

The curves in **Figure 17-18** illustrate how voltage in an ac circuit changes over time. The voltage begins at zero, and then increases to the first peak. The voltage then decreases, returning to zero and continuing to decrease to the negative peak. The voltage then increases back to zero, and the process repeats. Together, one complete positive curve and one complete negative curve form one ***cycle***.

The curve that represents alternating current in a basic circuit is a ***sine wave***. Note that the amplitude (height) and frequency of the wave are constant. ***Frequency*** is the number of cycles per second, or ***Hertz (Hz)***.

Alternating Current

Goodheart-Willcox Publisher

Figure 17-18. Alternating current reverses direction so quickly that the effect is not visible to the human eye.

In your home wiring, 120 volts ac cycles at 60 Hz. This is so fast that it cannot be seen with the human eye. A lightbulb appears to be glowing constantly when it is actually turning on and off at 60 Hz, or 60 times per second. Some home appliances (furnace, air conditioner, air compressor) require 240 volts ac. A hybrid electric drive train operates on up to approximately 600 volts ac.

Green Tech

Energy Efficiency

Automotive shops use large amounts of energy in various ways. One of the ways automotive shops can be more environmentally friendly is to conserve energy. Using appliances that have the Energy Star label is one way to help be more energy efficient. Another way to conserve energy is to install lights that are either set on timers or that use motion-activated sensors. This way, lights are only on when needed. Using programmable thermostats and clean air filters in your ventilation systems will help conserve energy.

Summary

- An atom is made up of electrons, protons, and neutrons. The negatively charged electrons circle around the nucleus of the atom.
- The atoms of some elements have a few electrons that are only loosely held to the atom. These electrons can be made to move from atom to atom, producing electricity.
- A conductor is an element that allows electron flow.
- An insulator does not have free electrons. The electrons are locked in their orbits, and this resists electron flow.
- A permanent magnet has an invisible magnetic field around it. This field acts on ferrous objects.
- Unlike charges attract each other, and like charges repel each other. This principle is used to produce current, motion, and other functions.
- An electromagnet can be made by wrapping wire around an iron core. Electricity in the wire produces a magnetic field.
- Electricity can be induced in a wire by passing the wire through a magnetic field.
- A simple electric circuit consists of a power supply (battery), conductor (wires), and load (power-using device).
- Voltage is the pressure that moves free electrons through a conductor.
- Current is the rate of electron flow.
- Resistance is the opposition to current and is used to limit current.
- Direct current moves in one direction only. Automobile electrical systems primarily operate on direct current.
- Alternating current moves one way and then the other. In automobiles, ac is found inside the alternator and in the wiring to some sensors.

Activities

1. Using sketches and principles you have learned about basic electricity, prepare a presentation showing how electricity can be created through magnetism.
2. Create an electromagnet using fine wire, an iron nail, and a 9-volt battery. After creating the magnet, use it to pick up small objects, such as paper clips.
3. Research Ohm's law on the Internet. In a classroom presentation, explain the relationship between voltage, current, and resistance.

Review Questions

Answer the following questions using the information provided in this chapter.

1. The three basic parts of an atom are _____, _____, and _____.
2. What is a free electron?
3. What causes an electron to jump from atom to atom, in relation to electricity?
4. A substance that allows the flow of free electrons is a(n) _____.
5. A(n) _____ is a substance that inhibits or stops the flow of free electrons.
6. When free electrons flow through a conductor with high resistance, _____ is produced.
7. What is magnetism?
8. When a piece of iron is magnetized, the molecules in the iron _____ to produce north and south poles.
9. An invisible _____ exists between the poles of a magnet.
10. What happens if you place two like charges near each other?
11. _____ is the branch of physics that deals with the interaction of electricity and magnetism.
12. How can you create a simple electromagnet?
13. What is induction?
14. List the parts of a basic electric circuit and describe their functions.
15. What is voltage?
16. The rate of electron flow in a circuit is called current, or _____, and it is measured in _____.
17. What is the function of resistance in an electric circuit?
18. What happens to current if voltage increases and resistance remains constant?
19. What happens to the voltage if current increases and the resistance remains constant?
20. According to conventional current theory, in which direction do electrons flow?
21. What is the difference between direct current and alternating current?

ASE-Type Questions

1. Technician A says electrons and protons form the nucleus of an atom. Technician B says electrons have a negative charge. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says electricity is the movement of free atoms from one place to another. Technician B says electricity is the movement of free elements from one place to another. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says silver is a good electrical conductor. Technician B says iron is a good electrical conductor. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. An atomic force that can attract or repel ferrous substances is known as:
   (A) magnetism.
   (B) electricity.
   (C) current.
   (D) voltage.
5. Technician A says an insulator is a substance that resists the flow of electricity. Technician B says the atoms in an insulator are very stable and resist electron movement. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says a load is a basic component of an electric circuit. Technician B says a power supply is a basic component of an electric circuit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. The electrical pressure that causes current is known as:
   (A) voltage.
   (B) amps.
   (C) resistance.
   (D) magnetism.
8. Technician A says that as voltage increases and resistance remains constant, current increases. Technician B says that as voltage decreases and resistance remains constant, the number of free electrons flowing through a circuit decreases. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says the electron flow theory states that electrons flow through a circuit from positive to negative. Technician B says the conventional current theory states that electrons flow through a circuit from negative to positive. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says dc circuits are not normally used in automotive circuits. Technician B says certain automotive computer sensors use ac. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Chapter 18
Circuit Types and Ohm's Law

After studying this chapter, you will be able to:

- Compare the operating characteristics of series, parallel, and series-parallel circuits.
- Explain the operation of a frame-ground circuit.
- Recall the three Ohm's law formulas that express the relationships among voltage, current, and resistance.
- Explain how changes in voltage and resistance affect current.
- Use Ohm's law and circuit-type formulas to calculate unknown circuit values.
- Use the formula for calculating electric power or wattage.
- Interpret electrical prefixes.

This chapter details the arrangement and action of basic electric circuits. Even very complex circuits consist of many basic circuits wired together. The first part of this chapter explains the basic circuit types and how they function. The last part of the chapter discusses Ohm's law, which governs the relationships between current, voltage, and resistance in electric circuits.

Circuit Types

A ***circuit*** is a closed electrical path for current. The three main types of circuits are series, parallel, and series-parallel circuits. In automotive systems, a combination of these circuit types is used to produce complex networks. However, if you understand the basic circuit types, you can troubleshoot any circuit by breaking it down into its basic circuit components.

Series Circuit

A ***series circuit*** has only one path for current. One or more electric loads are wired into this single path. See **Figure 18-1**.

Figure 18-2 shows the basic action of a series circuit. If a switch is connected in series with three lightbulbs, it controls all three bulbs. When the switch is closed (connected), the circuit is complete and the bulbs glow. If the switch is open (disconnected), none of the bulbs glow. If one of the bulbs burns out in a string of lights wired in series, all of the other lights go out. The broken filament in the burned-out bulb acts as an open switch to stop current flow. See **Figure 18-3**.

Goodheart-Willcox Publisher

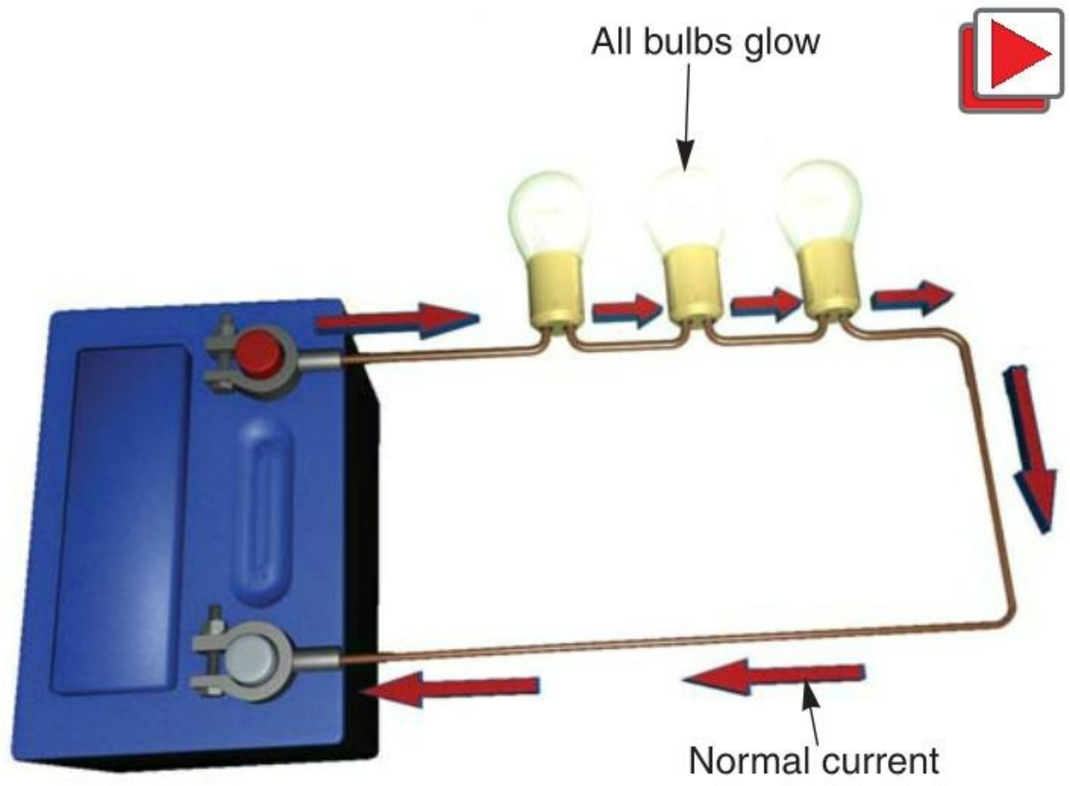
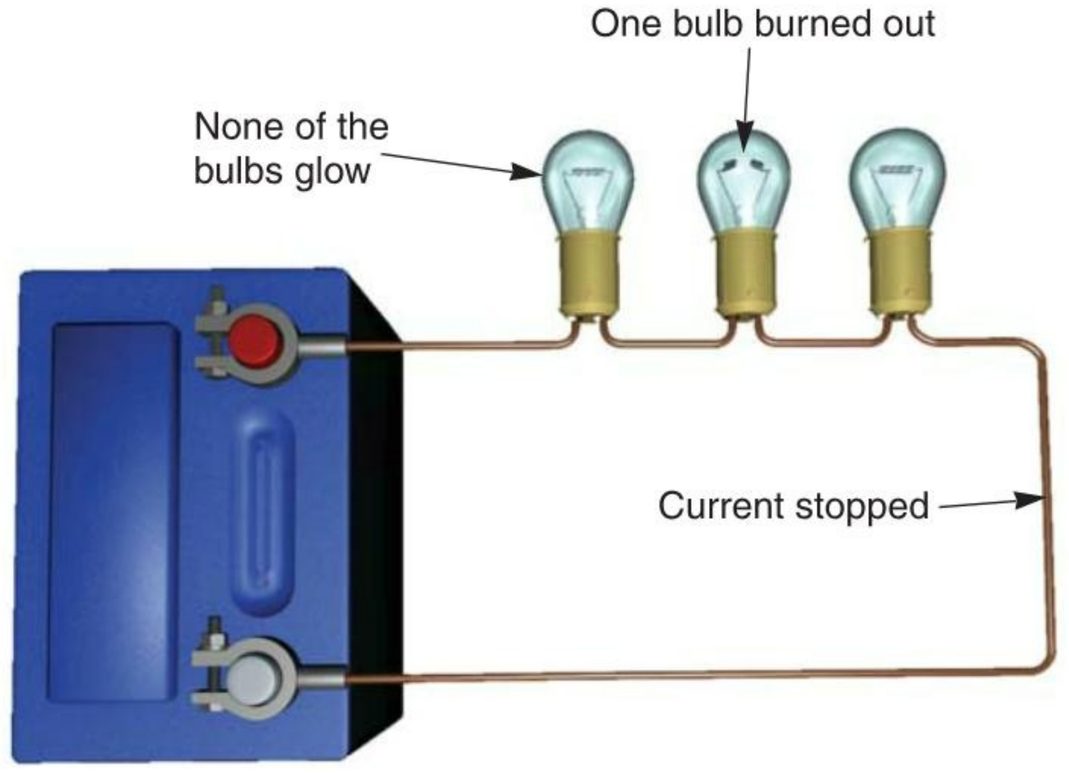
Figure 18-2. In this circuit, a switch is wired in series with three lightbulbs. When the switch is closed, all three bulbs glow. When the switch is open, it blocks current to all the bulbs.





Goodheart-Willcox Publisher

Figure 18-3. If one bulb burns out in a string of lights wired in series, all of the bulbs go out.

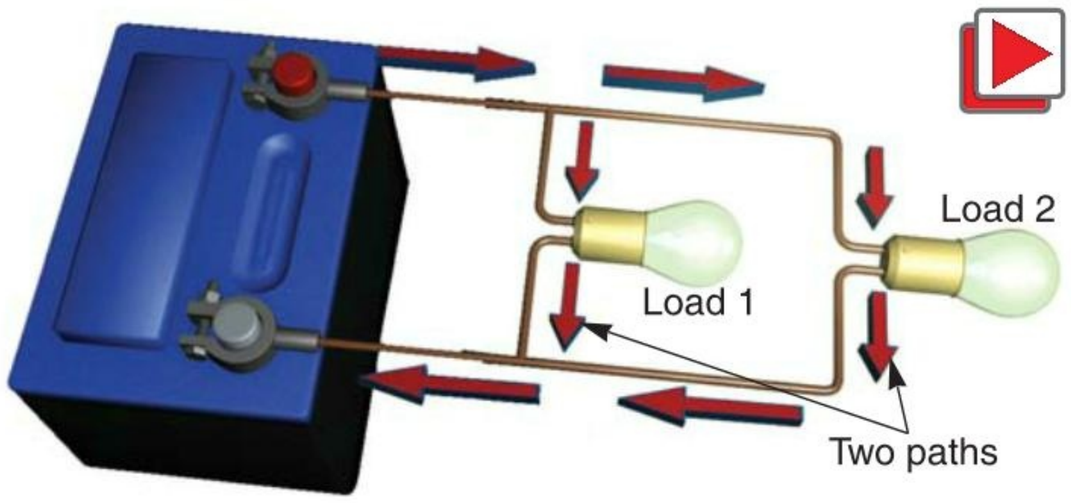
Parallel Circuit

A ***parallel circuit*** has more than one path for current, as shown in **Figure 18-4**. Two or more loads are placed on separate paths in the circuit. **Figure 18-5** shows the basic operation of a parallel circuit. Because the bulbs are wired in parallel, they can function independently. In a string of lights wired in parallel, one burned-out light does not affect the operation of the other bulbs in the parallel circuit. See **Figure 18-6**.

Series-Parallel Circuit

A ***series-parallel circuit*** is a combination of a series circuit and a parallel circuit. Some of the components are wired in series, and others are wired in parallel. See **Figure 18-7**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

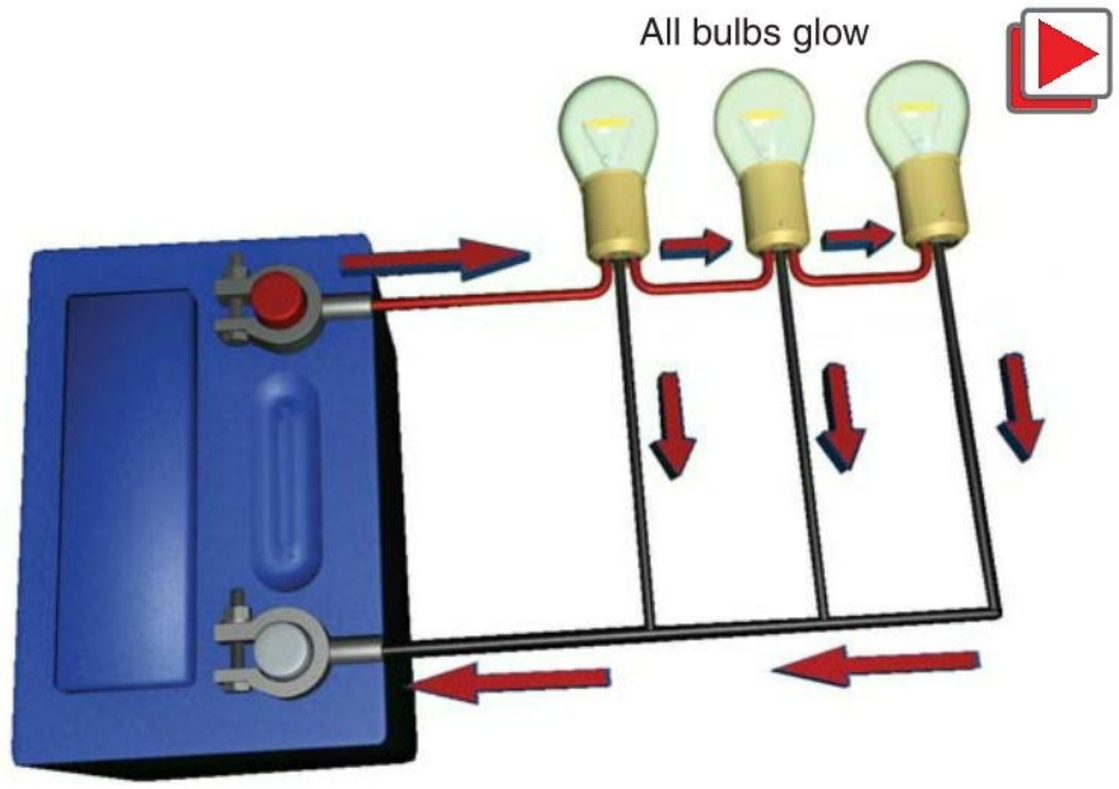
Figure 18-4. A parallel circuit has more than one path for current. In this example, two bulbs are wired in parallel. Each parallel branch operates independent of the others.

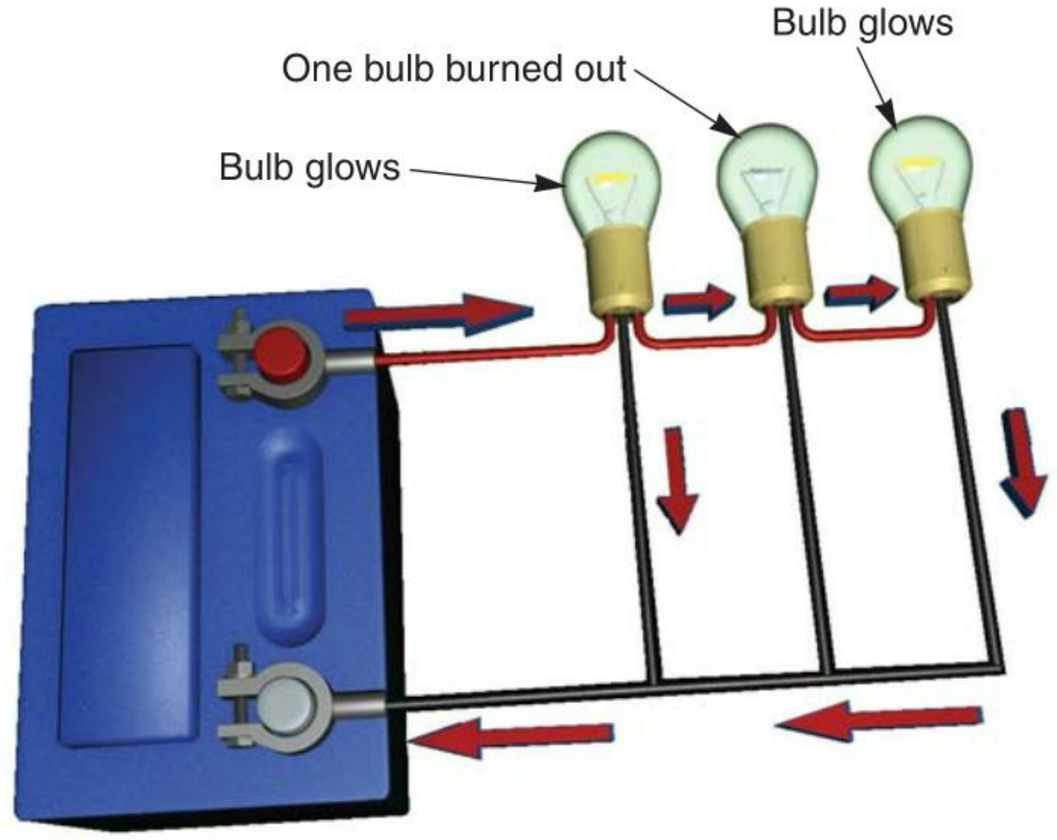
Frame-Ground Circuit

A ***frame-ground circuit***, also called a ***one-wire circuit***, uses the metal structure of the vehicle to return electricity to the power source. This eliminates the need to run yards of wire from the electric components back to the power source. Ground wires can be attached directly to the metal vehicle frame or body structure, which serves as a return path to the power source. The negative battery cable is also attached to the vehicle's frame or body. This allows the metal structure of the vehicle to serve as a large conductor, **Figure 18-8**.

Tech Tip

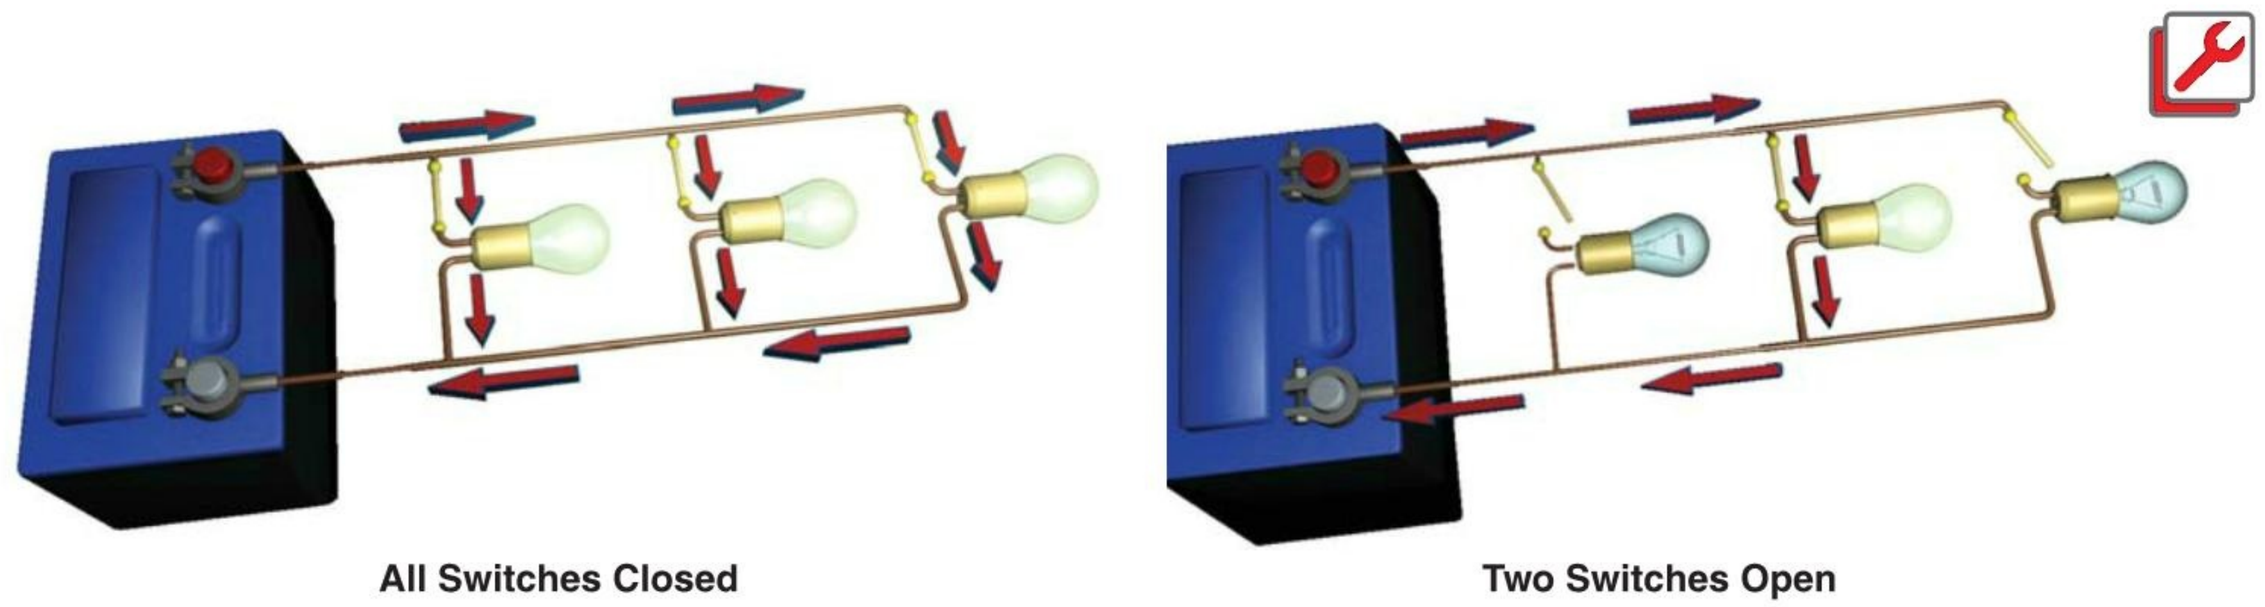
The following description of a frame-ground circuit is based on conventional current theory, which states that electrons flow from the positive terminal of a power source to the negative terminal.





Goodheart-Willcox Publisher

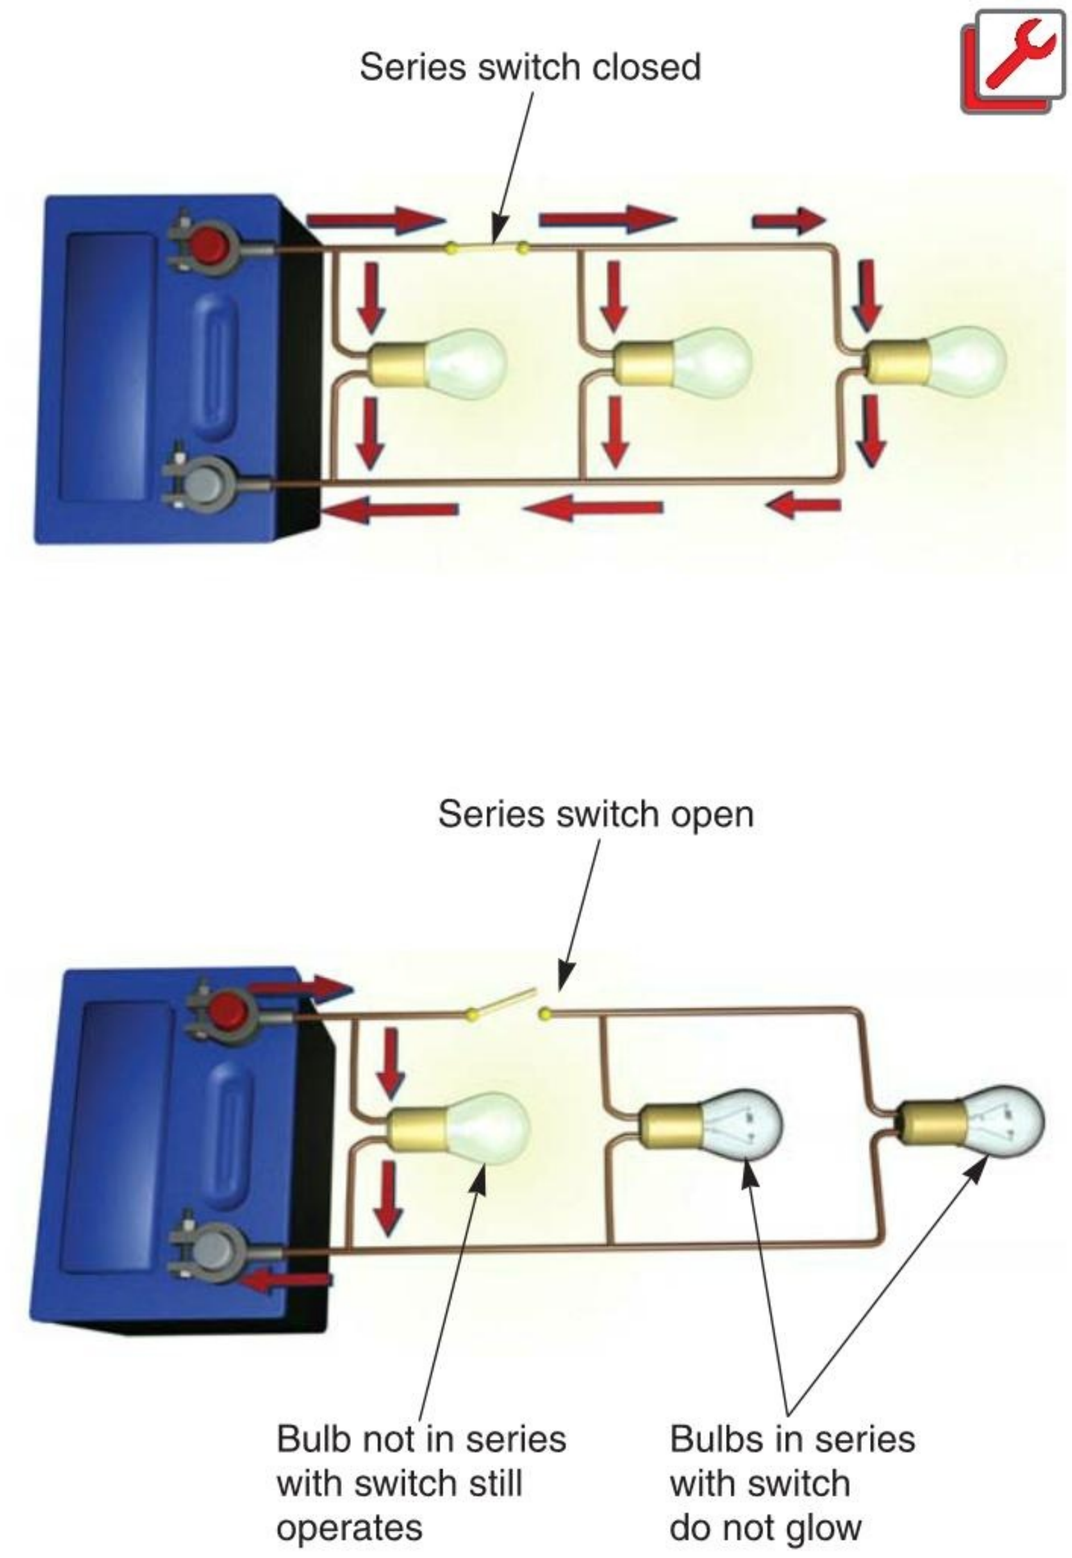
Figure 18-6. A string of lights wired in parallel can function even though some of the bulbs burn out.



Goodheart-Willcox Publisher

Figure 18-5. In these circuits, three sets of switches and bulbs are wired in parallel. When all switches are closed, all the bulbs glow. With two switches open, the lights in those branches of the circuit do not glow. However, the third bulb glows because it is wired in parallel with the other bulbs and its switch is closed.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

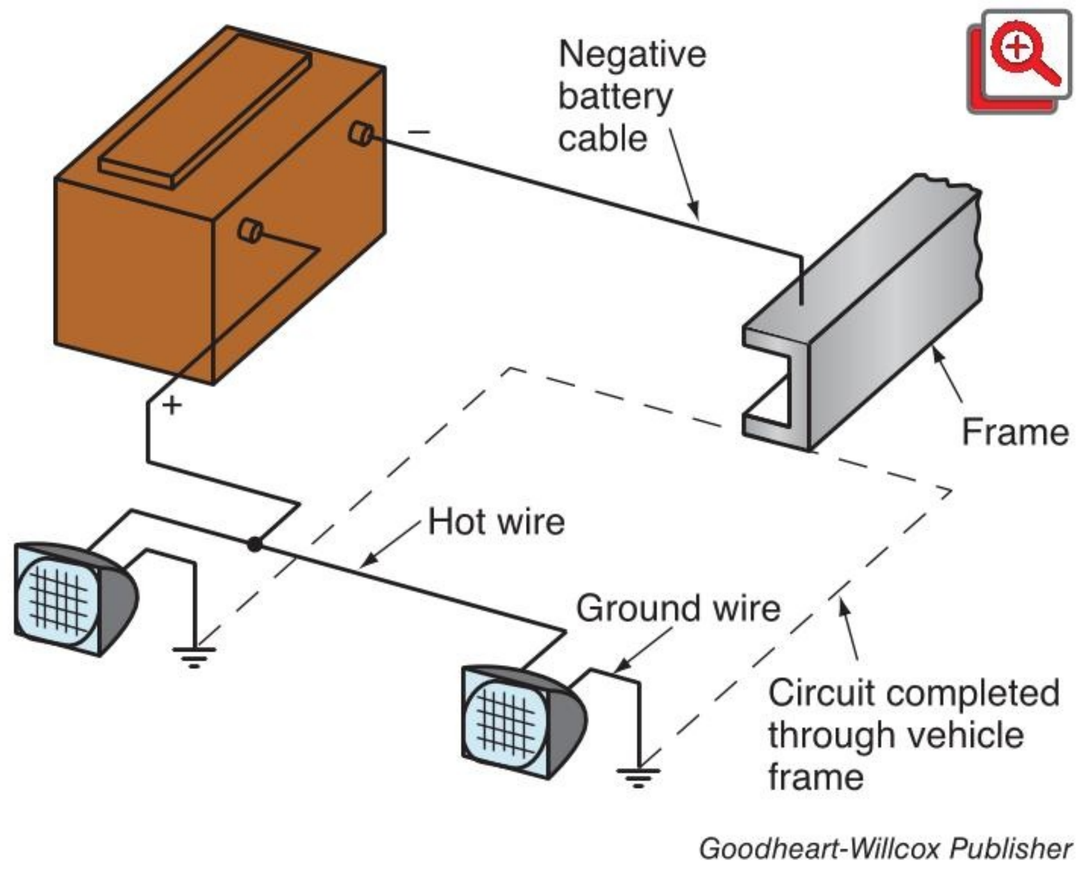
Figure 18-7. A series-parallel circuit is a combination series circuit and parallel circuit. In this example, three bulbs are wired in parallel. A switch is wired in series with two of the bulbs. When the switch is closed, all of the bulbs receive current. When the switch is open, current is blocked to two of the bulbs.

Electrons flow from the positive terminal of the battery to the load, through the frame, and back into the negative terminal of the battery to complete the circuit.

The wire that carries current to the load is the ***hot wire***. It is the section of the circuit between the positive terminal of the battery and the load. The ***ground*** is the part of the circuit between the load and the negative terminal of the battery. See **Figure 18-9**.

Ohm's Law

Ohm's law is a set of formulas that expresses the relationships between voltage, current, and resistance in an electric circuit. You must understand Ohm's law and electrical measurements to fully grasp electrical troubleshooting methods.



Goodheart-Willcox Publisher

Figure 18-8. Note how auto manufacturers use the frame or unibody structure of a vehicle to complete an electric circuit. The battery is connected to the frame of the vehicle. The ground side of the electric component is also connected to the frame. This allows the current to flow through the metal parts of the vehicle and back to the battery.

Ohm's law can be stated as three different formulas. See **Figure 18-10**. As these formulas show, voltage, current, and resistance interact to affect the operation of a circuit. If you know any two of the three electrical values in a circuit, you can calculate the third value using one of these formulas. In the formulas, *E* stands for voltage, *I* stands for current, and *R* stands for resistance.

- $E = I \times R$

  Voltage equals current multiplied by resistance

  volts = amps × ohms
- $I = E \div R$

  Current equals voltage divided by resistance

  amps = volts ÷ ohms
- $R = E \div I$

  Resistance equals voltage divided by current

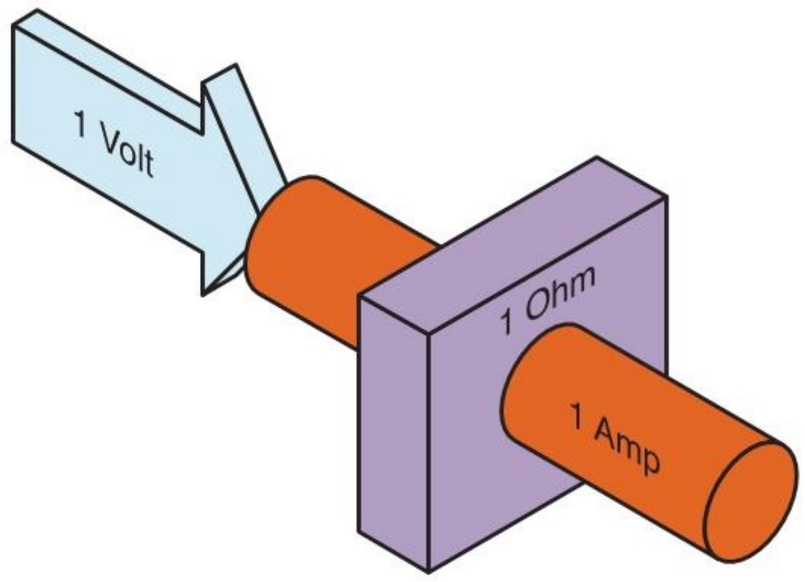
  ohms = volts ÷ amps

As shown in **Figure 18-11**, 1 volt is needed to push 1 amp of current through 1 ohm of resistance. Remember that voltage pushes current through a resistance. If any one value changes, it affects the others.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 18-9. Hot and ground wires in typical automotive circuits. A—The hot wire carries current to the horn. B—The large ground wire is bolted to the body structure to serve as a ground conductor going back to the battery.



Goodheart-Willcox Publisher

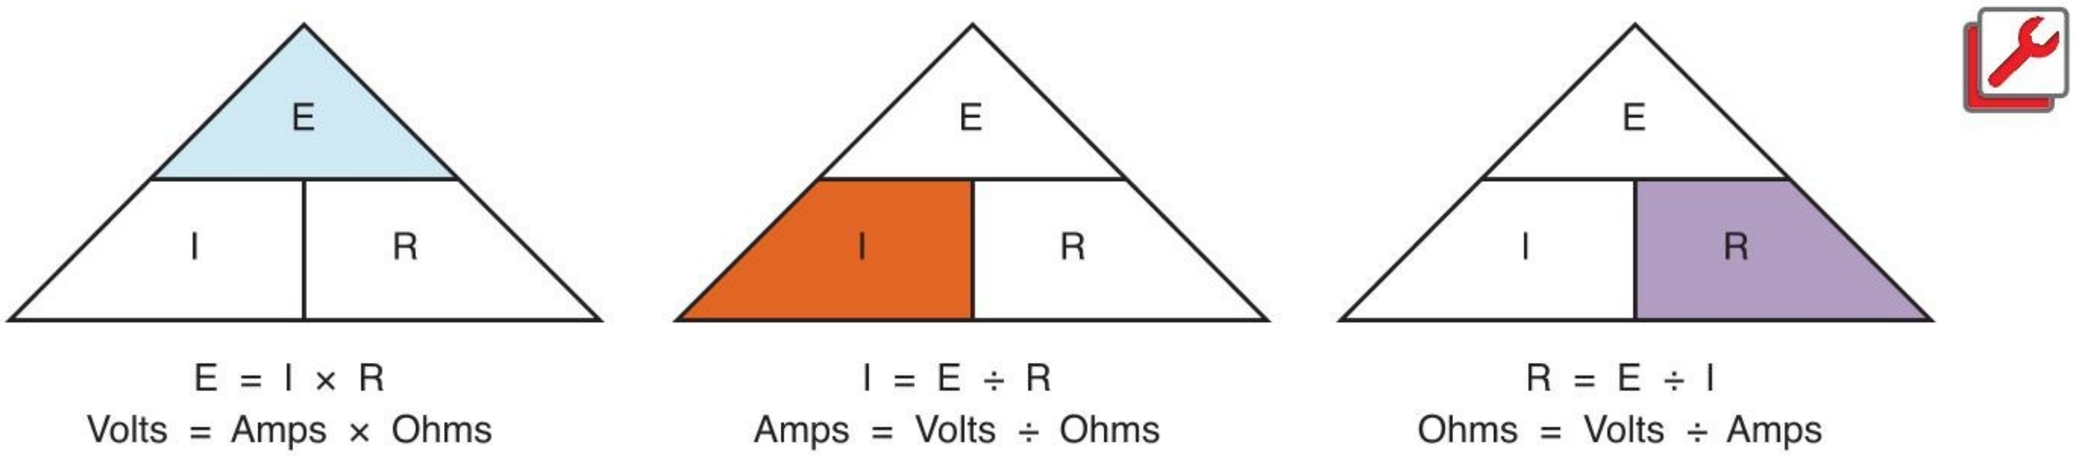
Figure 18-11. It takes 1 volt to push 1 amp through 1 ohm of resistance. This relationship allows you to use math to calculate the unknown value when you know the other two values.

Change in Resistance

A change in resistance alters the amount of current in a circuit. If resistance is low, current will be high. If resistance is high, current will be low.

For example, if a circuit has 12 volts (12 V) and a resistance of 3 ohms (3 Ω), you can use Ohm's law to calculate a current of 4 amps (4 A). However, if resistance increases to 12 ohms because of a bad connection, current drops to only 1 amp. See **Figure 18-12**.

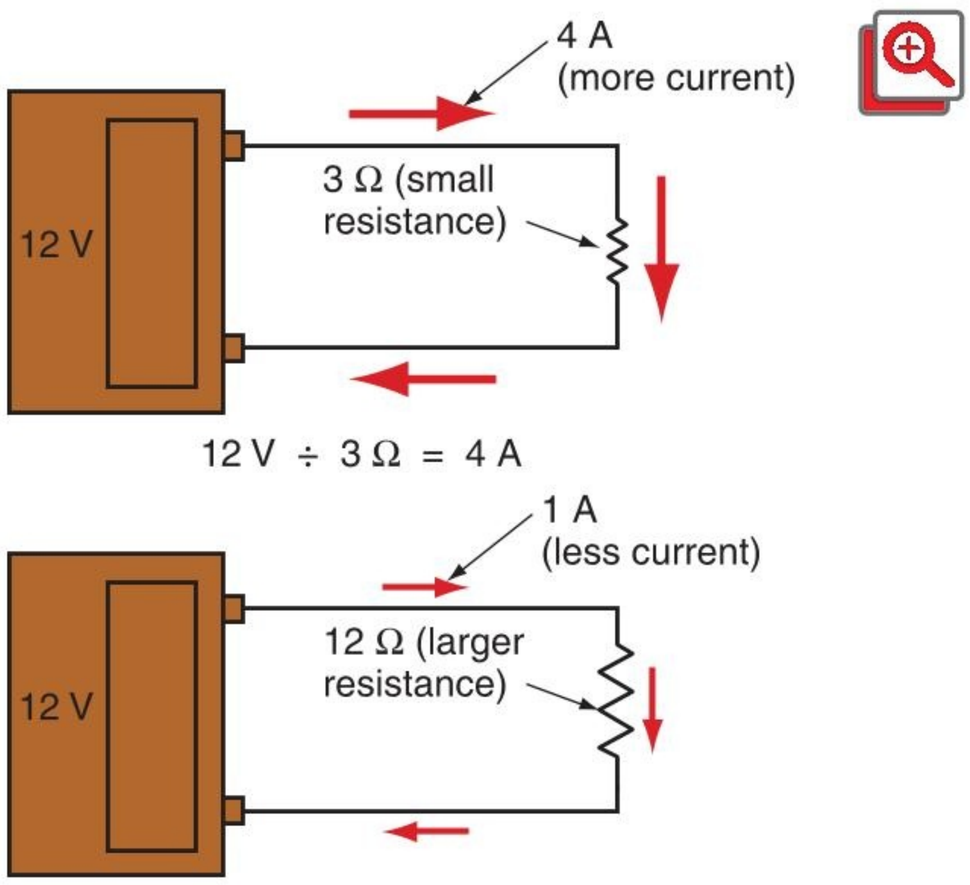
Most automotive electrical problems are caused by a change in circuit resistance. A poor electrical connection (increased resistance), for example, reduces current in the circuit. This might cause a lightbulb to burn dimly or upset a signal from a computer system sensor.



Goodheart-Willcox Publisher

Figure 18-10. These triangular diagrams may help you remember the formulas of Ohm's law. The horizontal bar in the center of the triangle stands for division. The vertical bar stands for multiplication. *I* (current) and *R* (resistance) are on opposite sides of the vertical bar, so they must be multiplied to find *E* (voltage). *E* is over *R*, so *E* is divided by *R* to find *I*. *E* is also over *I*, so *E* is divided by *I* to find *R*.

Copyright Goodheart-Willcox Co., Inc.

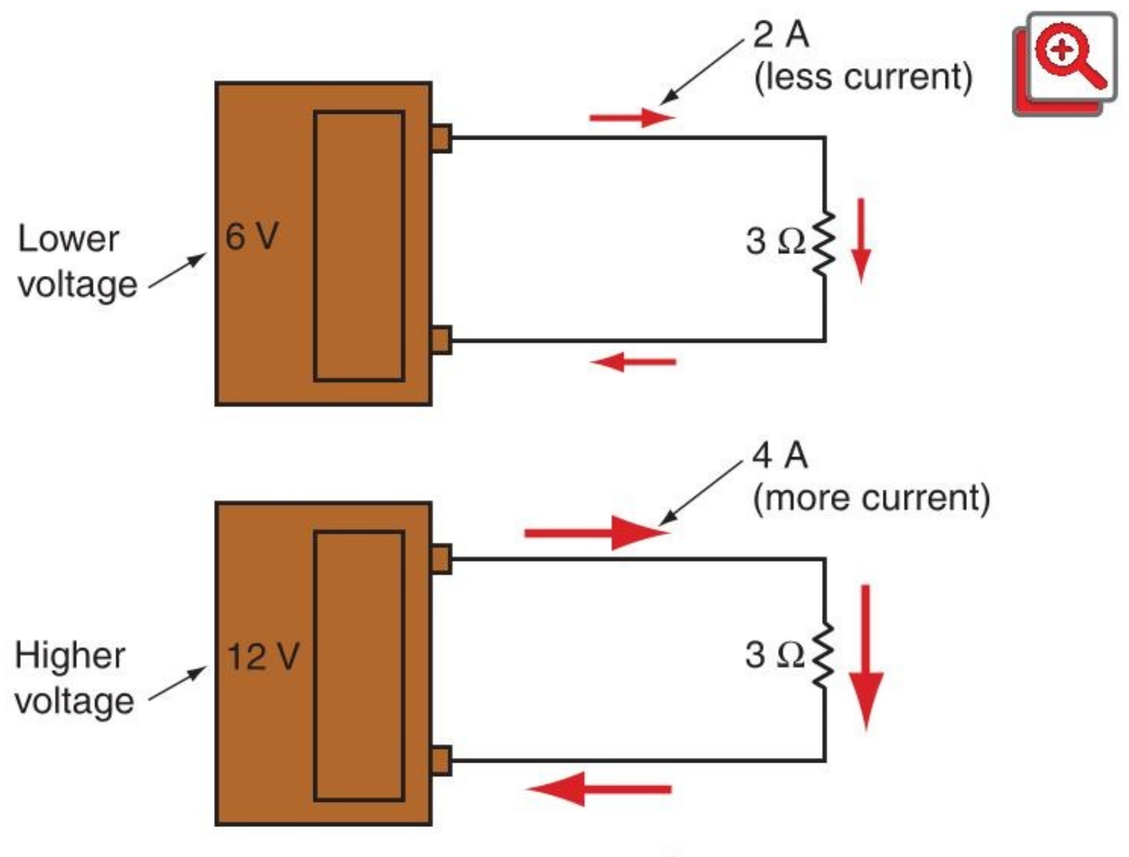


Goodheart-Willcox Publisher

Figure 18-12. If voltage remains constant, a circuit with high resistance has less current than a circuit with low resistance because more free electrons can flow through the smaller resistance.

Change in Voltage

A change in voltage also affects the amount of current in a circuit. A rise in voltage increases current, and a drop in voltage decreases current. Again, you can use Ohm's law to demonstrate this principle. See **Figure 18-13**.

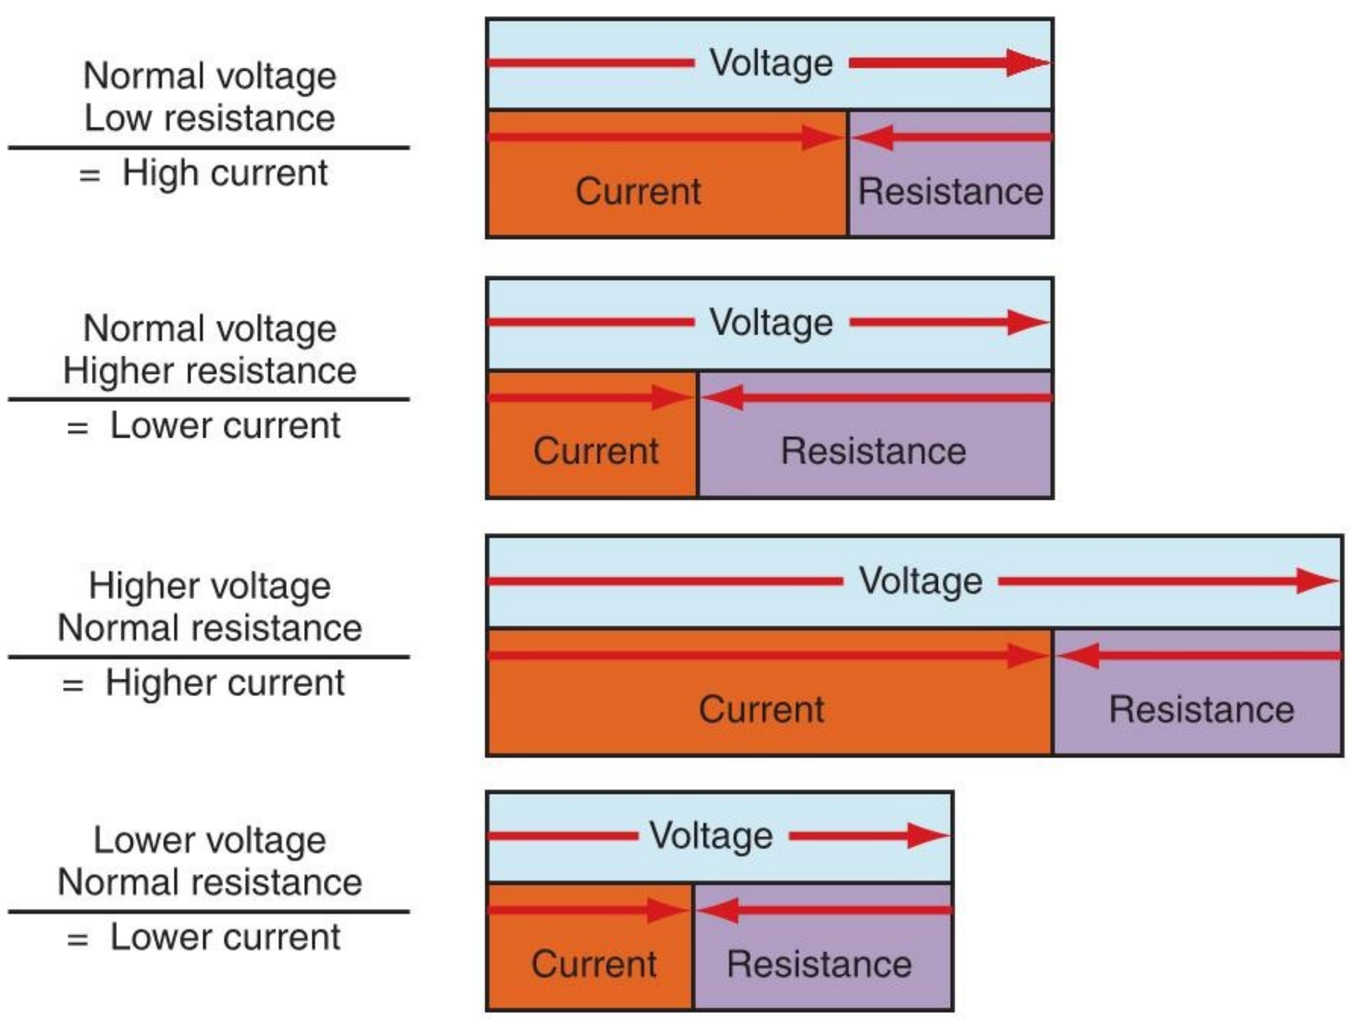


Goodheart-Willcox Publisher

Figure 18-13. In these circuits, different voltages are connected to the same resistance. Note that higher voltage produces higher current.

Change in Current

Any change in a circuit's current is a result of increased or decreased voltage or resistance. Current in a circuit depends on these two factors. Without sufficient current in a circuit, the load will not function properly. An electric motor might run too slowly or a bulb might burn dimly. With too much current in a circuit, components or wires may overheat or burn. **Figure 18-14** summarizes the effect of voltage and resistance on current.



Goodheart-Willcox Publisher

Circuit Calculations

Ohm's law applies to the total current, voltage, and resistance in electric circuits. To find these total values, however, you will need to apply formulas specific to the circuit types.

Series Circuit Calculations

Three general rules apply to a series circuit:

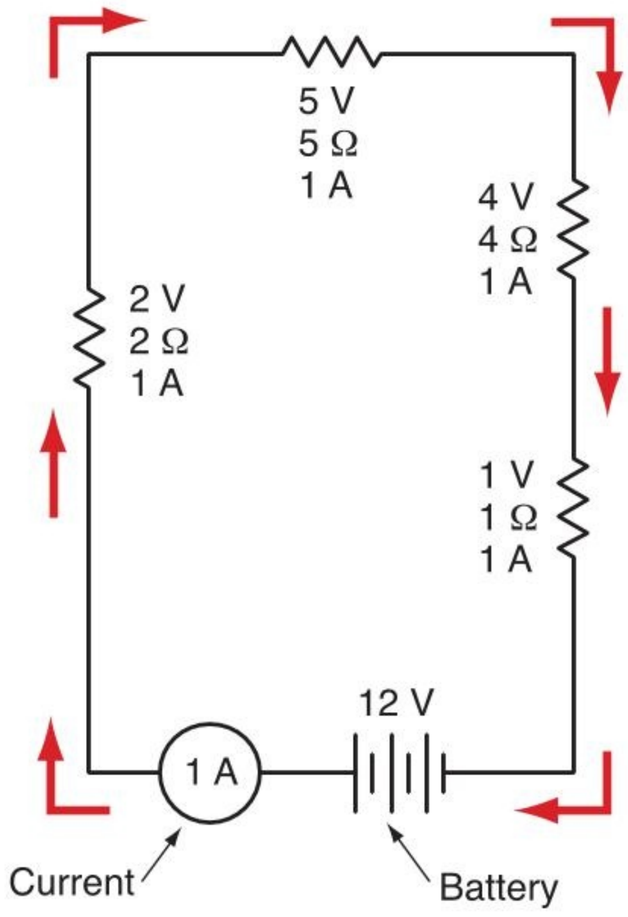
- Current is the same everywhere in a series circuit. No matter where you connect an ammeter in a series circuit, the reading will be the same.
- Total resistance (R_t) is the sum of all of the resistances in the circuit. The formula for total resistance in a series circuit is:

  $R_t = R_1 + R_2 + R_3 + \ldots + R_n$

  (In this formula, *n* equals the total number of resistances in the circuit.)
- The voltage drop across each resistance equals the voltage applied. The voltage used by all resistance elements equals the total voltage, or supply voltage (E_t).

To get the total resistance for the circuit, you add the two resistances. You can then use the total resistance with Ohm's law to find current. See **Figure 18-15**.

You can add the resistances to find that R_t equals 12 Ω. Divide volts by ohms to find the value of the current. In this case, the current equals 1 A (12 V ÷ 12 Ω). See **Figure 18-16**.



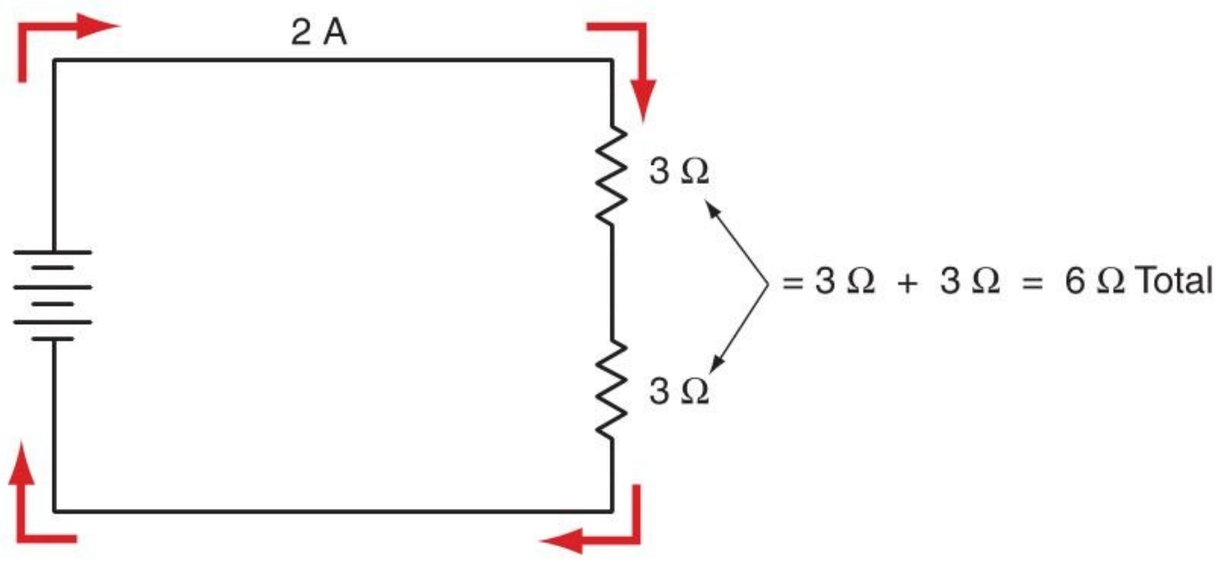
$E_t = 2\,V + 5\,V + 4\,V + 1\,V = 12\,V$

$R_t = 2\,\Omega + 5\,\Omega + 4\,\Omega + 1\,\Omega = 12\,\Omega$

$I_t = \frac{12\,V}{12\,\Omega} = 1\,A$

Goodheart-Willcox Publisher

Figure 18-16. Use Ohm's law to check resistance and current in this series circuit. Add all resistance values to get R_t. Then divide voltage by resistance to get current.



$I = \frac{E}{R} = \frac{12}{6} = 2\,A$

$R = \frac{E}{I} = \frac{12}{2} = 6\,\Omega$

$E = R \times I = 6 \times 2 = 12\,V$

Goodheart-Willcox Publisher

Figure 18-15. In a series circuit, add the individual resistance values to get total resistance. You can then use the total resistance to find the amount of current.

Copyright Goodheart-Willcox Co., Inc.

Parallel Circuit Calculations

Parallel circuits also have three basic rules:

- Total current (I_t) is the sum of all branch currents. In a circuit with three branches carrying 2 amps each, the total circuit current is 6 amps.
- Total circuit resistance is less than the resistance in any one branch. If each of two branches has a resistance of 4 Ω, the total resistance for the circuit is 2 Ω.
- The total voltage equals the supply voltage, and the voltage is the same throughout the circuit. If branches are parallel, they receive the same supply voltage.

Figure 18-17 illustrates how resistance controls current in a parallel circuit. Note that the current is lowest in the branch with the highest resistance and that current is highest in the branch with the lowest resistance. This figure also demonstrates the basic rule that current follows the path of least resistance.

Several methods can be used to calculate resistance in a parallel circuit, depending on the number of branches and the values of the resistances. The ***reciprocal method*** works on all parallel circuits. In general, the ***reciprocal*** of a number equals 1 divided by that number. In the reciprocal method of calculating resistance, the reciprocal of the total resistance equals the sum of the reciprocals of all of the branch resistances:

$$\frac{1}{R_t} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \ldots + \frac{1}{R_n}$$

In this formula, *n* equals the total number of resistance elements in the circuit. **Figure 18-18** shows how to use the reciprocal method to calculate total resistance in a parallel circuit that has four branches with different resistance values. After you have calculated the total resistance, you can use the voltage and resistance values to find total current.

Series-Parallel Circuit Calculations

In a series-parallel circuit, you can find the total resistance of the circuit by calculating the resistance of each parallel section and then adding the series resistances to these values to obtain a single ***equivalent resistance***. **Figure 18-19** shows how to calculate an equivalent resistance. First, use the reciprocal method to find the total resistance of the parallel portion of the circuit. This reduces the circuit to the equivalent of a series circuit. Then add the total resistance of the parallel portion to the total series resistance to find the equivalent resistance.

When working with more complex series-parallel circuits, start by working with the parallel sections of the circuit to arrive at *R* for each section. Then add any series resistance to these values to find the total resistance. See **Figure 18-20**.

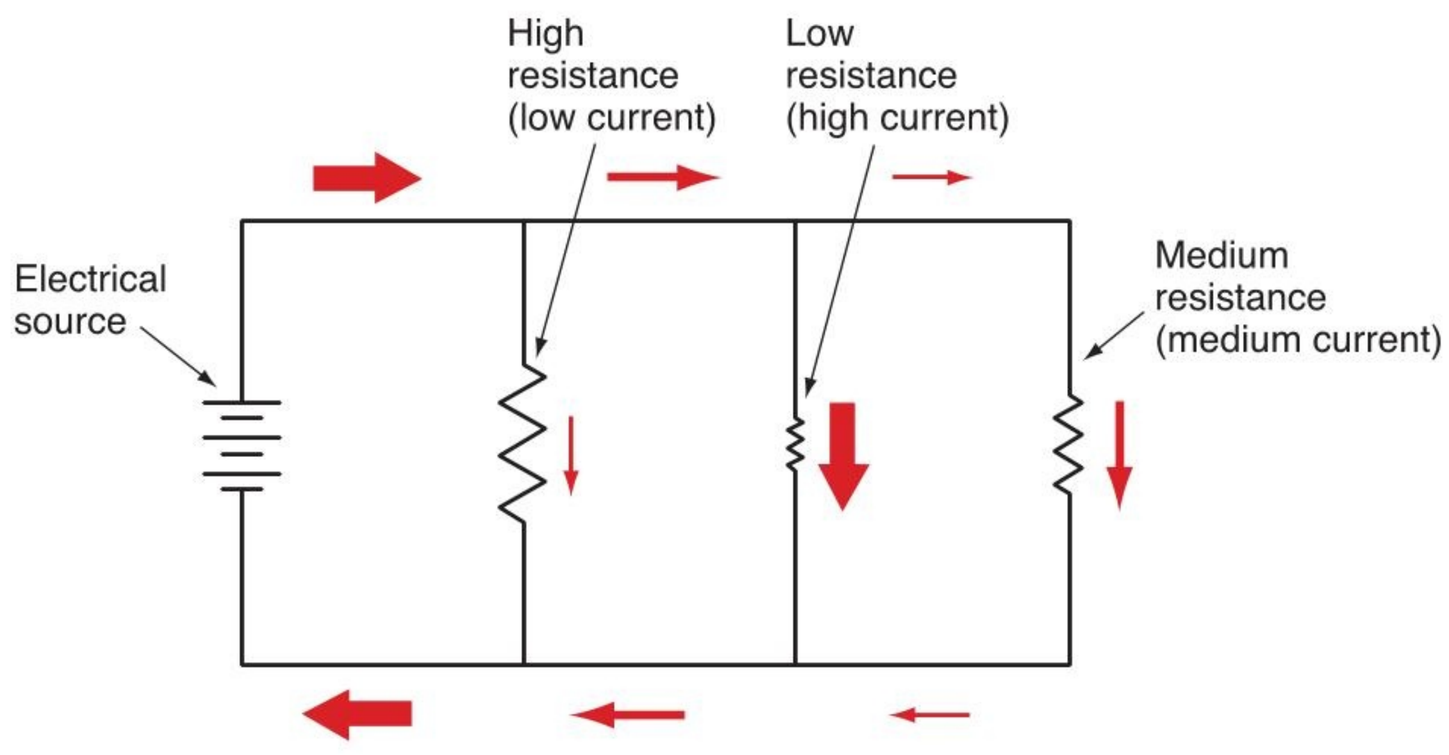
Electric Power Calculations

Electric power is the work done by an electric current. Its unit of measurement is the ***watt***. You can calculate electric power if you know the current and either the voltage or the resistance for the circuit. The formulas for power (*P*) are:

$$P \text{ (in watts)} = E \times I$$

or

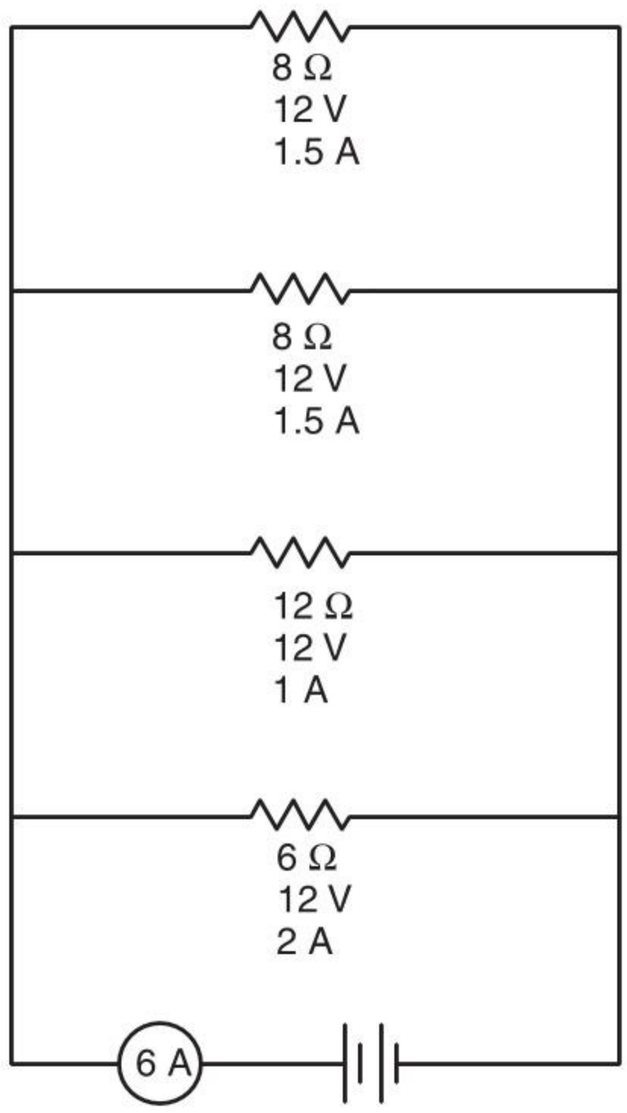
$$P = I^2 \times R$$



Goodheart-Willcox Publisher

Figure 18-17. Parallel circuit operation is more complex than series circuit operation. In this circuit, the parallel branches have different resistance values. There is less current in branches with high resistance than those with low resistance. Low resistance allows a greater amount of current.

Copyright Goodheart-Willcox Co., Inc.



Total Voltage = Supply Voltage = 12 V

Calculate Total Resistance

$$\frac{1}{R_t} = \frac{1}{8\ \Omega} + \frac{1}{8\ \Omega} + \frac{1}{12\ \Omega} + \frac{1}{6\ \Omega}$$

Convert to decimals and use a calculator:

$$\frac{1}{R_t} = 0.1250\ \Omega + 0.1250\ \Omega + 0.0833\ \Omega + 0.1667\ \Omega$$

$$\frac{1}{R_t} = 0.5000\ \Omega$$

$$\text{The reciprocal of } 0.5000 = \frac{1}{0.5000}$$

$$R_t = \frac{1}{0.5000} = 2\ \Omega$$

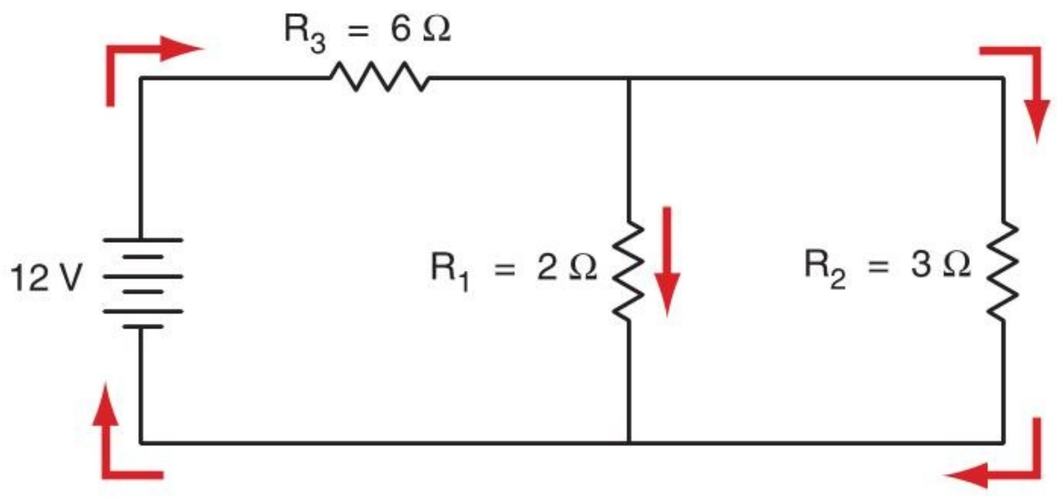
Calculate Total Current

$$I_t = 1.5\ A + 1.5\ A + 1\ A + 2\ A$$

$$I_t = 6\ A$$

Goodheart-Willcox Publisher

Figure 18-18. The reciprocal method can be used to calculate the total resistance in this parallel circuit. Notice that the total resistance is lower than the resistance in any one branch. Once total resistance is known, you can calculate total current.



Calculate Equivalent Resistance

Resistance in parallel part of circuit:

$$\frac{1}{R} = \frac{1}{2\ \Omega} + \frac{1}{3\ \Omega}$$

$$\frac{1}{R} = 0.50\ \Omega + 0.33\ \Omega$$

$$\frac{1}{R} = 0.83\ \Omega$$

$$R = \frac{1}{0.83\ \Omega}$$

$$R = 1.20\ \Omega$$

Resistance in series part of circuit:

$$R = 6\ \Omega$$

Equivalent Resistance (R_t)

$$R_t = R \text{ in parallel} + R \text{ in series}$$

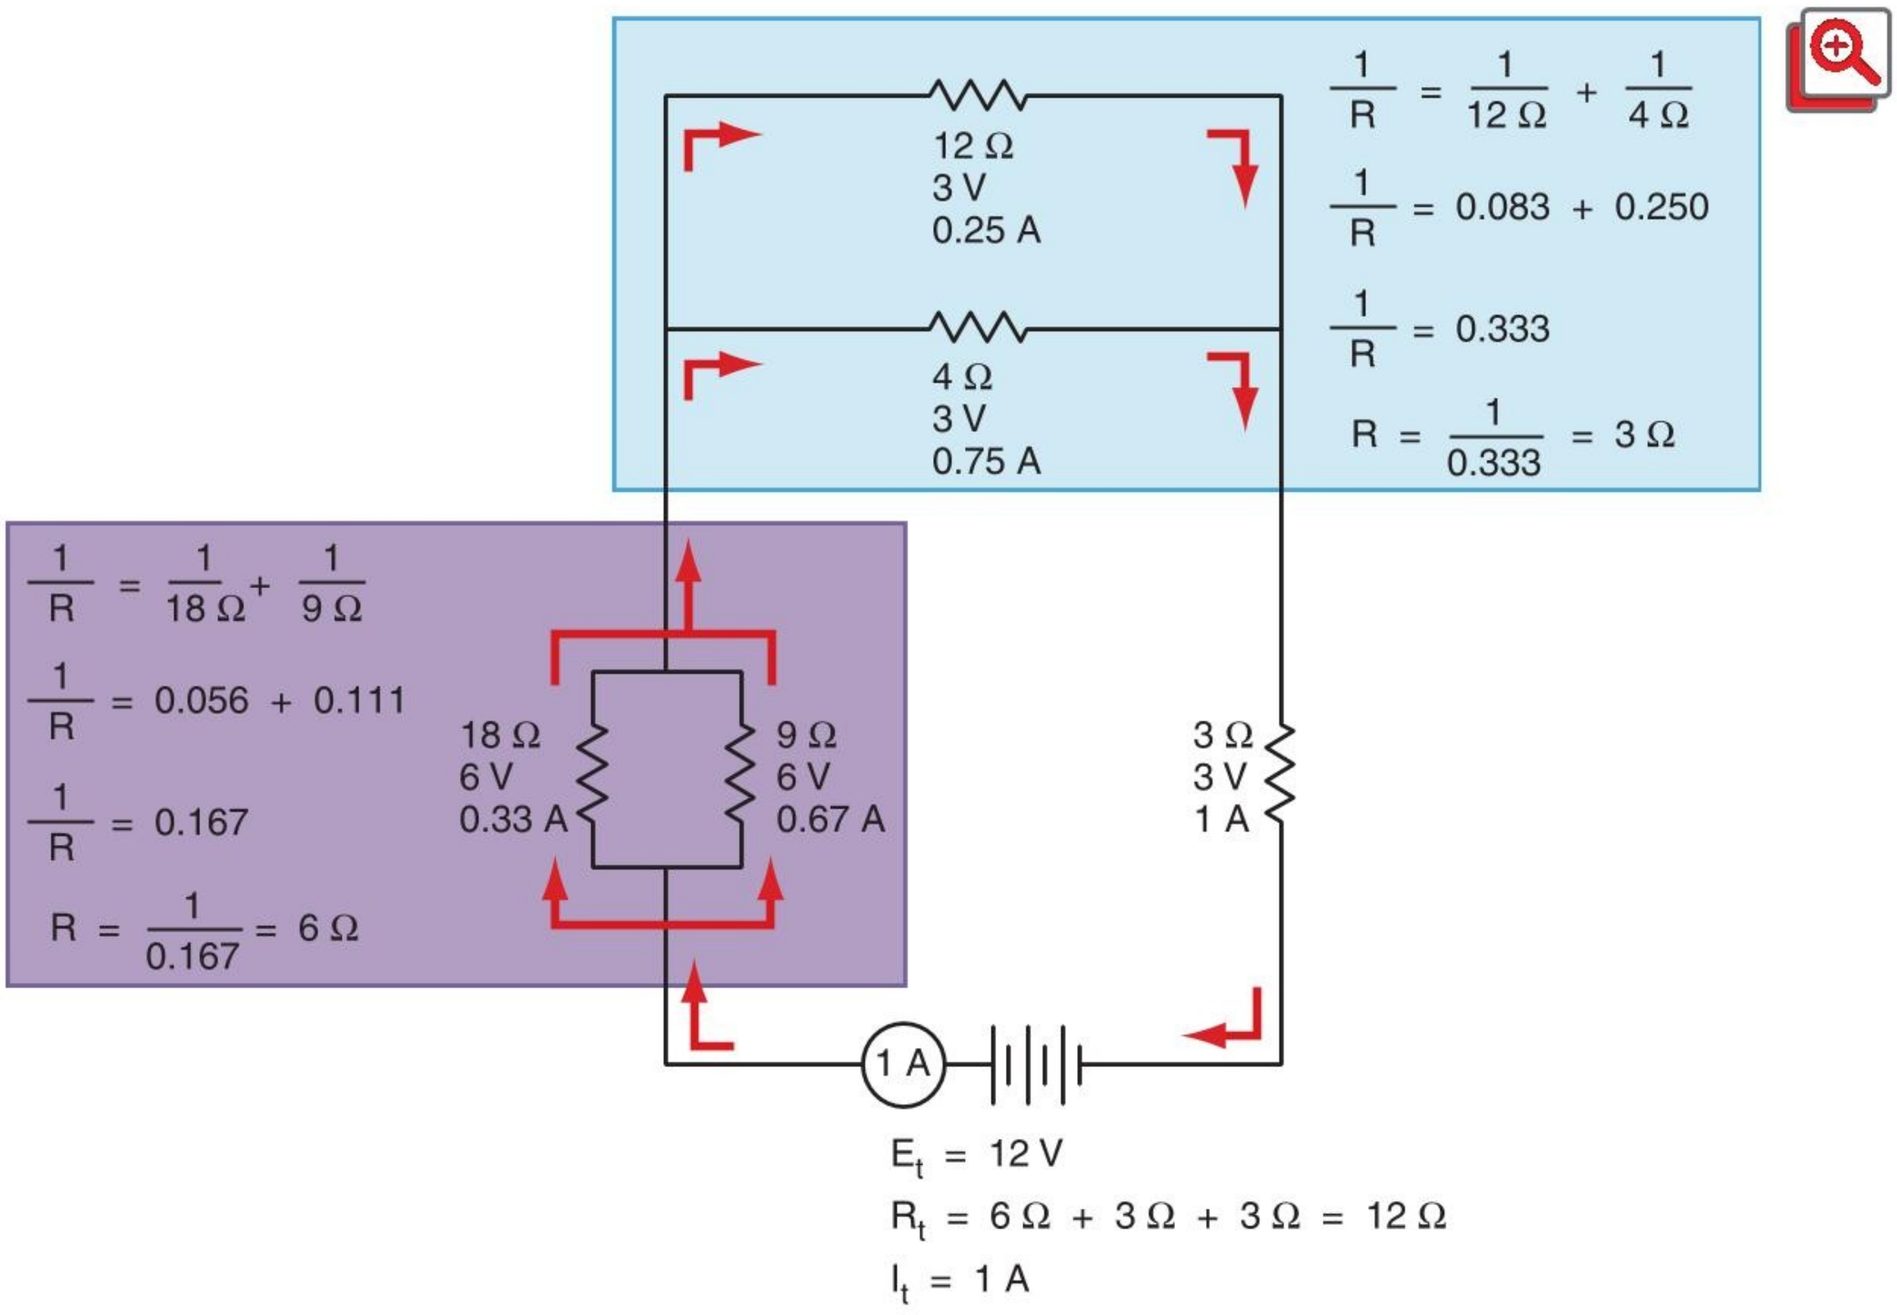
$$R_t = 1.20\ \Omega + 6\ \Omega$$

$$R_t = 7.2\ \Omega$$

Goodheart-Willcox Publisher

Figure 18-19. To calculate equivalent resistance in a series-parallel circuit, break the circuit into its individual series and parallel sections. Calculate the resistance in each parallel section. Then add the total resistance in the parallel sections to the resistances in the series sections to find the equivalent resistance.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 18-20. Even in complex series-parallel circuits, you can find the equivalent resistance by working with each parallel and series part separately.

Power ratings are sometimes used in automotive electronics. Lightbulbs, especially headlight bulbs, are sometimes rated in watts. Hybrid motor-generators and HV batteries can be rated in kilowatts (kW, or 1000s of watts). Vehicle batteries may also have a watt rating to indicate their power potential.

Prefixes for Electrical Units

Depending on the type of circuit, electrical values may be very large or very small. To avoid the need to read and write large numbers, prefixes are used with these values to indicate a multiplier, or exponent, of the value. Refer to **Figure 18-21**.

In automotive circuits, currents are sometimes very small. For these values, milliamperes (mA) are used to show current draw: 1 mA equals 0.001 (1×10^{-3}) A.

Some resistance values, such as those for spark plug wires, can be very large. In these cases, resistance may be given in kilohms (kΩ): 1 kΩ equals 1000 (1×10^{3}) Ω.

Note the symbols associated with each prefix in **Figure 18-21**. These symbols are used with base units such as volts, amperes, and ohms to indicate the prefixes for electrical values. Examples include:

- 5 MΩ (megohms) = 5,000,000 Ω.
- 10 kΩ (kilohms) = 10,000 Ω.
- 32 mA (milliamperes) = 0.032 A.
- 12 µF (microfarads) = 0.000012 farad.

Electronic specifications may be given in prefix form, so you should memorize the meaning of each prefix, especially *mega-*, *kilo-*, *milli-*, and *micro-*. These are the most commonly used prefixes in automotive electronics.

Workplace Skills

Electrical devices have been around since the days of Thomas Alva Edison and his greatest invention, the lightbulb. Edison worked very long hours, up to 20-hour days, in his test laboratory trying to perfect his electrical inventions. Appropriately, Edison's most famous saying was and still is, "Genius is one percent inspiration and 99 percent perspiration!"

Prefix	Symbol	Multiplier	Exponent Form	Example
tera-	T	1,000,000,000,000	10^{12}	1.5 TV = 1.5 × 10^{12} = 1,500,000,000,000 V
giga-	G	1,000,000,000	10^{9}	32 GV = 32 × 10^{9} = 32,000,000,000 V
mega-	M	1,000,000	10^{6}	4.6 MΩ = 4.6 × 10^{6} = 4,600,000 Ω
kilo-	k	1,000	10^{3}	2.8 kΩ = 2.8 × 10^{3} = 2,800 Ω
deka-	da	10	10^{1}	6 daV = 6 × 10^{1} = 60 V
deci-	d	0.1	10^{-1}	8 dA = 8 × 10^{-1} = 0.8 A
centi-	c	0.01	10^{-2}	7.2 cA = 7.2 × 10^{-2} = 0.072 A
milli-	m	0.001	10^{-3}	3.6 mA = 3.6 × 10^{-3} = 0.0036 A
micro-	μ	0.000 001	10^{-6}	19 μV = 19 × 10^{-6} = 0.000 019 V
nano-	n	0.000 000 001	10^{-9}	5 nV = 5 × 10^{-9} = 0.000 000 005 V
pico-	p	0.000 000 000 001	10^{-12}	43 pΩ = 43 × 10^{-12} = 0.000 000 000 043 Ω

Goodheart-Willcox Publisher

Figure 18-21. These prefixes are commonly used on wiring diagrams. Notice that the symbol M means something entirely different from the symbol *m*.

Summary

- The three basic types of circuits are series, parallel, and series-parallel circuits.
- A series circuit has one or more loads connected in the same path.
- A parallel circuit has two or more separate paths for current, and each path can operate independently of the others.
- A series-parallel circuit has both series and parallel sections in one circuit.
- Many automotive circuits are frame-ground or one-wire circuits. The vehicle's metal structure is used to carry current back to the source. This reduces the amount of wire needed to complete the circuits.
- Ohm's law consists of a set of formulas that express the relationships between voltage, current, and resistance in a circuit. If you know any two of the three values, you can use Ohm's law to calculate the unknown value.
- If circuit resistance increases, current decreases. If resistance decreases, current increases. If voltage increases, current increases also.
- Current is the same everywhere in a series circuit. Total resistance is the sum of all series resistances. The voltage drop across each series resistance equals the applied voltage source.
- In a parallel circuit, total circuit current is the sum of all branch currents. Total circuit resistance in a parallel circuit is less than any one branch resistance. The voltage applied to each branch is the same.
- To find the equivalent resistance in a series-parallel circuit, evaluate the parallel section to find its total resistance, and then use the formula for series resistance.
- Prefixes are commonly used to express very large or very small electrical values.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

circuit
electric power
equivalent resistance
frame-ground circuit
ground
hot wire
Ohm's law
one-wire circuit
parallel circuit
reciprocal
reciprocal method
series circuit
series-parallel circuit
watt

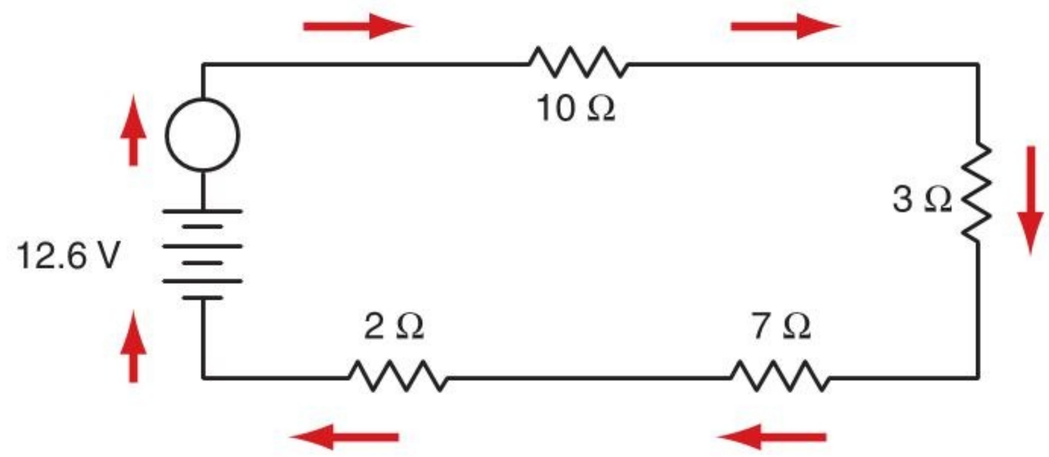
Activities

1. Look up your own car's wiring diagrams using an online service information program. Note the symbols and types of diagrams included in the literature.
2. Using service information for any make of hybrid vehicle, look up the wiring diagrams for the vehicle's electric drive train. Study its circuits and how sensors, the battery pack, power control module, and motor-generator are wired together.

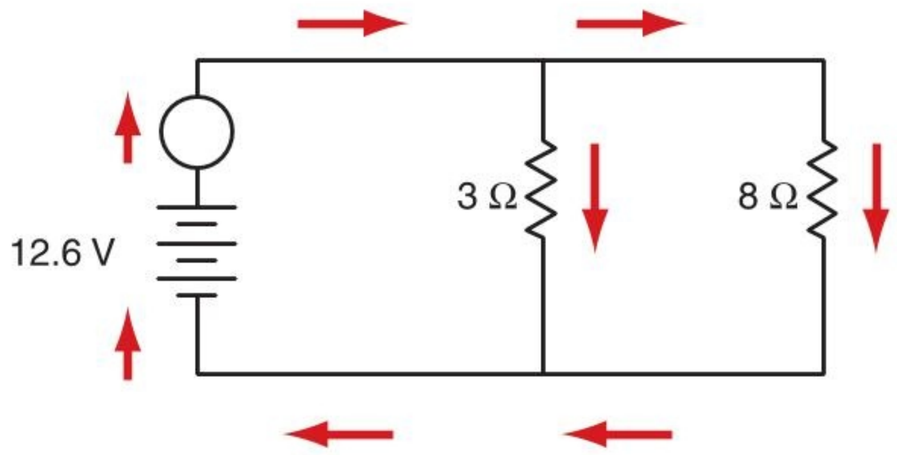
Review Questions

Answer the following questions using the information provided in this chapter.

1. In what way is a parallel circuit different from a series circuit?
2. What is a series-parallel circuit?
3. In a frame-ground circuit, the vehicle's _____ serves as a large conductor to carry current.
4. Why are many automotive circuits frame-ground circuits?
5. Write the formulas that express the relationships between voltage, current, and resistance in a circuit.
6. If resistance increases in a circuit, what will happen to current?
7. If a circuit has a current of 3 A and a resistance of 5 Ω, how much voltage is applied to the circuit?
8. If a circuit has a current of 25.4 amps with 12.6 volts applied, what is the circuit resistance?
9. In which type of circuit can you find total resistance by adding all of the individual resistances?
10. In which type of circuit is the total current equal to the sum of all the branch currents?
11. Calculate the total resistance and current for the following circuit.



12. Find total resistance and current for this circuit.



13. Describe how to find the equivalent resistance in a series-parallel circuit.
14. If you know the total current and resistance in a circuit, how can you find electric power in watts?
15. How many ohms are in 14.4 kΩ?
16. How many microamps are in 0.000034 A?

Copyright Goodheart-Willcox Co., Inc.

ASE-Type Questions

1. Technician A says a series circuit has only one path for current. Technician B says a series circuit can have only one load. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Which of the following is *not* a common type of electric circuit?
   (A) Parallel circuit.
   (B) Series-parallel circuit.
   (C) Frame-ground circuit.
   (D) Series-ground circuit.
3. Technician A says the term *hot wire* refers to the section of the circuit after the load or electric device. Technician B says the ground wire refers to the section of the circuit after the load or electric device. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says the ***frame-ground circuit***, also called a ***one-wire circuit***, uses the metal structure of the vehicle to return electricity to the power source. Technician B says the ground includes the portion of the circuit between the load and the negative terminal of the battery. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. A 12-volt circuit has a resistance of 2 ohms. How much current is in the circuit?
   (A) 4 amps.
   (B) 6 amps.
   (C) 1 amp.
   (D) 3 amps.
6. Technician A says a change in circuit resistance will change the amount of current in the circuit. Technician B says a change in circuit voltage will change the amount of current in the circuit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says current is the same everywhere in a series circuit. Technician B says current is the same in each branch of a parallel circuit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. One milliamp is equal to:
   (A) 0.001 amp.
   (B) 100 amps.
   (C) 1000 amps.
   (D) 10,000 amps.
9. 10,000 ohms can also be written as:
   (A) 10 kilohms.
   (B) 1 megohm.
   (C) 1 kilohm.
   (D) 10 megohms.
10. A 12-volt automotive circuit has a current of 3 amps. Technician A says the electric power in this circuit is 36 watts. Technician B says the electric power in this circuit is 4 watts. Who is right?
    (A) A only.
    (C) B only.
    (B) Both A and B.
    (D) Neither A nor B.

Just as a few simple digits (0-9) can be combined and arranged in different ways to create an infinite range of numbers, so too can a handful of basic electronics components be combined to perform a wide range of different functions. Understanding what these basic components do will help you understand how they work together in a complete circuit.

Chapter 19
Electric and Electronic Components

After studying this chapter, you will be able to:

- Identify electric and electronic components.
- Explain the function and operation of electric and electronic components.
- Interpret electric and electronic component ratings and values.
- Recognize the symbols and letter designations for electric and electronic components.
- Recall the properties of semiconductor materials.
- Recall the common types of transistors.
- Give examples of photonic devices.

This chapter will introduce the most common types of electric components and electronic components. You will learn about electric components such as resistors, coils, solenoids, relays, and fuses. You will also learn about diodes, transistors, light emitting diodes, and other electronic, or "solid state," components. The information in this chapter is very important if you are to become a successful technician in today's automotive industry.

Electric Components

Today's vehicles use an array of electric components, as illustrated in **Figure 19-1**. This section reviews the basic construction and operation of important electric components that can be found on late-model passenger vehicles.

Resistors

If a circuit had no resistance, it would burn up from excess current and heat. A lightbulb, for example, uses a small resistance element inside a sealed glass housing to generate heat and light. A ***resistor*** limits and controls current flow in a circuit. Resistor devices come in various shapes and sizes, depending on their function. Refer to **Figure 19-2.**

A fixed resistor has a set ohms value that does not change. A variable resistor has a range of internal resistance that can be adjusted. When you turn or slide a control knob, a contact moves along a resistor element. As the contact moves, a different amount, or length, of resistor is connected inside the device, changing the resistance value. Look at **Figure 19-3**. There are two basic types of variable resistors, rheostats and potentiometers.

Ford

Figure 19-1. Conventional electric components are still used to do many tasks in a vehicle's electrical system. You will learn about these components in this and other chapters.

	General Resistor Symbol
1000 Ω	Resistance Value
10 W	Watt (Power) Rating
5%	Tolerance

Goodheart-Willcox Publisher

Figure 19-2. In addition to the resistance value, resistors have a watt rating and a tolerance. The watt rating indicates how much load or power the resistor can handle. The tolerance indicates how much the resistance value of the resistor can vary from its nominal value.

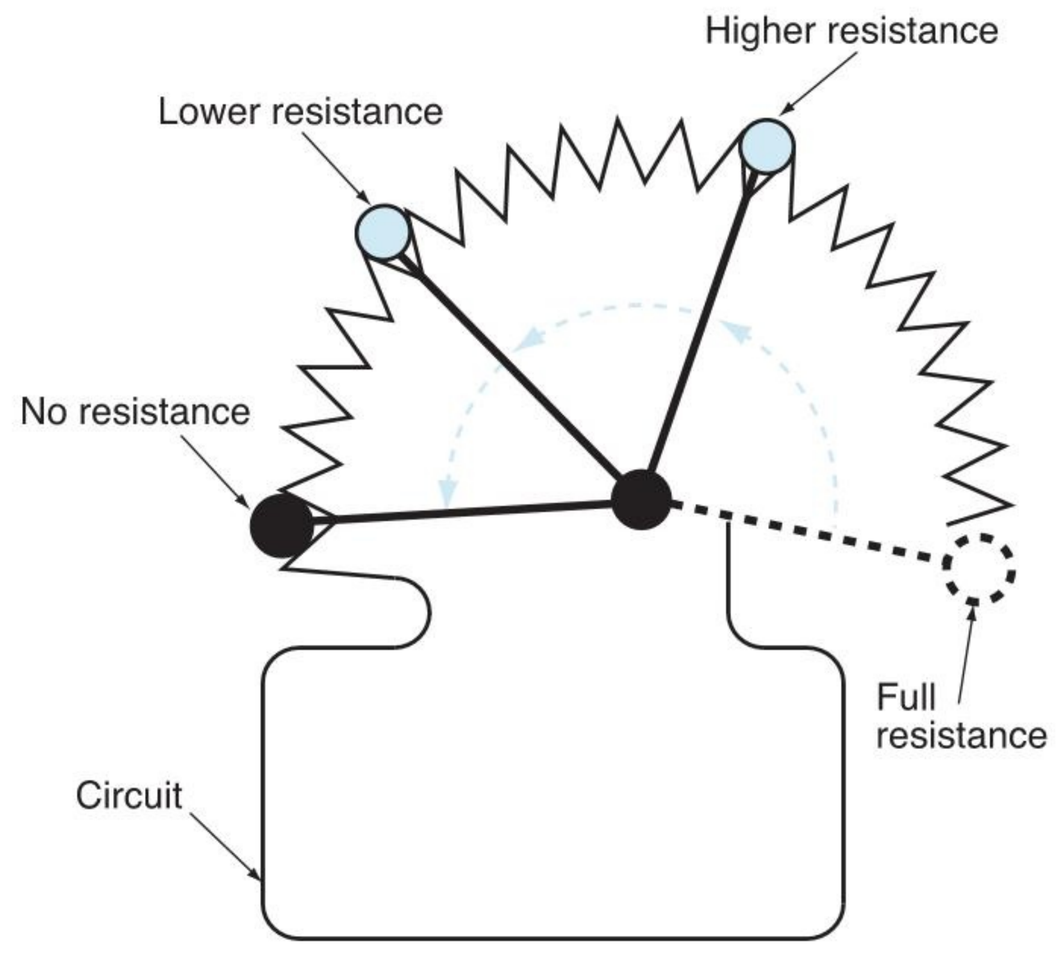
Variable Resistor	
Symbol	Letter Designation
	R V

Goodheart-Willcox Publisher

Figure 19-3. Variable resistors can produce a range of resistance values.

A rheostat is a variable resistor with two electrical terminals (connections). One terminal is wired to one end of the resistance unit. The other terminal is connected to a sliding contact. Turning the control knob moves the contact and alters the resistance value. See **Figure 19-4**.

A potentiometer is a variable resistor that has three electrical connections. It has one connection

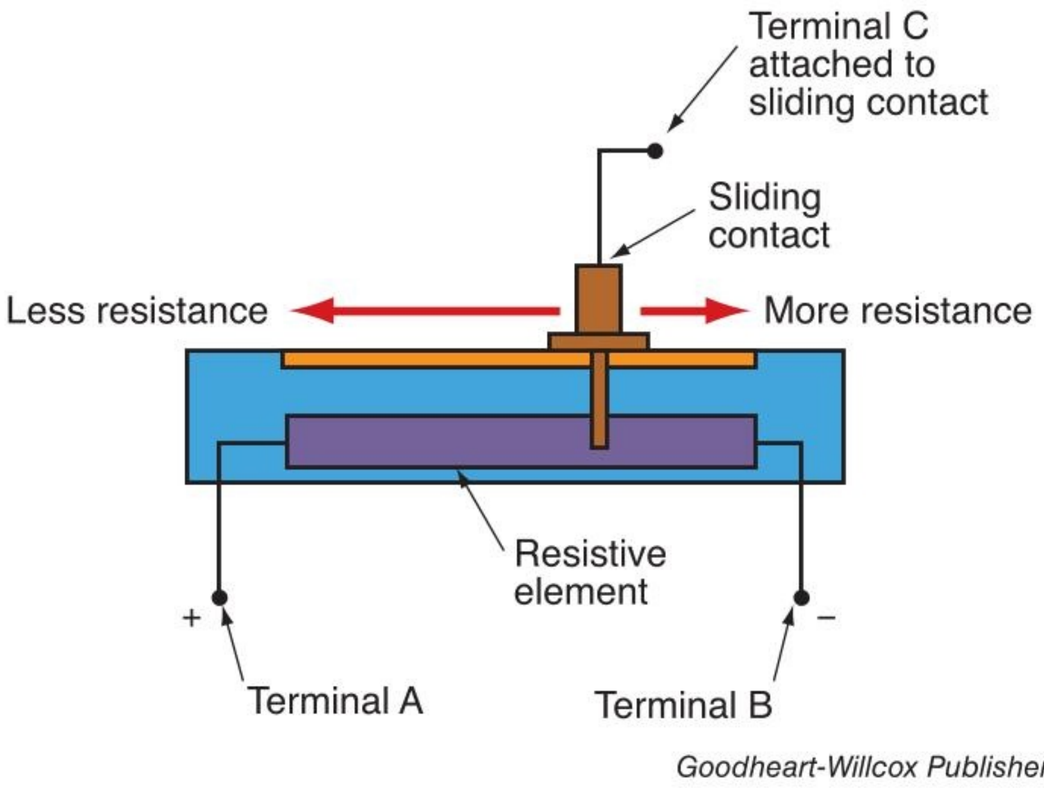


Goodheart-Willcox Publisher

Figure 19-4. This rheostat can provide a range from full resistance to no resistance at all.

at each end of the resistance unit and one for the sliding contact. This allows for more complex use of the variable resistance. For example, it can be used to produce a variable voltage drop or voltage signal. As the sliding contact is moved along the resistance unit, the internal resistance and resulting voltage drop change. This type of variable resistor might be used as a sensor for a computer system. See **Figure 19-5**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

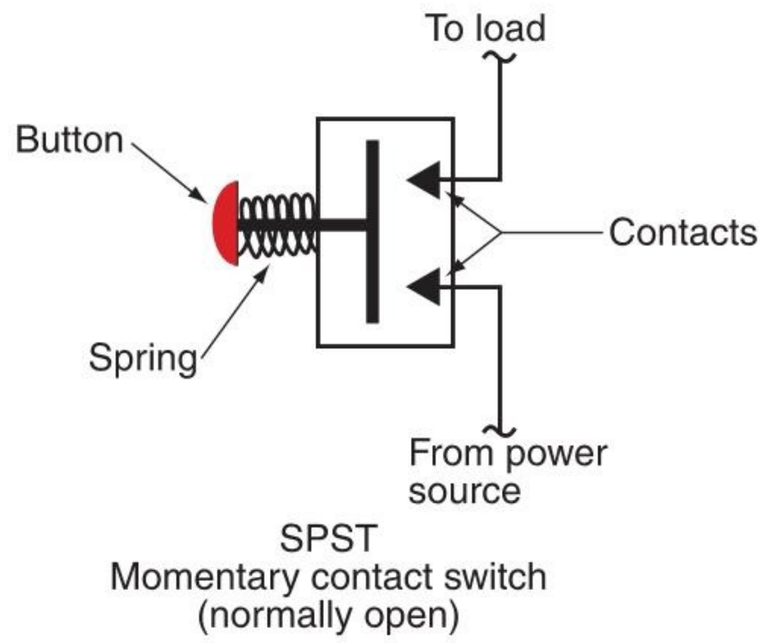
Figure 19-5. A potentiometer has three terminals. Terminal A is the positive terminal, terminal B is the negative terminal, and terminal C is connected to a contact that slides along a resistive element. As the sliding contact gets closer to terminal B, resistance between terminals B and C increases and voltage decreases. As the sliding contact moves closer to terminal A, resistance decreases and voltage increases.

Switches

A ***switch*** is used to connect or disconnect the power supply in a circuit. For a list of common types of switches and their corresponding symbols,

Figure 19-6. Switches are discussed in the following sections of this chapter.

A push-button switch has a spring-loaded button that, when pressed, makes or breaks an electrical connection across two contacts. A push-pull switch is a special type of push-button switch that stays in each position until it is moved. In some vehicles, a push-pull switch is used to turn the headlights on and off. When the driver pulls the switch out, the headlights come on and remain on until the driver pushes the switch back to the off position. See **Figure 19-7**.



Goodheart-Willcox Publisher

Figure 19-7. This push-button switch is normally open, which means the circuit is disconnected unless the button is pressed.

Switch	Symbol	Description
Single-Pole, Single-Throw Switch (Toggle Switch)		Has one swinging arm that can make contact with one stationary contact (pole). It is either open or closed and has two external terminals. This type of switch might be used for fog lights or other dash-mounted controls.
Single-Pole, Double-Throw Switch		Has one movable contact arm but two different stationary contacts. The arm can make an electrical connection with either of the stationary contacts.
Double-Pole, Double-Throw Switch		Has two moving arms, each having two stationary contacts.
Normally Closed Switch		Completes its internal connection when at rest (not activated). Activating the switch opens the internal contacts to stop current flow.
Normally Open Switch		Open or disconnected when at rest (not activated). A push-button switch is an example of a normally open switch.

Goodheart-Willcox Publisher

Figure 19-6. Common types of switches and their symbols are shown.

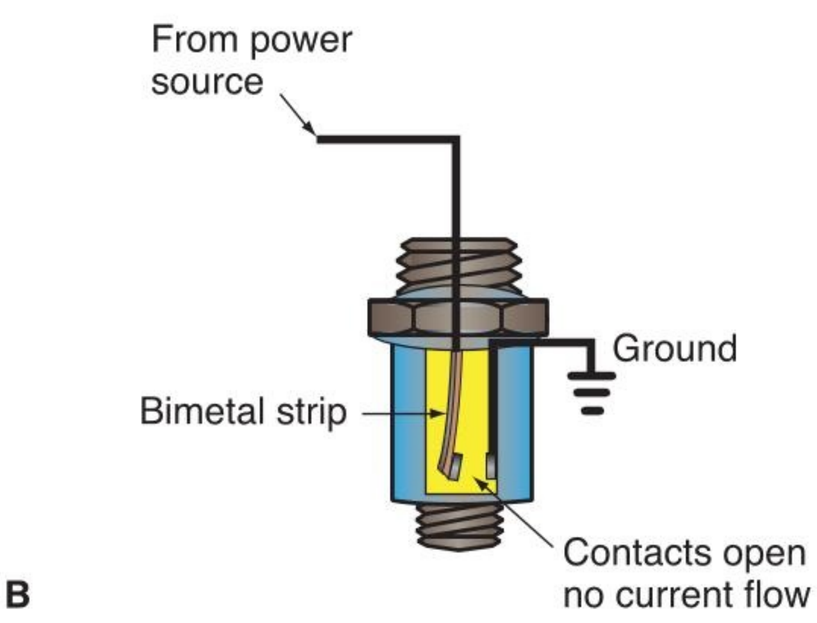
Copyright Goodheart-Willcox Co., Inc.

A thermal switch is a temperature-sensitive switch. It opens and closes with changes in temperature. This type of switch uses a bimetal strip (two different metals bonded together) so it warps and bends when heated. See **Figure 19-8**.

When the switch is cold, the bimetal strip is curved away from the internal switch contacts, so the circuit is open. When switch temperature increases, the two metals in the bimetal strip expand at different rates. This causes the strip to straighten, closing the switch contacts. One application for a thermal switch is to sense engine overheating and operate a dash warning light or even shut down power to the ignition system to prevent engine damage.

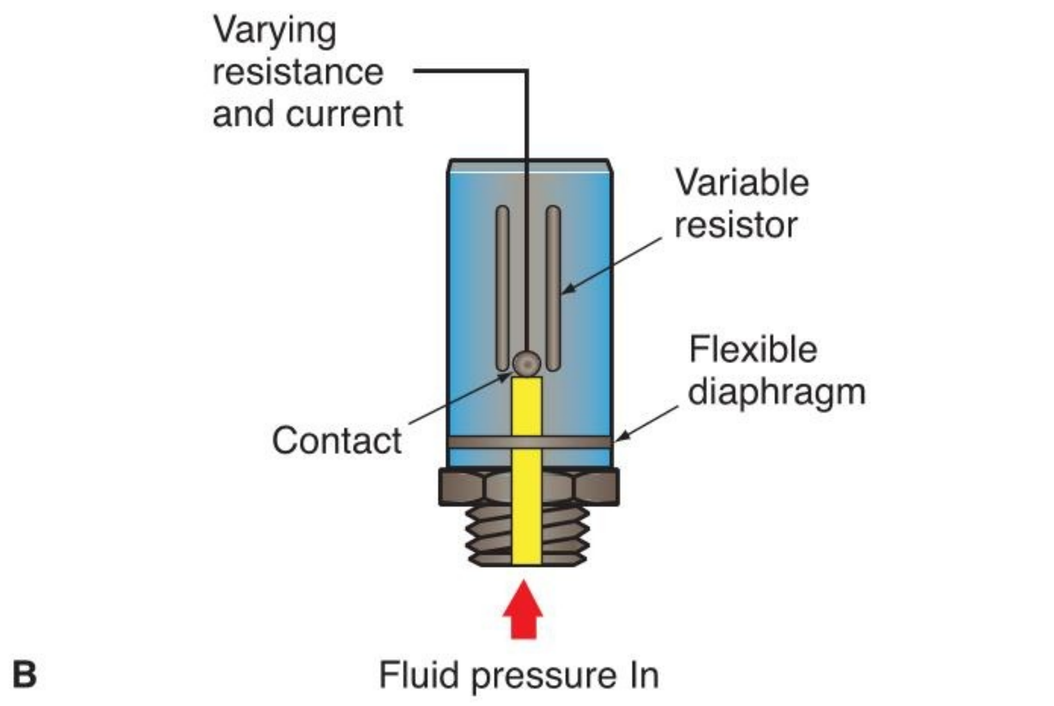
A pressure switch reacts to changes in internal pressure. Most pressure switches have an internal diaphragm attached to an electrical contact. When pressure drops below about 10 psi, the diaphragm is at rest and the contacts are open. When pressure becomes high enough, the diaphragm flexes to close the contacts, completing the circuit. A common application for a pressure switch is the engine oil light circuit. When the diaphragm closes the contacts, the oil pressure light on the dash is activated. See **Figure 19-9**.

A mercury switch uses liquid mercury to open and close its switch contacts. Mercury is a good conductor. It serves as a position switch that reacts to the location of a part. For example, a mercury switch can be used to activate the underhood light or the trunk light in a vehicle. When the switch is in one position, the mercury does not touch the contacts, so the switch is open. When the switch is tilted the other way (hood or trunk open), the mercury flows down over the contacts to close the switch. Refer to **Figure 19-10**.



Goodheart-Willcox Publisher

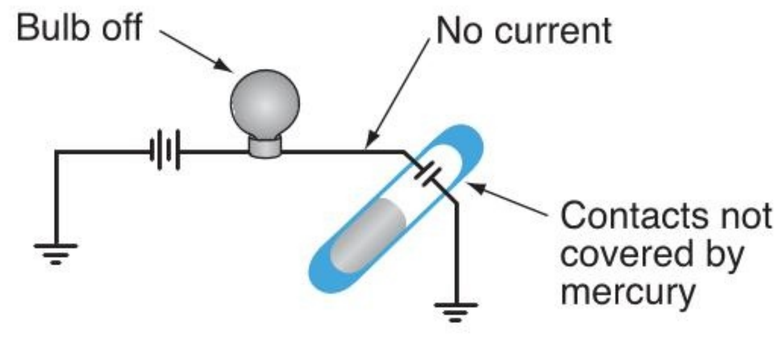
Figure 19-8. A thermal switch uses a bimetal strip to react to heat. The two metals have different coefficients of expansion—they expand at different rates as the switch heats up. The difference in expansion rates causes the bimetal strip to change shape, closing the contacts.



Goodheart-Willcox Publisher

Figure 19-9. This is one type of pressure switch that uses a variable resistor and contacts. It is used to operate the low oil pressure light and oil pressure gauge. Low pressure allows the diaphragm to close the contacts in the switch and activate the dash light. When oil pressure is normal, the variable resistor allows enough current flow to keep the oil gauge needle near the middle of its face, but since the contacts are open, the oil warning light stays off.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 19-10. In a mercury switch, the liquid mercury acts as a conductor. The circuit closes when the mercury flows over the contacts.

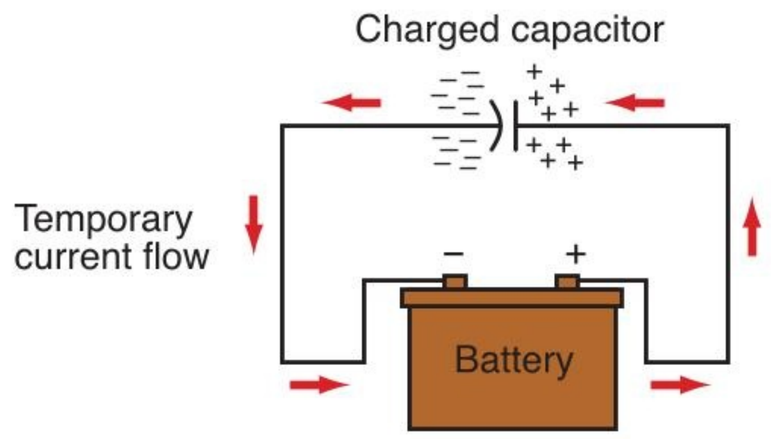
Dozens of other types of switches are found in modern vehicles. Examples include the ignition switch, dimmer switch, turn signal switch, stoplight switch, wiper switch, vacuum switch, and inertia switch. These specialized types of switches will be explained in later chapters where they apply.

Capacitors

A ***capacitor*** is a storage device for electrons, or electrical energy. A capacitor is made by wrapping two conductor strips around an insulating strip, or dielectric. The insulating strip allows the two conductors to be placed close together but keeps them from touching.

When direct current is applied to a circuit that contains a capacitor, electrons build up on the conductor strip attached to the negative terminal of the battery. As electrons build up, the capacitor becomes charged. Look at **Figure 19-11**. A positive charge collects on the other conductor strip.

When the charge in the capacitor equals the dc voltage from the battery, electrons can no longer flow through the capacitor. Therefore, small capacitors can be used to stop dc voltage. Larger capacitors can be used to even out voltage fluctuations. They supply extra voltage when the dc voltage dips, and they absorb voltage if the dc voltage spikes.



Goodheart-Willcox Publisher

Figure 19-11. A capacitor is an "electrical shock absorber" in ac circuits and will store an electrical charge in dc circuits. Direct current charges the capacitor. When fully charged, the capacitor blocks direct current.

Alternating current can pass through a capacitor. The alternating current charges a capacitor while current is in one direction. Then the capacitor discharges back into the circuit when the current changes direction.

In vehicles, capacitors can be used as a noise suppressor to prevent static in the radio or sound system. They are connected into the wiring to absorb or counteract voltage spikes that cause radio noise. In late-model vehicles, microscopic capacitors are found in computer circuits, sound systems, navigation systems, and printed circuits.

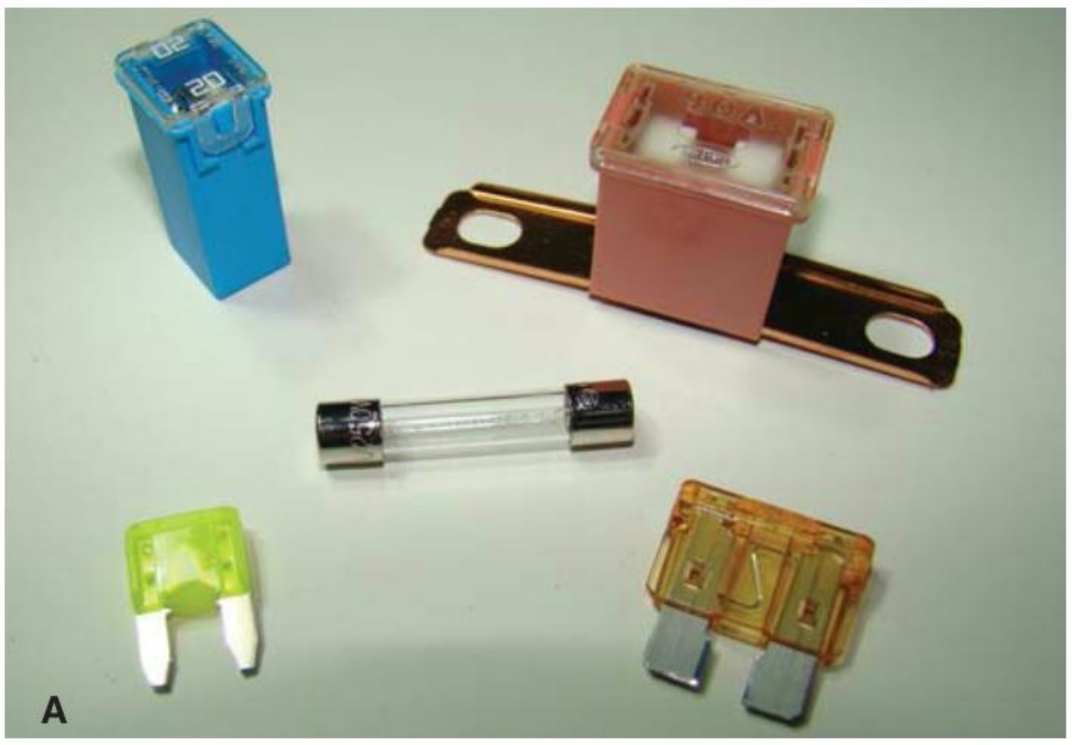
The size, or electrical storage ability, of a capacitor is rated in ***farads (F)***. A 1 farad capacitor connected to a 1 volt source stores 6.28×10^{18} electrons. Most capacitors cannot store this much electricity, however. Only "super-capacitors" used in hybrid drive trains or stereo systems can store more than this much energy. Most small capacitors are generally rated in microfarads (μF) or picofarads (pF). A microfarad equals a millionth of a farad. A picofarad equals a trillionth of a farad. Capacitors also have a voltage rating to prevent electrical arcing and component failure. Any voltage applied must not exceed the capacitor voltage rating.

Fuses

A ***fuse*** is used to protect a circuit from damage caused by excess current. It is connected in series with the circuit, right after the source, so that all current goes through the fuse. See **Figure 19-12**.

When current is normal, there is current through the fuse element. If something goes wrong in the circuit to increase current too much, the element overheats and melts. This breaks the circuit and protects the wires from overheating damage.

Copyright Goodheart-Willcox Co., Inc.



Fuse	
Symbol	Letter Designation
	F

B

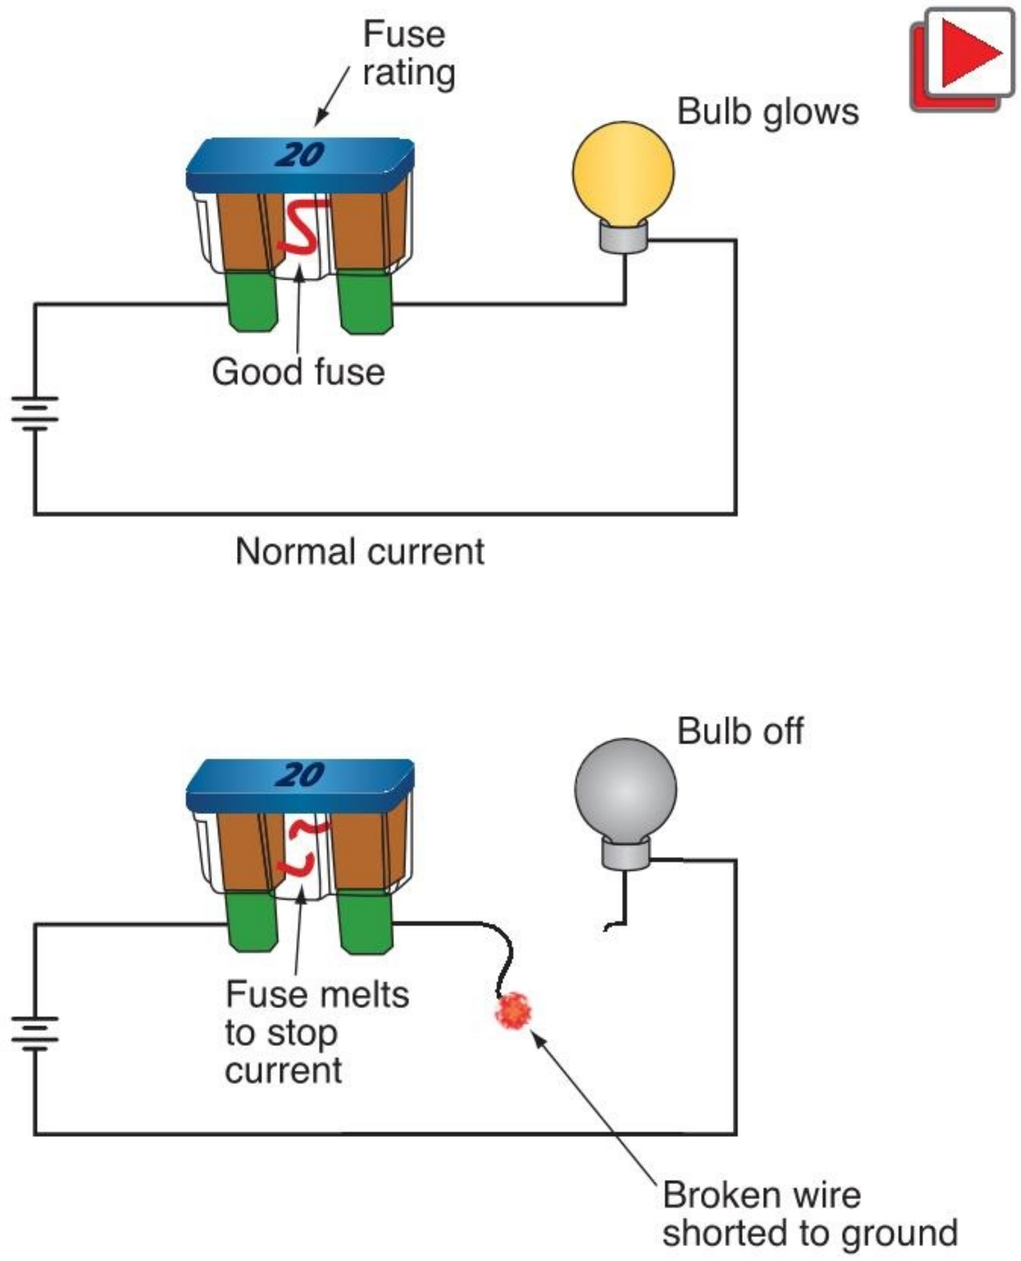
Goodheart-Willcox Publisher

Figure 19-12. Study fuses. A—Fuses help prevent a circuit from damage due to too much current. When current becomes too high, the fuse element blows, causing a break in the circuit and stopping current. B—Study the symbol and letter designation for fuses.

Without a fuse, an electrical fire could result from overheated wires glowing red-hot, causing their insulation to ignite. A ***short circuit*** results when a hot wire touches any ground. This may cause a tremendous amount of current through the circuit. The excess current can burn up wires in a fraction of a second. A fuse protects circuits from excess current and resulting damage. Fuse action is illustrated in **Figure 19-13**.

Fuse Ratings

A fuse rating is the amount of current a fuse can handle before its element melts. For example, "20 A" printed on the fuse means that the fuse is rated to protect a circuit designed for 20 amps. When you replace a fuse, always install a fuse with the same fuse rating. In automotive applications, the voltage value is understood to be 12 V.



Goodheart-Willcox Publisher

Figure 19-13. Any problem that increases current too much will make the fuse blow. Here, a wire has broken and shorted to ground. The resulting high current burns the fuse element in half to stop current and protect the circuit.

Caution

Never install a fuse with a higher fuse rating than specified. Even though this might keep the fuse from blowing, it can cause wires and electrical connections to overheat. You must correct the circuit problem and install a fuse with the same rating as the original.

Fuse Panels

A fuse panel, or fuse box, is a plastic housing with metal terminals that holds the vehicle's fuses and other related electric components, such as relays. Most fuse panels mount under the dash of the vehicle, in the engine compartment near the firewall, under the rear seat, or in the trunk of mid- or rear-engine vehicles. See **Figure 19-14**.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

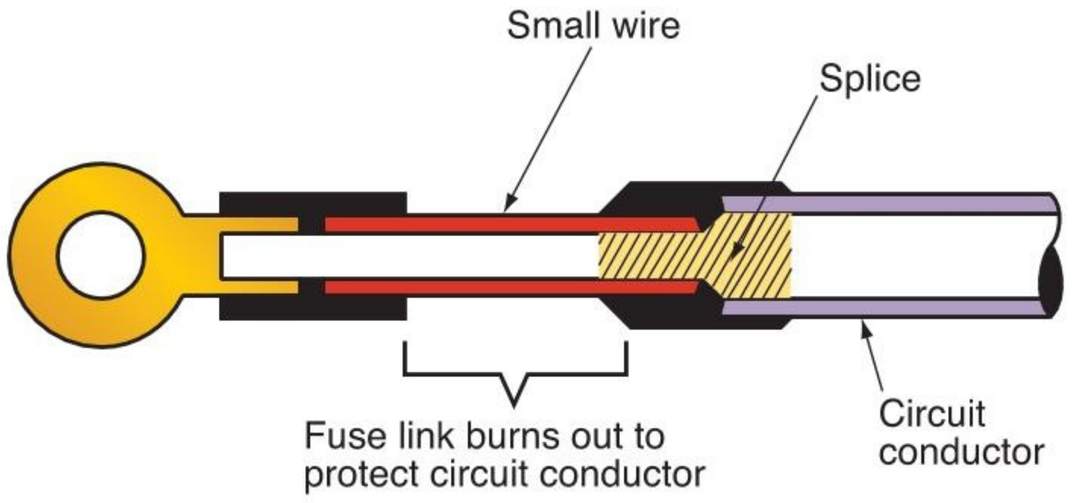
Figure 19-14. This fuse panel is located in the vehicle's engine compartment. You may have to remove the cover to gain access to the fuses.

Fuse panels usually have a guide showing fuse circuits and fuse ratings. In some vehicles, the fuse guide is printed on the back of the fuel panel cover. In others, the name of the circuit is abbreviated next to the fuse on the fuse panel. This shows which circuit is protected by each fuse. The fuse rating may also be printed next to the fuse socket in case a fuse is removed.

Fuse Links

A fuse link, or fusible link, is a section of smaller-gauge wire connected in series with the larger-gauge circuit wiring. It is designed to serve as a very large fuse.

Fuse links are normally located in the engine compartment, where power feeds from the 12-volt battery or starter solenoid. The fuse link is usually wired between the 12-volt battery and the fuse panel. Fuse links provide circuit protection before the fuse box in the passenger compartment. If a wire is shorted to ground before it reaches the fuse panel, the fuse link overheats and burns in half. This protects the rest of the wiring from major damage. See **Figure 19-15**.



Goodheart-Willcox Publisher

Figure 19-15. A fuse link, or fusible link, is sometimes wired into main circuits to protect them from major shorts to the 12-volt battery. This cutaway view shows the section of smaller-gauge wire that serves as a fuse. The smaller wire burns if the current exceeds circuit design limits.

Tech Tip

When replacing a fuse link, use the recommended wire size. Do not use the same wire size used in the rest of the circuit or you will no longer have circuit protection. Procedures for replacing a fuse link are explained in a later chapter.

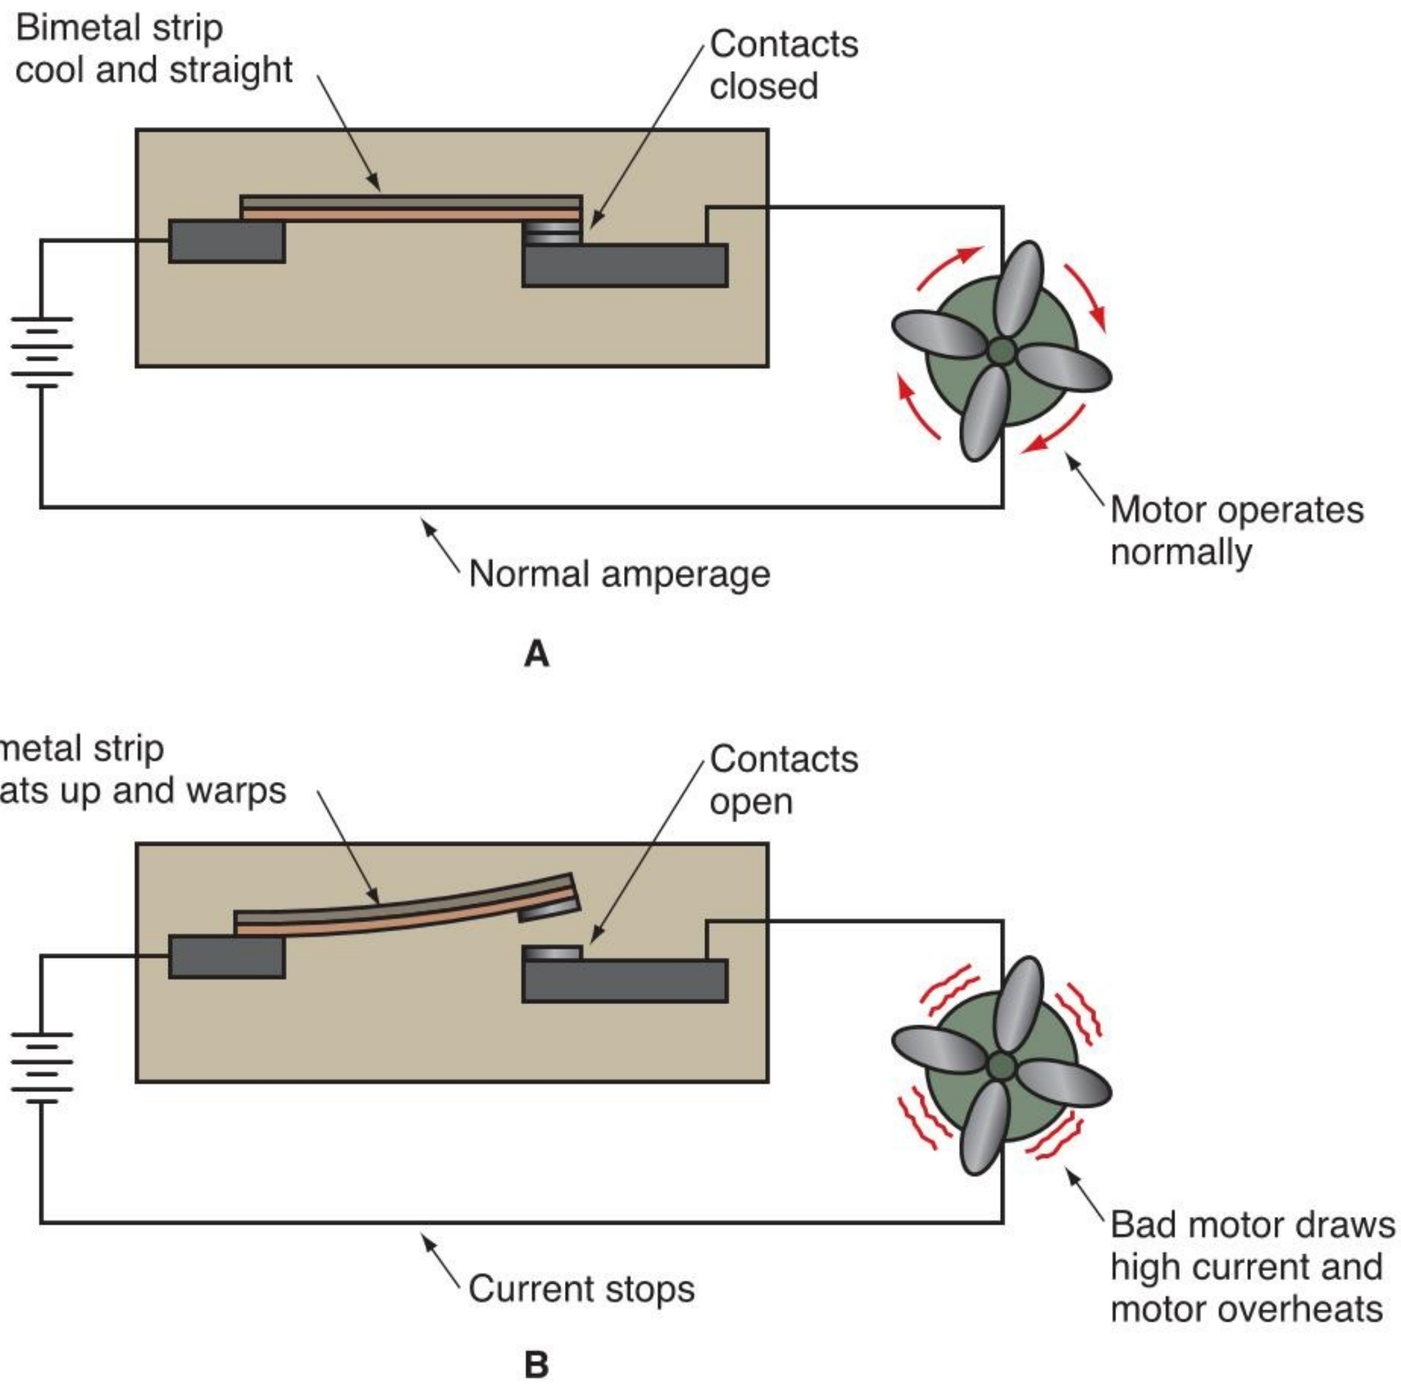
Circuit Breakers

A ***circuit breaker*** performs the same function as a fuse or fuse link: it protects a circuit from damage from excess current. However, a circuit breaker is not ruined when it is activated, or "tripped." Circuit breakers can sense a high-current condition and disconnect the circuit temporarily. They automatically reconnect the circuit after it cools down. If the high-current condition still exists, they trip again, and the cycle repeats. This action is ideal for the headlight circuit, which must not turn off permanently.

In a self-resetting circuit breaker, a bimetal strip acts as a movable contact. Under normal current, the bimetal strip remains cool and straight, and the contact remains closed. When a problem exists in the circuit, high current through the strip causes overheating. As the circuit breaker heats up, the high-expansion metal in the bimetal strip expands more than the low-expansion metal, making the strip warp, or bend. This opens the contacts in the circuit breaker. See **Figure 19-16**.

With no current, the circuit wiring and the bimetal strip cool to a temperature that is safe for circuit operation. The bimetal strip regains its original shape, closing the contacts and restarting current flow.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 19-16. Circuit breaker action is shown here. A—This circuit is functioning normally. The motor is in good condition and is drawing the specified current. B—This motor has bad bearings. It is overheating and drawing too much amperage. As a result, the bimetal strip overheats, bends, and opens circuit. After cooling, breaker allows the circuit to operate until it again overheats and draws too much current.

Warning

The circuit breaker's amp rating specifies the highest current that the breaker can tolerate without tripping. Never install a circuit breaker with a higher amp rating. This could cause wire or component overheating, and possibly an electrical fire. Always install a circuit breaker with the manufacturer's recommended amp rating.

Coils

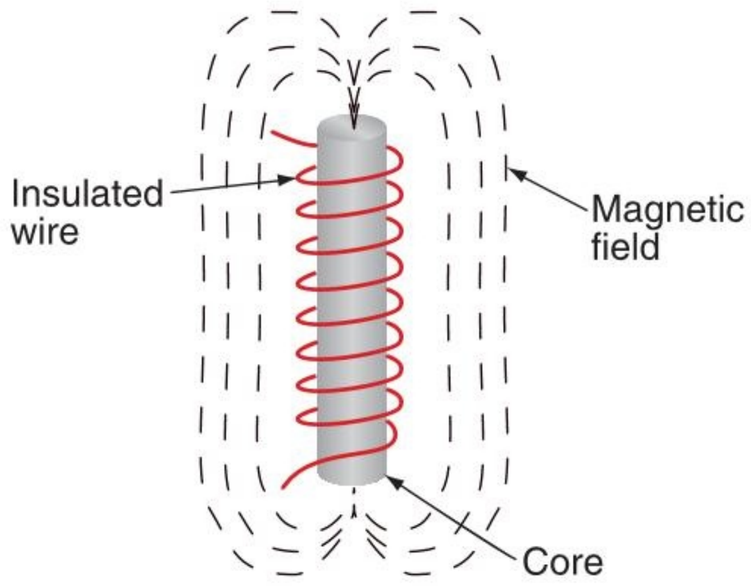
A ***coil***, also called a choke or inductor, consists of insulated wire loops placed close together to create an electromagnetic field. Coils are usually wrapped around an iron core to strengthen the electromagnetic properties.

Coils are used in electrical circuits to resist the fluctuation of current and voltage. Unlike capacitors, coils provide little opposition to direct current. In automotive applications, coils are commonly used in electric devices to provide a magnetic field. They are used in transformers, solenoids, motors, relays, sensors, and other components. See **Figure 19-17**.

Transformers

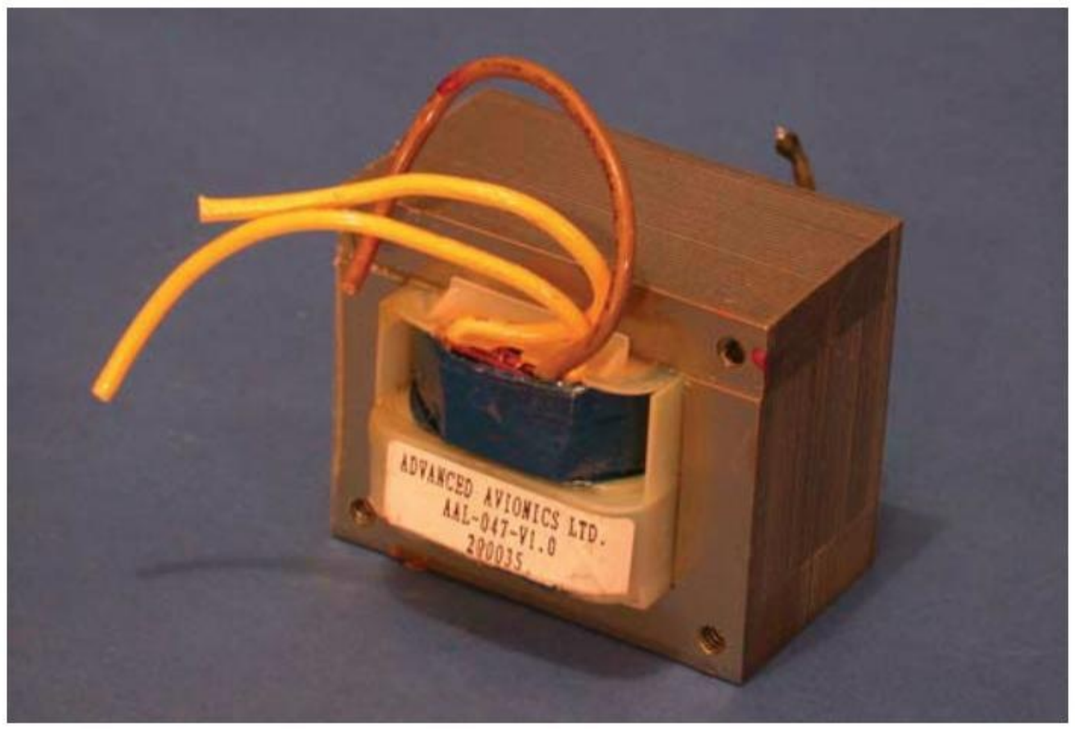
A ***transformer*** uses two sets of coils to transform voltage and current to higher or lower levels. For example, an ignition system coil is used to transform battery voltage into high voltage for firing the spark plugs. Other types of transformers are used to isolate different parts of a circuit, reduce voltage, or match the impedance of circuit sections. ***Impedance*** is resistance to alternating current at a given frequency. Refer to **Figure 19-18**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 19-17. A coil consists of insulated wire formed in loops and usually wrapped around a core. It is used in many kinds of electric devices.



Goodheart-Willcox Publisher

Figure 19-18. A transformer contains two coils in one housing. It can be used to isolate two circuits, increase voltage, or decrease voltage.

Transformers are made by wrapping an insulated wire around a core, usually an iron core. Another set of windings is wrapped around a second core. If current through one set of windings fluctuates (increases or decreases in strength), voltage is induced in the other set of windings. If the current and electromagnetic field around the windings stays the same, voltage is not induced in the other windings. See **Figure 19-19**.

The ***turns ratio*** represents the relationship between the number of windings, or wraps, of wire in each transformer coil. If both coils have the same number of windings, the turns ratio is one to one (1:1). The induced voltage in the second coil is the same as the voltage in the first coil. This equal input and output produces an isolation transformer, which isolates one circuit from another.

A step-up transformer is one in which the second coil has more windings than the first coil. The additional windings in the second coil generate a proportionally higher voltage. For example, in a transformer that has a turns ratio of 1:2, application of 12 volts to the first coil produces an output of 24 volts in the second coil. The most common step-up transformers on an automobile are ignition coils, which fire the spark plugs in the engine's ignition system.

In a step-down transformer, the second coil has fewer windings than the first coil. This reduces the output voltage compared to the input voltage. For example, in a transformer that has a turns ratio of 2:1, 12 volts in the first coil produces an output of only 6 volts in the second coil. Step-down transformers are found in computers to lower voltage for integrated circuits. See **Figure 19-20**.

The voltage and current in a transformer are inversely proportional. When a transformer increases voltage, current decreases. If a transformer reduces voltage, current increases. Current can be sacrificed to gain voltage, or voltage can be sacrificed to gain current.

Relays

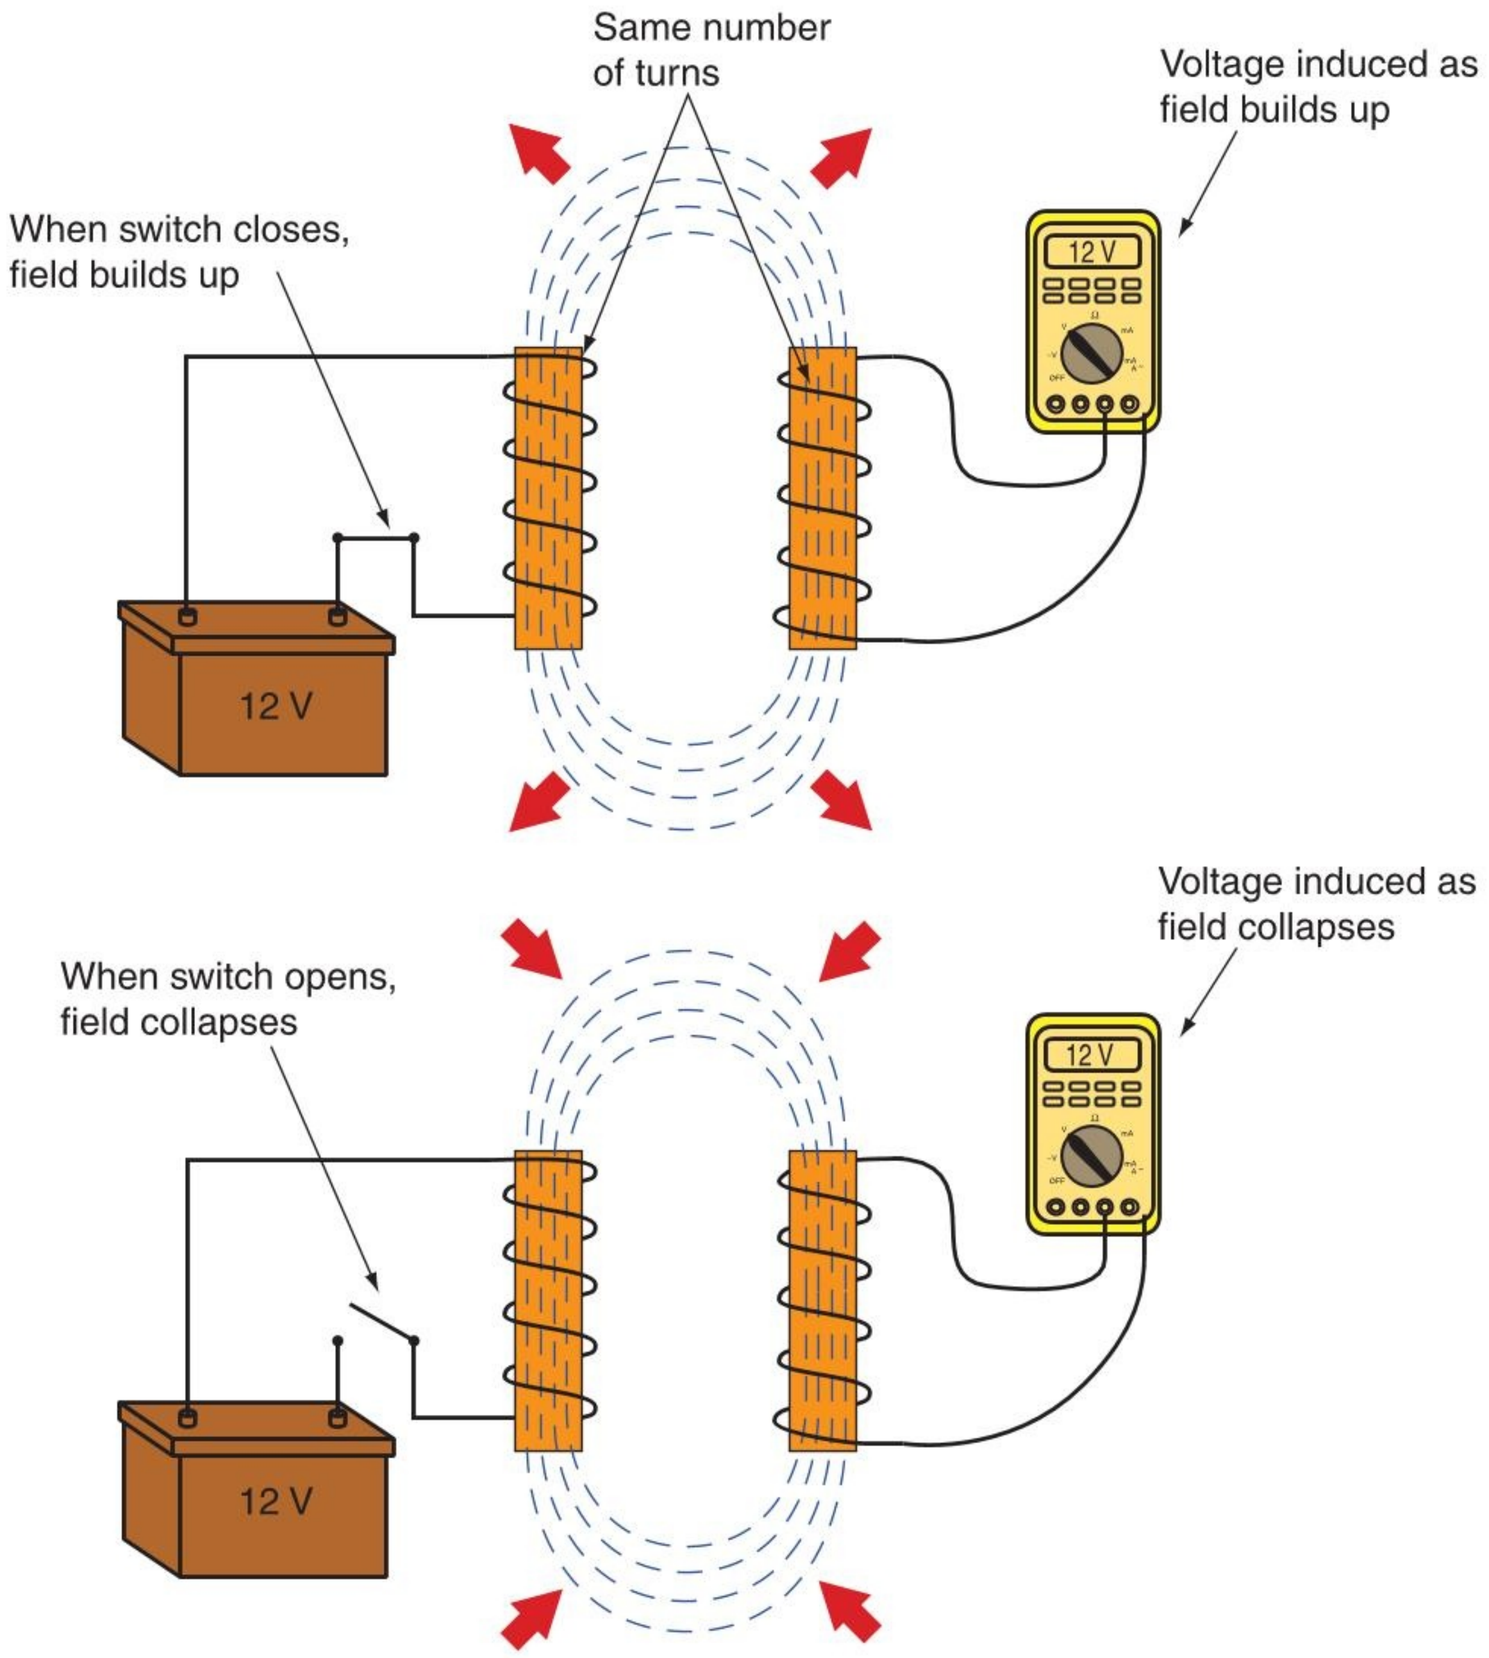
A ***relay*** is a device that uses a small input current to control a larger current in a circuit. A small coil opens and closes a set of contact points. Without relays, huge switches would be needed to carry the high current load of some electric circuits. Look at **Figure 19-21**.

A vehicle's horn is an example of an application that uses a relay. When you press the horn button on the steering wheel, a small control current flows to the horn relay. This closes the contacts in the relay and a larger current flows to and energizes the horn. Using a relay allows the wires running up the steering column to the horn button to be much smaller than they would otherwise have to be. Relays are normally located in the fuse box, **Figure 19-22**.

Solenoids

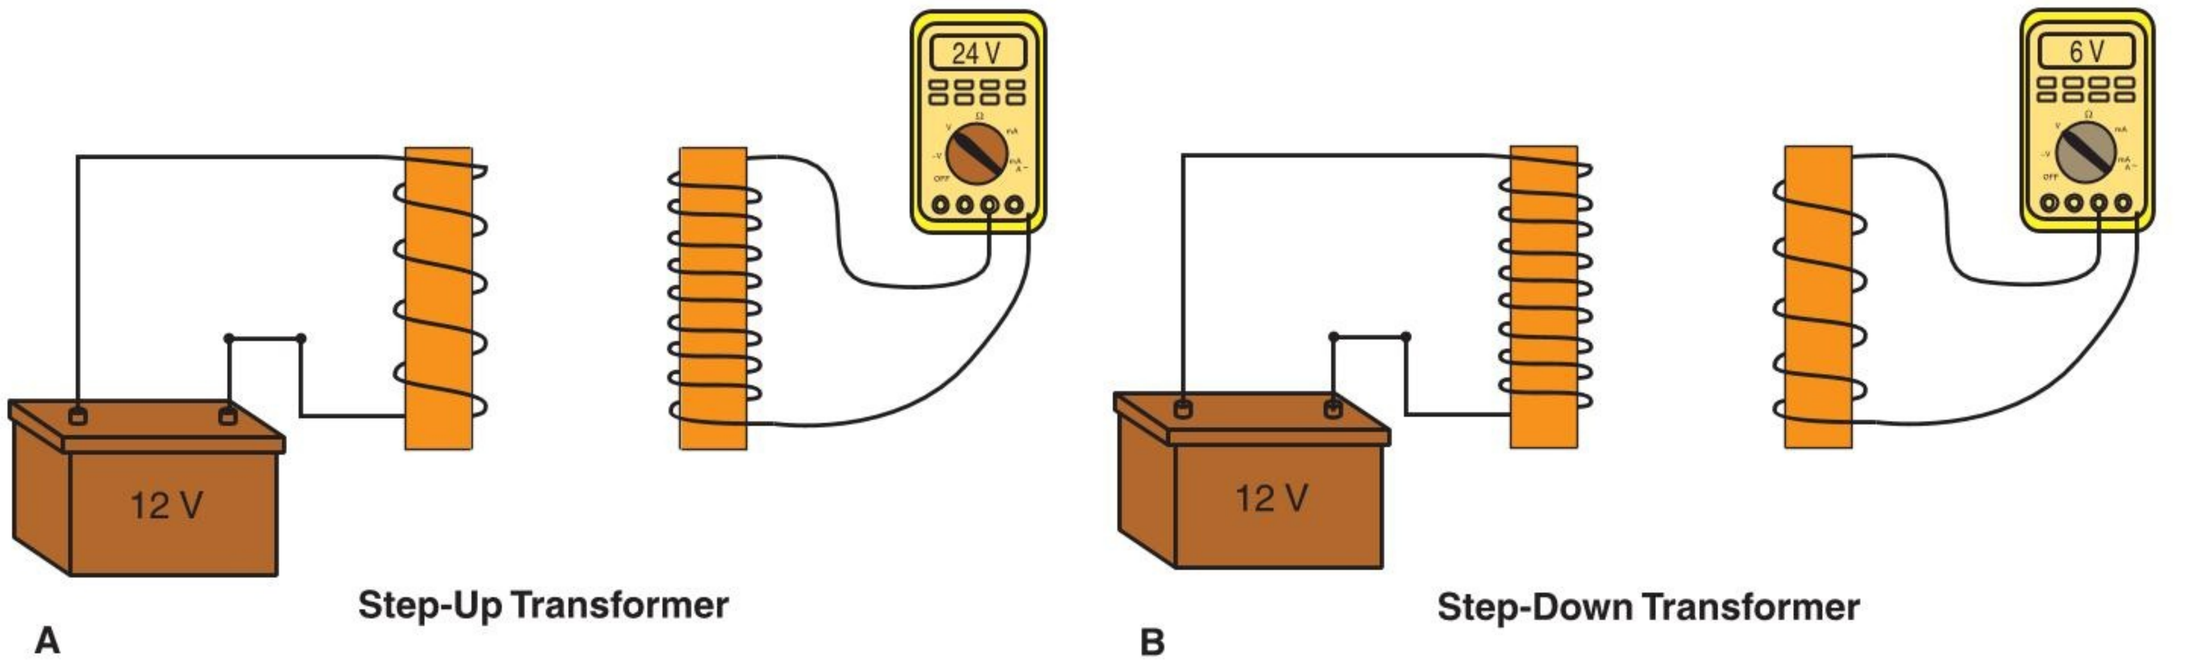
A ***solenoid*** is an electromagnet that moves a metal core, or plunger. The core movement can be used to close very large electrical contacts or move parts into engagement. See **Figure 19-23**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 19-19. The field around one coil can induce voltage in another coil when the field builds or collapses. If the number of windings are different, the transformer can be used to increase or decrease voltage.



Goodheart-Willcox Publisher

Figure 19-20. Transformers can be used to increase or decrease voltage. A—A step-up transformer has more windings in the second coil to produce higher voltage. B—A step-down transformer has fewer windings in the second coil to produce lower voltage.

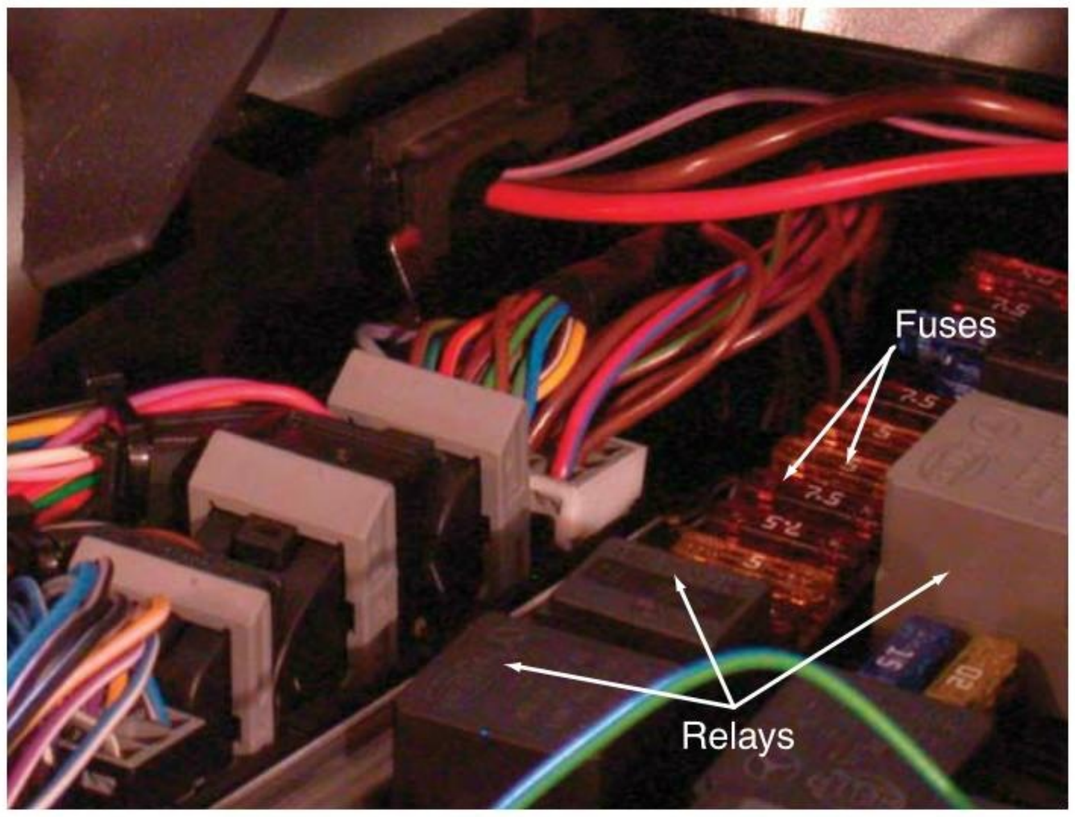
Goodheart-Willcox Publisher

Figure 19-21. Study the action of this relay. A—When the control circuit is open, the contact points in the relay are open and the load circuit is off. B—When the control circuit is activated, a magnetic field builds around the coil. The magnetic field attracts the point arm, pulling the contact points closed. This turns on the main circuit, allowing a high amount of current to the load.

Solenoids use electric current to produce motion. This motion might be used to operate a trunk latch. When there is current through the solenoid windings, the magnetic field pulls the core into the windings. Then, when current is broken, spring action pushes the core back out. Refer to **Figure 19-24**.

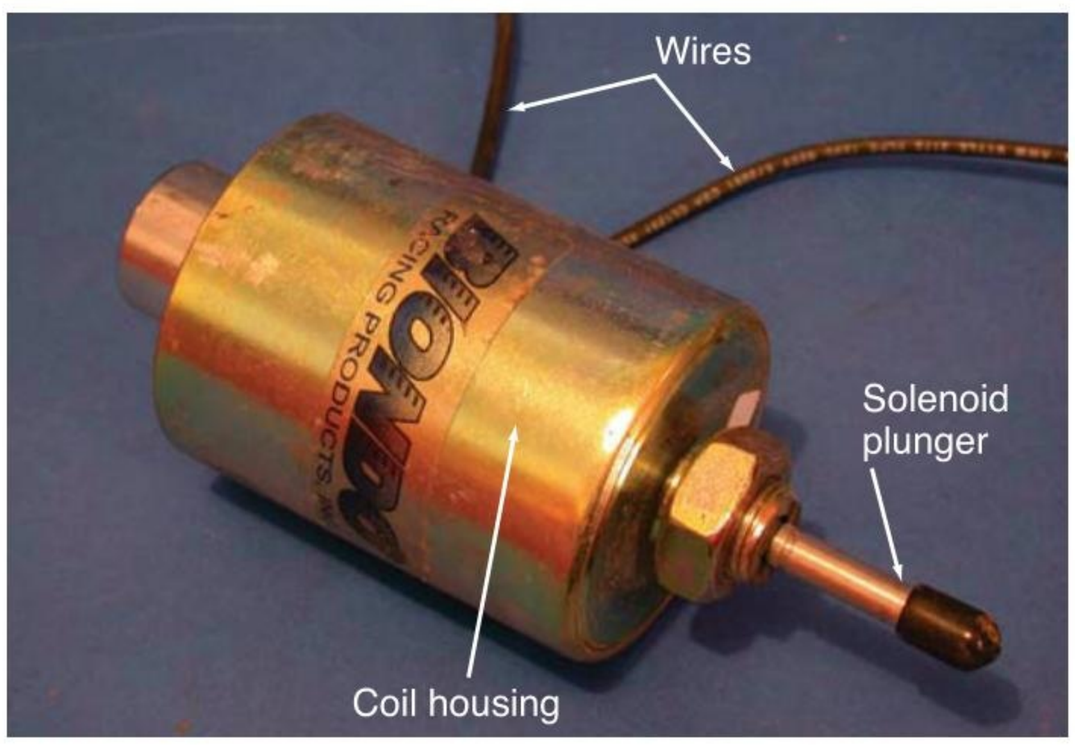
In an automobile, a starter solenoid is used to complete the battery-to-starting motor circuit. It serves as a huge relay to connect this high-amperage circuit. Some starter solenoids also move the starter gear into engagement with the flywheel ring gear on the back of the engine.

Smaller solenoids can be used to control engine throttle position and engine speed. Solenoids are also used to open and close gasoline injectors in an electronic fuel injection system.



Goodheart-Willcox Publisher

Figure 19-22. These are relays found under the hood of one make and model vehicle. You would have to refer to cover guide or manual to find out which circuit each relay controls.



Goodheart-Willcox Publisher

Figure 19-23. An electric shifter solenoid with its symbols is shown here.

Electric Motors

Electric motors use magnetic fields to produce a powerful rotating action, **Figure 19-25**. A set of windings is wound around a central core. This core is mounted on a shaft so it can rotate. The core and shaft are called an ***armature***. The shaft is mounted in bearings to allow the armature to rotate. Either stationary permanent magnets or stationary windings (electromagnets) are placed around the armature.

The ends of the armature coil are connected to two semicircular ***commutators***. The commutators are

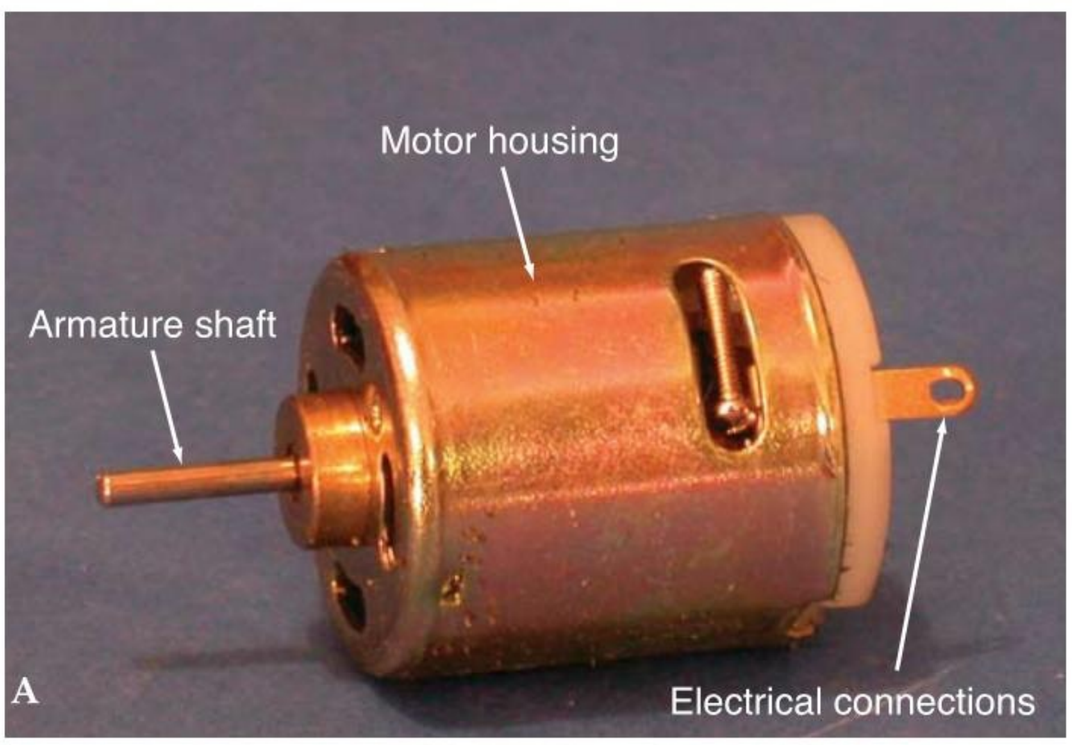
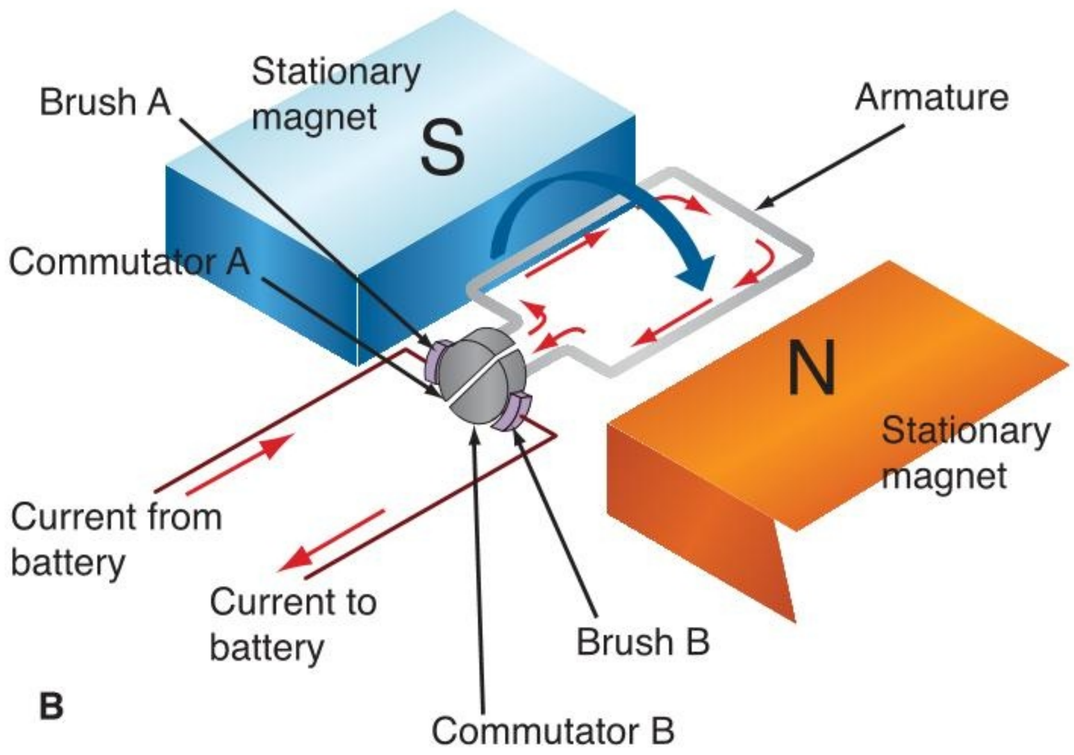
Ford

Figure 19-24. A solenoid can be used to operate a trunk latch. The magnetic field around the coil pulls the core into the coil, swinging the trunk latch back on its pivot to release the trunk. The spring forces the latch back into its original position when the magnetic field collapses.





Goodheart-Willcox Publisher

Figure 19-25. An electric motor uses magnetic fields to spin an armature.

attached to the armature, so they rotate with it, but they are also in contact with two stationary ***brushes*** that are connected to a power source.

Current flows from the negative terminal of the power source, through brush A and commutator A, through the armature, through commutator B and brush B, and back to the positive terminal of the power source. This sets up an electromagnetic field in the armature.

As shown in **Figure 19-26**, the armature's north pole is near the north pole of the stationary magnet, and its south pole is near the south pole stationary magnet. Since like charges repel, the armature swings a quarter turn. At this point, the north pole of the armature is near enough to be attracted to the south pole of the stationary magnet, so the armature swings another quarter turn.

Since the commutators rotate with the armature, the current now flows from the negative terminal through brush A to commutator B, which reverses the flow through the armature. Because the flow is reversed, north poles are together again, so the armature rotates a third quarter turn. Attraction between the opposite poles causes the fourth quarter turn, completing one full rotation. The process then begins again.

Goodheart-Willcox Publisher

Figure 19-26. Electric motors use magnetic fields to keep the armature spinning, based on the principles that like poles repel each other and opposite poles attract.

Electronic Components

Electronic components, or solid state components, are composed of semiconductor material, which allows the device to control electricity. They are typically smaller and lighter than most electric components, and they do not consume as much energy. This is the fundamental advantage of electronic components.

Semiconductors

As you may recall, a conductor passes free electrons, and an insulator blocks the flow of free electrons. A ***semiconductor*** is a crystal material that can act as either a conductor or an insulator, depending on conditions.

Semiconductors are made from silicon, germanium, or other substances that conduct a limited amount of electricity in a manner that can be controlled. For example, silicon is a nonmetallic element contained in many types of sand. To make a semiconductor, silicon is melted and cooked at about 2600°F (1428°C). Then the silicon is doped, or combined chemically, with substances such as phosphorus and boron. This causes the silicon to grow into useful crystals (substances with symmetrical atomic structures).

The two basic types of semiconductors are P-type and N-type. A ***P-type semiconductor*** is doped so that it has excess protons. This creates holes, or spaces in the atoms for free electrons. As a result, a P-type semiconductor is a relatively positive substance that attracts electrons. Remember that *P* stands for positive.

An ***N-type semiconductor*** is doped so that it has excess electrons. Substances are added to the silicon to provide free electrons that can move through the N-type semiconductor material. Remember that the *N* stands for negative.

In its pure state, silicon is a good insulator. Its semiconductor properties—N-type or P-type—are determined by the number of holes or free electrons that result from the doping process. Neither type is very useful by itself. By using the two types together, however, numerous useful devices can be manufactured.

Diodes

A ***diode*** is made by joining a piece of N-type semiconductor with a piece of P-type semiconductor. A wire lead is attached to each end of the diode. The result is a device that blocks direct current in one direction and passes direct current in the other direction. A diode, therefore, acts as an electric check valve, **Figures 19-27** and **19-28**.

When a diode is connected so that it acts as a conductor, it is said to have a ***forward bias***. The battery charge pushes the electrons and holes closer to the ***PN junction*** (the common edge of the P-type and

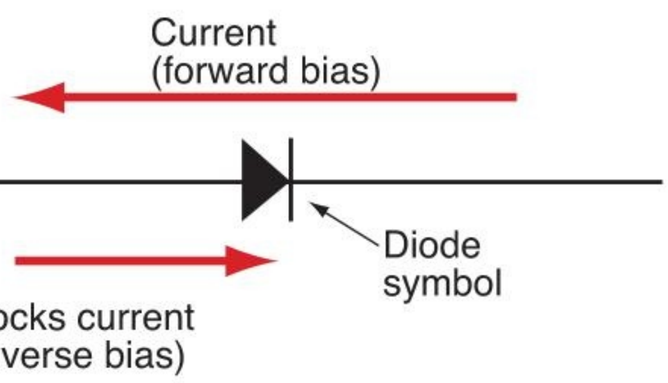
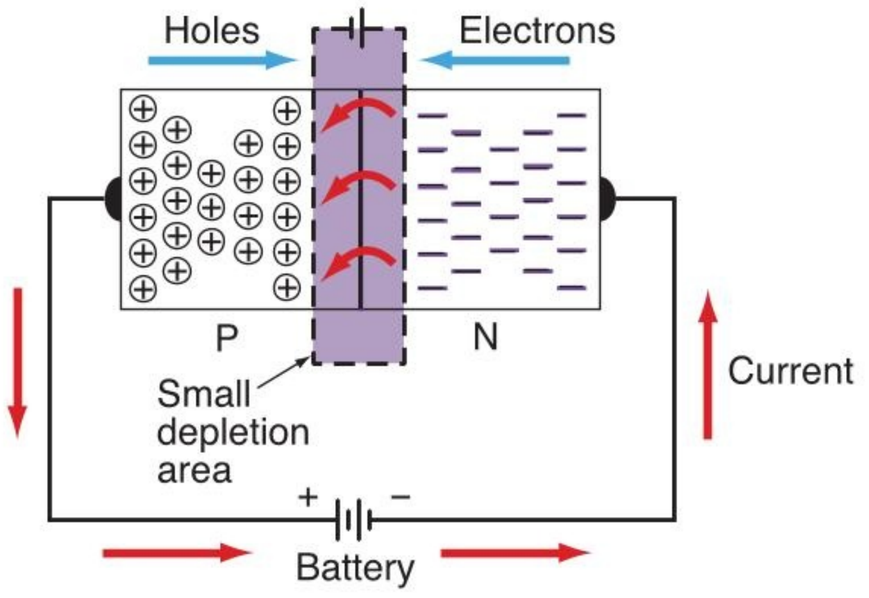
Figure 19-27. The simplest semiconductor device is a diode. A—Two small diodes on a circuit board. Note that they are labeled with a D for diode. Also notice the silver strip on each diode. Diodes usually have a strip on one end so you know how they should be installed in a circuit. B—These are the parts of a diode.

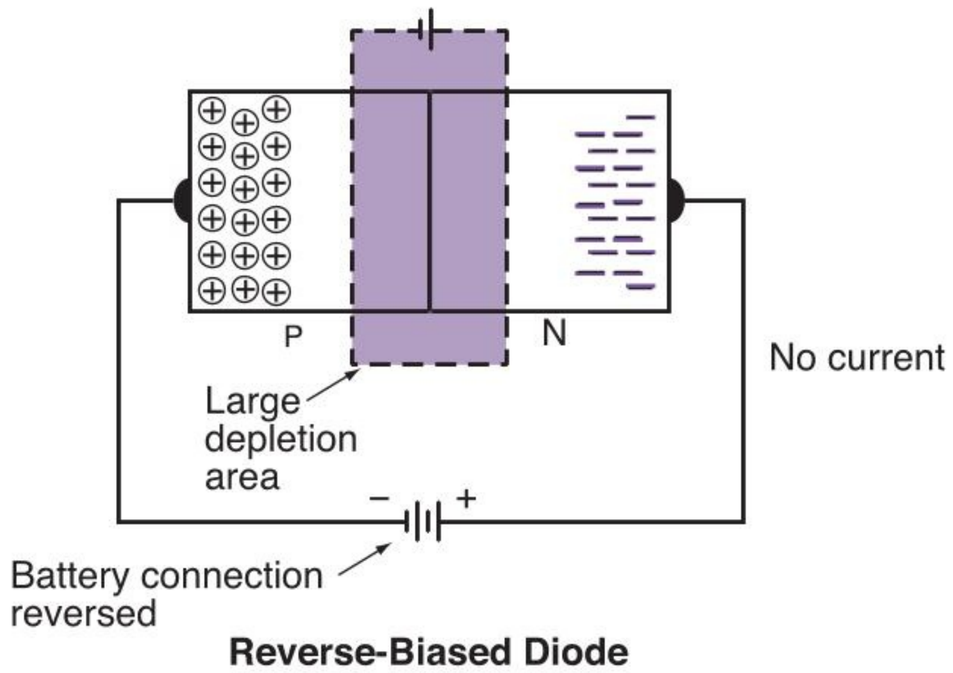


Goodheart-Willcox Publisher

Figure 19-28. The arrow in the diode symbol points in the direction of current.

N-type semiconductors). This reduces the size of the depletion area (area surrounding the PN junction that is void of holes and electrons) around the PN junction so that electrons can flow across the junction. A voltage drop of about 0.7 volts is needed to produce a forward bias current across a diode. See **Figure 19-29A**.





Goodheart-Willcox Publisher

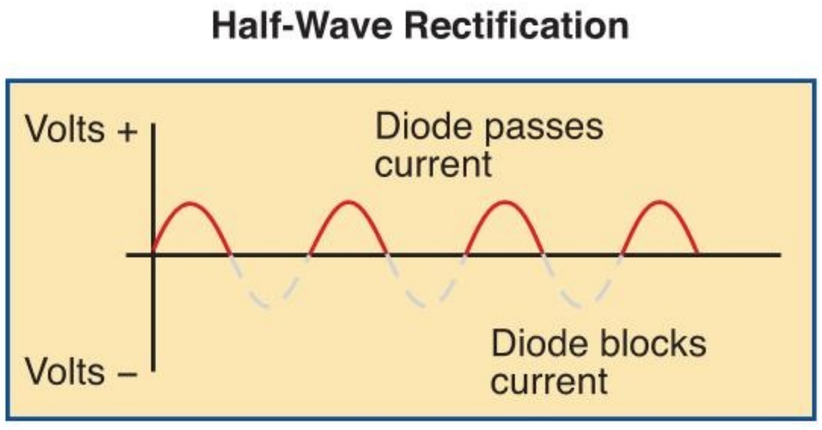
Figure 19-29. Diode operation is shown. A—A forward-biased diode has a small depletion area around its PN junction. Electrons flow easily across the depletion area. B—A reverse-biased diode has a large depletion area. The junction acts as an open switch to block current.

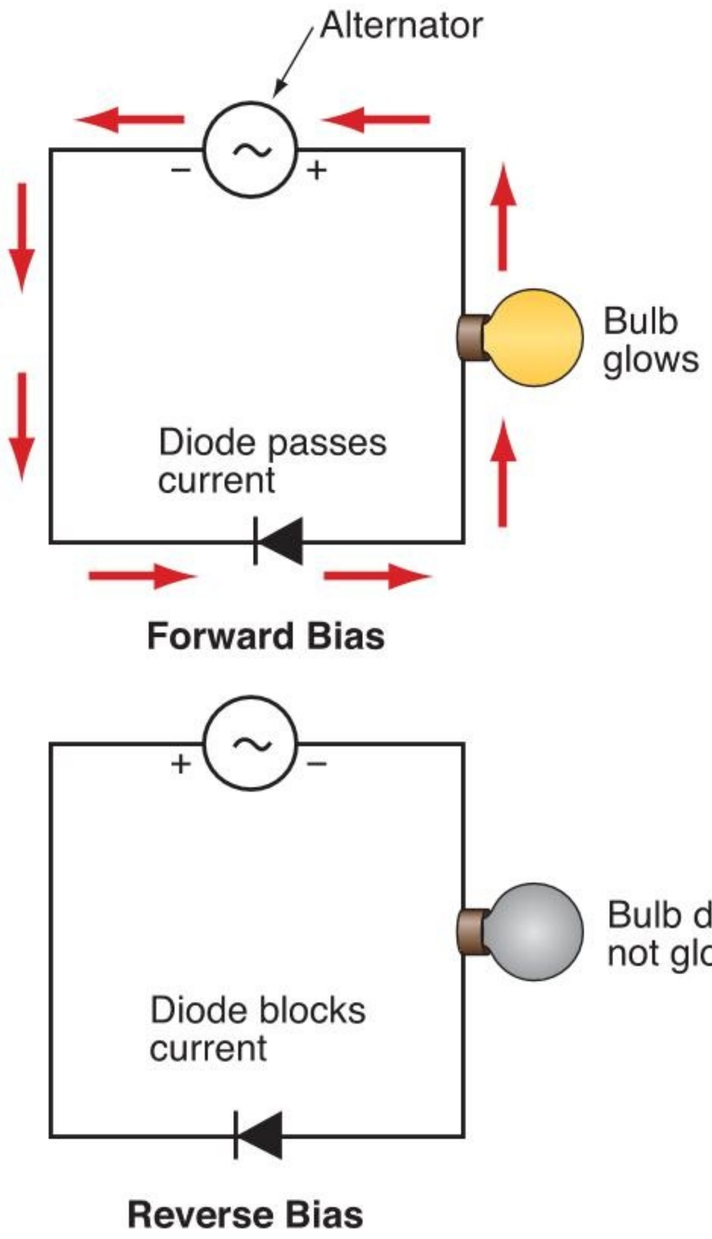
When a diode is wired so that it acts as an insulator, it has a ***reverse bias***. The battery connections are reversed, so the electric charge pulls electrons and holes away from the PN junction. This makes the depletion area larger, blocking current through the diode, as shown in **Figure 19-29B**.

Reverse bias voltage is a rating of the maximum voltage a diode can block without being damaged. If this voltage is exceeded, the diode is ruined. Automotive diodes are rated to operate on less than 15 volts.

Diodes are commonly used to convert alternating current to direct current. This process is called ***rectification***. If a diode is placed in a circuit with alternating current, the diode allows current in one direction only. Refer to **Figure 19-30**.

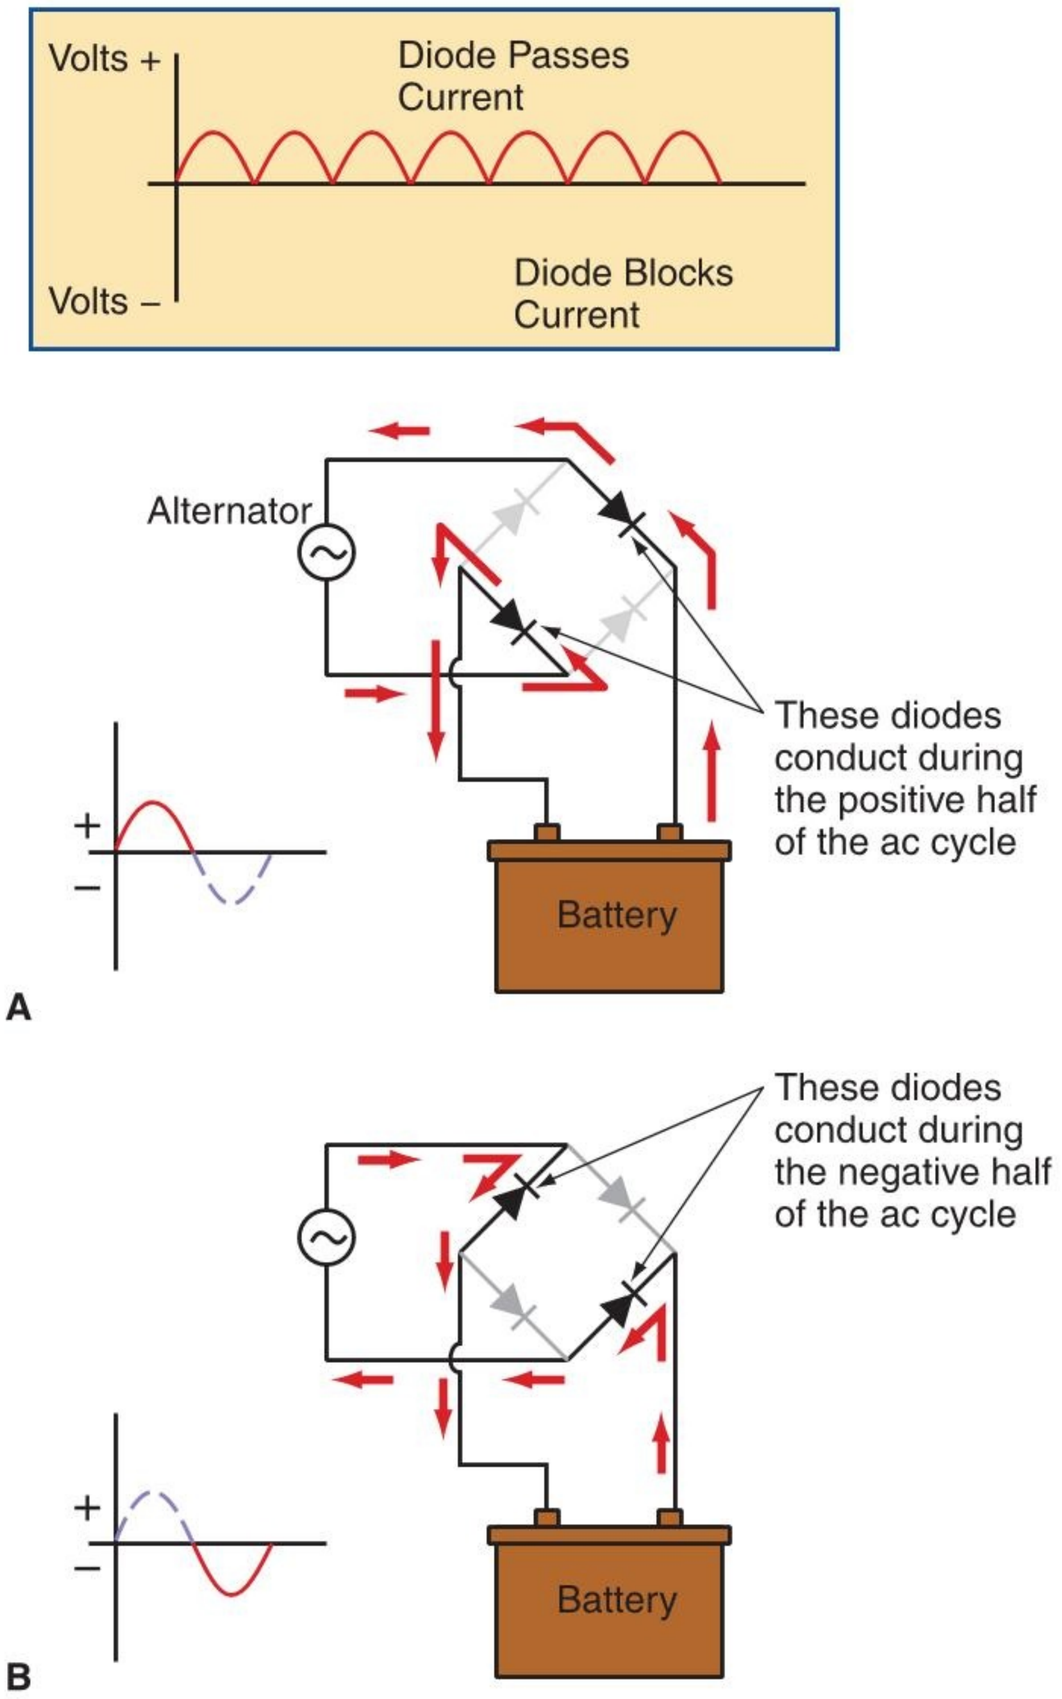
Copyright Goodheart-Willcox Co., Inc.





Goodheart-Willcox Publisher

Figure 19-30. When ac is fed into a diode, diode conducts current in one direction only, producing half-wave rectification. The bulb glows only when the diode has forward bias.



Goodheart-Willcox Publisher

Figure 19-31. Several diodes wires as shown produce full-wave rectification. Both halves of the ac sine wave produce direct current.

A single diode in series with an ac source produces ***half-wave rectification***. In this configuration, only half of each ac ***wave*** is allowed through. ***Full-wave rectification*** allows both halves of each ac wave through. Both halves flow in the same direction. **Figure 19-31** shows how diodes can be used to produce full-wave rectification.

Diodes are commonly used inside a vehicle's charging system alternator. The initial output of an alternator is ac. The ac must be rectified into dc for use in the automobile's electric and electronic systems.

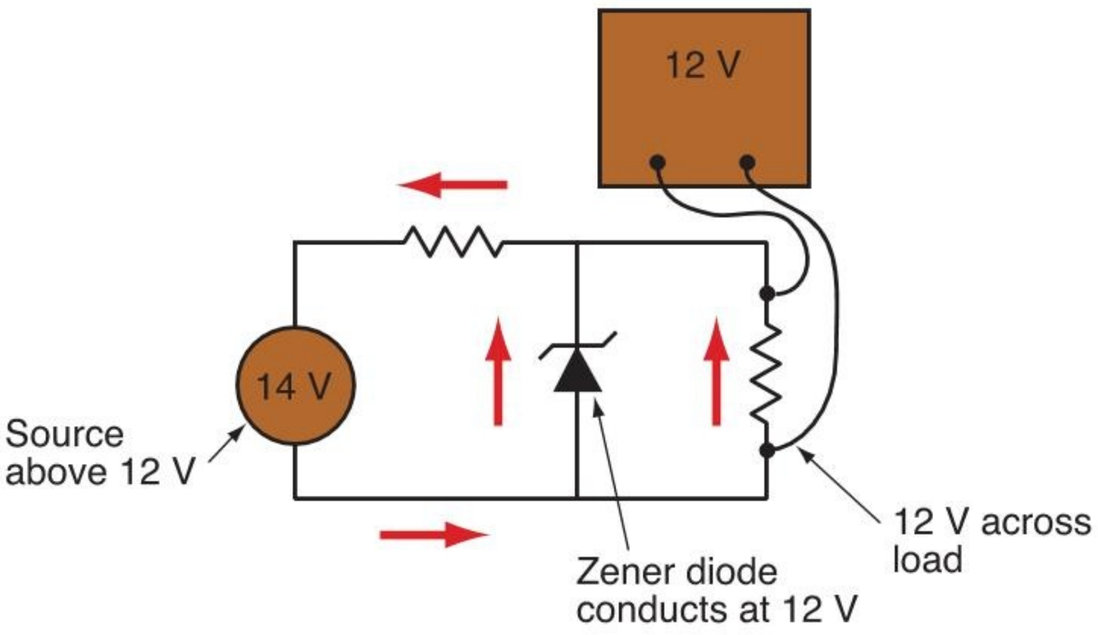
Zener Diodes

A ***zener diode*** is a special type of diode that serves as a voltage regulator. It conducts current normally when it is forward biased. It also blocks current when it is reverse biased. However, when a specific reverse-bias voltage is reached, the zener diode begins to conduct current. See **Figure 19-32**.

Transistors

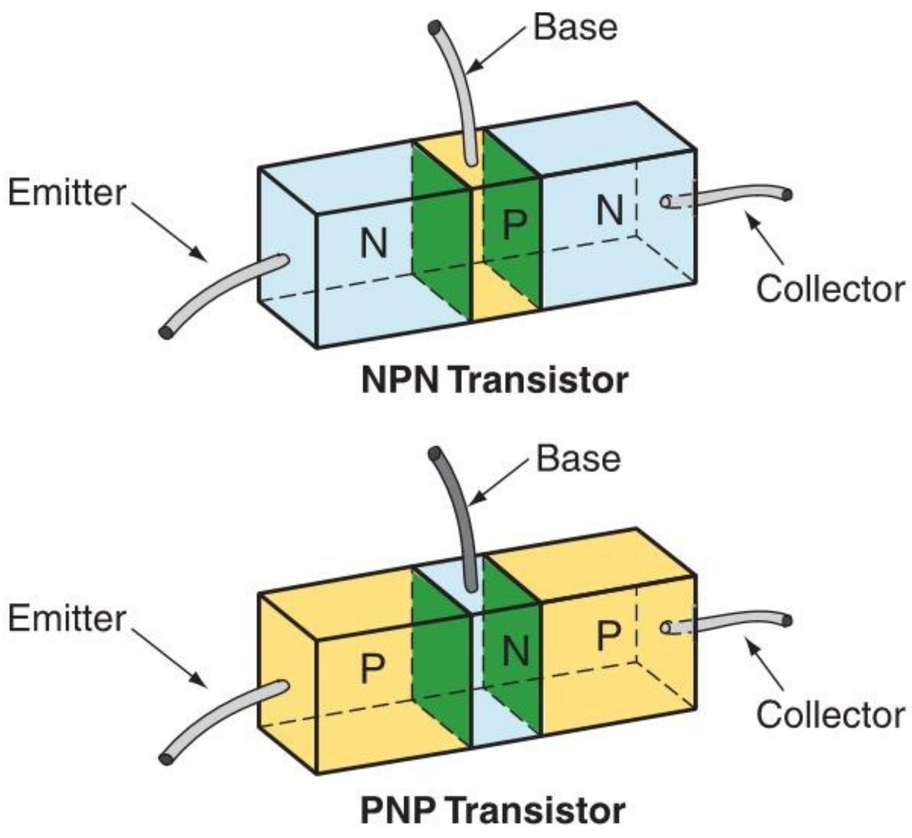
A ***transistor*** is a semiconductor device that regulates current or voltage in a circuit. It can act as a switch for electronic signals or serve as a current amplifier. *Trans-* stands for "transfer" and *-sistor* stands

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 19-32. A zener diode is commonly used as a voltage regulating device. When in reverse bias, it begins to conduct when a specific threshold voltage is reached. This limits the voltage drop across the zener diode.



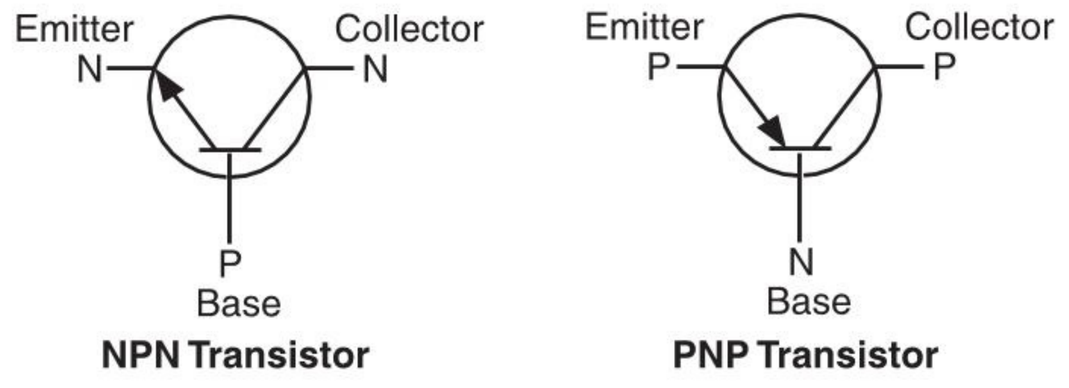
Goodheart-Willcox Publisher

Figure 19-33. The arrangement of semiconductor materials and leads in PNP and NPN transistors.

for "resistance." A transistor transfers, or changes, from a resistor to a conductor with electric stimulation.

A ***bipolar junction transistor (BJT)*** is made by joining three semiconductor materials. An ***NPN transistor*** has two N-type semiconductors and one P-type semiconductor bonded together. A ***PNP transistor*** has two P-type semiconductors and one N-type semiconductor. Small wire leads are attached to each type material. See **Figures 19-33** and **19-34**.

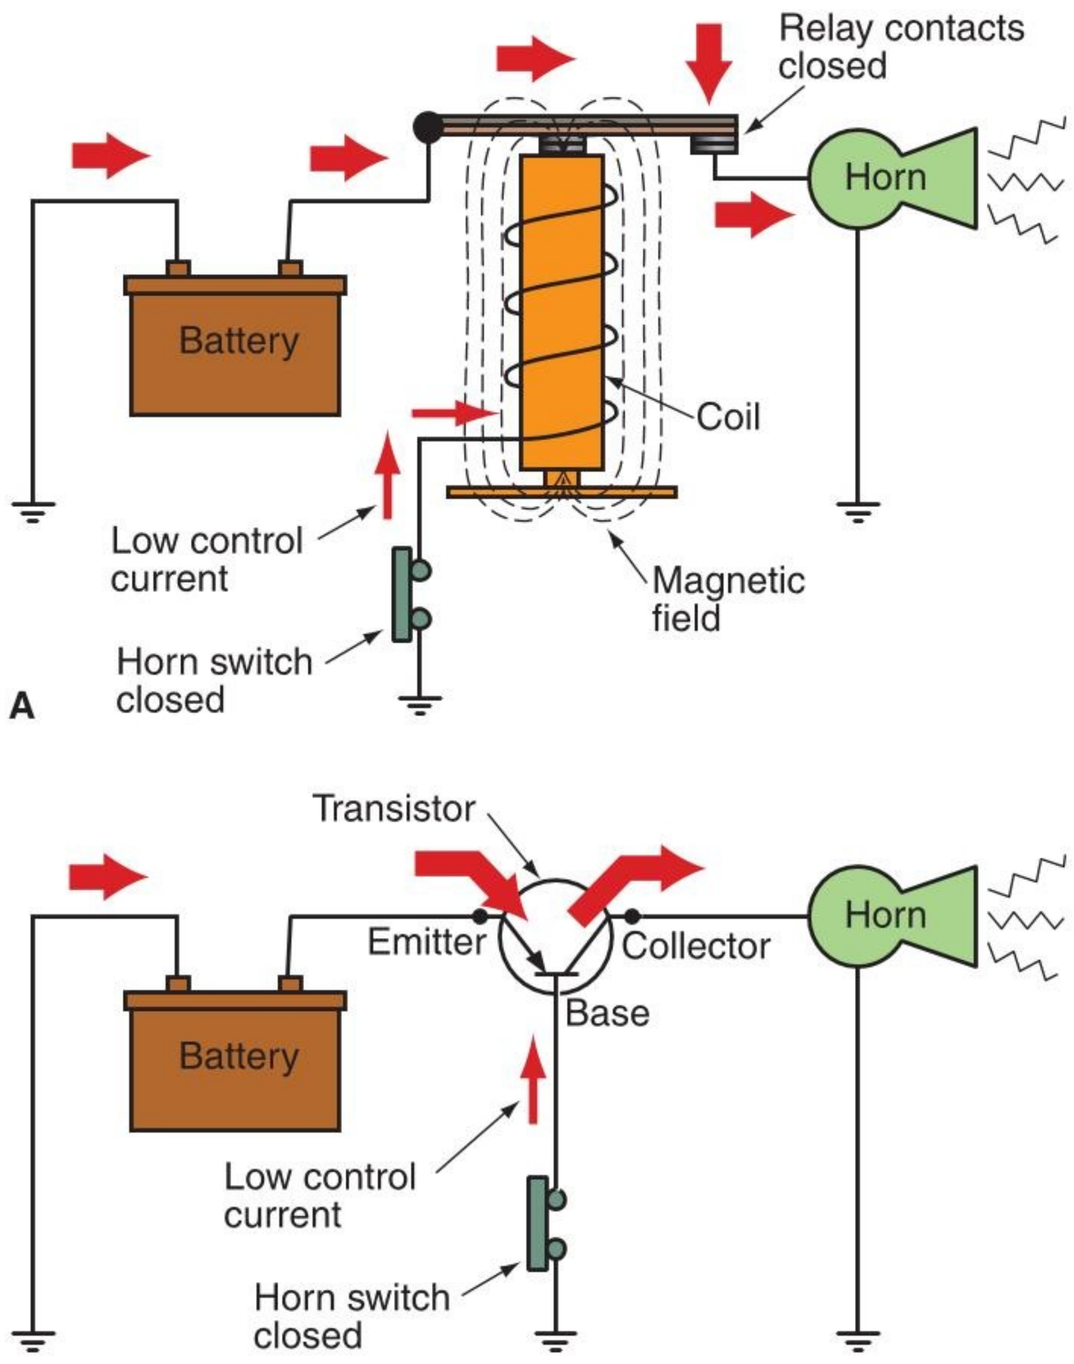
The base of a bipolar junction transistor is the "trigger" lead. A low current through the base turns the transistor on. When the transistor is on, a high circuit current passes through the emitter and collector leads. A transistor can



Goodheart-Willcox Publisher

Figure 19-34. The arrow in the transistor symbol always points to an N-type material.

act as an electronic switch, much like an electric relay. The action of a transistor compared to a relay to operate a horn circuit is illustrated in **Figure 19-35**.



Echlin

Figure 19-35. A relay does the same thing a transistor does. Current from the dash switch can be used to send higher current to another circuit for operation. A—In an electric relay, when a low control current passes through the relay windings, the resulting electromagnetic field closes the contact points, allowing a higher current to the horn. B—In a transistor, a low control current to the base makes the transistor act as a conductor, allowing a higher current to pass through the emitter-collector to operate the horn.

Copyright Goodheart-Willcox Co., Inc.

As you can see, a transistor and a relay can perform the same function. They both can use a low control current to operate a much higher circuit current. However, a transistor is much smaller than a relay, and it does not have moving parts to wear out.

Signal transistors are small transistors used to amplify low power signals or switch low currents on and off. These transistors are located in complex electronic circuits, such as those found in radios and computers. Smaller signal transistors often feed current to the base circuits of power transistors.

Power transistors are used to control high current levels. For example, power transistors are used to operate the speakers in radios. They are the output devices that regulate the fluctuating current that makes the speaker diaphragms vibrate and produce sound. Power transistors are normally mounted on a heat sink. A heat sink is used to transfer heat away from a transistor. This helps keep the transistor from overheating, which would damage the semiconductor, **Figure 19-36**.

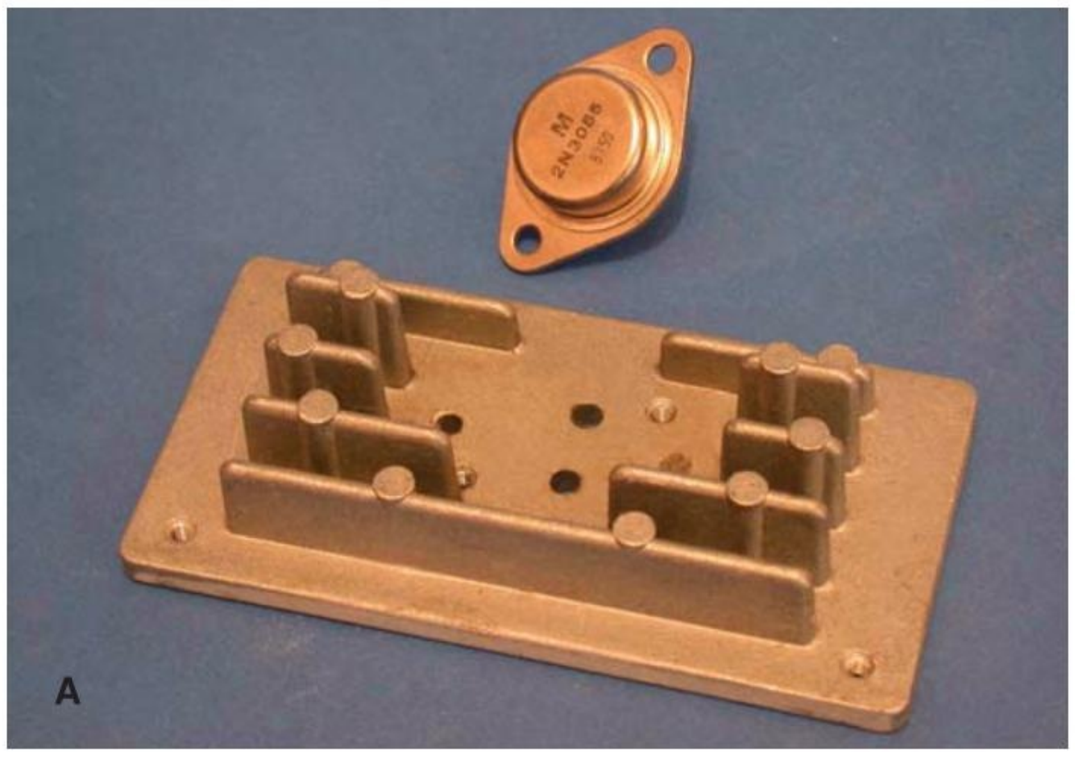


Figure 19-36. Transistors are used to ground circuits with medium current draw so they are energized. A—A power transistor is usually mounted on a heat sink. B—Silicone grease and a washer are used to help heat flow away from the transistor.

Piezoelectric Crystal

A ***piezoelectric crystal*** is a device that produces a low current output when physical pressure is applied. A diaphragm can be linked to the piezo crystal to make a microphone. Sound waves make the diaphragm flex back and forth, which places various amounts of pressure on the piezoelectric crystal. As a result, the crystal produces small voltage fluctuations. The strength of the voltage signal can be used as an indication of pressure from sound waves, like a microphone. Refer to **Figure 19-37**.

Photonic Devices

A ***photonic device*** is any device that can emit or detect light. A ***photon*** is a particle of electromagnetic light energy. Photonics is a fast-growing field of electronics, and photonic semiconductors are now being found in automotive electronics.

Light Emitting Diodes

A ***light emitting diode (LED)*** is a photonic semiconductor that emits light when it is electrically energized. Since an LED converts electricity directly into light, it is much more efficient than most other light sources. See **Figure 19-38**.

A light emitting diode is a PN junction with semiconductors made of gallium (a chemical element) that have been doped with special substances, such as phosphorus. When the LED is connected to a power source, light is emitted. The chemical makeup of the doping material determines the color of the LED light, **Figure 19-39**.

A light emitting diode chip is housed in a plastic bulb. Wire leads extend out the bottom of the housing.

LEDs can be used as indicator lights in the dash panel and interior dome lights. They are now used for exterior applications such as taillights, marker lights, and headlights.

Fiber Optics

Fiber optics is a field of electronics in which light is used to carry data through small strands of plastic or glass fiber. Each fiber is about the size of a human hair. Hundreds of fibers can be bundled into a

Copyright Goodheart-Willcox Co., Inc.

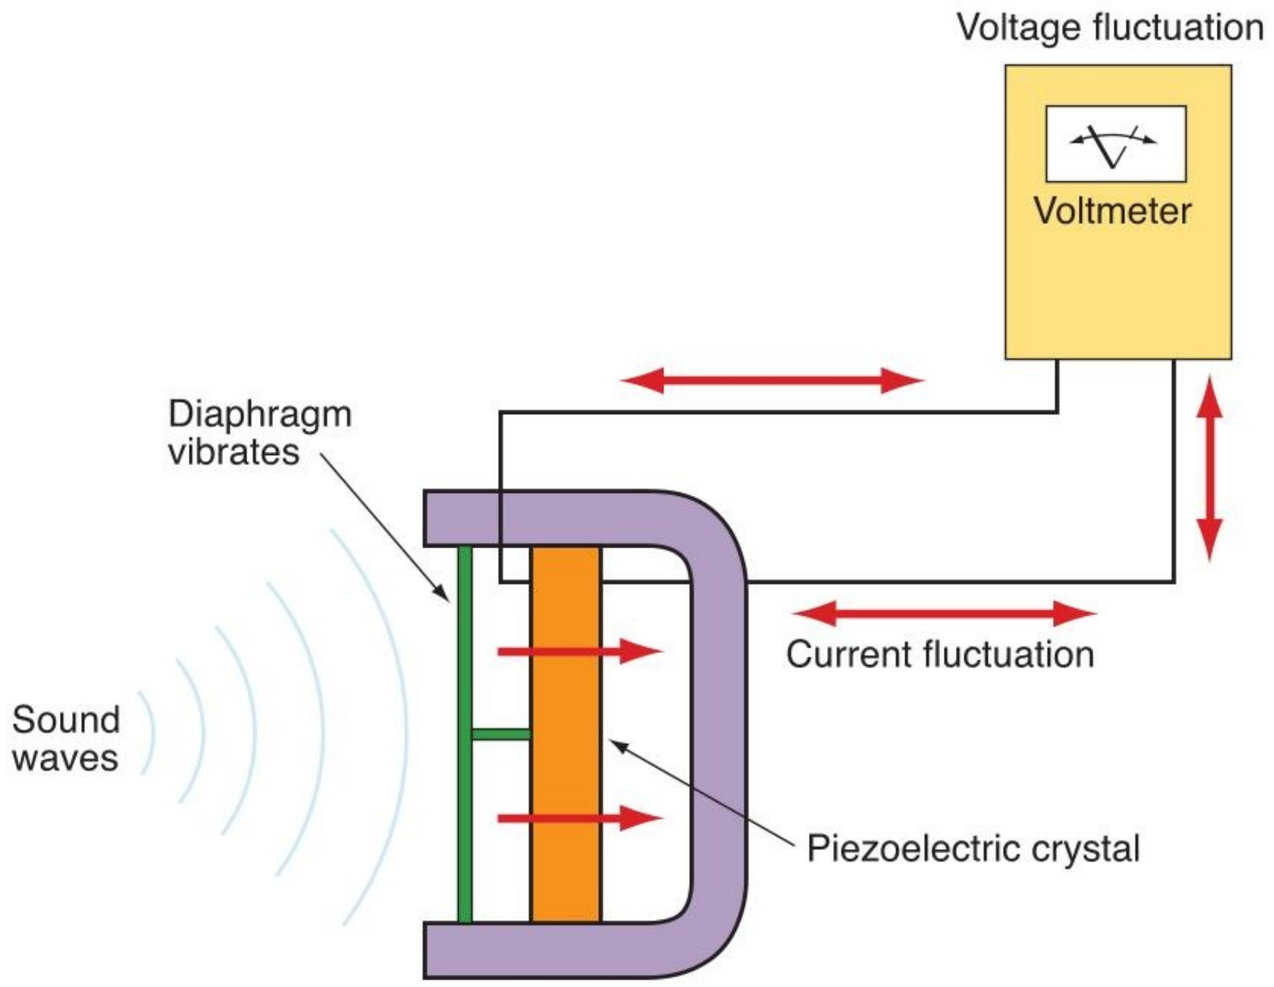

Figure 19-37. A piezoelectric crystal converts physical pressure into electrical output. This is ideal for making a microphone.

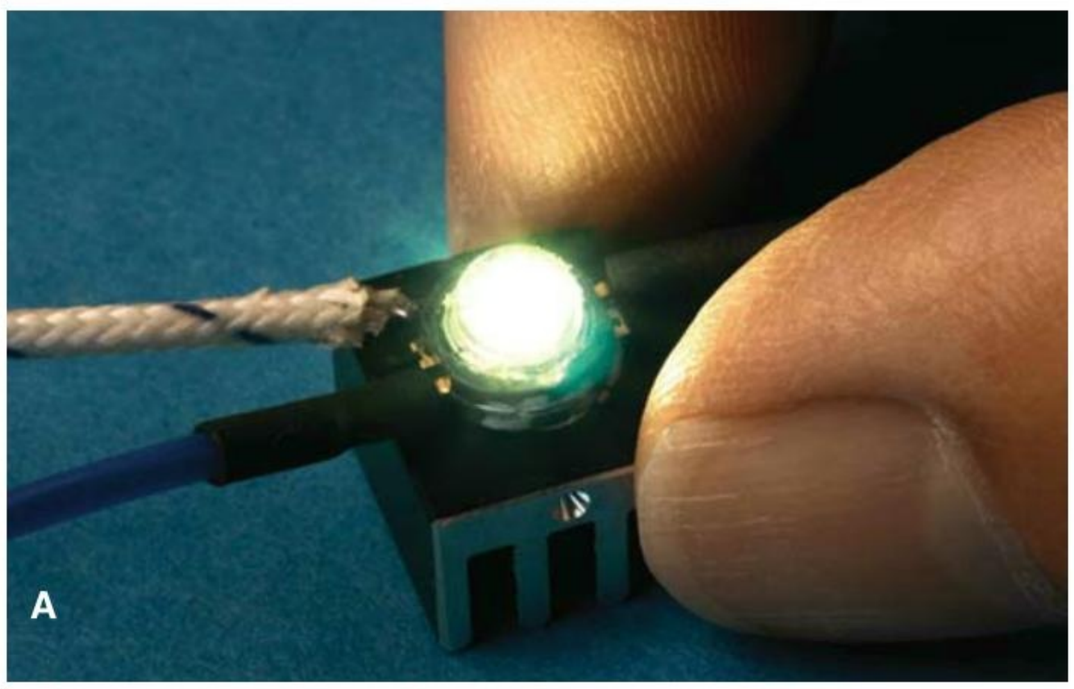

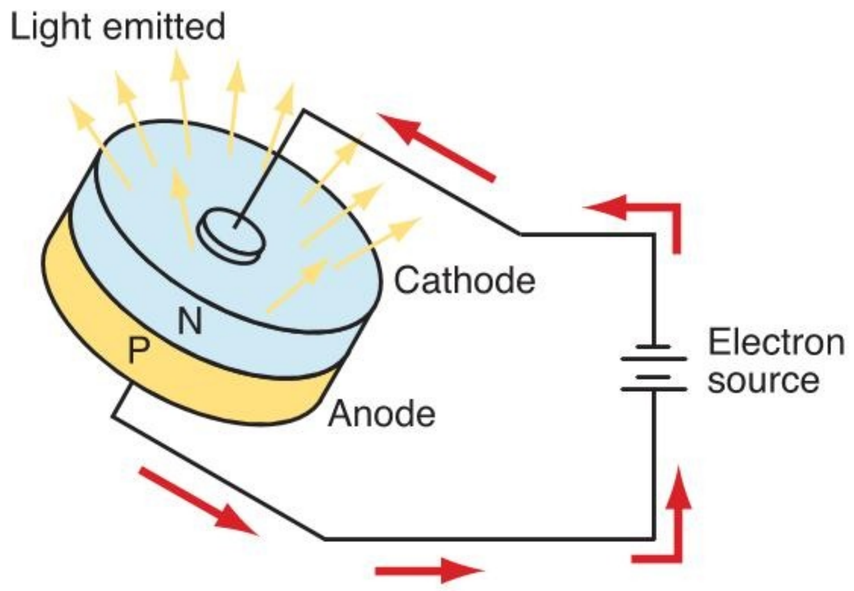

Figure 19-38. LEDs will put out a large amount of light while drawing little current. A—A small LED can emit a tremendous amount of light for its size. B—When current passes through the semiconductors, light is emitted.

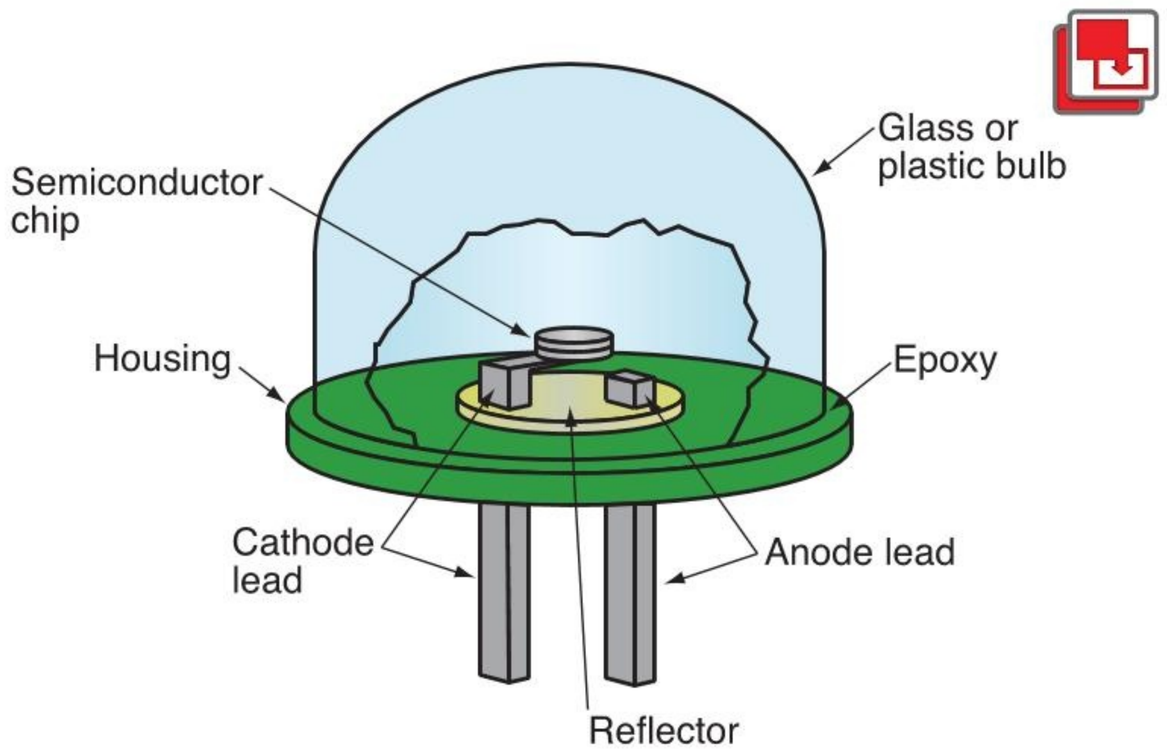

Figure 19-39. Study the parts of a light emitting diode.

single cable to transfer huge amounts of data. Look at **Figure 19-40**.

Fiber-optic cables carry light generated by LEDs or laser diodes, which are similar to LEDs but more powerful. The data stream to be carried is fed into the circuit as voltage, which modulates (changes) the light waves. The outer part of each fiber is coated with a substance that makes the light bounce off the inner wall of the fiber and shoot out the other end.

A light detector can be used to sense the light signal. The signal can then be amplified into a higher current signal to operate other devices. One strand of fiber-optic material can be used to send the same amount of electrical data as a large bundle of conventional metal wires.

Copyright Goodheart-Willcox Co., Inc.

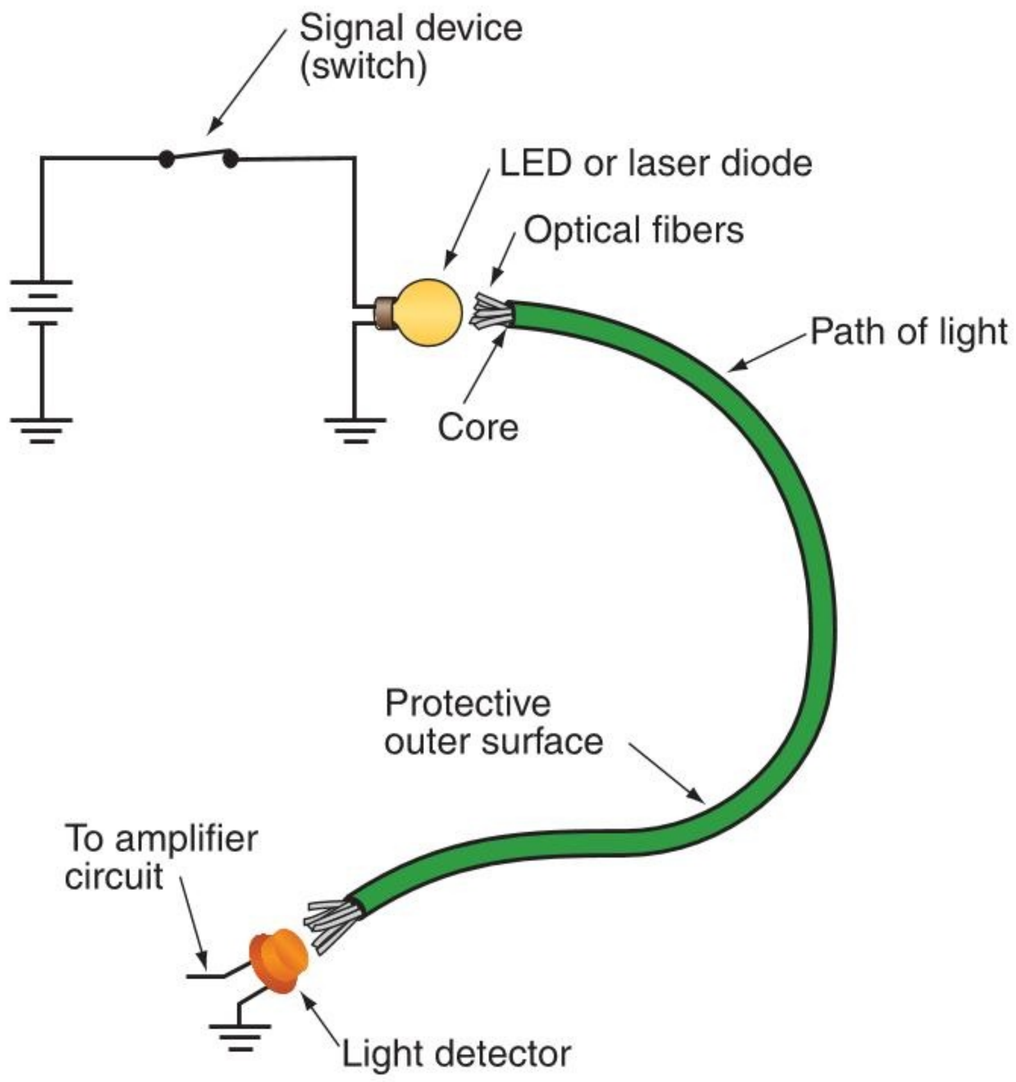

Figure 19-40. A fiber-optic cable consists of hundreds of optical fibers that carry information modulated onto light waves produced by a laser diode or LED.

Photonic systems are more reliable and efficient than all-electronic systems. They are also faster and take less space. Laser and fiber development are progressing rapidly, enabling error-free transmission of signals over distances greater than 100 miles without reamplification.

Photovoltaic Cells

A ***photovoltaic cell***, or solar cell, is a photonic device that converts light directly into current. A basic photovoltaic cell, **Figure 19-41**, consists of a glass outer layer that contains a transparent negative terminal, an antireflective layer to increase the cell's efficiency, a layer of N-type semiconductor material, a layer of P-type semiconductor material, and a metal base.

More layers, containing other types of semiconductors, are often used to help increase efficiency. The photovoltaic cell converts the photons to electrons, which form a current that can be used to power external devices. The cell's electromagnetic field also provides a voltage output of about 0.5 V.

If we connect several photovoltaic cells in series, we can increase voltage output. Four silicon photovoltaic cells in series would generate approximately 2 V. If we connect the cells in parallel, the voltage stays the same, but the current output increases. This makes it possible to use the output for higher load devices, such as a small fan to cool the inside of a vehicle when it is sitting in the hot sun. See **Figure 19-42**.

Photoresistors

A ***photoresistor*** is a semiconductor that acts as a resistor in the dark but changes to a conductor when exposed to light. If a battery is connected to the photoresistor with the light source off, no current is allowed through the device because the photoresistor has high resistance. When the light source is turned on, resistance becomes much lower, and the photoresistor changes to a conductor to allow current.

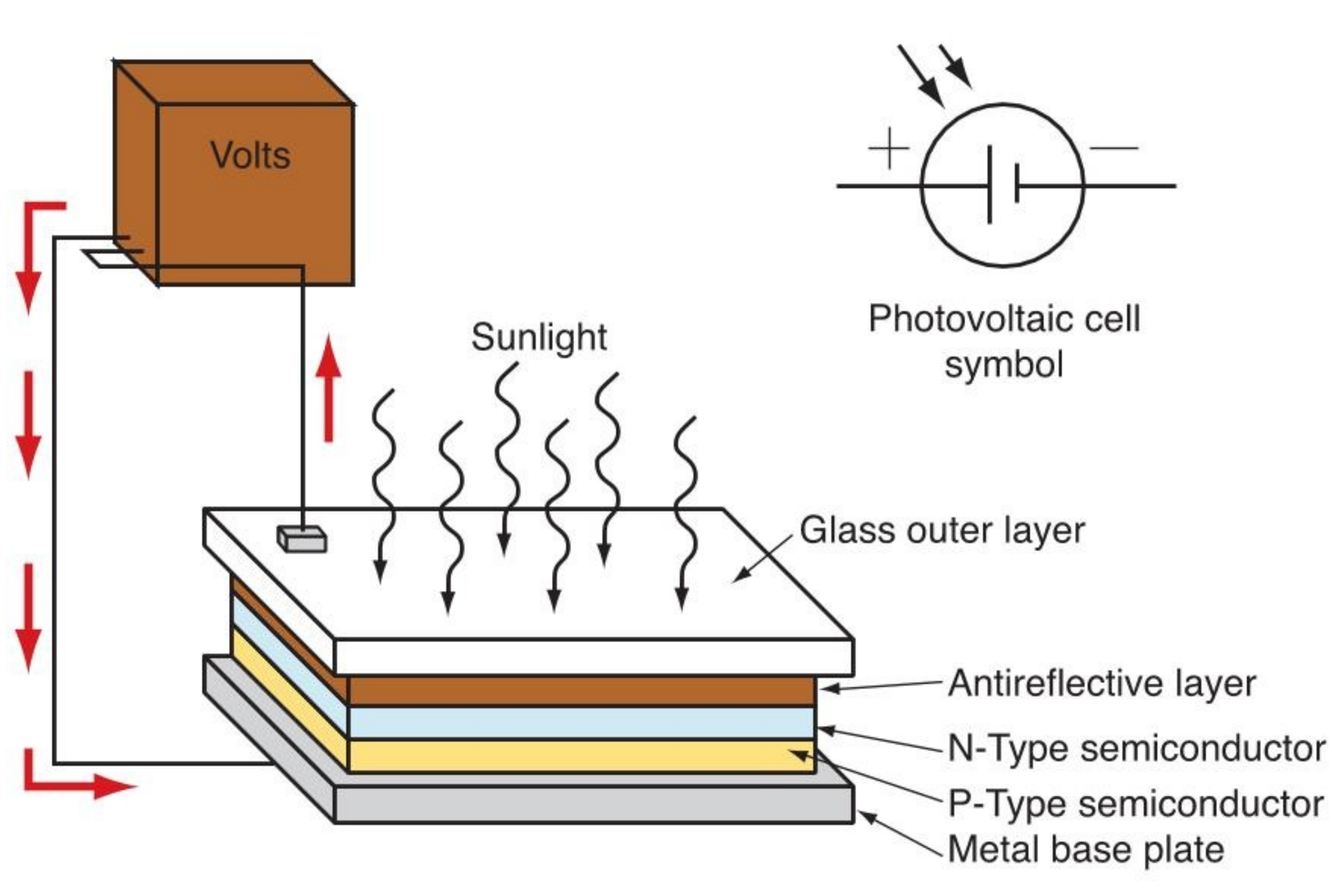

Figure 19-41. A solar cell converts light into electricity. The semiconductor surfaces trap light energy and feed electrons to the output leads.

Copyright Goodheart-Willcox Co., Inc.

Figure 19-42. Ambient light is making this photovoltaic cell develop a low voltage. Sunlight would make it develop a higher voltage.

Photodiodes

All PN junctions are sensitive to light. A ***photodiode*** is a PN junction device that can function in one of two ways, depending on how it is connected in a circuit. It can produce a low voltage when excited by light. It can also be used to control current by allowing current flow when excited by light.

Phototransistors

A ***phototransistor*** performs a function similar to that of a photodiode. When light strikes the phototransistor, the emitter-collector junction conducts current. When light is blocked, the emitter-collector junction changes to an insulator and blocks current. A phototransistor might be used as a sensor in a control circuit in an automatic headlight dimming system to turn the headlights on and off by reacting to light conditions.

Liquid Crystal Displays

A ***liquid crystal display (LCD)*** is a device that has a fluid crystal material sandwiched between two sealed glass plates. This device can polarize light (make all the light waves vibrate in a single plane) to display numbers, letters, or other images. Both glass plates have a polarizing film on them, but one is turned at 90° to the other. See **Figure 19-43**.

When the liquid crystals are aligned with the top plate, they reflect light. However, when a charge is applied, their orientation changes, and they block the light. The areas of blocked light can be arranged by applying the charge to areas of a specific shape to form the images we see.

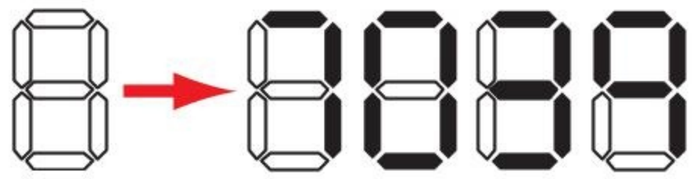

Figure 19-43. In a basic LCD numeral display, seven charge areas are arranged as shown here. By applying a charge to different combinations of the charge areas, the LCD can display the numerals 0 through 9.

Liquid crystal displays have thousands of practical uses. LCDs are used in the instrument cluster of late-model vehicles to show speed, tachometer graphics, odometer displays, and other information.

Customer Relations

Always "go the extra mile" to improve customer satisfaction. For example, you might want to place faulty parts in a plastic bag to show your customers. This will help demonstrate the shop's integrity and show each customer that you want them to understand your repair work.

Summary

- A resistor limits current flow in a circuit. A fixed resistor has only one resistance value. A variable resistor can be changed to have various resistance values. A tapped resistor can be connected differently to change its internal resistance.
- A switch connects and disconnects power to and from a circuit. Many different kinds of switches have been developed to meet different needs.
- A capacitor is a storage device for electricity. It is commonly used to smooth current in a circuit.
- Fuses are used to protect circuits from high current. Without a fuse, a short could cause enough current to burn up wires and components.
- Circuit breakers are another form of circuit protection device. They also stop current if current draw becomes too high. However, circuit breakers are not ruined after one use.

Copyright Goodheart-Willcox Co., Inc.

- A coil is an insulated wire wrapped in loops, usually around an iron-containing core.
- A transformer uses two coils located close together. A transformer can isolate circuits, increase voltage, or decrease voltage.
- A relay uses a small input current to control a larger circuit current.
- A solenoid is an electromagnet used to move an iron plunger or core. It can be used to complete a very high-amperage circuit, something like a relay. It can also be used to engage parts—to move the engine throttle linkage, for example.
- An electric motor uses magnetic forces to spin an armature. The spinning action can be used to do work.
- Electrical and electronic symbols are used on wiring diagrams instead of isometric drawings of the individual parts. This saves time in creating the diagrams and makes the diagrams clear and easy to read.
- Electronic devices are composed of semiconductor material, which allows the device to control electricity. Examples include diodes, transistors, solar cells, and integrated circuits.
- A semiconductor is a substance that can change from an insulator to a conductor with external stimulation. A P-type semiconductor has more holes, which gives it a relatively positive charge; N-type material has more electrons.
- A diode passes current in one direction only.
- Transistors switch or amplify current in a circuit.
- Photonic semiconductors are devices that emit or detect light. They are used extensively in electronics to provide information and to produce direct current.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

armature
bipolar junction transistor (BJT)
brush
capacitor
circuit breaker
coil
commutator
diode
electric motor
electronic components
farads (F)
fiber optics
forward bias
full-wave rectification
fuse
half-wave rectification
impedance
light emitting diode (LED)
liquid crystal display (LCD)
NPN transistor
N-type semiconductor
photodiode
photon
photonic device
photoresistor
phototransistor
photovoltaic cell
piezoelectric crystal
PN junction
PNP transistor
P-type semiconductor
rectification
relay
resistor
reverse bias
reverse bias voltage
semiconductor
short circuit
solenoid
switch
transformer
transistor
turns ratio
wave
zener diode

Activities

1. Using what you've learned in this chapter, sketch a schematic for a circuit that includes a resistor, a switch, a capacitor, and a fuse.
2. Use the Internet to research any of the topics covered in this chapter. Look up articles, pictures, and animations of these components.

Review Questions

Answer the following questions using the information provided in this chapter.

1. A(n) _____ is an electric component that limits current in a circuit.
2. Explain the difference between a normally open and a normally closed switch.
3. How does a typical thermal switch operate?
4. Explain the operation and application of a mercury switch.
5. What component can be used to block direct current while allowing alternating current to pass?

Copyright Goodheart-Willcox Co., Inc.

6. How does a fuse protect a circuit?
7. What could happen if you install a new fuse that has a higher fuse rating than the old fuse?
8. A(n) _____ is a section of small wire connected to a larger wire to protect a circuit.
9. A(n) _____ does the same thing as a fuse but it is not ruined when activated by high current.
10. Which type of transformer decreases voltage but increases current?
11. What is the basic purpose of a relay?
12. What is a solenoid?
13. A(n) _____ component is typically smaller, lighter, and more energy efficient than its electric equivalent.

Matching

For questions 14 through 21, match the electrical symbols in the left-hand column by placing the letter of the description in the right-hand column beside the number of the matching symbol.

14.
15. 16.
17.
18.
19. 20.
21.

A. Capacitor
B. Fuse link
C. Fixed coil
D. Lightbulb
E. Transformer
F. Fuse
G. Variable capacitor
H. Relay
I. Variable resistor
J. Solenoid

22. What material, used extensively in electronics, can act as either an insulator or a conductor?
23. Explain the difference between P-type and N-type semiconductors.
24. How does a diode function?
25. For what purpose are zener diodes commonly used?
26. What semiconductor device is used to switch or amplify current in a circuit?
27. What type of transistor is controlled by voltage?
28. What semiconductor device emits light when it is electrically energized?
29. Explain how fiber-optic material can be used to transmit information.
30. What is a photovoltaic cell?

ASE-Type Questions

1. Technician A says the small base circuit of a transistor controls current flow. Technician B says the small emitter circuit controls current flow. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says a rheostat has at least three electrical connections. Technician B says a potentiometer has at least three electrical connections. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. A particular type of resistor has a tolerance of 3%. Technician A says this indicates that the resistor's current value can be 3% above or below its stated specification. Technician B says this indicates the resistor's resistance value can be 3% above or below its stated specification. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says that a diode only allows current flow in one direction? Technician B says a diode simply regulates current flow in both directions.
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

5. Technician A says a push-button switch has a spring-loaded button that, when pressed, makes or breaks an electrical connection. Technician B says pressure switch is a special type of push-button switch that stays in one position until you move it. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says a mercury switch can be used to activate the underhood light in a vehicle. Technician B says a pressure switch can be used in the engine oil light circuit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says a capacitor blocks dc current and is commonly used as a noise suppressor for automotive radios. Technician B says a capacitor has the ability to store electrical energy. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Technician A says a 20-amp automotive fuse will handle 25 amps of current without blowing. Technician B says that a replacement fuse must have the same amp rating as the original. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says a circuit breaker is designed to protect a circuit from high current. Technician B says a circuit breaker's rating is given in amps. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says coils are usually wrapped around an iron core. Technician B says coils block direct current flow. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. Technician A says a transformer can be used to isolate a circuit. Technician B says a transformer can be used to change the voltage in a circuit. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. Technician A says the voltage and current in a transformer are inversely proportional. Technician B says impedance is resistance to alternating current at a given frequency. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
13. An electrical device that uses a small input current to control a larger current is known as a(n):
    (A) transformer.
    (B) relay.
    (C) inductor.
    (D) solenoid.
14. Technician A says a semiconductor can act like an insulator. Technician B says a semiconductor can be used as a conductor. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
15. When a diode is forward biased, it acts like a(n):
    (A) conductor.
    (B) insulator.
    (C) resistor.
    (D) transistor.
16. Technician A says a diode is commonly used to convert alternating current into direct current. Technician B says one diode in series with an ac source produces full-wave rectification. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

17. Technician A says a transistor is a device used to amplify current in a circuit. Technician B says a transistor is a device used to rectify current in a circuit. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
18. All of the following are common types of transistors *except:*
    (A) power transistor.
    (B) field-effect transistor.
    (C) zener transistor.
    (D) high-frequency transistor.
19. Technician A says a thyristor is a controllable diode. Technician B says a thyristor can be used to control different amounts of current. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
20. All of the following are photonic devices *except:*
    (A) light emitting diodes.
    (B) field-effect transistors.
    (C) solar cells.
    (D) photoresistors.

Chapter 20
Electrical Tools and Test Equipment

After studying this chapter, you will be able to:

- Identify tools that are commonly used during electrical repairs.
- Summarize the use of test equipment for various vehicle systems.
- Summarize the use of multisystem test equipment such as scan tools and engine analyzers.
- Select the proper tool or tester for the job.

As discussed, today's vehicles are virtually impossible to fix without the right tools and equipment. This is especially true with electrical and electronic repairs. Modern vehicles, with their on-board computers, sensors, actuators, and complex wiring, require the skill of a well-trained and well-equipped technician.

Electrical Repair Tools

Electrical repair tools include the soldering tools and wire stripping tools used by the automotive electronic technician. Study the benefits, methods, and dangers of using these essential tools.

Soldering Tools

Solder is an alloy that has a relatively low melting point compared to other metals. ***Soldering*** is the process of using heat and molten solder to join wires, terminals, and other components. Soldering is the best method of making permanent electrical connections. Soldered connections have low resistance. They also resist corrosion and vibration failure.

Soldering tools are used to heat components (wires or terminals) and melt the solder onto the connection to form a permanent electrical circuit path. A ***soldering gun*** has a transformer that sends high current through a high-resistance tip to quickly generate heat for soldering. A soldering gun has a high power rating and is trigger-operated. It is ideal for automotive electrical repairs because the tip heats up in only a few seconds.

A ***soldering iron*** must be plugged into a wall outlet and allowed to heat up for several minutes before use. This makes it slightly less convenient than a soldering gun, with its trigger and fast heat-up. However, the tip on a soldering iron is generally smaller and more suited to delicate work on circuit boards.

Copyright Goodheart-Willcox Co., Inc.

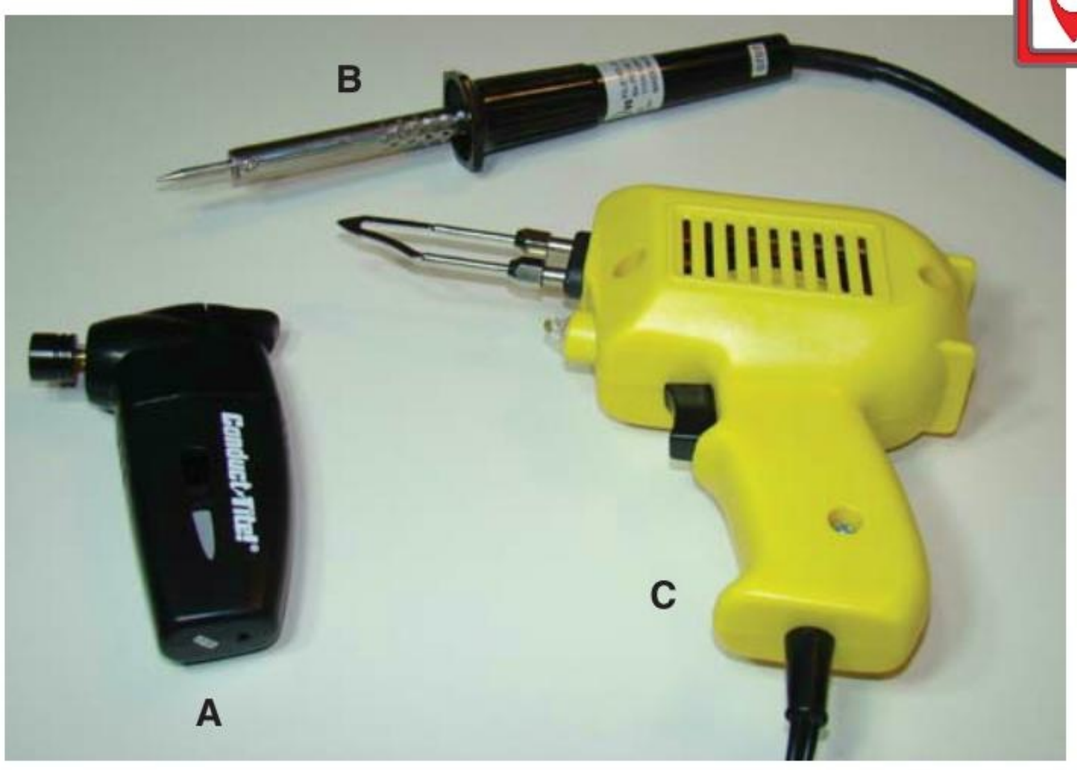
A ***soldering torch*** burns butane gas to instantly generate heat for soldering wires and electric components together. The soldering torch is gaining popularity because it does not have to be plugged into a wall outlet, and it generates heat even more quickly than a soldering gun. Refer to **Figure 20-1**.

Warning

Never solder near flammable materials. The heat of a soldering gun can cause fabric, carpet, some cleaning solvents, gasoline, and other combustible materials to catch fire.

Various soldering aids have been developed for use in soldering. For example, a ***flux brush*** can be used to apply a paste-type flux to a joint. ***Flux*** chemically cleans the metal surfaces so the molten solder flows out and bonds with the base metals properly. If a metal surface is very dirty or corroded, it should be cleaned with a wire brush before the flux is applied.

Soldering picks can be used to scrape corrosion from components before solder is applied. They can also be used to help hold or pin down small components while soldering.



Goodheart-Willcox Publisher

Figure 20-1. A soldering torch, iron, or gun will heat wires and metal connectors enough to melt solder onto the components. When the solder cools and hardens, it forms a metal conductor between two components. A—A miniature soldering torch uses butane gas to heat and melt solder to join components not located in confined places. B—A soldering iron can reach tight places more easily than a soldering gun or torch. C—The metal tip of an electric soldering gun heats up quickly to melt solder and join electric components and wires.

A ***heat sink*** is a spring-loaded, clamp-on aluminum device that helps prevent overheating of electronic components while soldering. For example, a heat sink might be clamped onto the wires going to a transistor before the leads to a circuit are soldered. The heat sink absorbs heat away from the transistor, preventing damage to the sensitive semiconductor materials due to overheating.

A ***desoldering bulb*** is a tool for removing molten solder during electrical repairs. The technician uses a soldering gun, iron, or torch to melt the solder for component removal or disconnection. Then the technician squeezes the bulb, places it near the molten solder, and releases the bulb to suck the solder away from the joint. This frees the wire, lead, or component for removal.

Other soldering aids include a ***soldering sponge***, which is soaked in water and used to clean the tip of the soldering gun or iron. ***Holding devices*** free the technician's hands to use the soldering gun and solder.

Wire Stripping Tools

To make an electrical repair, insulation must often be stripped from the wires to expose the metal conductor. The wires can then be soldered together or joined with crimp-on type electrical connectors. ***Wire stripping pliers*** are designed for quickly peeling the plastic insulation off metal wires. See **Figure 20-2**.

Crimp Connecting Tools

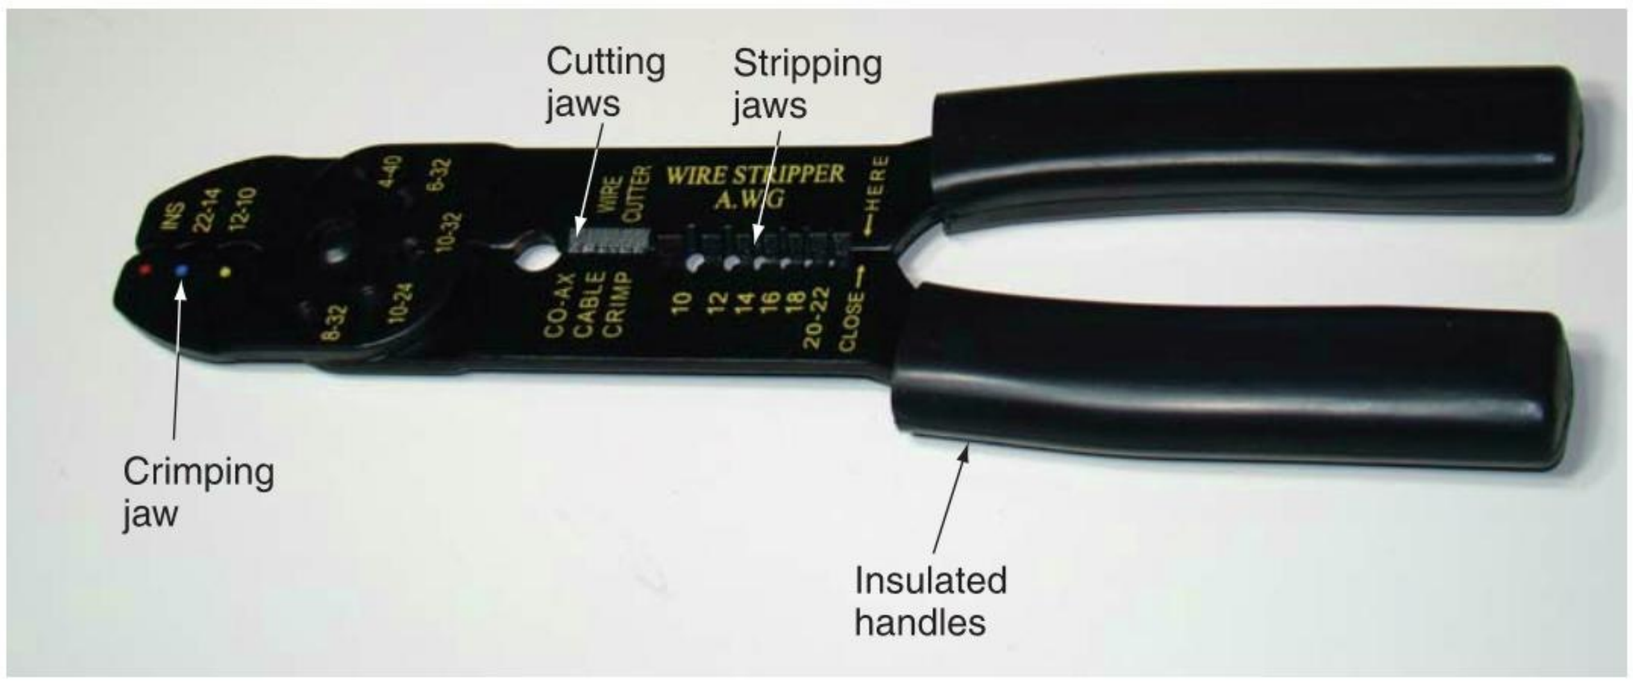
Crimp connectors provide an easy way of joining wires or installing a terminal on a wire. Before using crimping tools, you must first strip the wire. Make sure the right amount of conductor is exposed. If the conductor is too short or too long, the crimp connector will not work properly. After stripping the insulation from the wire, twist the conductor to hold the wire strands together so they will feed into the crimp connector easily.

Use ***crimping pliers*** to crush the metal part of the connector around the wire conductor. Use the correct size of jaws with the crimping tools. The jaws should be positioned over the metal part of the terminal. Electrical pliers may be used to crimp the tabs of crimp connectors around wires.

Electrical Test Equipment

Most automotive repair shops today have equipment that can diagnose problems in many different vehicle systems. Scan tools, engine analyzers, and exhaust gas analyzers are among the most common.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 20-2. Wire stripping pliers have jaws for peeling off plastic or rubber insulation from wires. They include conventional pliers, as well as cutting holes of different diameters for stripping and cutting.

Scan Tools

A ***scan tool***, or scanner, checks the operation of vehicle sensors, actuators, wiring, and computers. Scan tools connect to a diagnostic link, or underdash test terminal, on the vehicle. They measure computer system operating voltages and interpret on-board trouble codes, providing the technician with information about the condition and possible issues with all of the vehicle's circuits. Refer to **Figure 20-3**.

When connected to the diagnostic link and after data exchange with the on-board computers, this type of scan tool will display all the vehicle's stored trouble codes. Each trouble code represents a specific circuit problem or condition. By checking the assemblies, wires, and components related to the trouble code, the technician can find and correct vehicle problems much more easily.

A more advanced scan tool is shown in **Figure 20-4**. It can retrieve and help analyze diagnostic trouble codes and collect computer system information. It can also monitor the operation of hundreds of sensors in real time and display the results as a graph, chart, or gauge reading.

Test Lights

Test lights are frequently used to check a circuit for power or ***continuity*** (complete circuit path). They

Snap-on Tool Corp.

Figure 20-3. This basic scan tool, or code reader, reads trouble codes from the vehicle's computer to help pinpoint the locations of any problems. Plug the scanner into the vehicle's diagnostic link under the left side of the instrument panel, or dash.

Snap-on Tool Corp.

Figure 20-4. This advanced scan tool will complete more troubleshooting functions than a code reader. Besides reading trouble codes, it will perform live tests and monitor circuit electrical values. It will also act as an oscilloscope to trace voltage over time.

Goodheart-Willcox Publisher

Figure 20-5. A circuit-powered test light uses circuit voltage to illuminate a small lightbulb. The test light must be grounded and then touched on terminal of connector. If test light glows, you know that you have power flowing through the circuit to that test point. Use only a high-impedance (resistance) test light tool to ensure current draw through the tool will not damage delicate computer circuits.

provide the quickest method of checking for voltage or a complete circuit. See **Figure 20-5**.

A circuit-powered test light is energized by the circuit voltage. The alligator clip is connected to any ground on the vehicle. Then the pointed probe is touched to a circuit conductor. If the circuit has power, the test light glows. If the tester does not glow, something is preventing current flow in the circuit.

Caution

Some electronic circuits and components can be ruined by the current draw of a test light. Always use high-impedance or high-resistance test lights or a meter. Refer to the appropriate service information if you are not sure about a testing procedure.

A self-powered test light, or continuity tester, contains a small battery and is used to check a circuit for continuity or low resistance. The source of circuit voltage must be disconnected. The self-powered test light's alligator clip is grounded and the probe is touched to the circuit. If the test light glows, the circuit is complete back to ground. This type of test light is not used as much as the circuit-powered test light.

OTC/SPX Corp.

Figure 20-6. Noid lights are test lights used to check the operation of electronic fuel injectors. Noid lights plug into the wiring harness going to the fuel injectors. If the computer is working and all wiring harness leads are good, the noid lights will glow or flicker to show an injector opening pulse (voltage signal).

Noid lights are used to check for power in the wiring harness going to electronic fuel injectors. A noid light is plugged into the harness connector going to an injector. If the computer is sending power to the injector, each noid light will glow, indicating there is sufficient power flowing to open the injector. Refer to **Figure 20-6**.

Multimeters

A ***multimeter***, also called a volt-ohm meter or VOM, is used to measure exact electrical values in vehicle circuits. It combines a voltmeter, ohmmeter, and ammeter into one case. A multimeter is an essential tool of the auto electronic technician

An ***analog multimeter*** uses a needle or pointer to show electrical readings. In addition to measuring constant values, it can detect changes in voltage, current, or resistance. The needle moves left or right to show temporary or rapid changes in electrical values. An analog meter can still be handy because it will show intermittent voltage and current fluctuations more clearly than a digital meter.

Copyright Goodheart-Willcox Co., Inc.

A ***digital multimeter*** uses a liquid crystal display to show a digital readout, **Figure 20-7**. It does not have a swinging pointer to show changing electrical values. Digital multimeters are therefore better suited for measuring constant values. The digital multimeter has replaced the analog type in many applications because of its convenience.

A ***digital-analog meter*** is a digital meter that has both an alphanumeric display and a bar graph to show fluctuating electrical values. This is the most commonly used type of multimeter in the auto repair shop. The alphanumeric display shows voltage, resistance, current, and other values as a decimal number in the display window. The bar graph is a small line or series of dots that shows rapid changes in electrical values. For example, if you wiggle a loose electrical connection, the bar graph moves right and left to show a rapid change in conduction, but the digital number display is too difficult to read with rapid readout changes in electrical values.

Tech Tip

A high-impedance (resistance) digital-analog multimeter is recommended for testing most computer circuits. It draws very little current and will not damage delicate computer circuits. A conventional analog meter draws more current and might burn up integrated circuits and other small electronic components.

Goodheart-Willcox Publisher

Figure 20-7. A—A digital multimeter uses an alphanumeric display to give readings. A digital meter is for taking readings that do not fluctuate. It also draws less current than older analog instruments and may prevent component damage. B—A digital-analog meter combines the best properties of digital and analog meters. It can show both steady and fluctuating readings, and draws less current than most analog meters.

A multimeter that uses a conventional pickup must touch metal components in a circuit to take a reading. For example, to measure current with a conventional pickup, you must disconnect the wires and attach them to the leads of the multimeter. Then the meter shows current draw through the circuit.

A multimeter with an ***inductive pickup*** does not have to touch the metal components in a circuit. It measures the magnetic field around a current-carrying wire. For example, an inductive pickup might be used to measure current output from an alternator. The inductive pickup is placed around the wire insulation to make an amperage reading. See **Figure 20-8**.

Inductive Wire Tracers

An ***inductive wire tracer*** can be used to find internal breaks in wires and disconnected wires or

Goodheart-Willcox Publisher

Figure 20-8. An inductive pickup clamps around the outside of the insulation to measure the strength of magnetic field around wire. The meter converts magnetic field strength into a current value in amps. Inductive meters are accurate to within approximately plus or minus one amp. A conventional ammeter hardwired in series with the circuit are accurate to within plus or minus one milliamp (0.001 amp).

Copyright Goodheart-Willcox Co., Inc.

terminals. A pulse generator is connected to the circuit. This produces a pulsing, low-voltage alternating current in the wiring. Then the inductive probe is moved along the wire. The tracer makes an audible beeping sound if the wire has continuity and is carrying the pulsing signal. When the tracer moves past a break in a wire or a poor connection, the signal stops or changes in tone. This shows you the location of the wiring problem.

Tech Tip

You might want to isolate the computer and other delicate electronic components before using an inductive wire tracer. This will ensure that they are not damaged during the testing.

Oscilloscopes

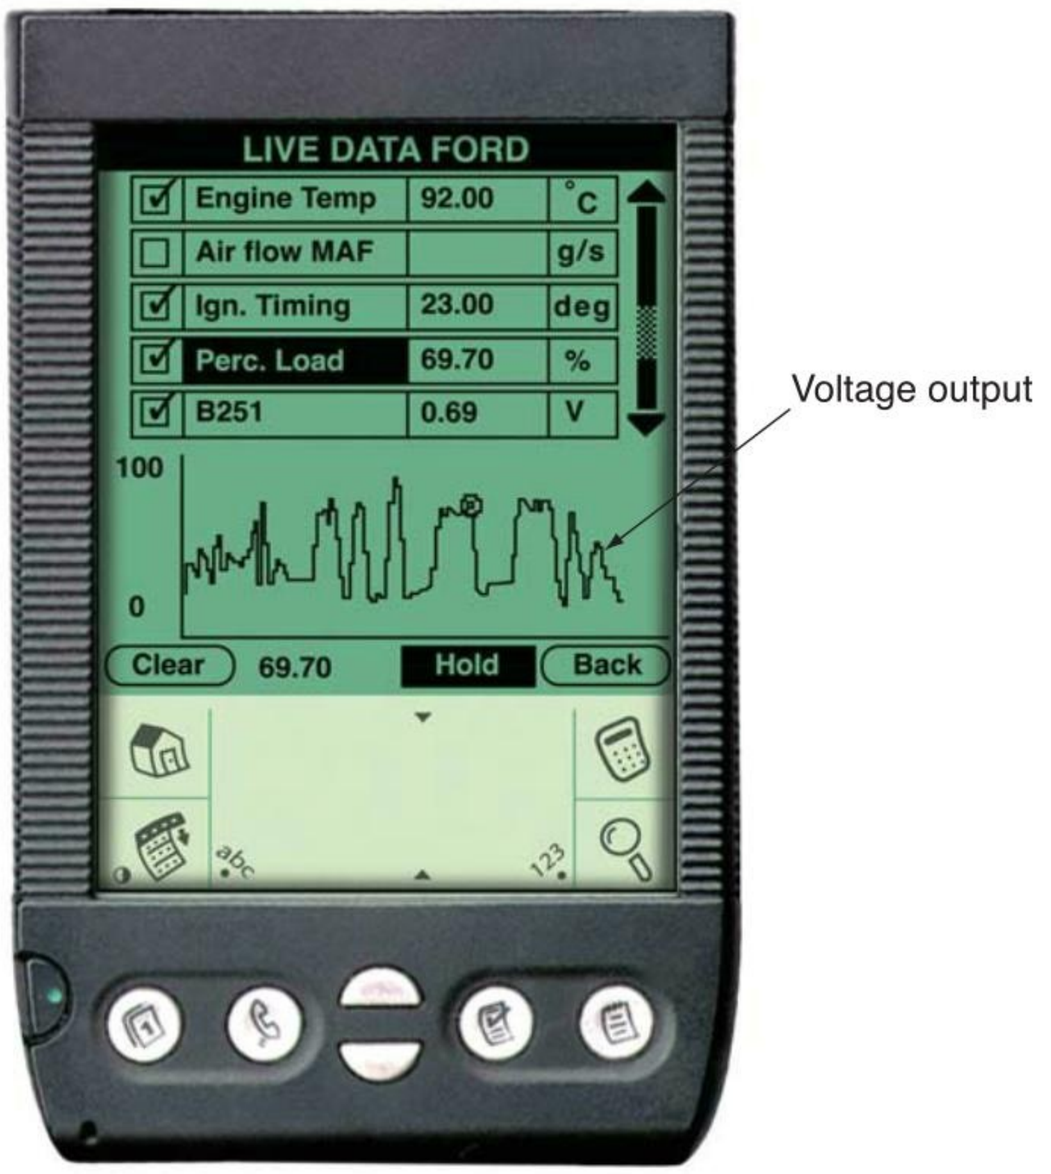
An ***oscilloscope***, or scope, is a diagnostic tool that displays a line pattern, or trace, representing circuit voltages in relation to time. By comparing the test scope pattern to a known good pattern, the technician can determine whether something is wrong in the vehicle's circuit. Oscilloscopes are sometimes needed to check ignition systems, engine speed sensors, and other operating voltages over time.

A handheld scope usually consists of an oscilloscope and a multimeter combined in one housing. It is used for advanced troubleshooting of electrical/electronic problems. The handheld scope can be used to perform voltage, current, and resistance measurements over short intervals of time. It can display instantaneous voltage variations coming from sensors, actuators, or vehicle control units. Adapters are available that allow an oscilloscope to measure other variables, such as pressure, temperatures, high current, or weak magnetic waves. See **Figure 20-9**.

Load Testers

A ***load tester*** is used to test the condition of 12-volt batteries, as well as conventional charging and starting systems. Load testers are commonly used to draw current out of the battery while measuring voltage. If the voltage stays within specifications with the specified current draw, the battery is good. If not, a battery problem may exist. To check the operation of the charging system, the load tester measures current to the battery with the engine running. A load can be placed on the system to measure maximum alternator output. A load tester can also be used to check the condition of the starting system. Starter current draw can be measured and compared to specifications. See **Figure 20-10**.

Modern load testers have an inductive current pickup. The amp (current) lead is clamped around the outside of the battery cable.



OTC/SPX Corp.

Figure 20-9. A scope is handy when trying to find problems that are difficult to locate. The scope will measure voltage or current over time very accurately. A—This handheld scope displays live data, such as engine temperature, ignition timing, duty cycle, sensor output voltage, and sensor/actuator waveforms showing voltage output over time. B—Some oscilloscopes can be connected to a flash memory card so data can be downloaded into the shop's computer for further evaluation with diagnostic software.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 20-10. A load tester is the best way to check the condition of a vehicle's battery, charging system, or starting system. Today's load testers have inductive pickups that clamp around the battery cable to measure high current draw from the starter or battery. A large carbon pile resistor in the load tester absorbs the high heat of the high current draw.

Charging System Analyzers

A ***charging system analyzer*** quickly measures charging system voltage to determine alternator operation. It has indicator lights that inform you of the alternator output. Some handheld charging system testers are connected across the battery and place a high current load on the system to check current output from the alternator.

System-Specific Test Equipment

Test equipment that is specific to one system on a particular make and model vehicle is available. For example, an alarm tester is designed to help diagnose a specific vehicle alarm system.

A ***keyless entry tester*** checks the condition of the key chain sending unit and the signal sensor of a vehicle's keyless entry system. If the doors do not unlock when the sending unit on the key chain is pressed, the technician can use this tester to help troubleshoot the system.

A ***park assist tester*** helps troubleshoot the output from a laser at the rear of the vehicle in a park assist system. It can be held next to the sensor to detect a laser output and determine if the unit is working properly.

A ***tire pressure monitor calibration tool*** can be used to calibrate and test the tire pressure sensors. Basically, you must set the tire pressure to specifications. Then, you must follow factory instructions to ready the vehicle for tire pressure monitor calibration (turn the key on and off several times, press brake pedal, or turn a light switch on and off several times). This will activate Bluetooth or another wireless system so the calibration tool can communicate with the vehicle. Finally, you can aim the tool at each tire as directed by the tool to calibrate the sensors and test their operation.

Diesel Test Equipment

Diesel engines do not have electric ignition systems. However, they do use glow plugs to aid cold starting. Special tools are needed to do electrical tests on a diesel engine.

A ***glow plug analyzer*** can be used to test diesel glow plugs and the operating condition of a diesel engine. It measures the internal resistance of or current flow to each glow plug. Some analyzers can also measure glow plug temperature. These glow plug testers can detect a dead cylinder because the temperature and resistance of a glow plug in a nonfiring cylinder are different from the temperature and resistance in the other cylinders. A dead cylinder in a diesel engine will show up as a cool cylinder and cool glow plug. See **Figure 20-11**.

Hybrid Tip

Most hybrid vehicles operate on high voltage levels that can damage low-voltage test meters. Only a meter with high-voltage insulation can be used to take electrical measurements on high-voltage hybrid components such as the battery pack, orange high-voltage cables, and the motor-generator. See **Figure 20-12**.

Copyright Goodheart-Willcox Co., Inc.

OTC/SPX Corp.

Figure 20-11. A glow plug analyzer checks electric heating elements that warm engine combustion chambers to aid in starting a cold diesel engine.

Goodheart-Willcox Publisher

Figure 20-12. This high-voltage meter can safely measure dc and ac voltage up to 1000 volts with 0.1% accuracy. Never use conventional low-voltage instruments on high-power, hybrid circuits. Low-voltage instruments are delicate and would instantly burn out if connected to a voltage higher than its insulating rating.

Summary

- Soldering tools are needed to make wiring repairs. Soldering is the best method of joining wires and terminals.
- Wire stripper pliers are used to pull insulation from wires.
- A noid light provides a quick way of checking a circuit for power or continuity.
- A multimeter is used to measure voltage, current, and resistance. An analog multimeter uses a conventional needle to show readings. A digital multimeter uses vacuum fluorescent or liquid crystal displays to give readouts.
- Most manufacturers warn against using a test light to test some electronic circuits. They can draw too much current and damage delicate electronic components.
- An inductive wire tracer uses a signal generator to produce a weak ac signal in the vehicle's wiring. The probe can then be used to find internal breaks or disconnected wires.
- An oscilloscope is a diagnostic tool that displays a line pattern, or trace, representing circuit voltages in relation to time.
- Test equipment for charging and starting systems includes a battery tester, load tester, and charging system analyzer.
- System-specific test equipment includes alarm testers, keyless entry testers, and park assist testers.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

analog multimeter
charging system analyzer
continuity
crimp connector
crimping pliers
desoldering bulb
digital-analog meter
digital multimeter
flux
flux brush
glow plug analyzer
heat sink
holding device
inductive pickup

Activities

1. Use the Internet to research solder with different type of cores, such as rosin-core solder and acid-core solder. Write a summary explaining why one is used more often than the other.
2. Visit an automotive repair shop. Examine the scan tools used by their technicians. Write a short report on your findings.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Why is soldering the method of choice for making electrical repairs?
2. Describe the advantages of using a solder gun, iron, and torch.
3. What types of tests are conducted using a scan tool?
4. What is an oscilloscope?
5. How is a circuit-powered test light used?
6. When might you use an digital-analog multimeter instead of a digital only multimeter?
7. Why can older analog multimeters damage computers?
8. What is a load tester?
9. Name three examples of test equipment that may be specific to a particular vehicle make and model.
10. What special equipment might be needed to work on diesel engines?

ASE-Type Questions

1. Technician A says soldered connections have high resistance. Technician B says solder has a relatively low melting point compared to other metals. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says that a soldering gun is generally better suited to delicate work on circuit boards than a soldering iron. Technician B says using a soldering torch heats up faster than a soldering iron. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says an inductive wire tracer generates pulses of ac in the wiring being tested. Technician B says an inductive wire tracer checks for continuity in the wiring. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says that the best way to splice a broken wire is to use a crimp connector. Technician B recommends soldering. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Technician A says an oscilloscope can be used to check ignition system operating voltages. Technician B says an oscilloscope can be used to check output signals from computer system sensors. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

6. Technician A says a load tester can be used to check the condition of a vehicle's battery. Technician B says a load tester can be used to check the condition of a vehicle's starting system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Which of the following tools measures voltage over time?
   (A) Luminosity meter.
   (B) Pyrometer.
   (C) Oscilloscope.
   (D) Load tester.
8. Technician A says a scan tool can be used to check computer system actuator operations. Technician B says a scan tool can be used to check the operation of computer system sensors. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says that before using a tire pressure monitor calibration tool, tire pressure should be set to specifications. Technician B says the tire pressure monitor calibration tool must be plugged into the vehicle's computer. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. A diesel engine has a possible dead cylinder. Technician A is going to use a magnetic timing meter to check this problem. Technician B is going to use a glow plug harness tester to check for a possible dead cylinder. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Chapter 21
Wiring Diagrams and Wiring Repairs

After studying this chapter, you will be able to:

- Compare wire types and sizes.
- Explain the effects of wire size on resistance.
- Identify wire protection devices.
- Apply proper techniques to cut and strip wires.
- Perform proper procedures to join components or wires by soldering.
- Identify wire terminals and connectors.
- Perform proper procedures for making connections using various types of connectors and terminals.
- Perform proper procedures for servicing factory connectors without damaging them.
- Perform proper procedures for repairing wiring and fuse links.
- Use component location charts and illustrations while troubleshooting problems.
- Interpret wiring diagrams.
- Use a grid to locate specific components on wiring diagrams.
- Select and use the appropriate wiring diagrams to troubleshoot an electrical problem.

A late-model vehicle may have well over a quarter mile of wires linking its electric/electronic components. Hundreds of connectors are used to join these wires into workable circuits. The wires, connectors, and wiring harnesses must carry current under adverse operating conditions such as summer heat and winter cold. They must be able to withstand vibration, moisture, and road salt. A problem with even one wire or connector can adversely affect the operation or performance of the engine, drive train, and other major systems. It is therefore essential that you fully understand automotive wiring and know how to repair it correctly.

Automotive Wiring

Automotive wiring includes many types of conductors, from very small wires and printed circuit conductors to large battery cables. You must be familiar with different types of wiring and understand their characteristics. This knowledge will enable you to work successfully on the electrical wiring of any make or model vehicle.

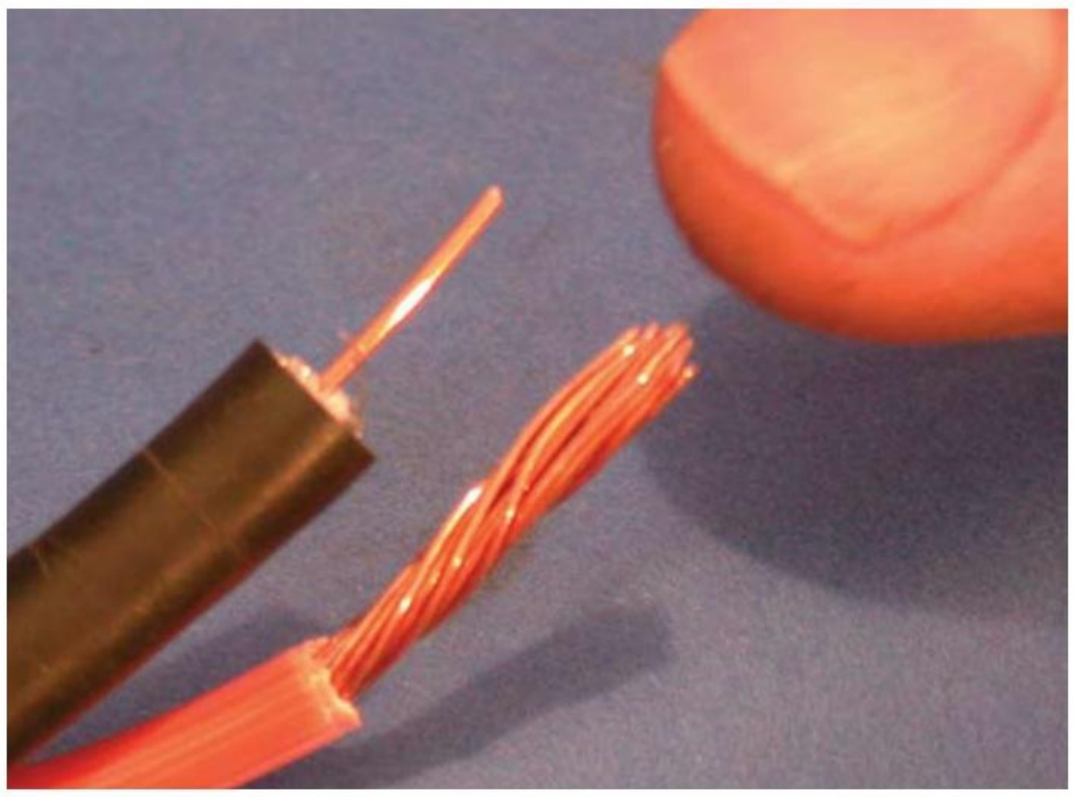
Types of Wire

The ***wire*** used in automotive circuits consists of a central metal conductor surrounded by plastic insulation. The type of metal used to make the conductor in a wire, as well as the type of insulation bundling, and shielding, varies depending on the application.

Solid and Stranded Wire

An electric wire consists of either a solid metal (usually copper or similar metal alloy) conductor or a stranded wire conductor inside a plastic outer covering. Both types are shown in **Figure 21-1**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 21-1. Solid wire can be found inside components and shielded cable, such as an antenna cable, where there is little or no movement. Stranded wire is used in most auto wiring because it can withstand movement and vibration without breaking.

A ***solid wire*** has a single conductor inside the plastic insulation. This type of wire is sometimes used inside components such as relays or sensors. Solid wire is a good conductor, but it is not very flexible. The metal conductor may break with severe or prolonged vibration.

Stranded wire has numerous individual metal strands twisted together inside the insulation. Stranded wire is normally used throughout a motor vehicle because it is flexible and can withstand vibration without breaking.

Parallel Wire

Parallel wire has two or more individually insulated conductors or wires molded into one flat or round body of multicolor insulation. For example, wires for a computer circuit are often made as one set of parallel wires connecting components. Speaker wires are also usually parallel wires. Parallel wiring lays flat, stays organized for easy pinpoint testing, and can carry multiple signals or circuit currents efficiently.

Primary and Secondary Wire

Primary wire is small wire that carries low voltage (13–15 volts dc) to the components, circuits, and ECUs in a vehicle. Primary wire is used in insulated wiring harnesses throughout most of the vehicle. Another name for primary wire is body wiring.

Secondary wire is used to carry high voltage (but little current) in the engine's ignition system. Since it carries very little current, but high voltage, the conductor is relatively small and the insulation is very thick. This keeps high voltage from arcing through the insulation to ground. See **Figure 21-2**.

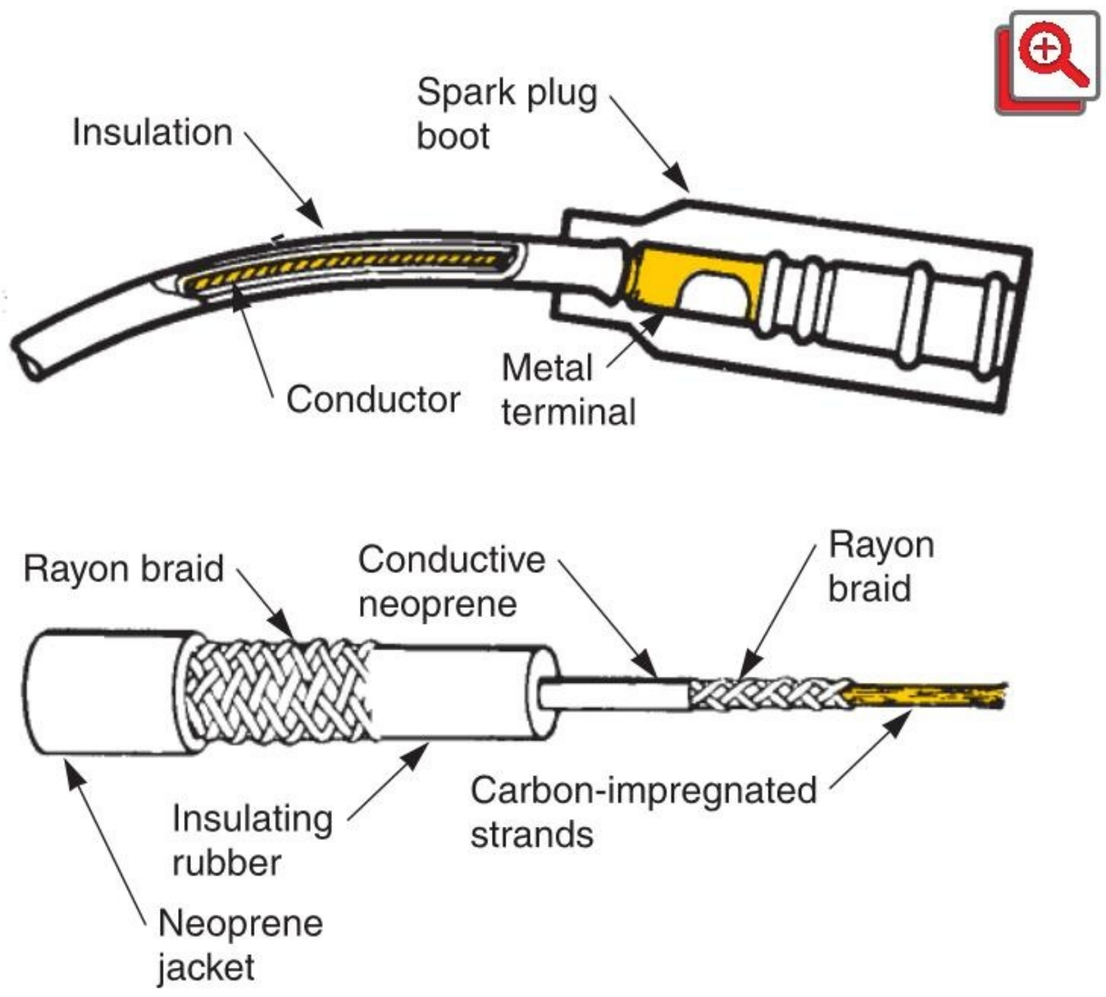
Secondary resistance wire, or ***carbon-core wire***, has internal resistance designed into the metal conductor. It is designed to help prevent radio interference or static from the high-voltage pulses going to the spark plugs.

Secondary nonresistance wire has a stranded metal conductor with no extra carbon resistance. This type of wire is used only in high-performance applications, such as off-road racing, because it causes static in nearby radios. Secondary wire is discussed fully in a later chapter.

Cables

The term ***cable*** refers to a wire with a large-diameter conductor. Examples include battery cables, starter cable, hybrid high-voltage cables, and coax cable. The outside diameter of a cable is generally much larger than that of a wire, and cables can contain one or more conductors.

Cables that carry battery current to the starting motor and return current to the battery from ground are commonly called ***battery cables***. The positive battery cable connects the positive terminal of the battery to the vehicle's electrical system. It usually connects to



Champion Spark Plugs/Federal Mogul Corp.

Figure 21-2. Secondary wire has a small conductor but very thick insulation. The insulation prevents the high voltage from leaking to ground.

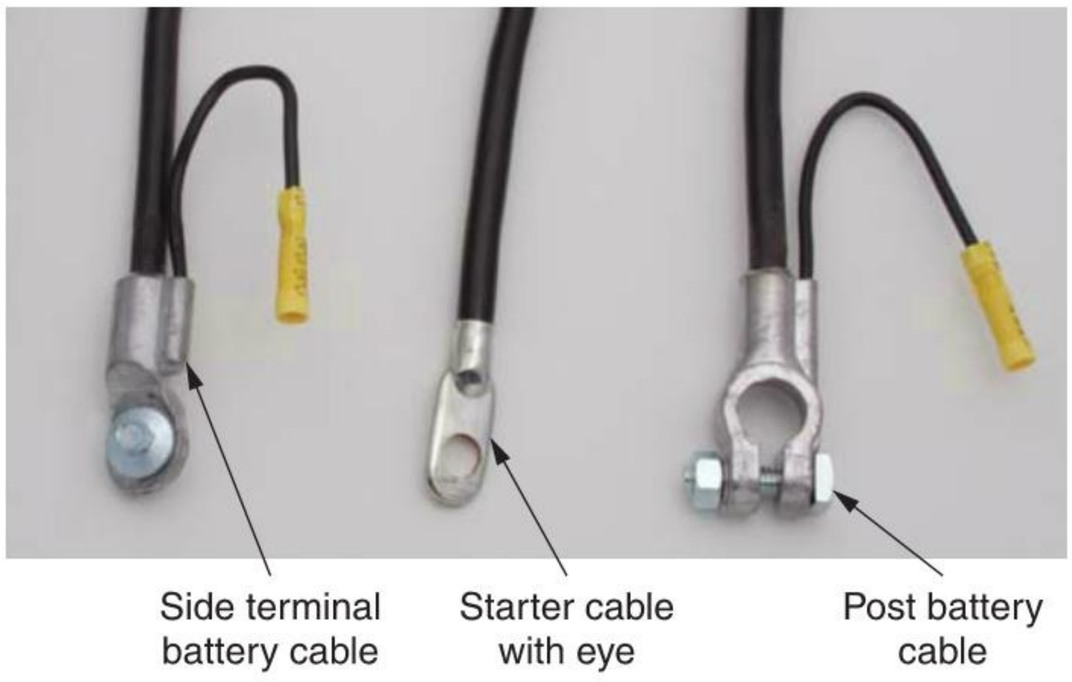
Copyright Goodheart-Willcox Co., Inc.

the starting motor solenoid. Smaller wires connect the solenoid terminal to the fuse box and other devices. The negative battery cable connects from the battery negative to ground. This cable usually bolts to the side of the engine block to provide a good ground connection for the starting motor. The negative cable does not have to be insulated. See **Figure 21-3**.

Coaxial cable, also called coax or shielded wire, has a center conductor surrounded by a braided metal shield. Insulation separates the conductor and the braided metal shield. This keeps magnetic pulses, such as magnetic waves from cell phone towers, from inducing unwanted voltage pulses into the center conductor. Induced current or voltage can upset computer system operation or cause static in radios.

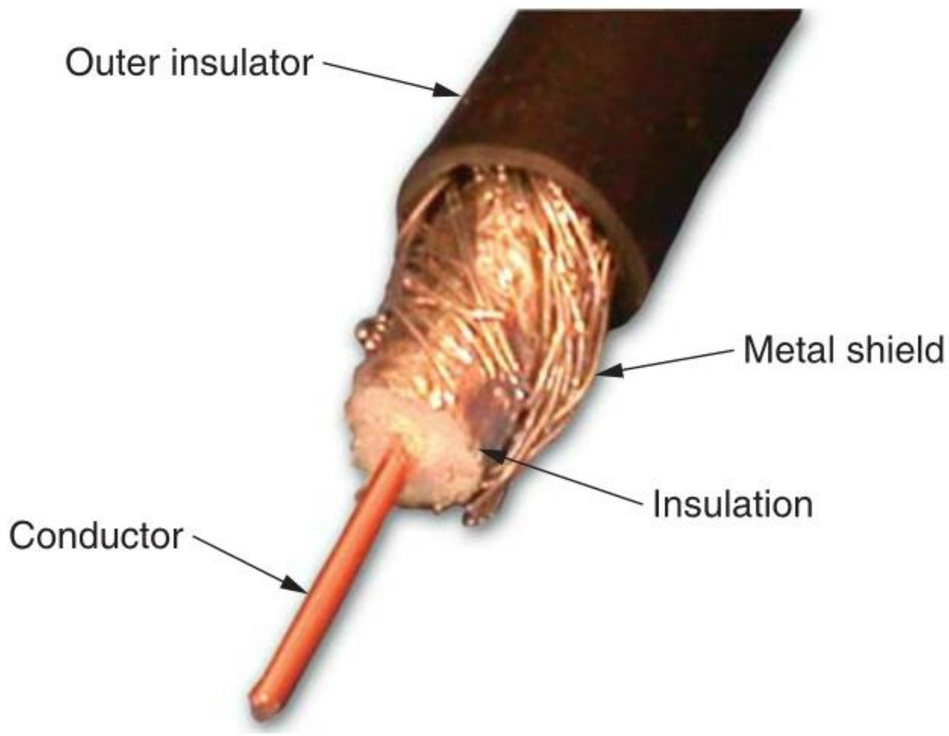
Coaxial cable is commonly used as antenna wire for AM-FM radios. The antenna lead must be protected from unwanted magnetic fields from the engine's ignition system and other electromagnetic power sources. This prevents electromagnetic induction in the center wire conductor and keeps static energy from entering the cable and upsetting the reception of the stereo. See **Figure 21-4**.

Twisted pair wire consists of multiple insulated conductors wrapped around each other in a spiral pattern. This design helps prevent unwanted magnetic fields from being induced into the wire. For instance, twisted pair may be used to connect the computer and various sensors, especially those near the ignition system and those that generate a weak electrical signal. This helps keep high-voltage pulses from upsetting the small voltage signals going to the computer. ***Shielded twisted pair wire*** may also have a sheath of metal around the conductors to block radio interference.



Goodheart-Willcox Publisher

Figure 21-3. Battery cables are very large and have a small gage number.



Goodheart-Willcox Publisher

Figure 21-4. Coaxial cables block any magnetic fields that might induce current into the wire. With low voltage and current levels in many circuits, this is important to ensure proper operation.

Hybrid power cables carry electric current to and from a hybrid vehicle's motor-generator, power control unit, and HV battery. They feed tremendous amounts of regenerative braking energy into the HV battery to store kinetic energy electrically. Upon acceleration, the hybrid power cables feed this current back into the motor-generator to help accelerate and propel the vehicle.

Tech Tip

Refer to the text index for more information about hybrids and required safety precautions for working on high-voltage power lines.

Hybrid power cables are normally orange for easy identification and safety. Hybrid cables are even larger than 12-volt battery cables, up to No. 00 (double ought) or No. 000 (triple ought). Refer to **Figure 21-5**.

Warning

Never come into contact with the metal conductors of hybrid drive cables. Many hybrid power trains operate on up to 600 volts. Always wear thick insulated rubber gloves and use nonconductive plastic tools and high-voltage test equipment when working on an electric drive system to protect from electric shock and equipment damage.

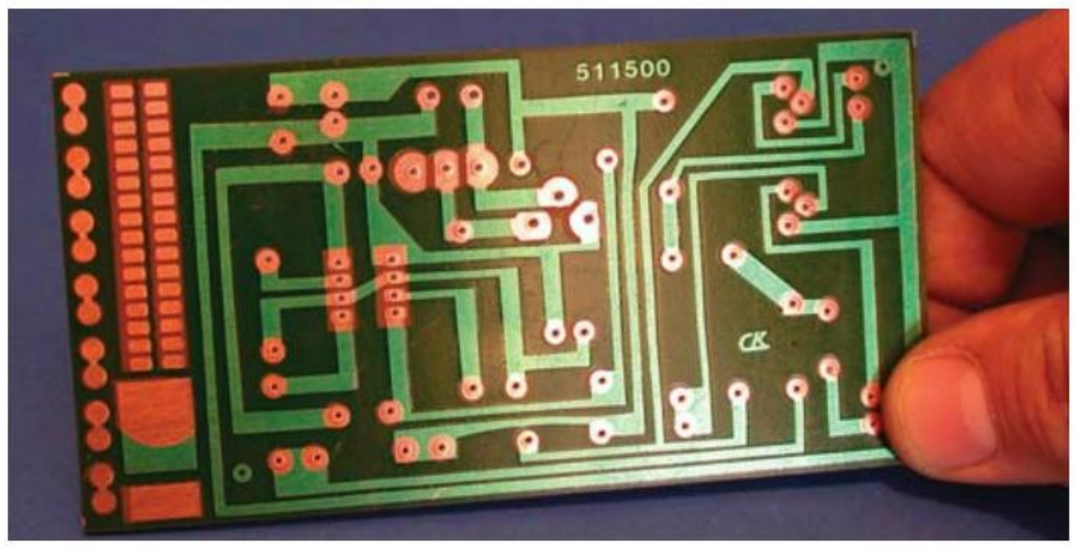
Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 21-5. These power cables carry high voltage to and from the motor-generator in a hybrid vehicle.

Printed Circuits

Printed circuits consist of copper foil bonded onto a plastic or fiber base to form a compact conductor. See **Figure 21-6**. Printed circuits are used on the back of the instrument panel cluster and in many electronic circuits. On instrument panel printed circuits, components snap or fasten to conductor strips and do not need to be soldered. This is illustrated in **Figure 21-7**.



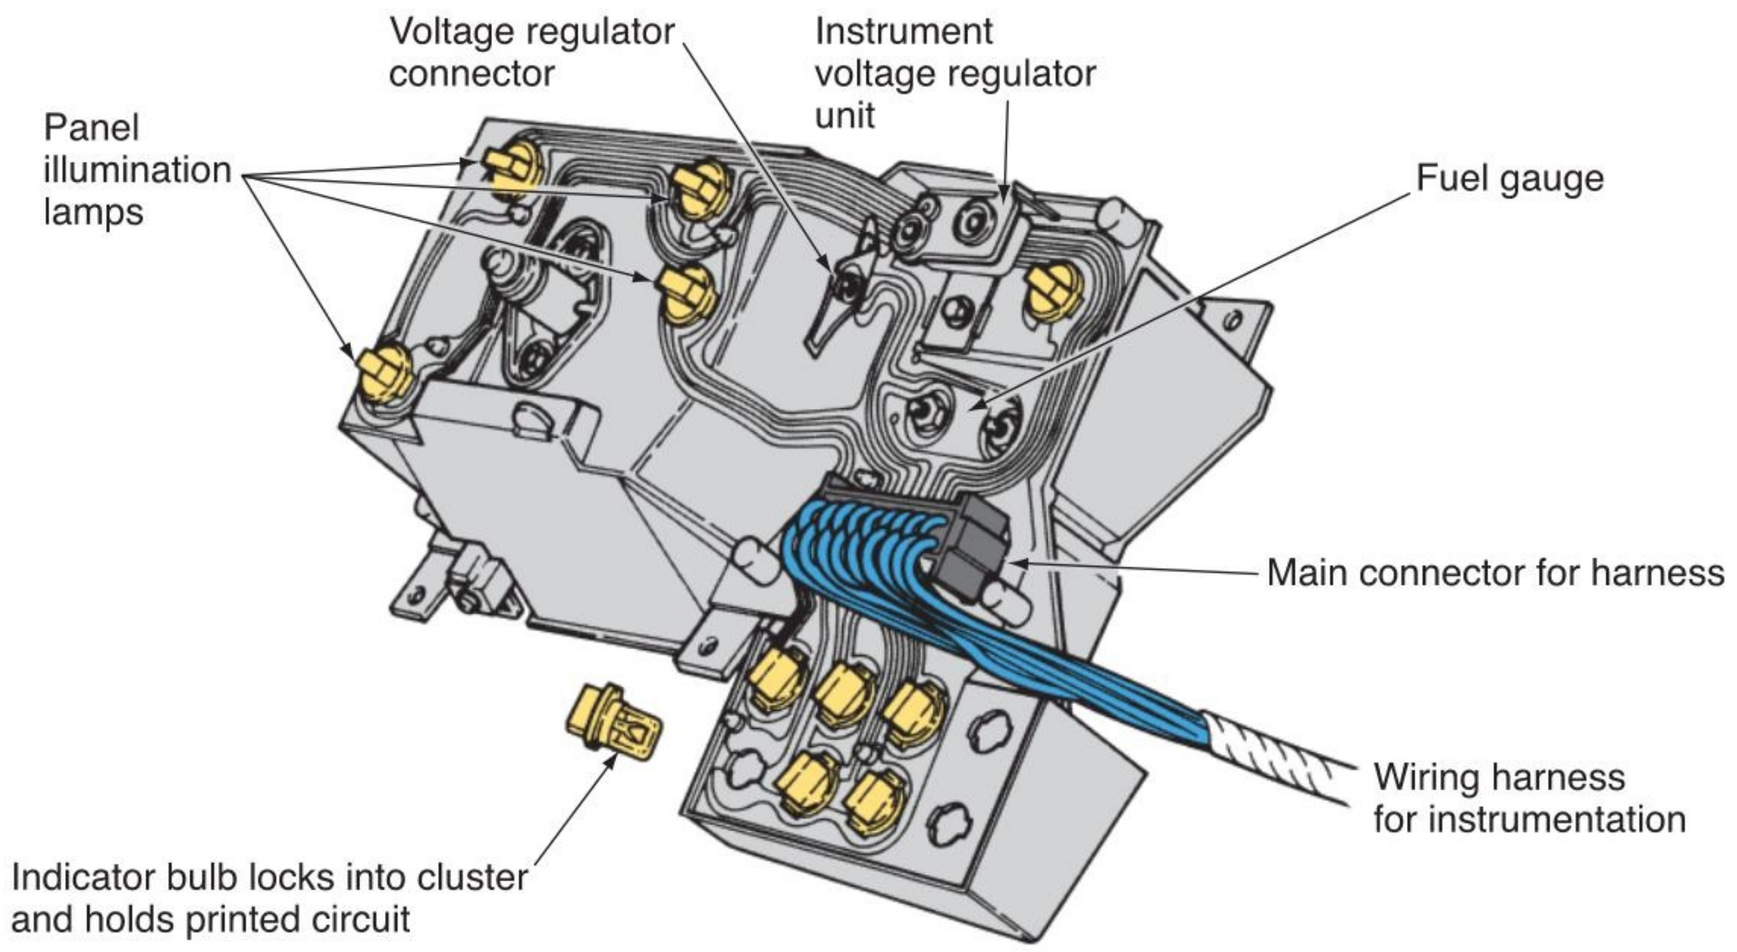
Goodheart-Willcox Publisher

Figure 21-6. Printed circuit wiring is made by depositing thin metal strips onto a plastic or fiber base material. The metal strips replace wires in the printed circuit.

Wire Size

Wire size, or ***wire gage***, is determined by the diameter or cross-sectional area of the wire's metal conductor. It does not include the thickness or diameter of the insulation. Wire size limits how much current, or amperage, a wire can carry without overheating. If a small wire carries too much current, it can burn up almost instantly, melting the metal conductor and its insulation. To avoid this, wire size must be matched to the circuit amperage draw at peak load conditions. See **Figure 21-8**.

In automotive technology, wire size is rated by the ***American Wire Gage (AWG) system***. Gage numbers



Goodheart-Willcox Publisher

Goodheart-Willcox Publisher

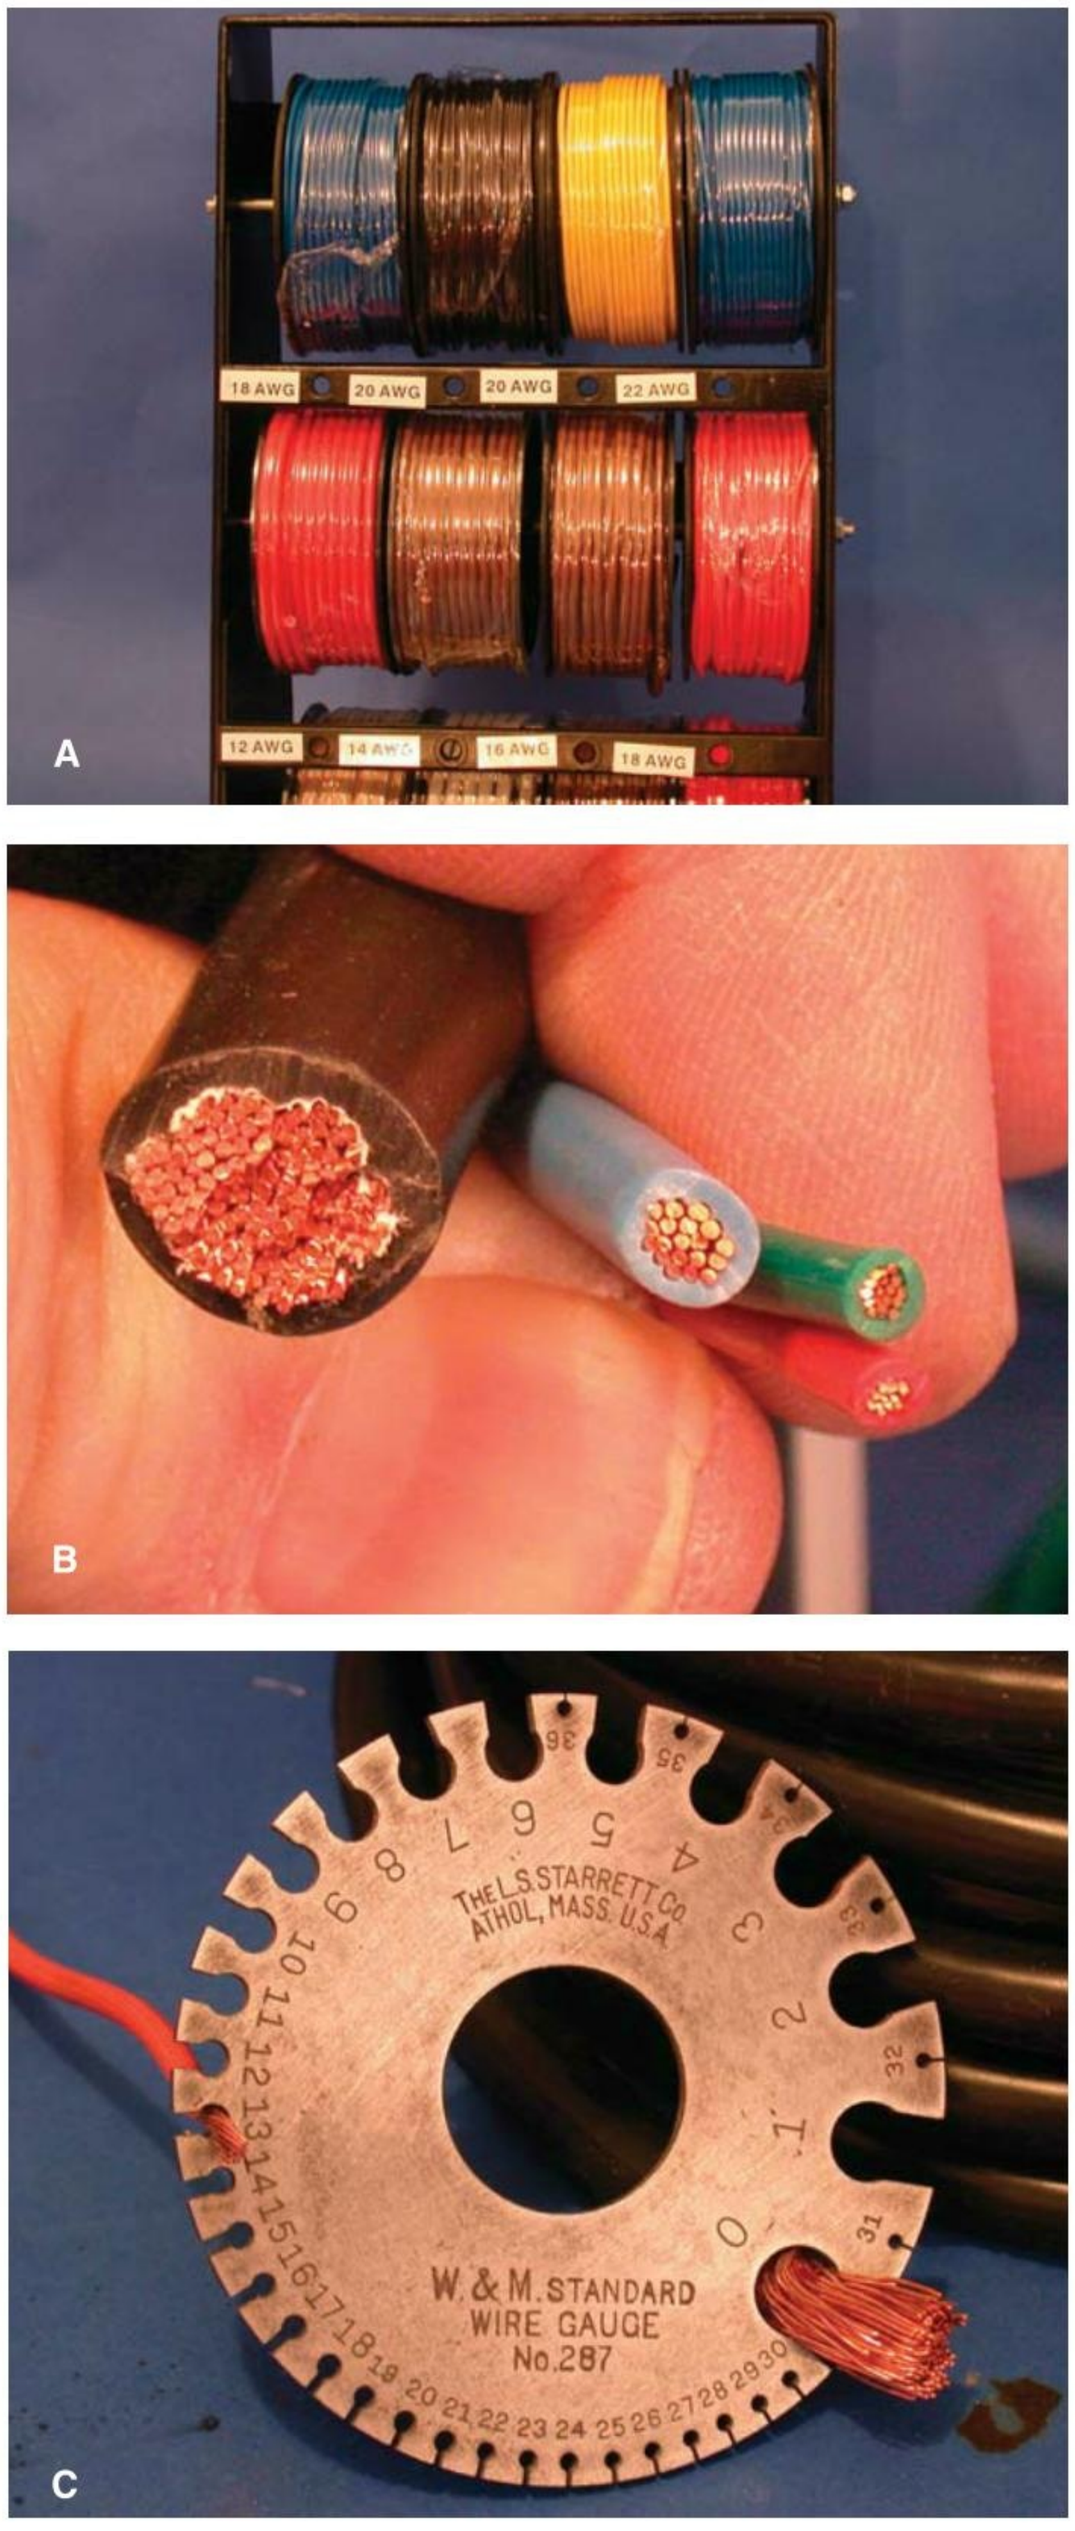
Figure 21-8. Always use the same wire size when replacing damaged wires. A—Wire size is determined by the diameter of the conductor. It does not include insulation thickness. B—In the AWG system, larger gage numbers indicate smaller wire diameters. In this illustration, actual wire sizes are shown (without insulation) for comparison.

are used to indicate conductor diameters. See **Figure 21-9**. A smaller number or wire gage denotes a larger conductor diameter, and vice versa. This system was designed for solid wires. However, stranded wire is also rated this way, with some variations depending on the wire manufacturer and weaving of the conductor strands.

Wire gages in an automobile generally range from gage 0 to gage 30. Wire gage 0 is a very large battery cable for carrying extremely high current without overheating. Wire gage 30 has a tiny conductor for electronic applications with low current draw. **Figure 21-10** is a chart of AWG wire sizes. Wire diameters are generally measured in mils or circular mils. A ***mil*** equals 0.001″, and a ***circular mil*** equals the area of a circle that has a 0.001″ diameter.

The resistance in a wire depends on several factors, including the ambient temperature, thickness of the wire, type of metal used, and type of wire (solid or stranded). Resistance is measured in ohms per 1000 feet. The Resistance column in **Figure 21-10** shows resistance for stranded copper wire at a temperature of 77° F.

Smaller diameter wire has more resistance than a larger diameter wire of the same material and design. This is why smaller wire overheats and burns if used to replace larger wire. The electrons moving through



Goodheart-Willcox Publisher

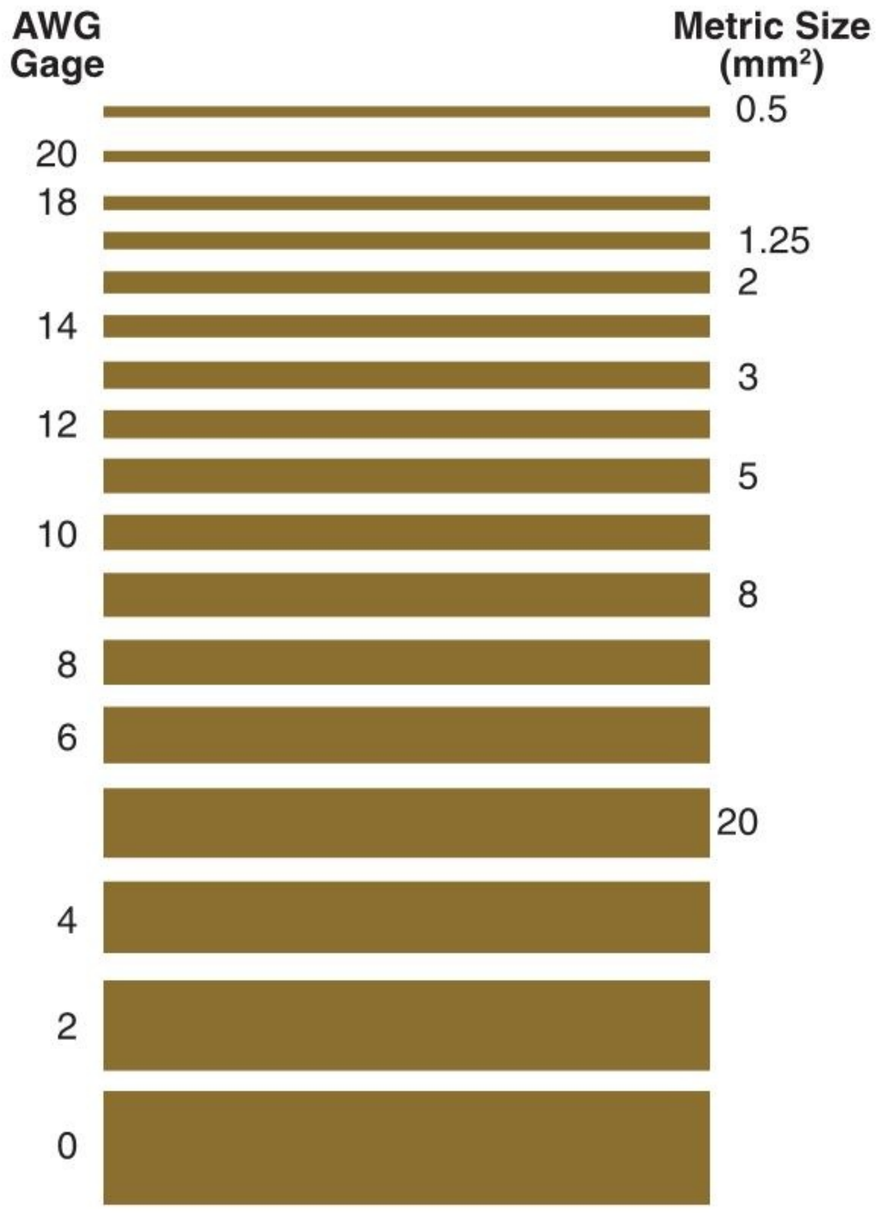
Goodheart-Willcox Publisher

Figure 21-10. This chart shows sizes, diameters, and resistances for stranded wire. Solid wire is similar, but has slightly less resistance.



Goodheart-Willcox Publisher

Figure 21-11. Actual wire sizes in the AWG and metric systems. Notice that AWG wire diameter increases as the gage number decreases, whereas metric wire diameter increases as the size number increases.

the smaller wire create so much electrical friction that the atoms vibrate violently, separating the molecular bond between the atoms in the metal conductor.

Caution

The automobile manufacturer mathematically sizes every wire to match its circuit load during the vehicle's design stage of production. Never change wire size from the OEM (original equipment manufacturer) gage when doing repairs. This could void the vehicle warranty and lead to circuit failure problems.

Figure 21-11 compares AWG gages and metric wire sizes. A ***metric wire size*** is given as the cross-sectional area of the wire in square millimeters (mm^2). Therefore, unlike AWG gage numbers, metric wire sizes increase as the diameter of the wire increases.

Battery cables, ground cables, starting motor cables, and hybrid power cables are much larger than the rest of a vehicle's wiring. Depending on the vehicle, engine displacement and type, and battery size, conventional battery cables typically range from 4 gage to the thicker 0 gage. Starting motor, starter solenoid, and other high-power circuits might use 7 to 4 gage wire.

Wire Current-Carrying Rules

Several rules apply to wires and their ability to carry current. These include:

- Wire resistance increases as conductor diameter decreases.
- Resistance depends on the material used in the conductor. For example, silver has less resistance than copper; copper has less resistance than aluminum.
- Resistance increases as the length of the wire increases.
- In most conductors, resistance increases as temperature increases.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

Excess current heats a conductor and can melt or burn its insulation. To prevent this problem, always replace a wire with a new one of the same gage, conductor material, and length.

Wire Protection Devices

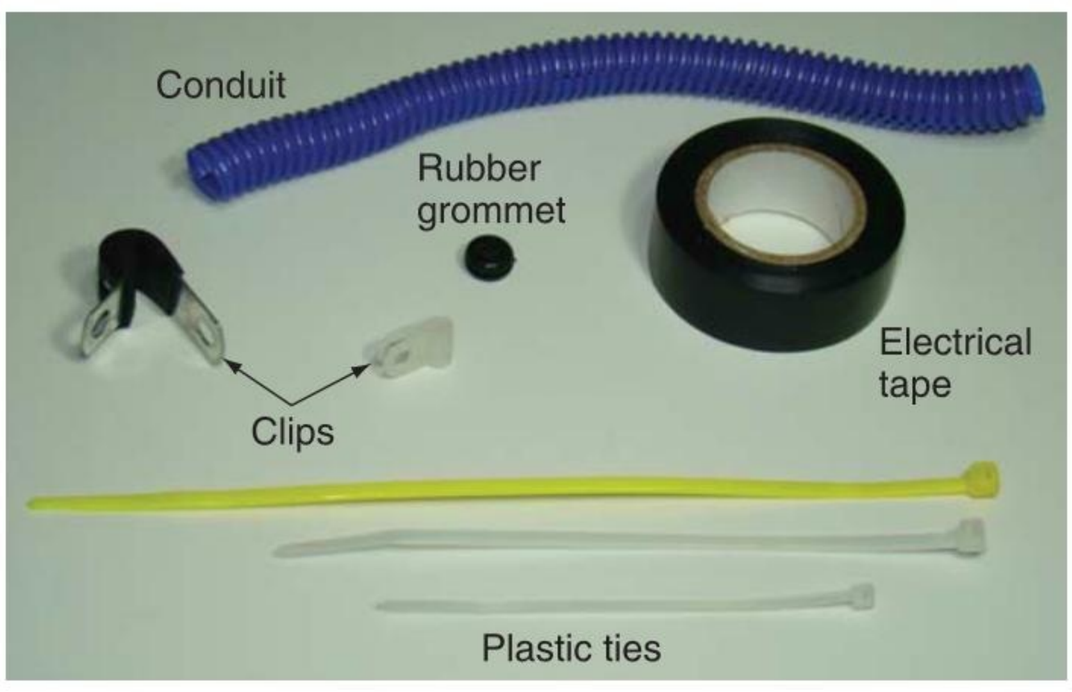
Wires are protected from damage by various kinds of ***wire protection devices***. These devices include electrical tape, plastic tubing, retainers, clips, boots, and straps. Examples are shown in **Figure 21-12**.

When you work with wire, always replace all wire protection devices. Remember that the manufacturer would not have installed these devices if they were not needed. Failing to reinstall even one retaining clip could lead to wiring failures.

Wiring Harnesses

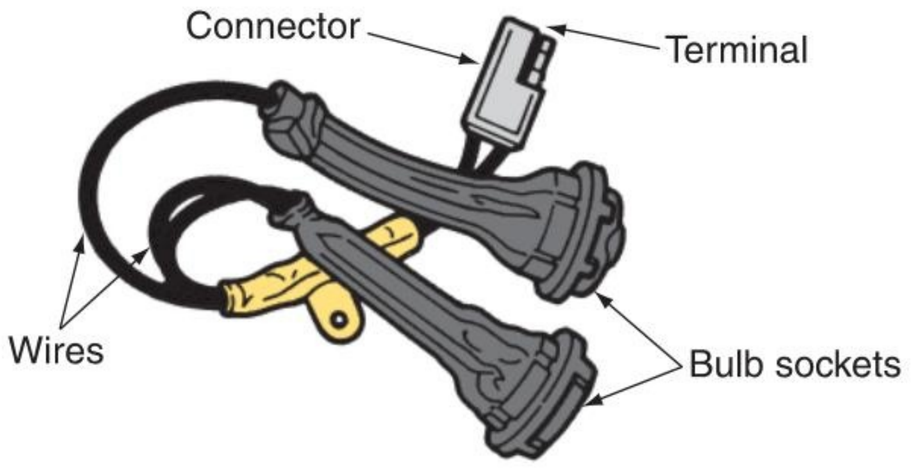
A ***wiring harness*** is a set of several wires wrapped together with tape or enclosed together in a plastic sheath for protection. Wires and connectors branch out from the harness to connect to various components. A wiring harness organizes and protects the wiring and also makes for a neater appearance than dozens of individual wires running separately.

Wiring harnesses are usually named after their location in the vehicle. For example, the harness that feeds to the sensors and other devices on an engine is called an engine wiring harness. See **Figure 21-13**.

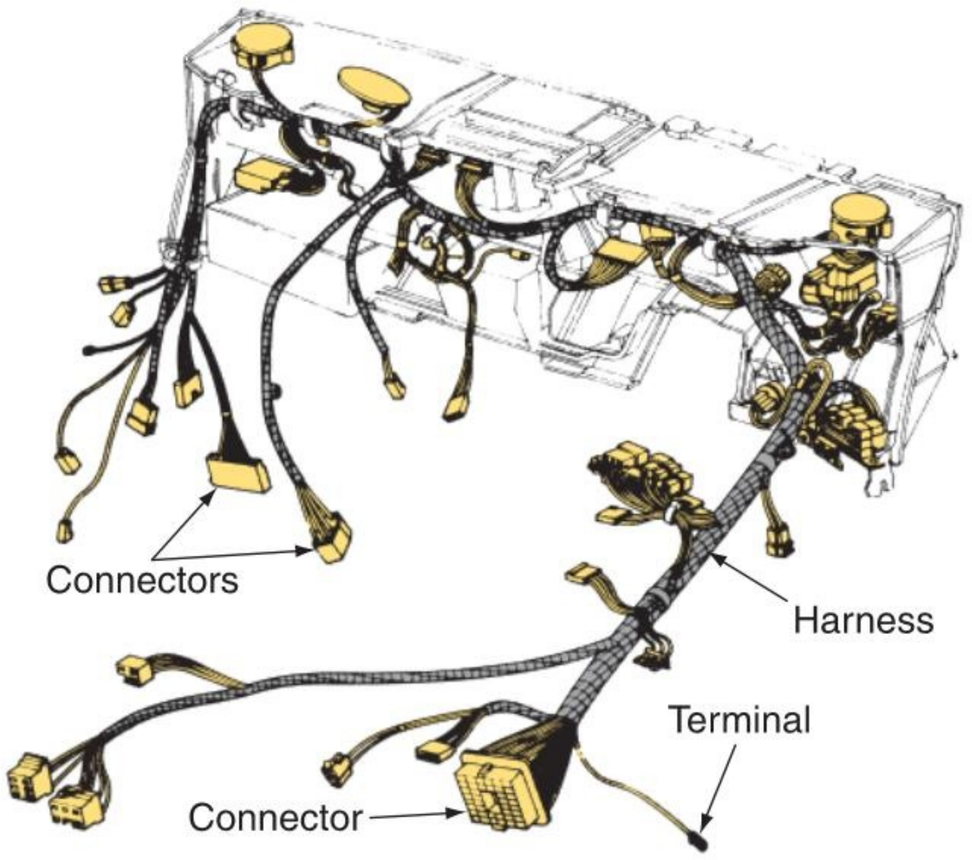


Goodheart-Willcox Publisher

Figure 21-12. Wire protection devices are needed to protect wires from damage caused by vehicle movement, vibration, heat, cold, and other potential dangers.



Simple Harness



Complex Harness

A

B

Goodheart-Willcox Publisher

Figure 21-13. Always look closely and study the wire connector to see how it is released and pulled apart without damage to the plastic lock mechanism. If you damage the locking clip on an electrical connector, the connector can come loose and disconnect the circuit. A—Wiring harnesses can be simple or complex. Connectors allow the wires to connect to other wires and components. B—This wiring harness had to be disconnected before the engine was removed from the vehicle.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

If many wires are damaged—by fire, for instance—it is usually best to install a new wiring harness. The harness can be purchased from the vehicle manufacturer or an auto salvage yard. This saves time and results in a better repair.

Cutting and Stripping Wire

Wire can be cut using diagonal cutting pliers, electricians' pliers, or most wire stripping pliers. Whichever tool you use, be sure to cut completely through the wire on the first try. If you cut partway through stranded wire and then cut again, the strands may be damaged or cut unevenly. See **Figure 21-14**.

When splicing an old wire to a new wire, cut off a small piece of the old wire and strip off its insulation. A new cut exposes uncorroded or undamaged new wire that has been protected inside its insulation.

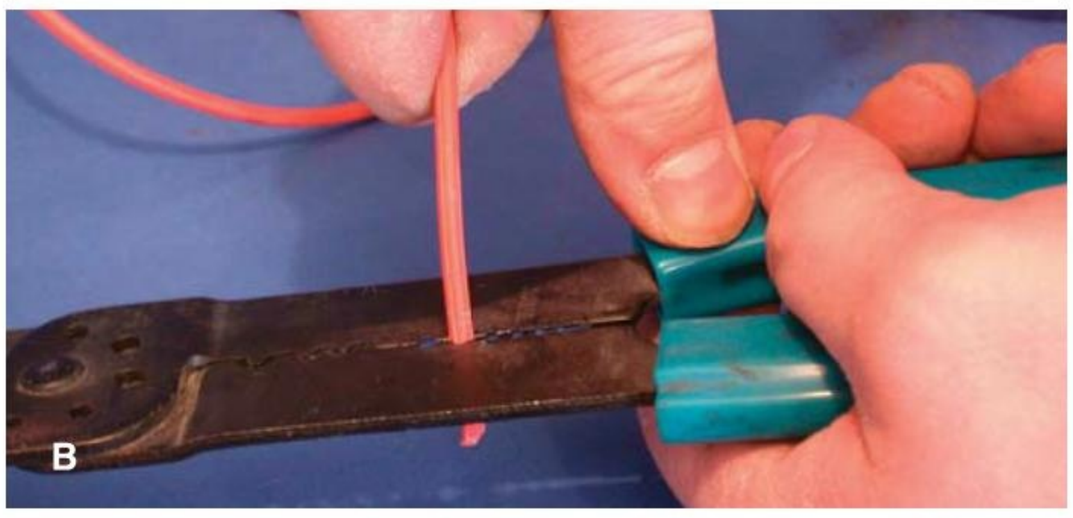
It is best to use wire strippers to strip (remove the insulation from) wires. Select a stripping hole size that matches the specific wire size. Clamp the wire insulation in the stripping jaws. Then pull the wire through the jaws. This cuts and strips the insulation without damaging the metal conductor. See **Figure 21-15**.

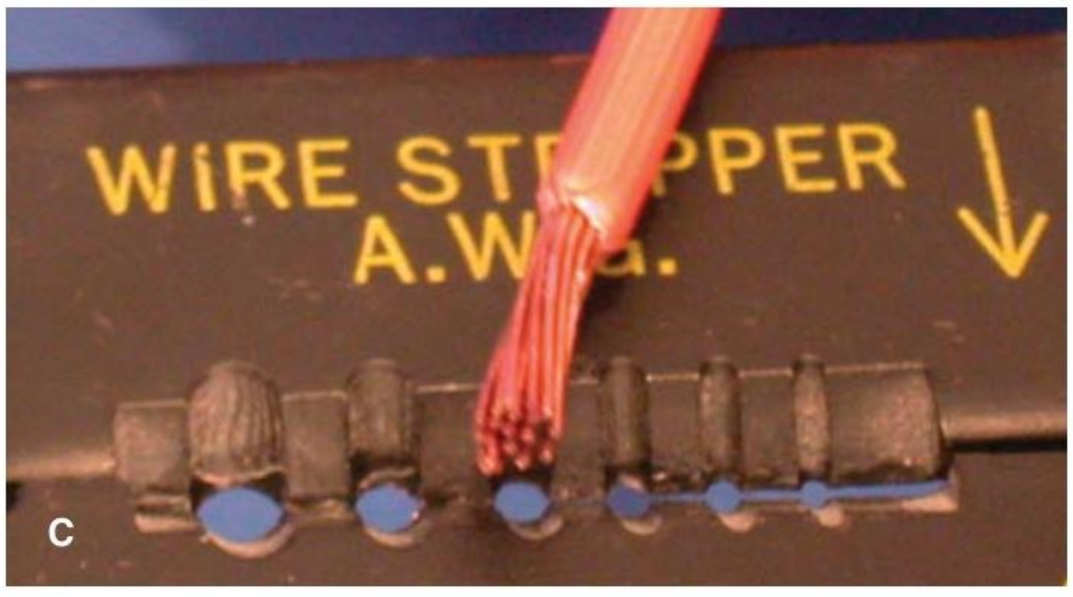
Soldering

Soldering involves using heat and solder to join electric components or wires. Soldering is an essential skill that you must master before attempting even basic electrical repairs. Solder comes in roll form for easy application to an electrical connection.

Goodheart-Willcox Publisher

Figure 21-14. When cutting wire, cut all the way through on the first try. This will ensure that strands are cut evenly and are not damaged.





Goodheart-Willcox Publisher

Figure 21-15. Always use stripping pliers to peel off insulation. A—Insert the wire into the correct size stripping jaw. Jaw size must match wire size. B—Use your thumb and fingers to pull the wire through the stripping jaws. C—After stripping, make sure none of the strands have been broken or damaged.

Solder

Solder is an alloy (mixture of metals) that has a relatively low melting point. Several different types of solder are available. Traditionally, most solder has been made of a mixture of lead (Pb) and tin (Sn). One common type contains 60% lead and 40% tin. However, lead can be toxic if absorbed into the skin or if soldering fumes are inhaled over a prolonged period of time. The trend in the industry is to use solder that does not contain lead. To increase safety, silver (Ag), tin-silver (SnAg), and tin-copper (SnCu) solder are now commonly used instead of lead solder.

Copyright Goodheart-Willcox Co., Inc.

Rosin-core solder contains a flux (lead-free cleaning agent) inside the solder designed for doing electrical repairs. Modern rosin-core fluxes are water-soluble. ***Acid-core solder*** has an internal acid flux and should *not* be used for electrical repairs. The acid can cause corrosion and electrical problems. Acid-core solder is sometimes used to repair metal engine radiators. See **Figure 21-16**.

Tinning

Tinning is a process of heating, cleaning, and preparing the surface of the soldering gun tip and the electric components to accept molten solder. It consists of placing a thin coat of solder on the soldering gun tip or the parts to be soldered. This makes the solder joint easier to create and results in a better electrical connection. After tinning, heat transfers more easily from the soldering gun tip into the parts to be soldered.

Before tinning, inspect the tip of the soldering gun or iron. If the tip is pitted, use a file to form a clean, smooth surface. Badly pitted tips should be replaced.

To tin the soldering tip, first heat the tip. If needed, wipe debris from the tip using a water-soaked sponge. Then melt some solder onto the tip. Make sure the solder adheres all the way around the tip. See **Figure 21-17**.

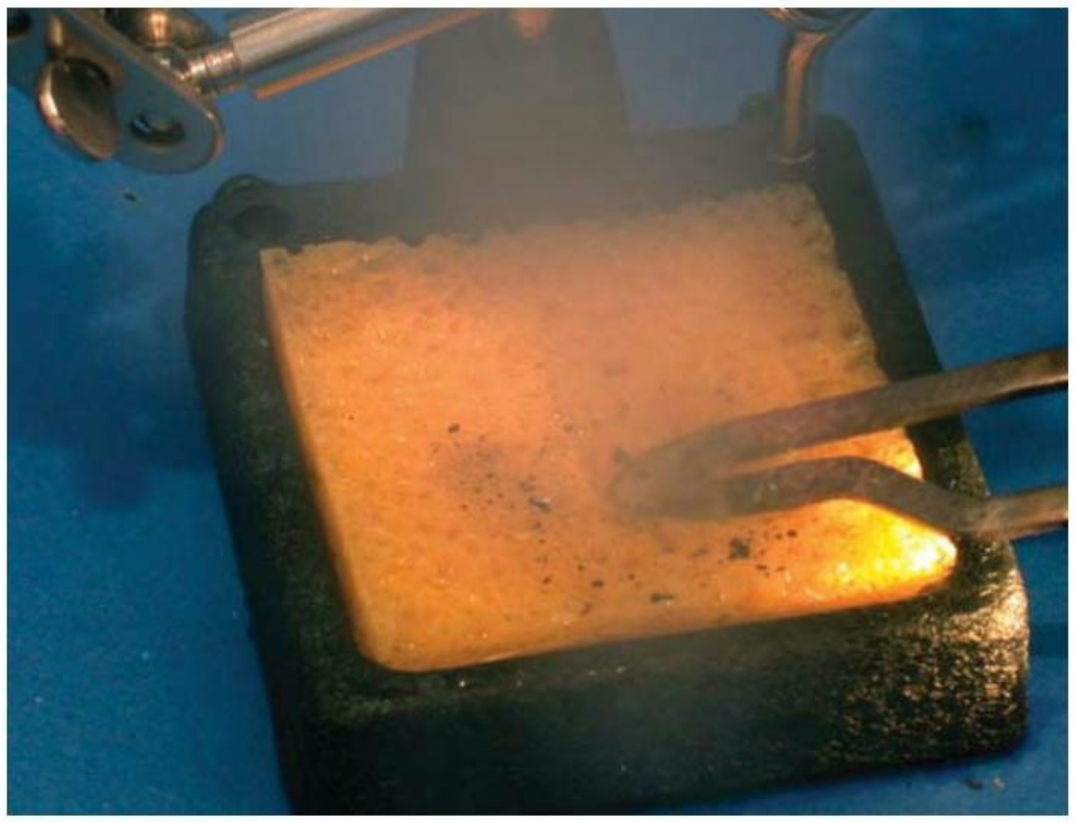
Soldering Technique

Follow these basic procedures for soldering:

1. Preheat the electric components with the soldering tip or torch until the solder melts when touched and held onto the hot surfaces.

Goodheart-Willcox Publisher

Figure 21-16. Solder with water-soluble flux is used to solder electrical and electronic connections.



Goodheart-Willcox Publisher

Figure 21-17. To clean the soldering tip, dip the hot tip into a water-soaked sponge. The water instantly boils to remove oxidation and debris from the soldering tip.

Warning

Do not overheat the components or flux! If you apply enough heat to burn the flux, you will contaminate the joint and must clean it again. If you try to solder through burned flux, the solder will not stick to the wires or components. If the wire insulation melts, it will also contaminate the joint and the solder will not stick or bond properly.

2. After sufficient preheating, keep the soldering gun tip in contact with the connection. Touch the solder onto the wires or component leads. Allow the preheated parts to partially melt the solder. See **Figure 21-18**. Then apply a little heat to both the wire leads and solder. This will make the solder flow out onto the metal surfaces of the conductors.
3. If the solder does not bond, reclean the metal parts. Recut and strip the wires. Brush on fresh paste-type flux and try again.
4. After a smooth puddle of molten solder forms, remove the heat and solder. Do not wiggle or move the joint for a few seconds after heat removal. This could weaken or break the electrical solder connection. Inspect the joint after allowing it to cool for a few seconds.

Stranded wires can be soldered together without connectors or leads. The procedure for soldering stranded wires is illustrated in **Figure 21-19**.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 21-18. Touch the solder to the wire and terminal, but not to the soldering gun tip. This will ensure that the parts are hot enough that solder bonds to them properly for a good electrical connection. A common mistake is touching solder to gun tip and letting hot solder flow down over cool metal components. This results in a weak, high-resistance electrical connection.

Tech Tip

When soldering, always preheat the components. Never touch solder onto the soldering gun tip and allow solder to drip onto the joint. The components will not be hot enough, and the solder will not bond to the components securely. This will result in a poor electrical connection or one that comes apart easily.

Covering Exposed Conductors

Electrical tape is commonly used to cover and protect the soldered conductors. Use moderate pressure while wrapping the tape around the joint. Wrap the tape to achieve a neat, smooth, tight layer of tape.

Liquid electrical tape is a liquid coating that can be brushed over conductors to insulate them from moisture. When the liquid electrical tape dries, it creates a plastic or rubber-like substance that protects the conductor. See **Figure 21-20**. Liquid electrical tape is an excellent choice when a joint must be protected from moisture. It will keep the joint dry, while electrical tape may not.

Heat shrink tubing is another alternative to electrical tape. This hollow plastic tubing shrinks when heat is applied. The heat shrink tubing slides over the joint. Then it is heated with a heat gun. The high temperatures make the plastic tubing shrink down tightly around the wires to produce an insulating barrier over the conductor.

Connectors

Various types of connectors are used on today's vehicles. ***Connectors*** are wire-splicing devices with metal ***terminals***, or connection points, for joining the ends of two or more wires. Many connectors have locking clips that hold the connectors together, ensuring a good electrical connection. **Figure 21-21** shows the most common types of single-wire connectors and terminals.

Crimp Connectors

Crimp connectors can be used to make many electrical repairs. They provide a quick and easy way of joining wires or installing a terminal on a wire by crimping, or crushing, a metal lug around the wire conductor.

To use a crimp connector, first strip the wire. Make sure the right amount of conductor is exposed. If the conductor is too short or too long, the crimp connector will not work properly. After stripping the insulation from the wire, twist the conductor to hold the wire strands together so that they will feed into the crimp connector easily. See **Figure 21-22**.

Use crimping pliers to crush the metal part of the connector around the wire conductor. Crimping jaws of various sizes are normally provided, so make sure you use the right ones. **Figure 21-23** shows the crimping procedure for creating a butt splice, in which the two wires butt against each other inside a splice connector.

Tech Tip

A common mistake is to place the jaws of the crimping pliers over the plastic part of the connector rather than over the metal lug inside the connector. This will compress only part of the metal lug, and a weak connection will result. Make sure the jaws are positioned correctly over the metal lug before crimping an electrical connector. Refer to **Figure 21-24**.

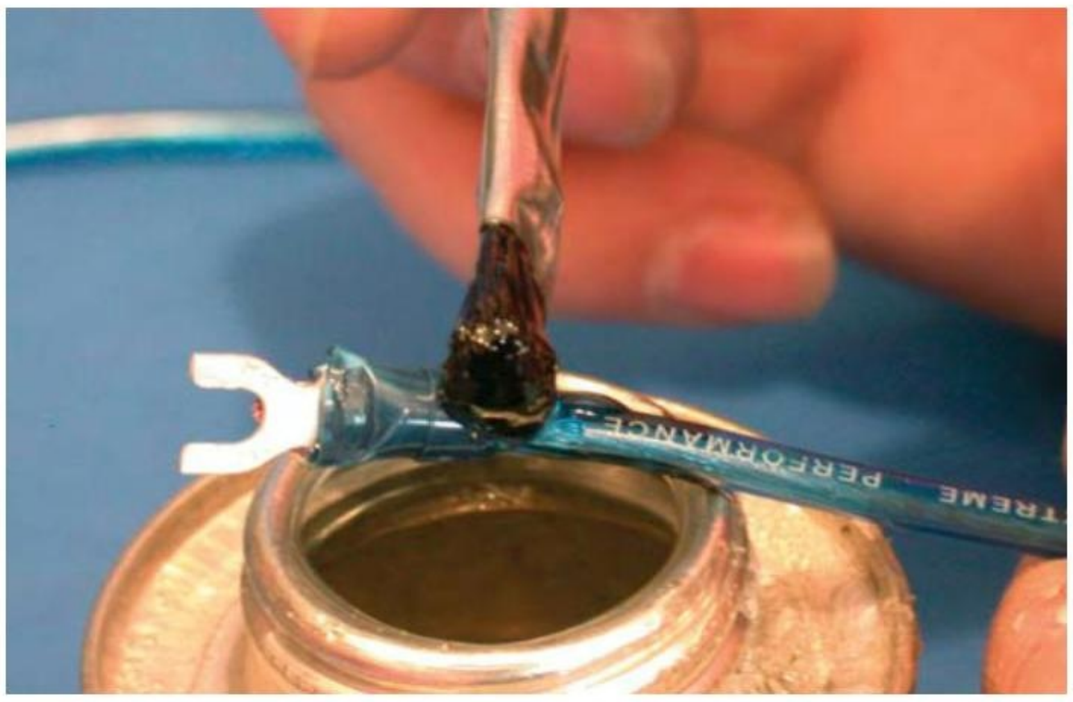
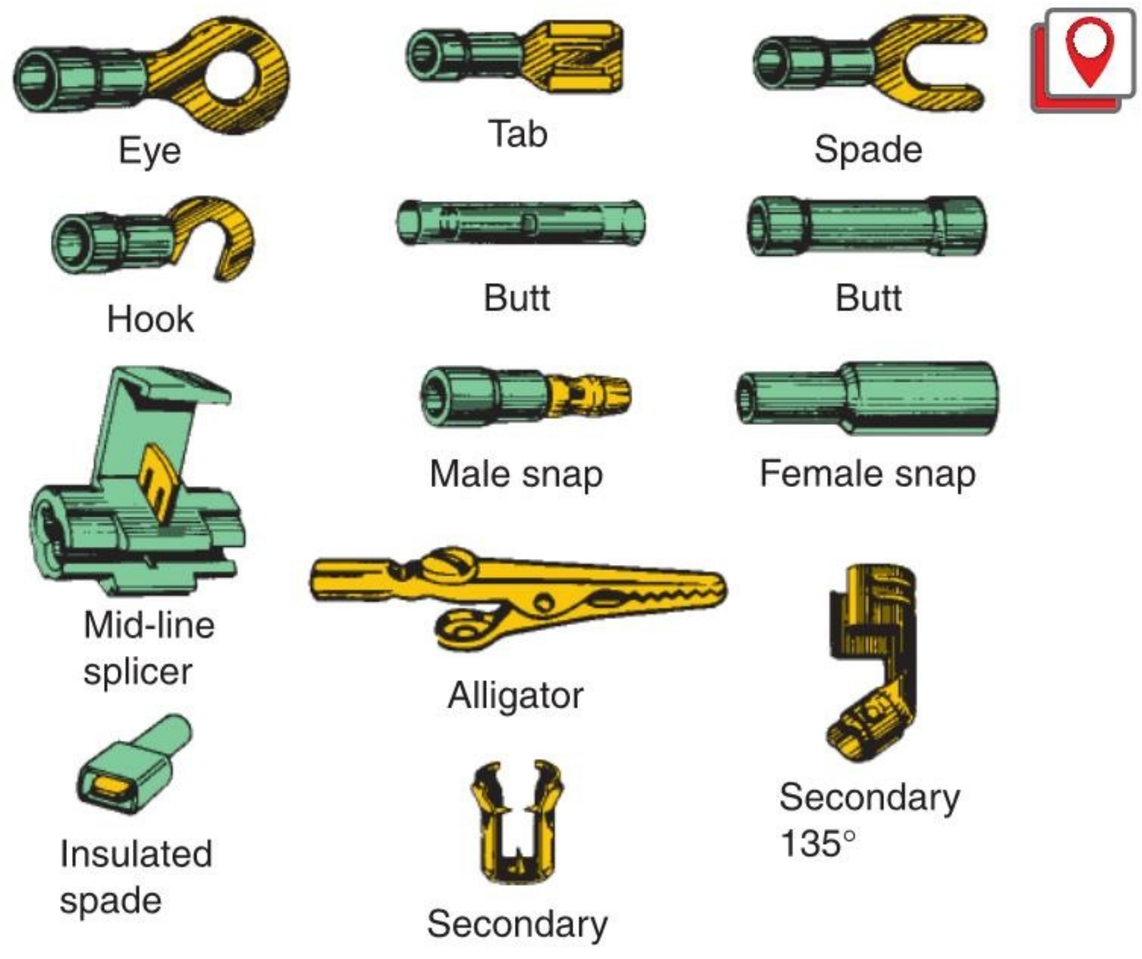
Goodheart-Willcox Publisher

Figure 21-19. Joining wires using a solder joint. A—Strip about one inch of insulation from both wires. B—Wrap or twist the wire ends together. C—Use a soldering stand to hold the wires together while soldering. The magnifying glass allows you to view the solder more closely as it flows into the wire strands. D—Solder the twisted ends by the heating wires, not the solder, so that heat conducts into the wire strands and liquefies the solder. After it cools, cover the soldered splice with shrink wrap or electrical tape.



Goodheart-Willcox Publisher

Figure 21-20. Liquid electrical tape is sometimes used in place of conventional electrical tape. It is ideal when the conductor must be sealed to keep out moisture.



Belden

Goodheart-Willcox Publisher

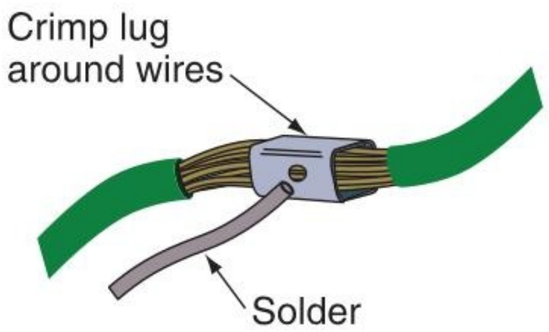
Figure 21-24. Forming a crimp connection using electrical pliers.

Caution

If a wire pulls out of a crimp connector, it may cause a short circuit. Make sure the connector is secure. Solder a connector to the wire when possible. To solder a connector to two wires, first crimp the connector around the wires. Then solder the wires and metal lug together. This makes for an excellent repair. Refer to **Figure 21-25** and **Figure 21-26**.

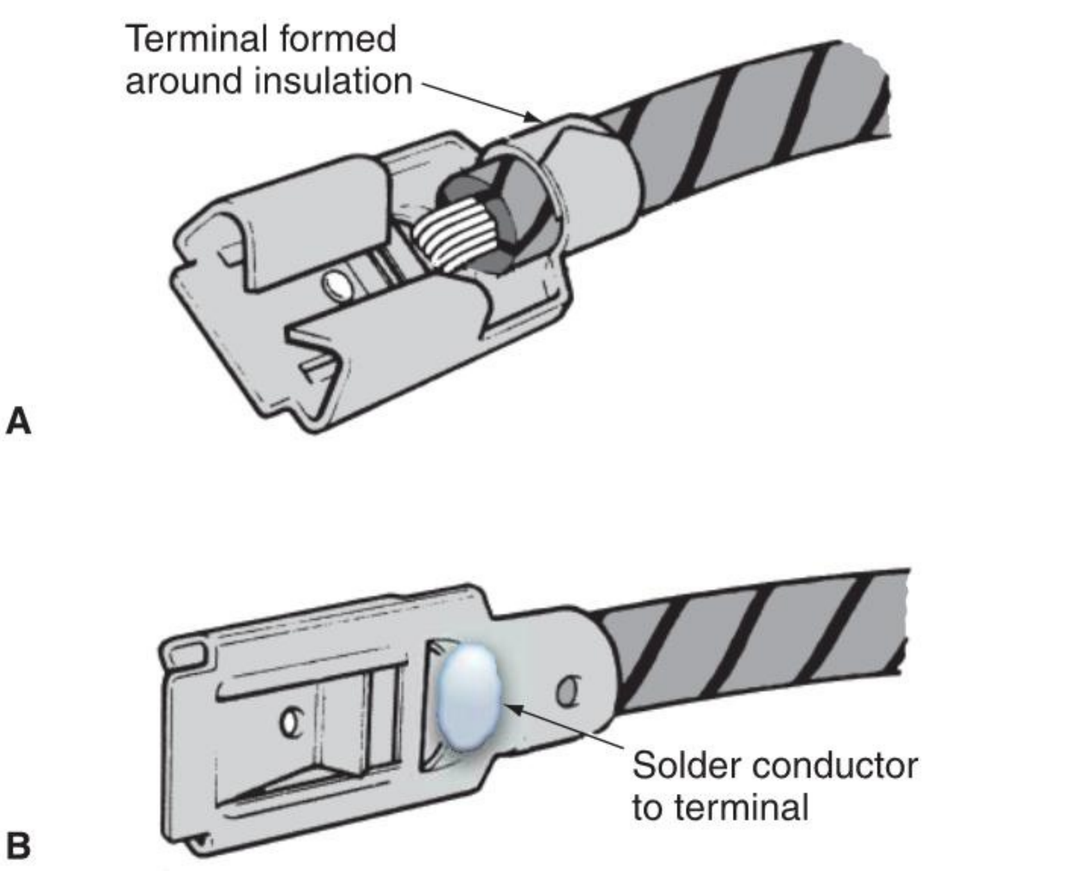
Self-Stripping Connectors

A ***self-stripping connector*** cuts through a wire's insulation and locks onto the conductor. This type of connector is useful when you must connect to an existing wire in a harness. Self-stripping connectors are often used to splice in a wire for an electric accessory, such as trailer lights, or to bypass a bad connection or wire. See **Figure 21-27**.



Goodheart-Willcox Publisher

Figure 21-25. One of the best ways to join two wires is to crimp a metal lug over both wire ends. Then solder the wires and lug together into a single junction. Tape over the exposed conductor after checking the joint.



Lister Diesels

Figure 21-26. In this type of connection, the terminal is crimped down around the wire insulation. Then the wire conductor is soldered to the terminal.

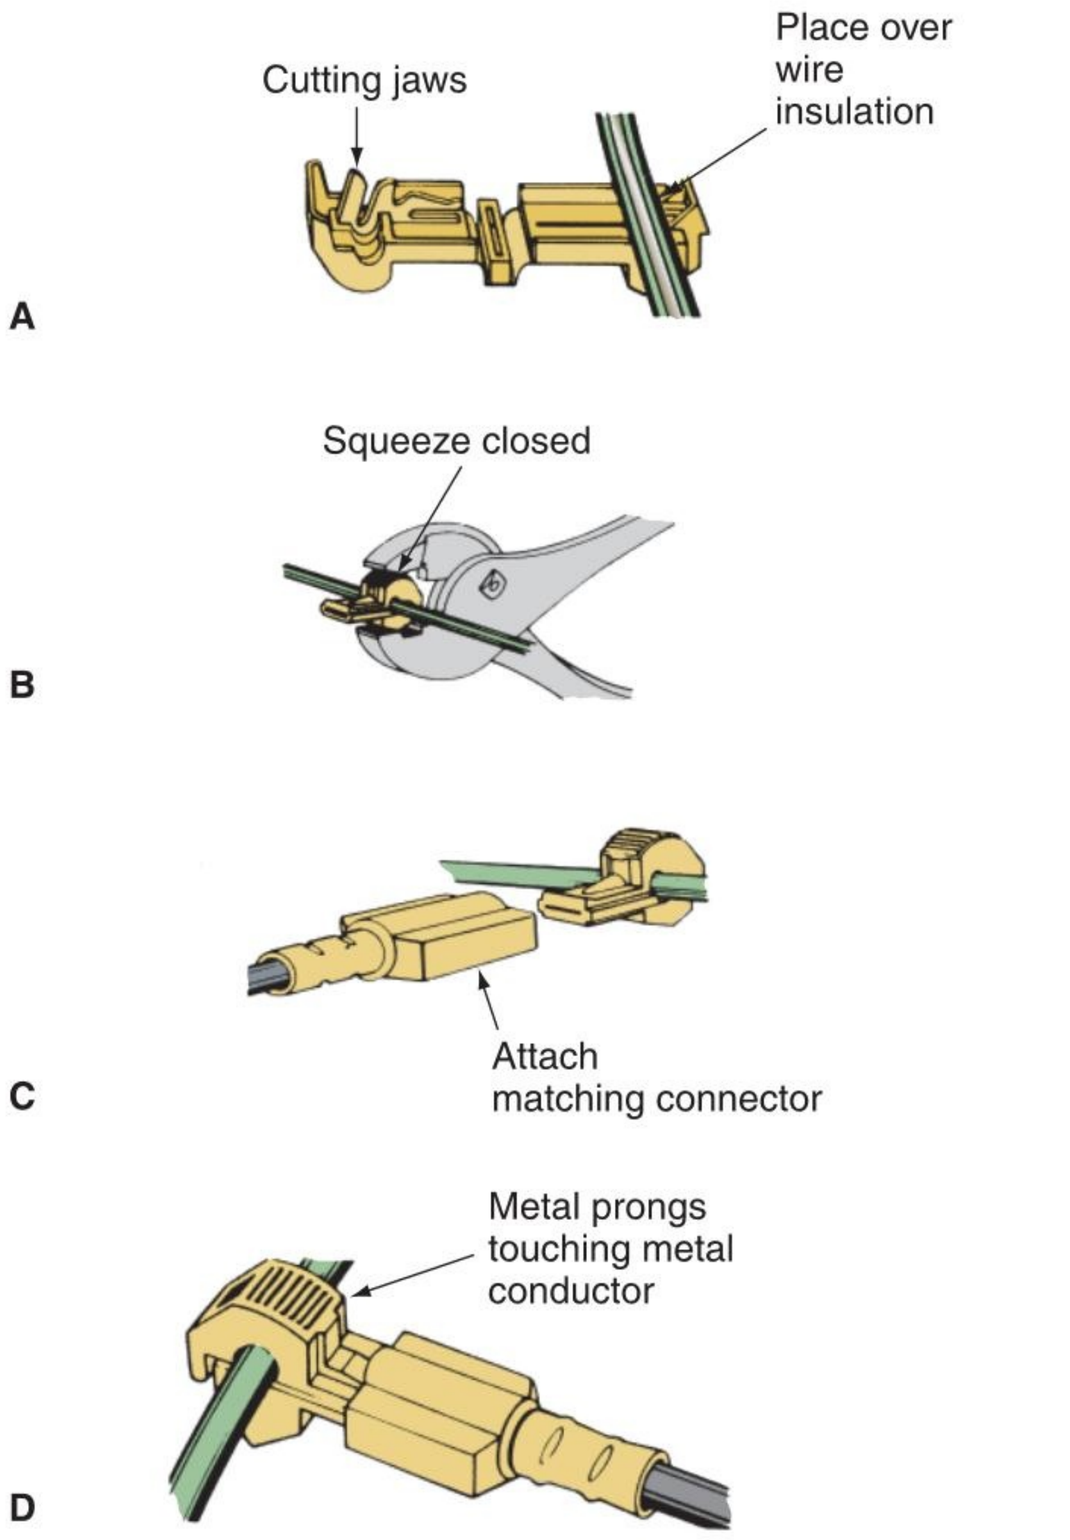
Factory Connectors

Various types of connectors are installed on vehicles at the factory. ***Harness connectors*** are multi-terminal connectors that join several wires and have a special locking feature. In most cases, the connector consists of a two-part plastic housing that snaps together to prevent the conductor terminals from working free.

Disconnecting Factory Connectors

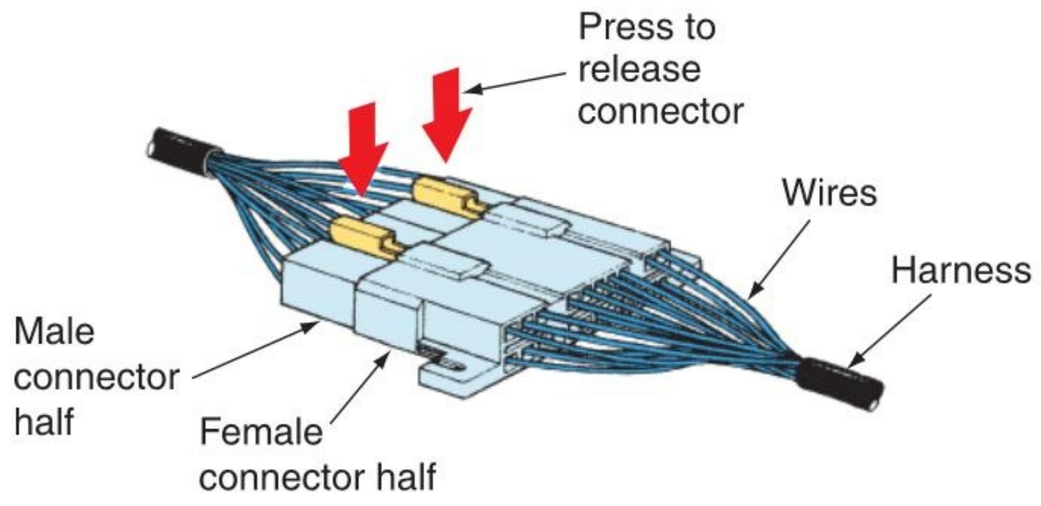
Most electrical connectors require special methods or tools for disconnection. Many have a plastic latch that holds the two halves of the connector together. You may have to squeeze or pry up on the latch to free the connector. **Figure 21-28** shows an example.

Copyright Goodheart-Willcox Co., Inc.



G-P Parts

Figure 21-27. This self-stripping connector makes it easy to splice into an existing wire. It snaps over the wire and cuts through the insulation to make contact with the conductor.



Toyota

Figure 21-28. Factory harness connectors house several wires and terminals. Most have a locking feature. You must release the tabs before pulling the connector apart.

Tech Tip

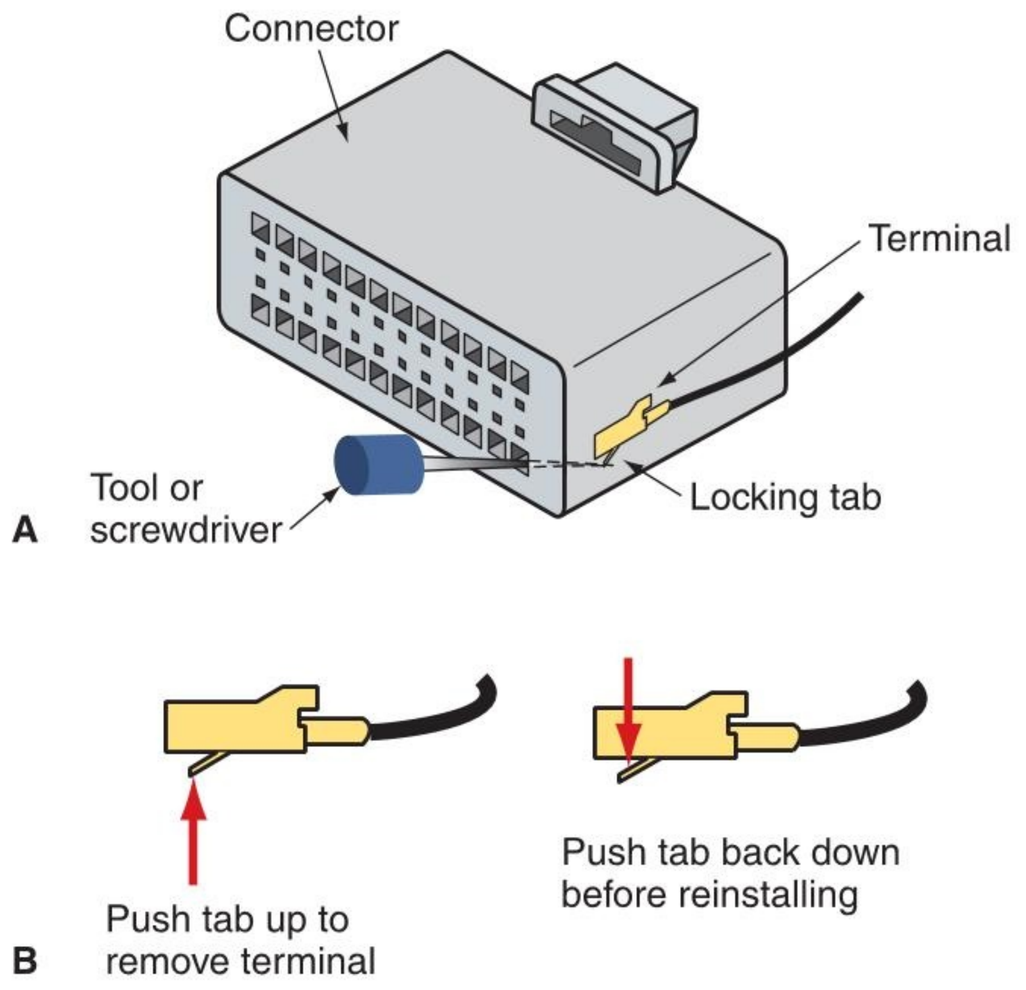
Connector damage can result if you force a connector apart. Always obtain the right tool and use the proper methods when disconnecting harness connectors. If in doubt about how to release a connector, refer to the service manual.

Terminal Replacement

Sometimes it is necessary to replace a terminal inside a factory connector. The terminal usually has a small metal tab or lever that locks inside the plastic connector. A small screwdriver or special tool can be used to free the terminal. Then the wire and terminal can be pulled out of the plastic connector.

When reinstalling a terminal in a factory connector, make sure the small metal tab is bent outward properly. It must stick out far enough to lock tightly inside the connector. Use a small screwdriver or pick to bend the tab out if needed. See **Figure 21-29**.

Special connector tools are available to release terminals from several types of automotive connectors. You must slide the correct side of the tool inside the connector to release the locking device on the terminal. Refer to **Figure 21-30**.



Goodheart-Willcox Publisher

Figure 21-29. Sometimes the terminals inside factory connectors become damaged. A special tool or small screwdriver is needed to free the terminal from the connector.

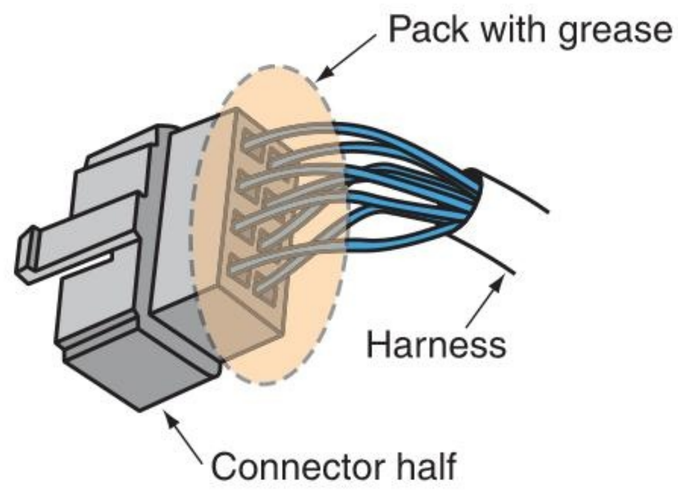
Lisle Corp.

Figure 21-30. Some makes of cars require special tools to quickly and safely disconnect their plastic wiring harness connectors. A—This special tool is designed to release various types of terminals from their connectors. B—The tool has different ends to fit and release connectors from various manufacturers.

Protecting Electrical Connections

Most manufacturers recommend that you apply ***dielectric grease*** to the terminals before refastening connectors. This special grease blocks moisture and helps prevent corrosion without affecting electrical conduction. If corrosion or moisture is a problem, you can also pack the outer opening of the connector with dielectric grease. This not only keeps moisture away from the terminals but also prevents an increase in circuit resistance. See **Figure 21-31**.

Some electrical connectors are equipped with a soft rubber boot that you must pull off before you can service the connection. Be sure to reinstall the boot completely to keep moisture and water from entering and contacting the conductors, possibly affecting circuit operation. If a wire is fed through a metal body panel, make sure a rubber grommet is properly installed, as shown in **Figure 21-32**. If the grommet pops out of the metal body panel, the wire insulation may be cut and abraded, causing a "dead short" to ground. A "dead short" is due to any current carrying conductor that is accidentally connected to earth or frame ground. With no resistance in the short circuit, all current will flow into ground, usually overheating and burning wires.

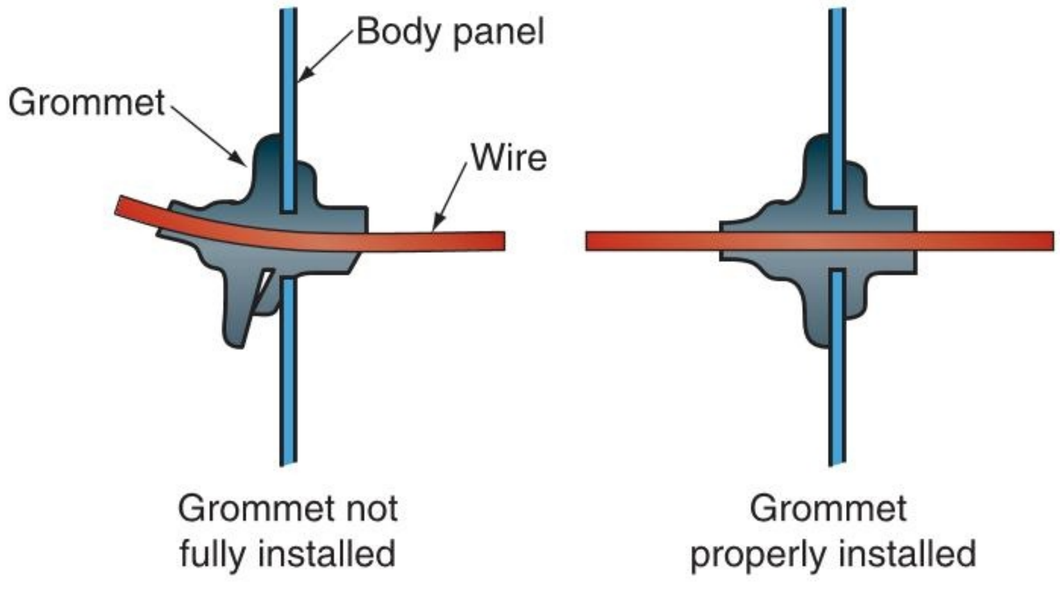


Goodheart-Willcox Publisher

Figure 21-31. Special grease can be applied to terminals and the outside of a connector to prevent corrosion and a bad electrical connection.

Wiring Repairs

Wiring repairs include many tasks that return a circuit to its normal operating condition. This might involve replacing a burned wire or connector, soldering a wire to a terminal, or crimping a terminal over a wire.



Goodheart-Willcox Publisher

Figure 21-32. Make sure grommets are fully installed to keep wires from abrading and shorting to ground.

Copyright Goodheart-Willcox Co., Inc.

Bypassing a Connector

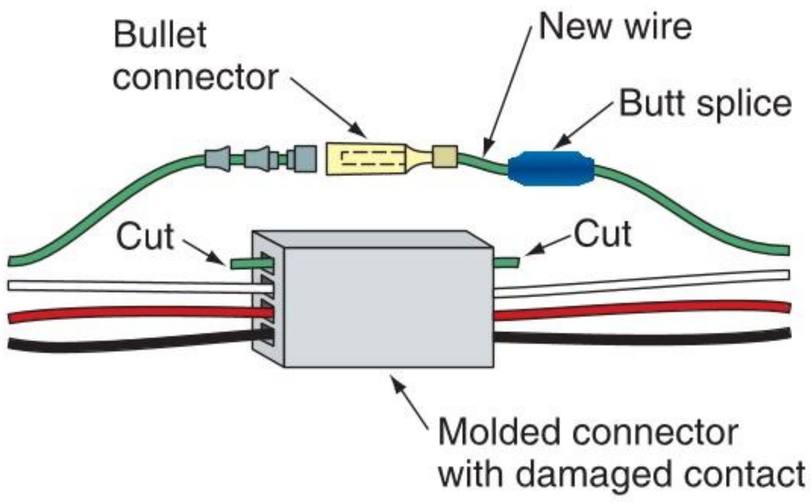
You may need to bypass (route the electron flow around) a connector if the connector is burned or its metal terminals are damaged and a new one is not available. A connector bypass or replacement might also be required if the wiring harness is very complex or difficult to remove and replace. Refer to **Figure 21-33**.

To bypass a connector, use a new piece of wire to make an electrical path around the terminals in the connector. Cut off the affected wires leading into both sides of the connector. Then butt-splice a new piece of wire to join the cut ends. A ***butt splice*** is a splice in which the wires are placed end-to-end, without overlap. Crimp connectors will work, but you should solder the wires together, if possible.

Bypassing a connector can save time, especially if the connector contains several terminals. If all of the other wires and terminals are good, they can remain joined using the existing connector. Only the bad electrical connection is bypassed.

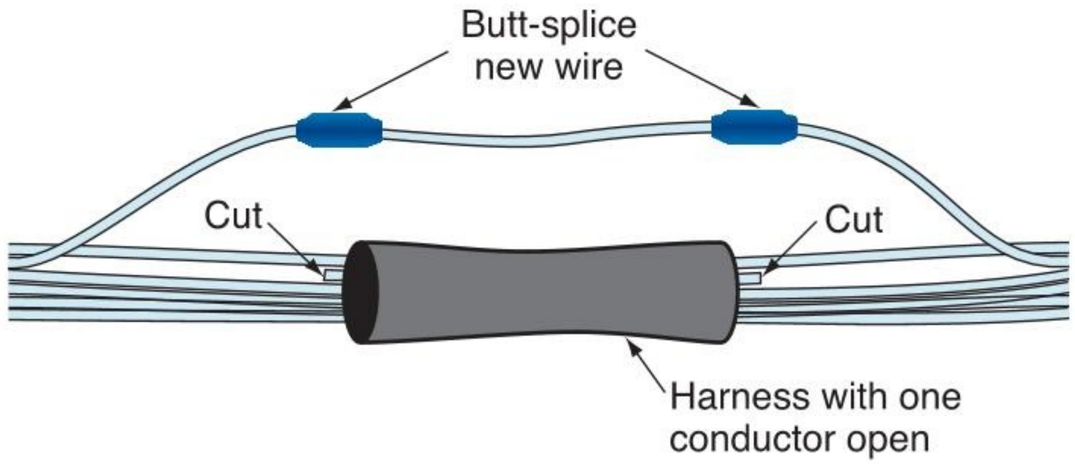
Bypassing a Wire

If tests find one wire to be broken or shorted inside a wiring harness, the easiest solution might be to bypass the wire by running a new wire in place of the bad one on the outside of the wiring harness. To bypass a wire, use a new piece of wire to make an electrical connection around the bad section of a wiring harness. The rest of the harness can remain intact. This method is useful if the wire runs through a complex or hidden harness, such as one that runs under the dash or through the firewall. See **Figure 21-34**.



Goodheart-Willcox Publisher

Figure 21-33. When a connector is burned or damaged, it is sometimes easier to bypass the bad connection with a new wire. Butt splice the new wire as shown.

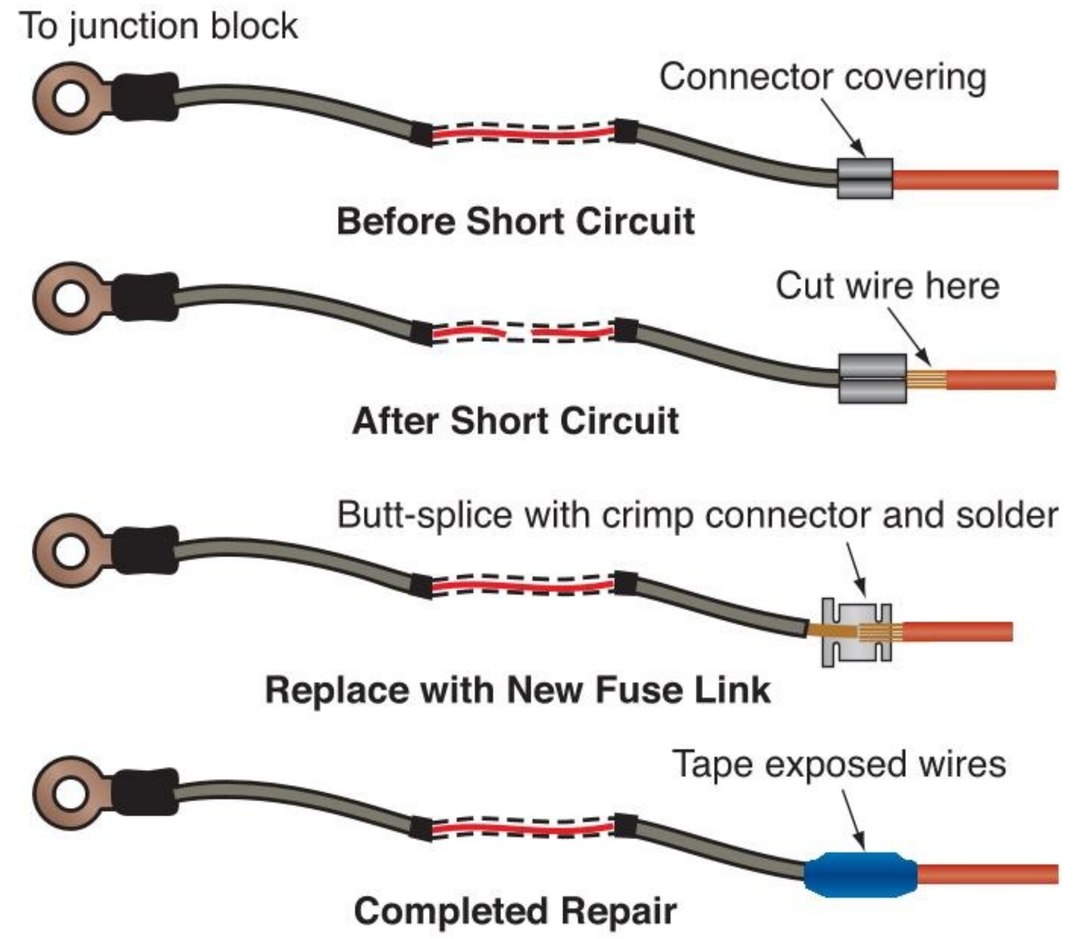


Goodheart-Willcox Publisher

Figure 21-34. If a wire is broken or shorted inside a complex wiring harness, you can fix the problem by bypassing the bad wire. Cut the bad wire on each end of the harness where it is easily accessible. Then run new wire to connect the cut ends.

Fuse Link Service

A ***fuse link*** protects the wiring before it gets to the fuse box. The fuse link burns in half to protect the circuit if any unfused wire (cables between the battery and fuse boxes) is shorted and draws excess current. This may shut down the power to several major circuits, such as the starting and lighting circuits. See **Figure 21-35**.



Goodheart-Willcox Publisher

Figure 21-35. To replace a fuse link, cut off the old link and solder on a new link or the correct gage wire.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

Before replacing a fuse link, it is important to correct the short circuit problem. Correcting the short will keep the new fuse link from burning. Disconnect the 12-volt battery positive and use an ohmmeter to find the short to ground. The shorted circuit will show little or no resistance (ohms) on your ohmmeter.

Service Procedure

This is the procedure to replace a fuse link:

1. Disconnect the negative battery cable.
2. Remove or cut off the burned fuse link.
3. Strip the ends of the main circuit feed wire.
4. Obtain a factory fuse link or the correct gage replacement wire. Either should be a smaller gage than the main circuit wiring.
5. Use an all-metal connector to butt-splice the link to the main circuit wire.
6. Solder the wires and connectors together.
7. Tape, coat, or shrink wrap the soldered connections.
8. Reconnect the 12-volt battery and check circuit operation.

Tech Tip

Refer to the service manual for additional information about the fuse links for specific vehicle makes and models. The manual will provide any special procedures and specifications needed to replace the fuse link wire.

Adding Electric Accessories

Many computer circuits have wiring that is sensitive to any change in voltage, current, and resistance. Taping or splicing into them could upset circuit operation. Therefore, when adding electric accessories or optional devices to a vehicle, avoid splicing into the factory wiring if possible. It is best to wire any additional electric circuit as an independent fused circuit going directly to the 12-volt battery and a new ground. This would apply to trailer or camper wiring, fog lights, alarms, and other new devices.

Twisted Cable Service

Many sensors operate on very low current and voltage levels, and their signals can be affected by any induced voltage. Therefore, some computer system wiring harnesses use shielded twisted cable. This cable is designed to prevent voltage from being induced into the wire and upsetting the operation of the computer. Follow service manual recommendations when replacing this type of cable to prevent computer system problems. Wires should be tightly twisted in the same direction before soldering.

Wiring Diagrams

Wiring diagrams, also called ***wiring schematics***, are drawings that show how the wires connect to each component in an electric or electronic circuit. Symbols represent components, and lines represent wires. Wiring diagrams serve as electrical "road maps." Wiring diagrams show how wires connect to each other and to components.

Electrical/Electronic Symbols

The electrical symbols you have studied in this chapter are only a few of the many electrical and electronic symbols used on wiring diagrams to show circuit components and wiring connections. Symbols are used to save space and to simplify reading. **Figure 21-36** shows some of the symbols that are commonly used in automotive wiring diagrams. To become a competent technician, you must be able to understand these symbols.

Symbols are used in the diagram to replace the isometric drawing of the 12-volt battery, fuse, switch, motor, and lightbulb. The wiring diagram clearly shows the relationship of the electric components in the circuit. An example of how an electric circuit compares to a wiring diagram is shown in **Figure 21-37**.

Tech Tip

The symbols and diagrams used in factory service manuals vary. Refer to a symbol chart in each manual to find the symbol used for each electric or electronic component.

Figure 21-37. Compare the circuit illustration with the wiring diagram that describes it. Both represent the same components and electrical connections.

Wiring Harnesses Names

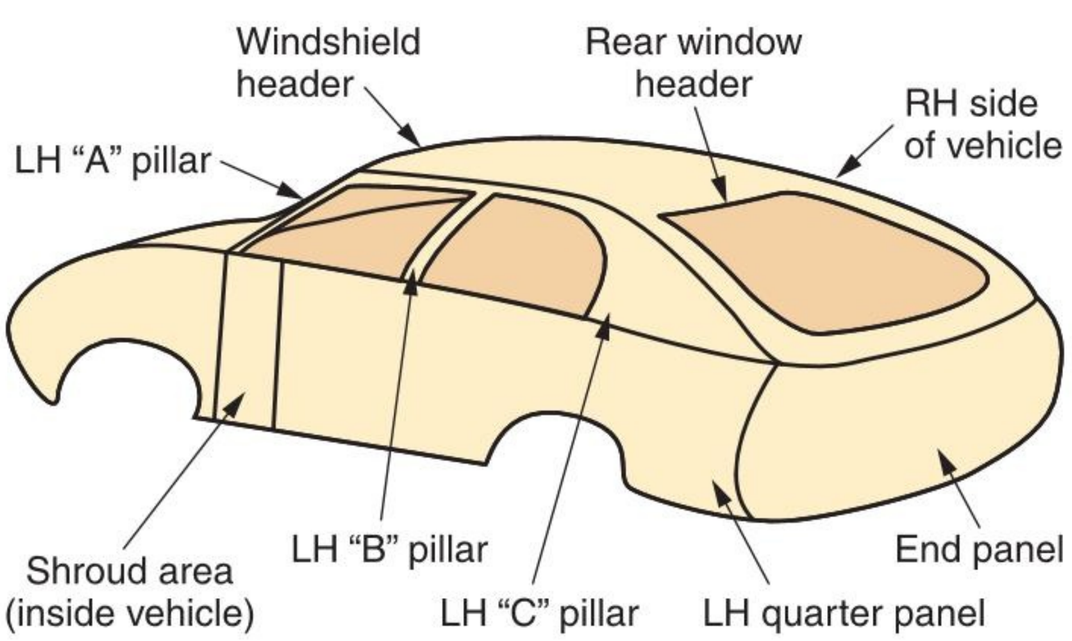
Most wiring harnesses are named after their location on a vehicle. They can also be referenced by location. Therefore, when using wiring diagrams, you may need to know the body part names to determine wire locations. Refer to **Figure 21-38**.

The left side of a vehicle is normally the driver's side. The left side may be abbreviated "LH" on a wiring diagram. The right side of the vehicle, abbreviated "RH," is on the passenger side. If you forget which side is which, imagine yourself sitting in the vehicle and looking forward. The vehicle's right and left are now your right and left.

Wire Code Identification System

The ***wire code identification system*** is an alpha-numeric (numbers and letters) method of identification that explains the color, location, and gage size of wires on a wiring diagram. Wire code identification systems vary with the manufacturer. Refer to the service information for specifics. See **Figure 21-39**.

A ***wire color code*** (red, blue, green with black stripe, etc.) on a specific wire allows you to trace or follow one wire to different locations in the vehicle. Even if a wire travels through the vehicle's firewall and is hidden, you can still find the other end of the wire by locating the identical color code markings. The wires can be a solid color or have stripes, bands, or hash marks. This makes it easy to tell one wire from another. Refer to **Figure 21-40**.



Goodheart-Willcox Publisher

Goodheart-Willcox Publisher

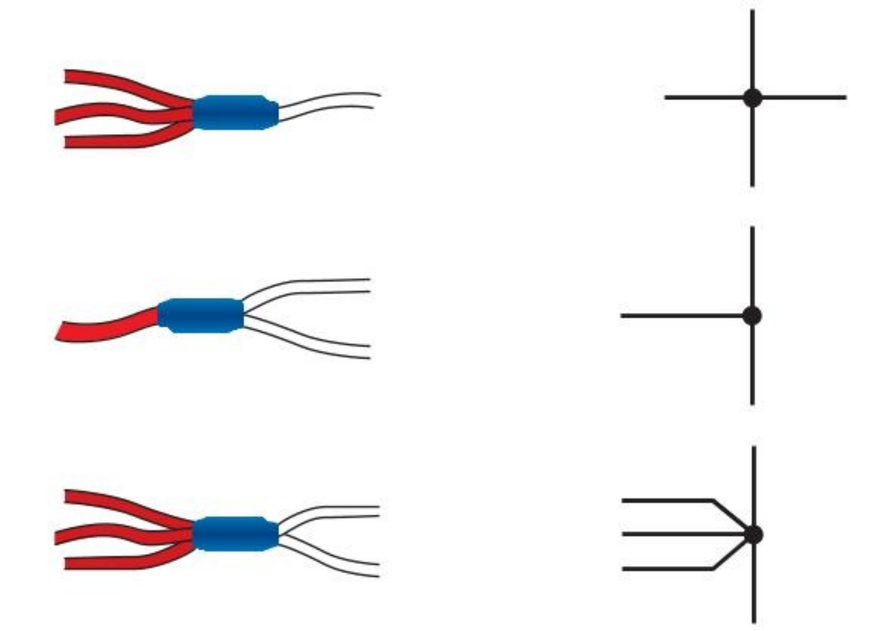
Figure 21-40. Since codes vary, always refer to the charts that explain abbreviations and codes. These charts give color codes and circuit identification codes.

Wiring Splices

Wiring splices are places where two or more wires are connected. They are normally shown on a wiring diagram as a dot where the wires connect. They can also be shown as lines (wires) that run together, but most wiring diagrams use the dot to avoid confusion. Refer to **Figure 21-41**. Splice code charts can be used with a wiring diagram to give added information about the circuit. An example is given in **Figure 21-42**. A capital "S" indicates a splice in this diagram.

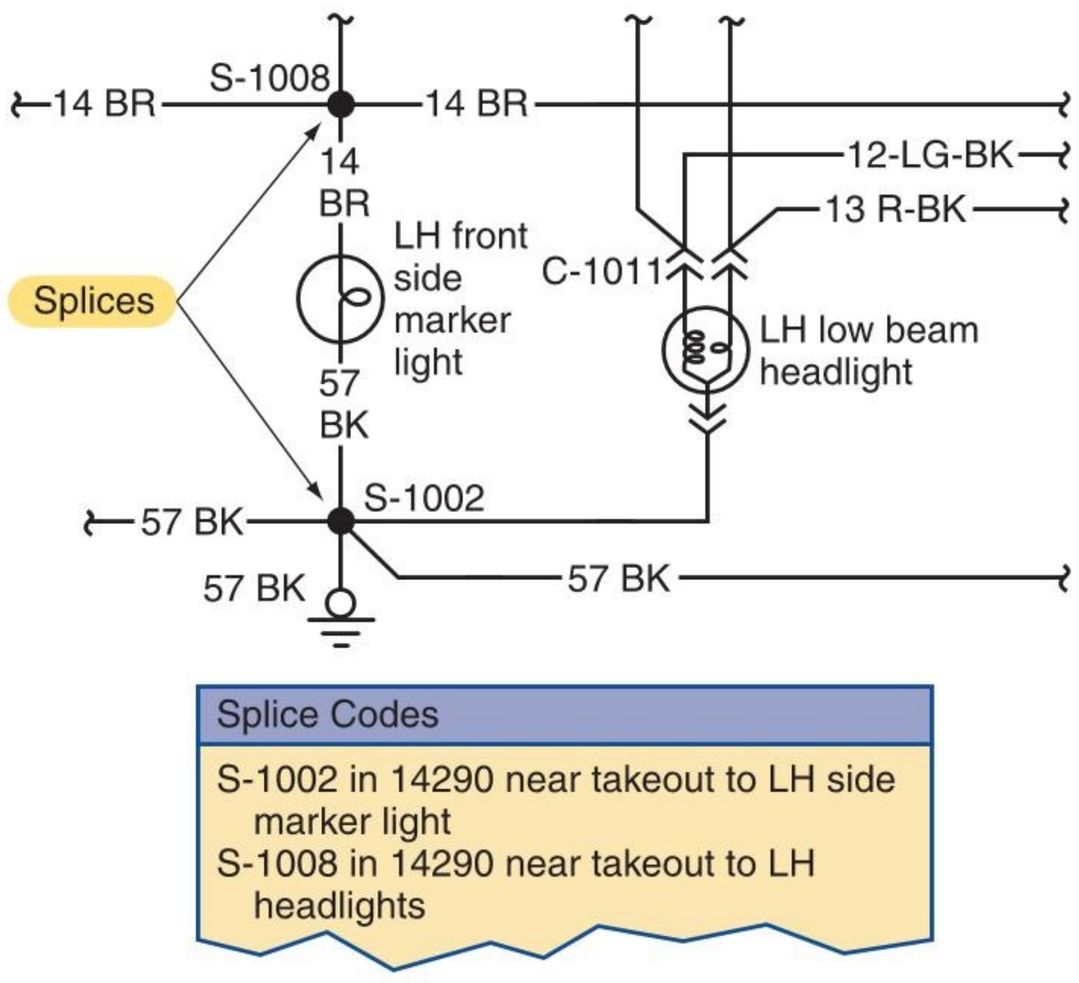
Electrical Grounds

Electrical grounds show where circuits connect or fasten to the metal frame or chassis of a vehicle.



Goodheart-Willcox Publisher

Figure 21-41. Wire splices are usually shown by placing a dot over the wires. However, note the possible variation when a wire is spliced at a connector.

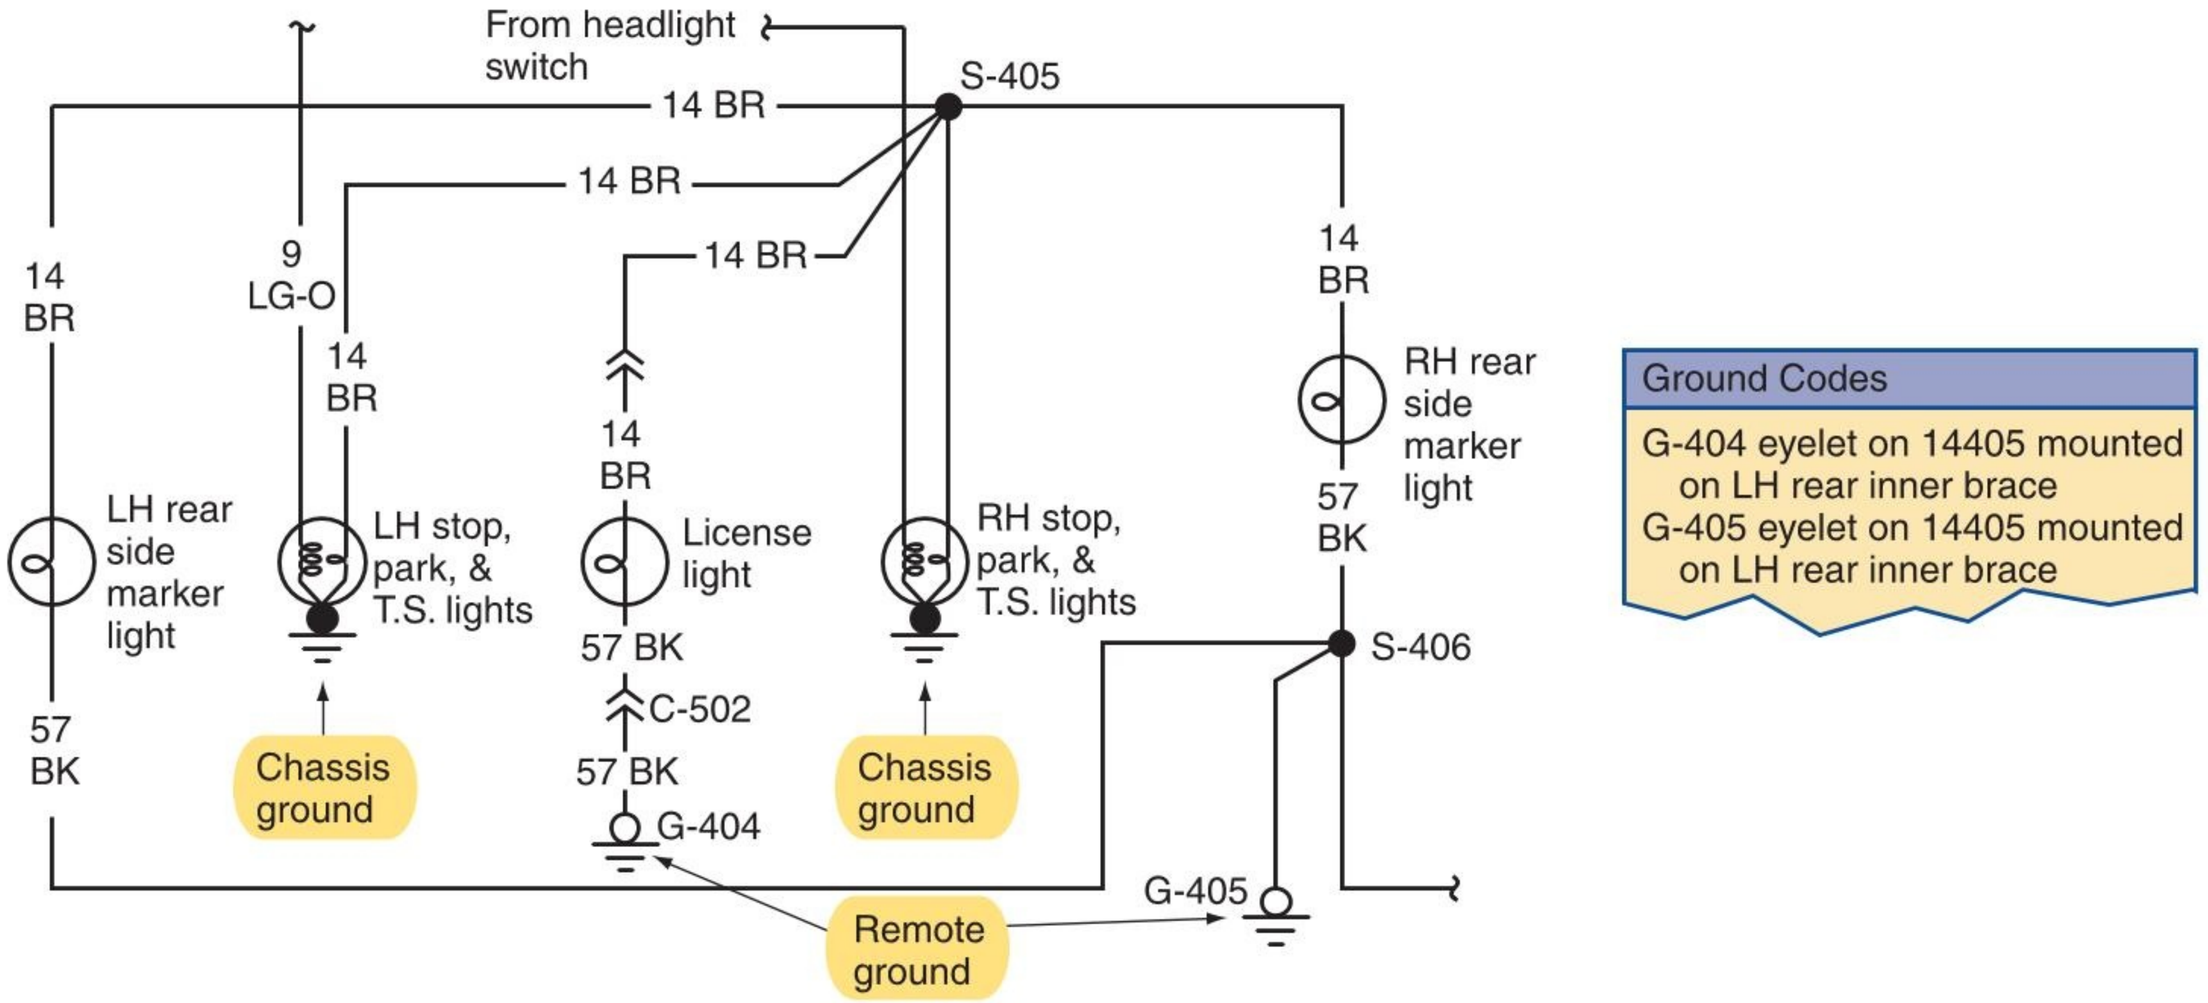


Ford

Figure 21-42. Many wiring diagrams have additional charts that give more information. In this diagram, S-1002 and S-1008 are splices, and the accompanying chart gives their exact location.

A ***remote ground*** has an extra wire running from the circuit to ground. A ***chassis ground*** uses the metal part of a component to attach to ground. Refer to **Figure 21-43**.

Copyright Goodheart-Willcox Co., Inc.



Ford

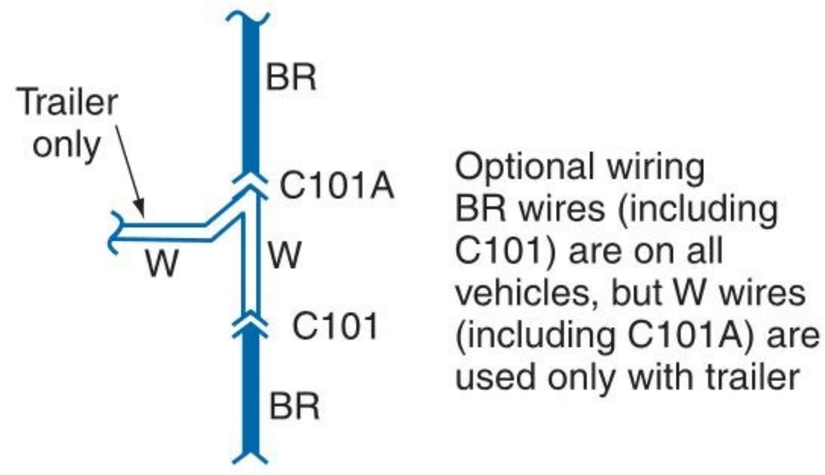
Figure 21-43. Grounds are sometimes numbered and prefaced with a capital "G" on wiring diagrams.

Note the difference in the symbols for each type of ground. Also notice the chart that supplements the wiring diagram. A capital "G" indicates a ground on some schematics.

Alternate Circuits and Optional Wiring

An alternate circuit is a possible circuit variation given on a wiring diagram. For example, a wiring diagram may show the electrical connections for a vehicle with an automatic transmission and for a vehicle with a manual transmission. This allows one diagram to serve as two diagrams.

Optional wiring is wiring provided in a circuit that may not be in use. In **Figure 21-44**, wiring is provided for trailer lights, even though the trailer package harness may not be installed on the vehicle.

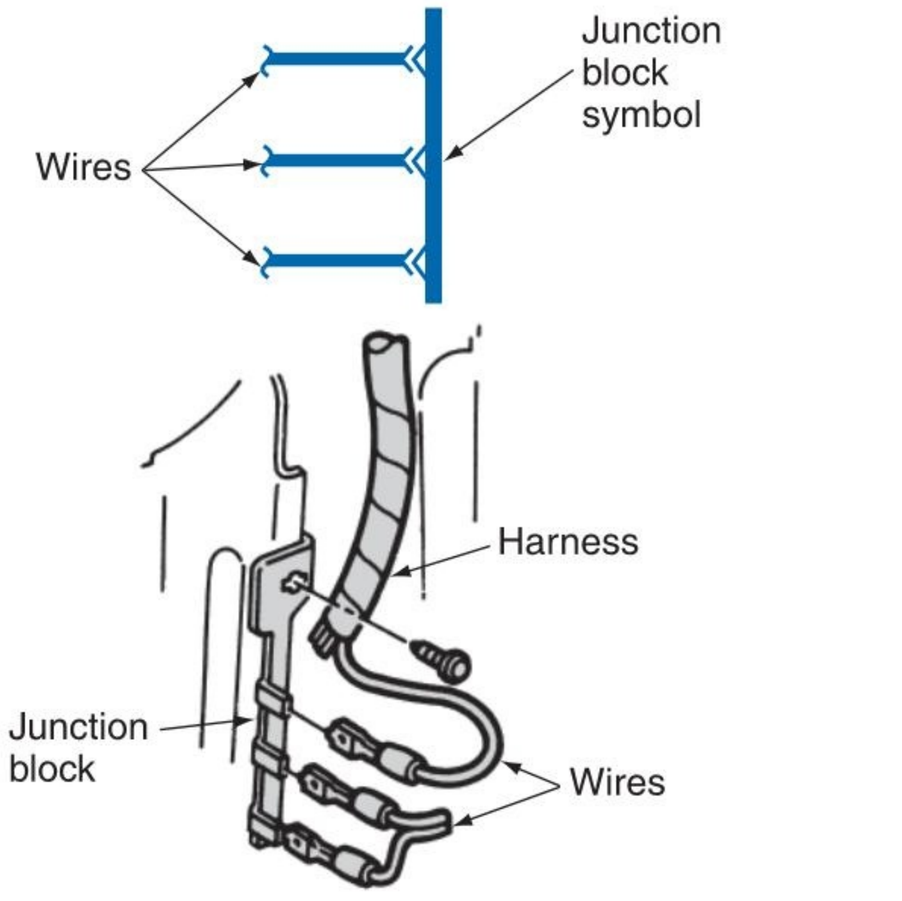


Goodheart-Willcox Publisher

Figure 21-44. Optional wiring may or may not be used. This example shows optional wiring for trailer towing.

Junction Blocks

A ***junction block*** is a component that allows several wires to be connected to a common conductor. The junction block serves as a splice, but the wires can easily be removed from the junction. See **Figure 21-45**.



Goodheart-Willcox Publisher

Figure 21-45. A junction block and its symbol.

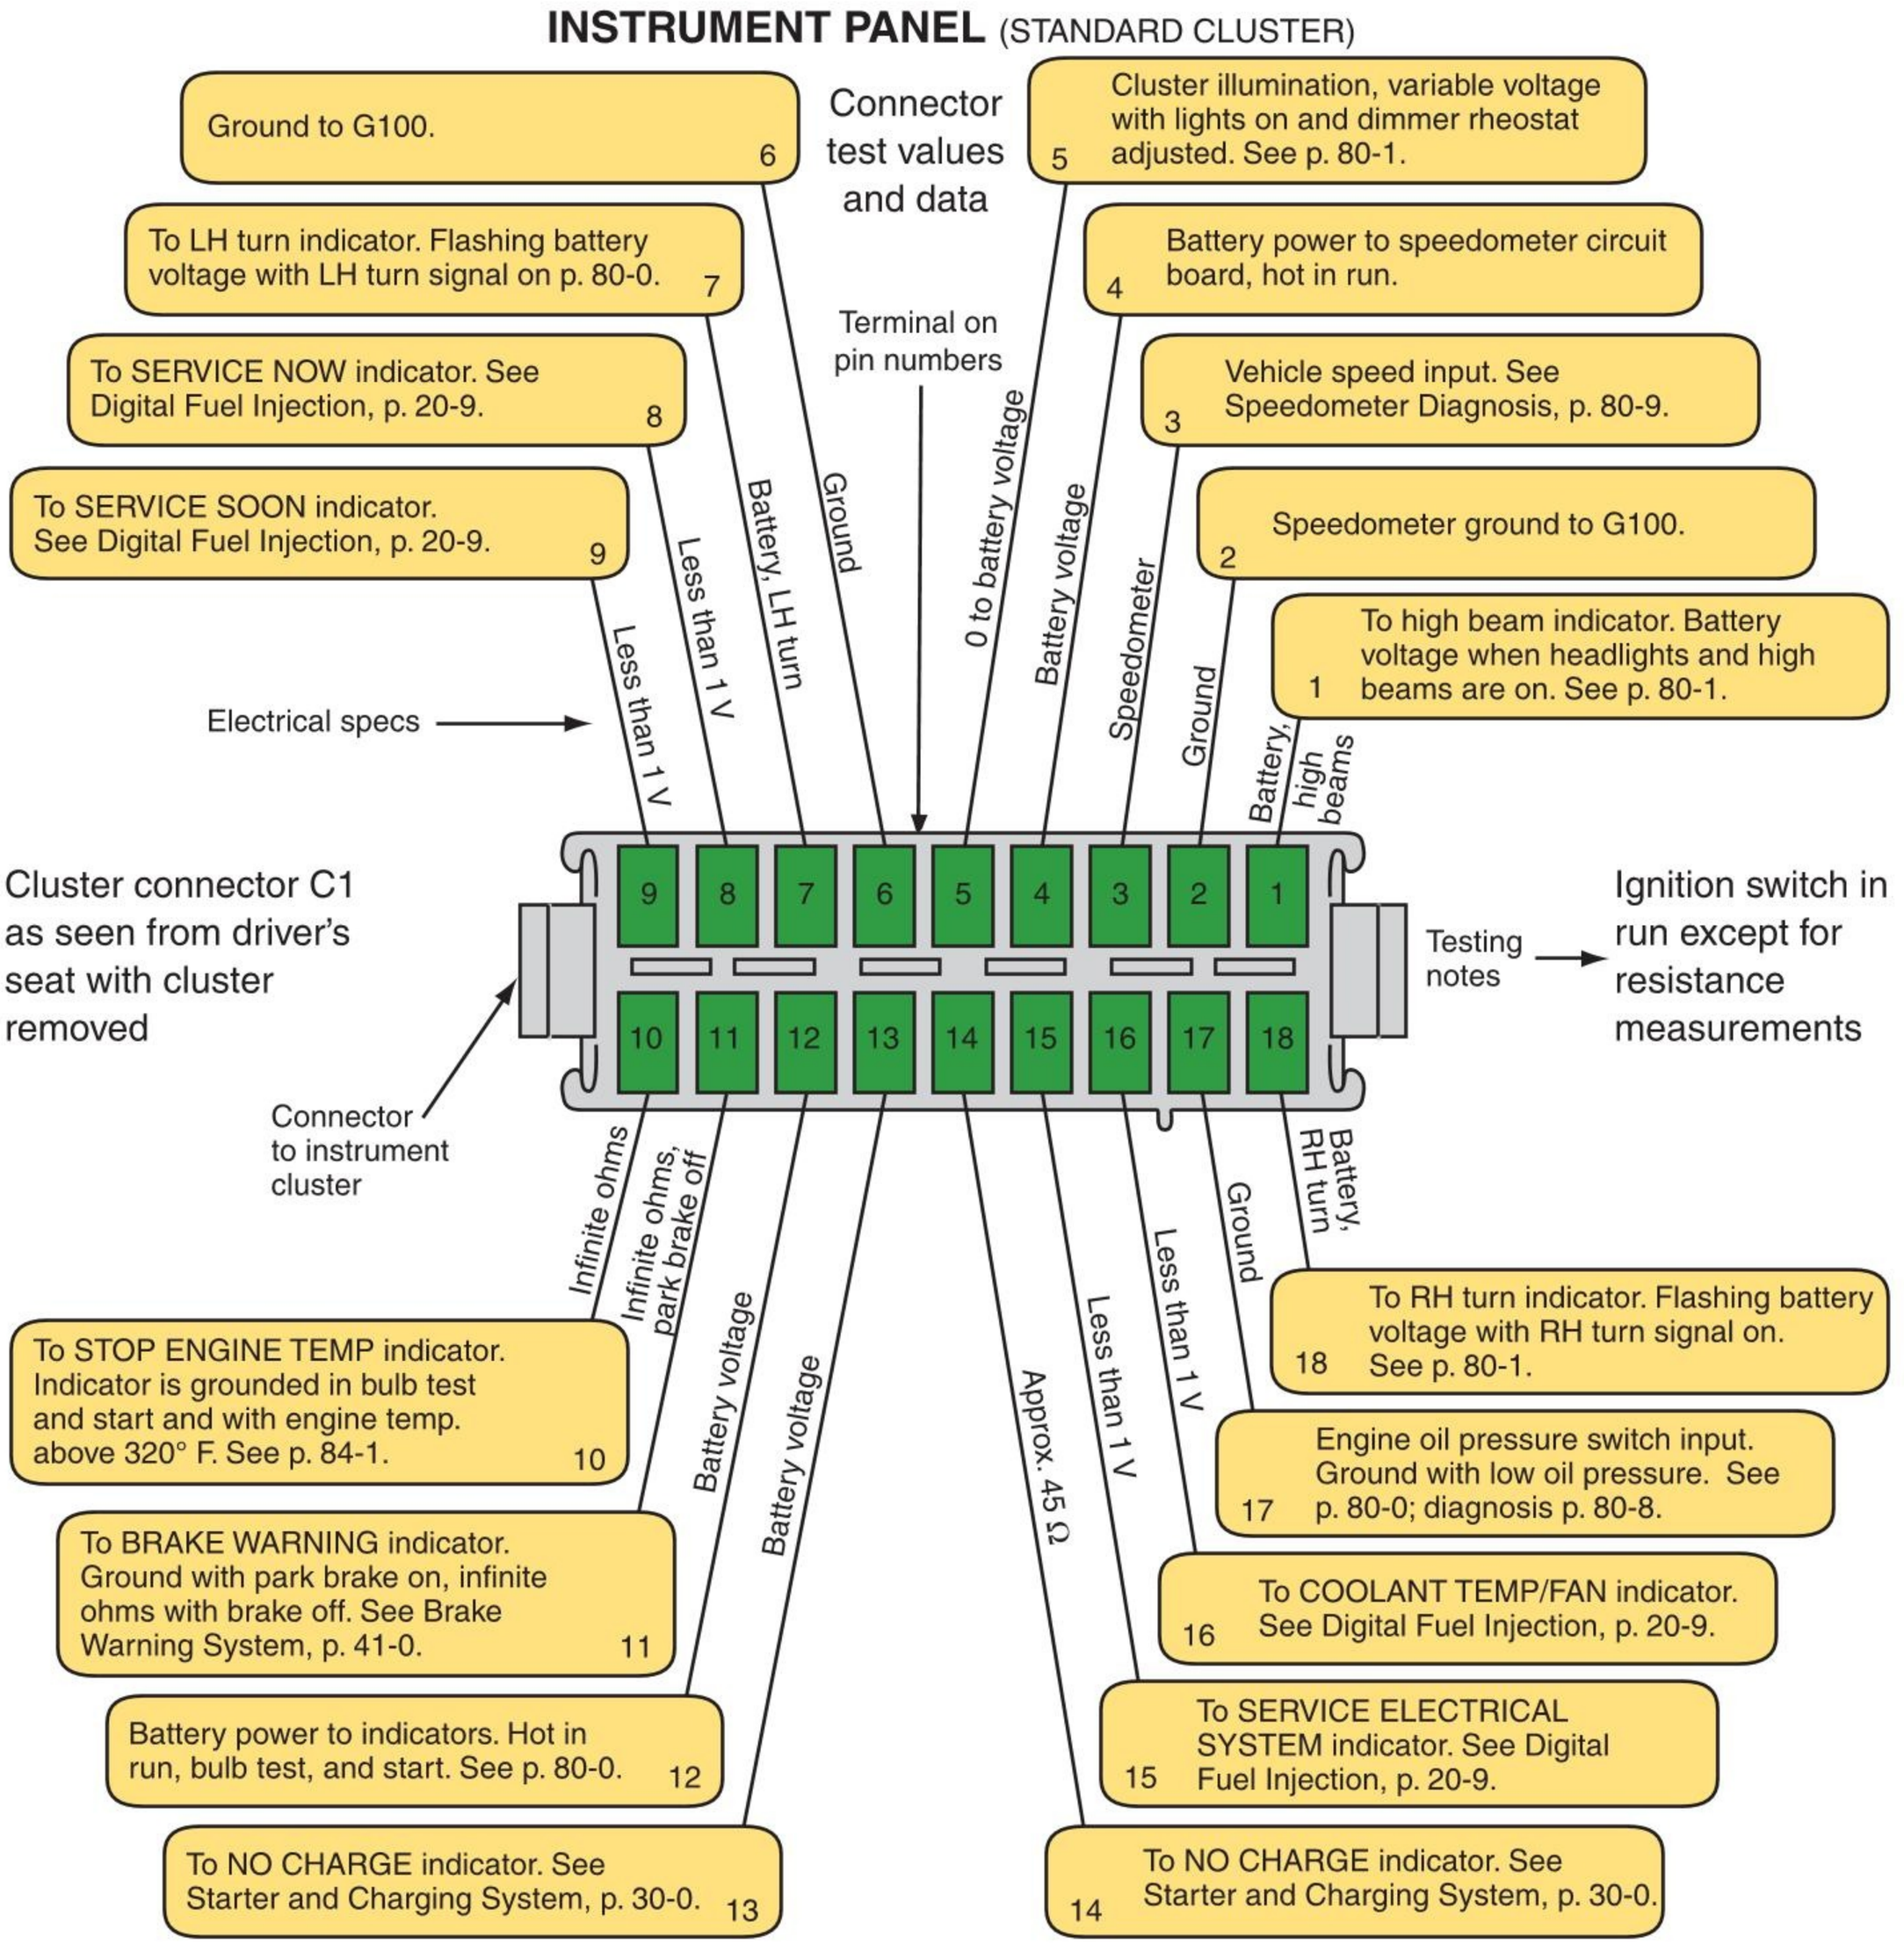
Connector Electrical Values

The electrical values of a connector are the voltage, current, and resistance specifications at a connector for a known good circuit. An end view of the connector is usually illustrated. The electrical value that should be present at each terminal in the connector is also given. This allows you to use a multimeter to check the circuit for problems quickly and efficiently. If your measurements include any values that are higher or lower than these given values, a circuit problem exists. An example of a service manual page showing connector electrical values for one make of vehicle is shown in **Figure 21-46**.



Goodheart-Willcox Publisher

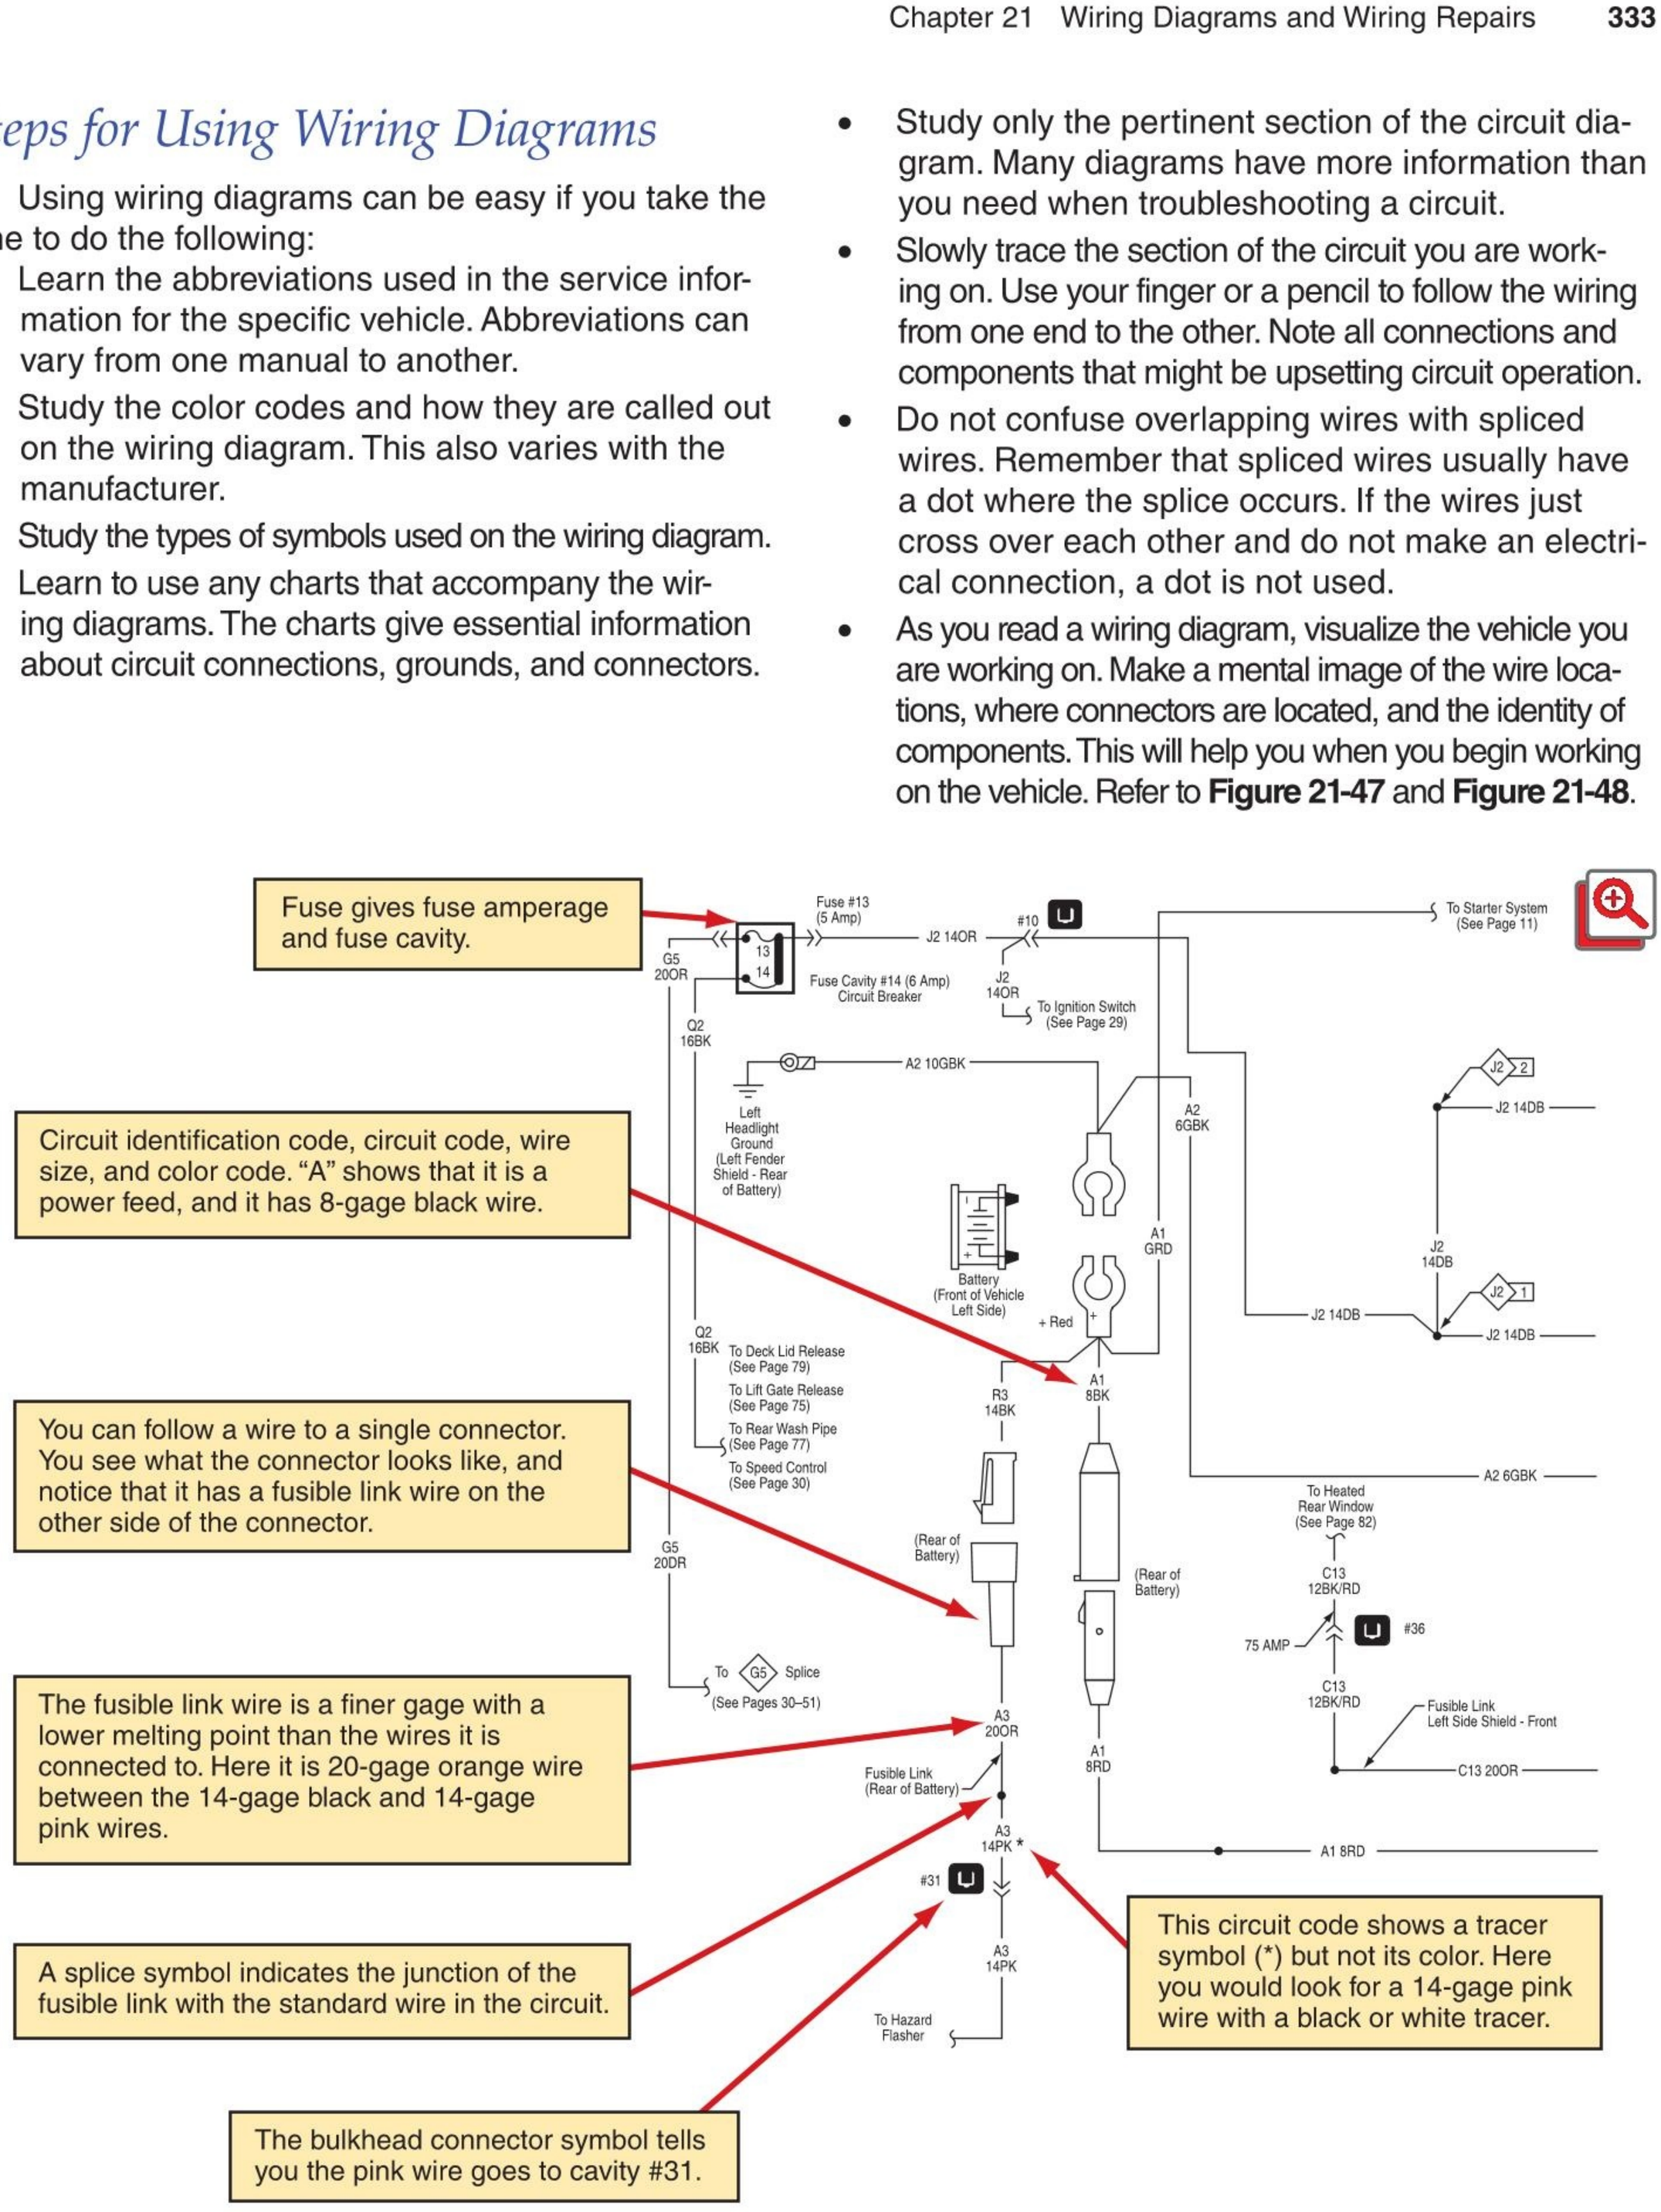
Figure 21-46. This connector illustration shows terminal numbers, actual test values, and the destination of terminal wires. It is useful when you are trying to find faults in a specific section of wiring.

Copyright Goodheart-Willcox Co., Inc.

Steps for Using Wiring Diagrams

Using wiring diagrams can be easy if you take the time to do the following:

- Learn the abbreviations used in the service information for the specific vehicle. Abbreviations can vary from one manual to another.
- Study the color codes and how they are called out on the wiring diagram. This also varies with the manufacturer.
- Study the types of symbols used on the wiring diagram.
- Learn to use any charts that accompany the wiring diagrams. The charts give essential information about circuit connections, grounds, and connectors.
- Study only the pertinent section of the circuit diagram. Many diagrams have more information than you need when troubleshooting a circuit.
- Slowly trace the section of the circuit you are working on. Use your finger or a pencil to follow the wiring from one end to the other. Note all connections and components that might be upsetting circuit operation.
- Do not confuse overlapping wires with spliced wires. Remember that spliced wires usually have a dot where the splice occurs. If the wires just cross over each other and do not make an electrical connection, a dot is not used.
- As you read a wiring diagram, visualize the vehicle you are working on. Make a mental image of the wire locations, where connectors are located, and the identity of components. This will help you when you begin working on the vehicle. Refer to **Figure 21-47** and **Figure 21-48**.



Chrysler

Figure 21-48. Study the meaning of the symbols and other information this wiring diagram contains.

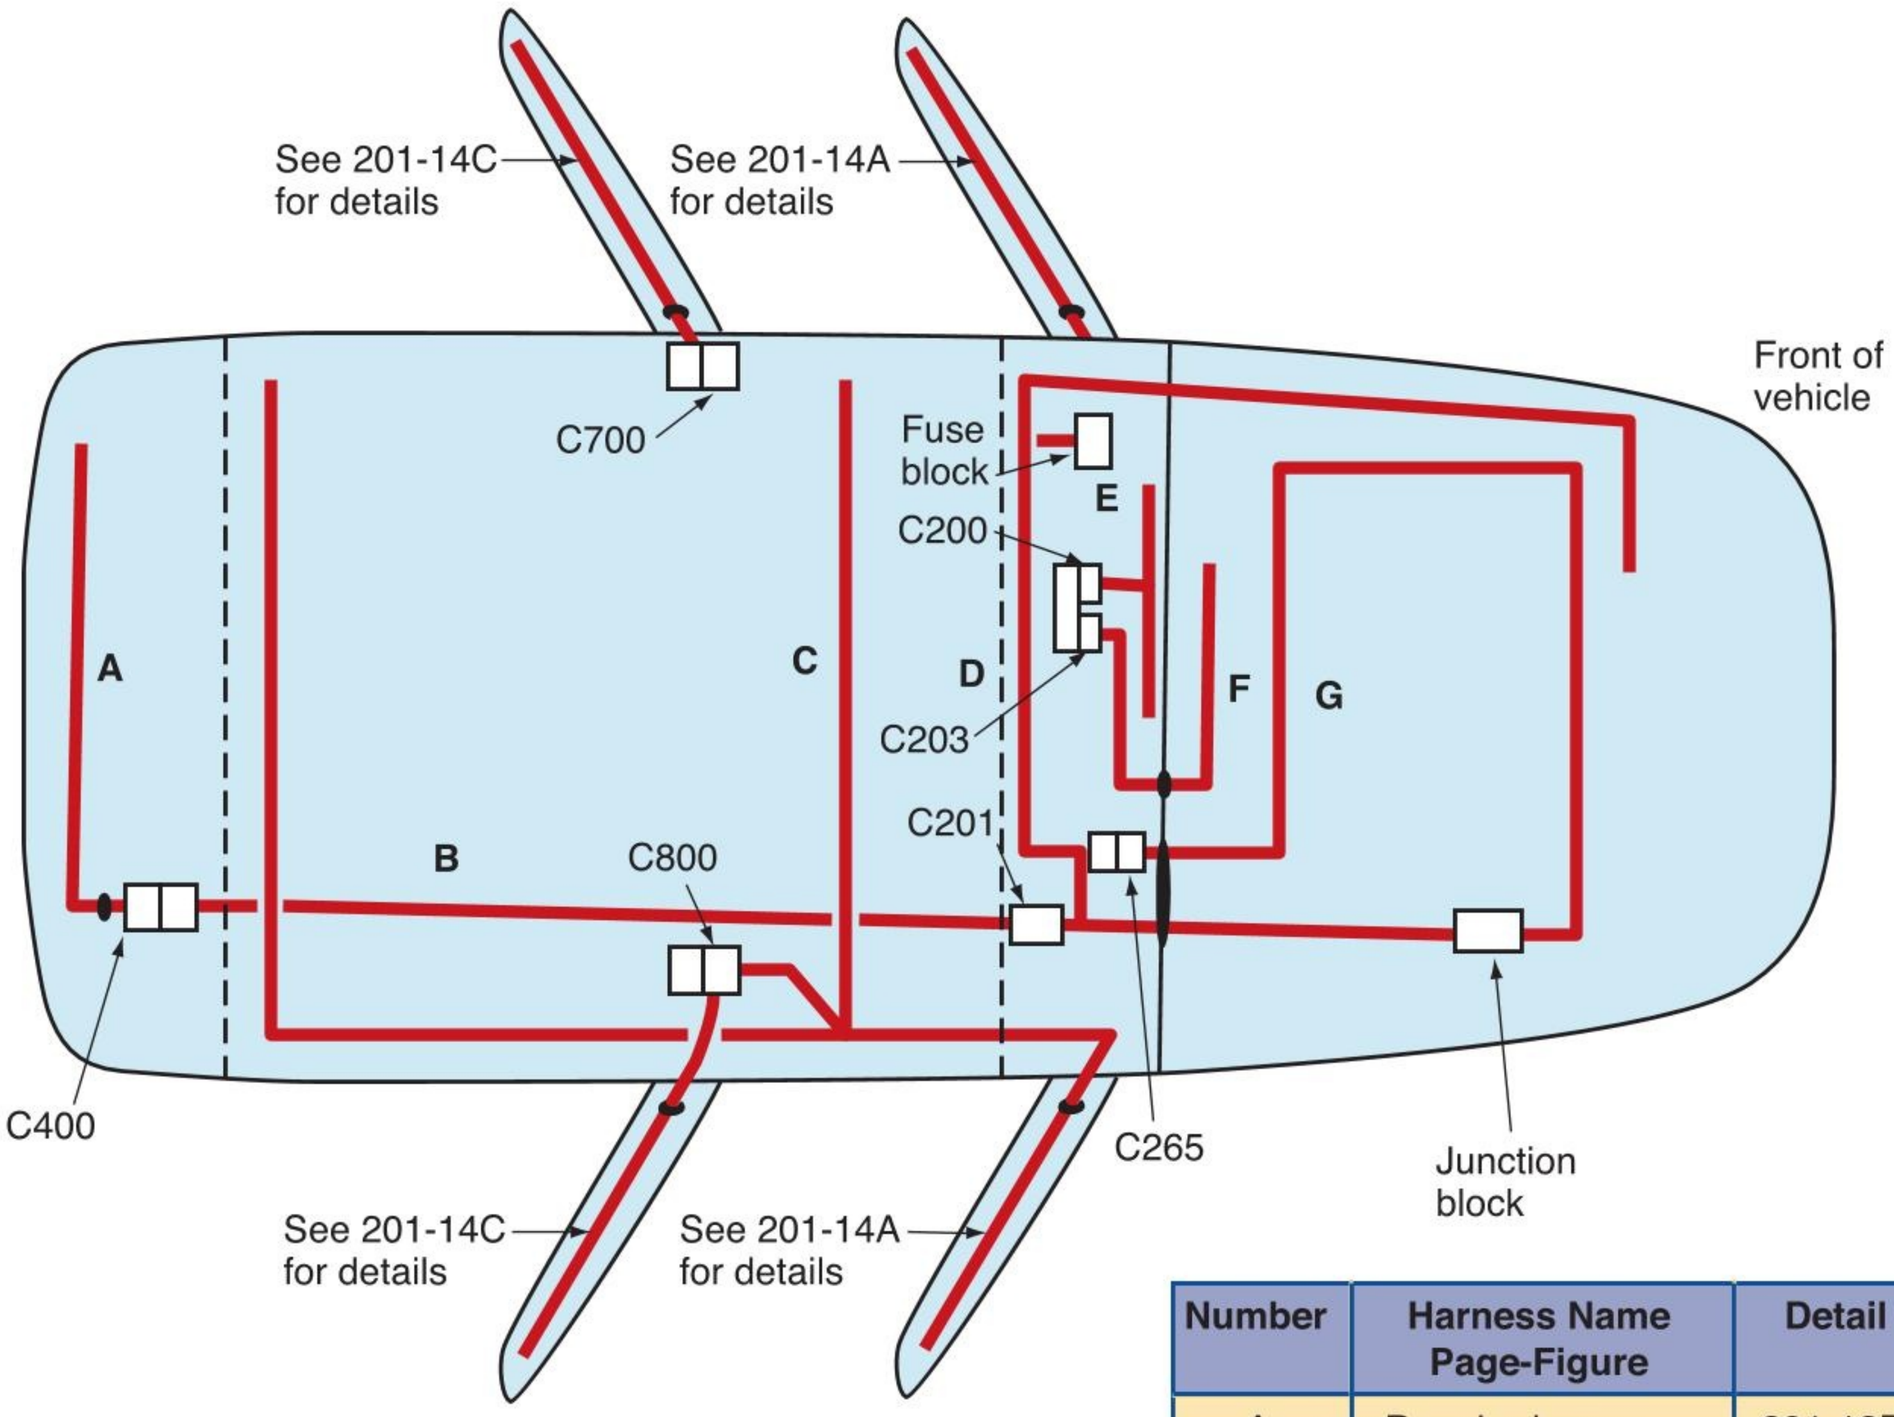
Types of Wiring Diagrams

Wiring diagrams may take many different forms, depending on the specific information they contain. For example, a wiring diagram that shows harness routing looks quite different from one that shows a block diagram of a circuit.

Harness Routing Diagram

A ***harness routing diagram*** shows how major wiring is arranged and where it is located in the vehicle. This type of diagram shows how the main harnesses feed through the body of the vehicle. Notice that a code system is used to identify the sections of the harnesses in **Figure 21-49**.

Copyright Goodheart-Willcox Co., Inc.



Number	Harness Name Page-Figure	Detail View
A	Rear body	201-12B
B	Front body	201-12A
C	Cross body	Left–201-15A Right–201-12D
D	Dash	201-8B
E	Instrument panel	201-16A
F	Air conditioning	201-8A
G	Engine	201-2A

Goodheart-Willcox Publisher

Figure 21-49. This illustration shows main harness routing. It shows the locations of main connectors for making electrical tests. This might be helpful when you are trying to find shorts in harness wires.

Connector Diagram

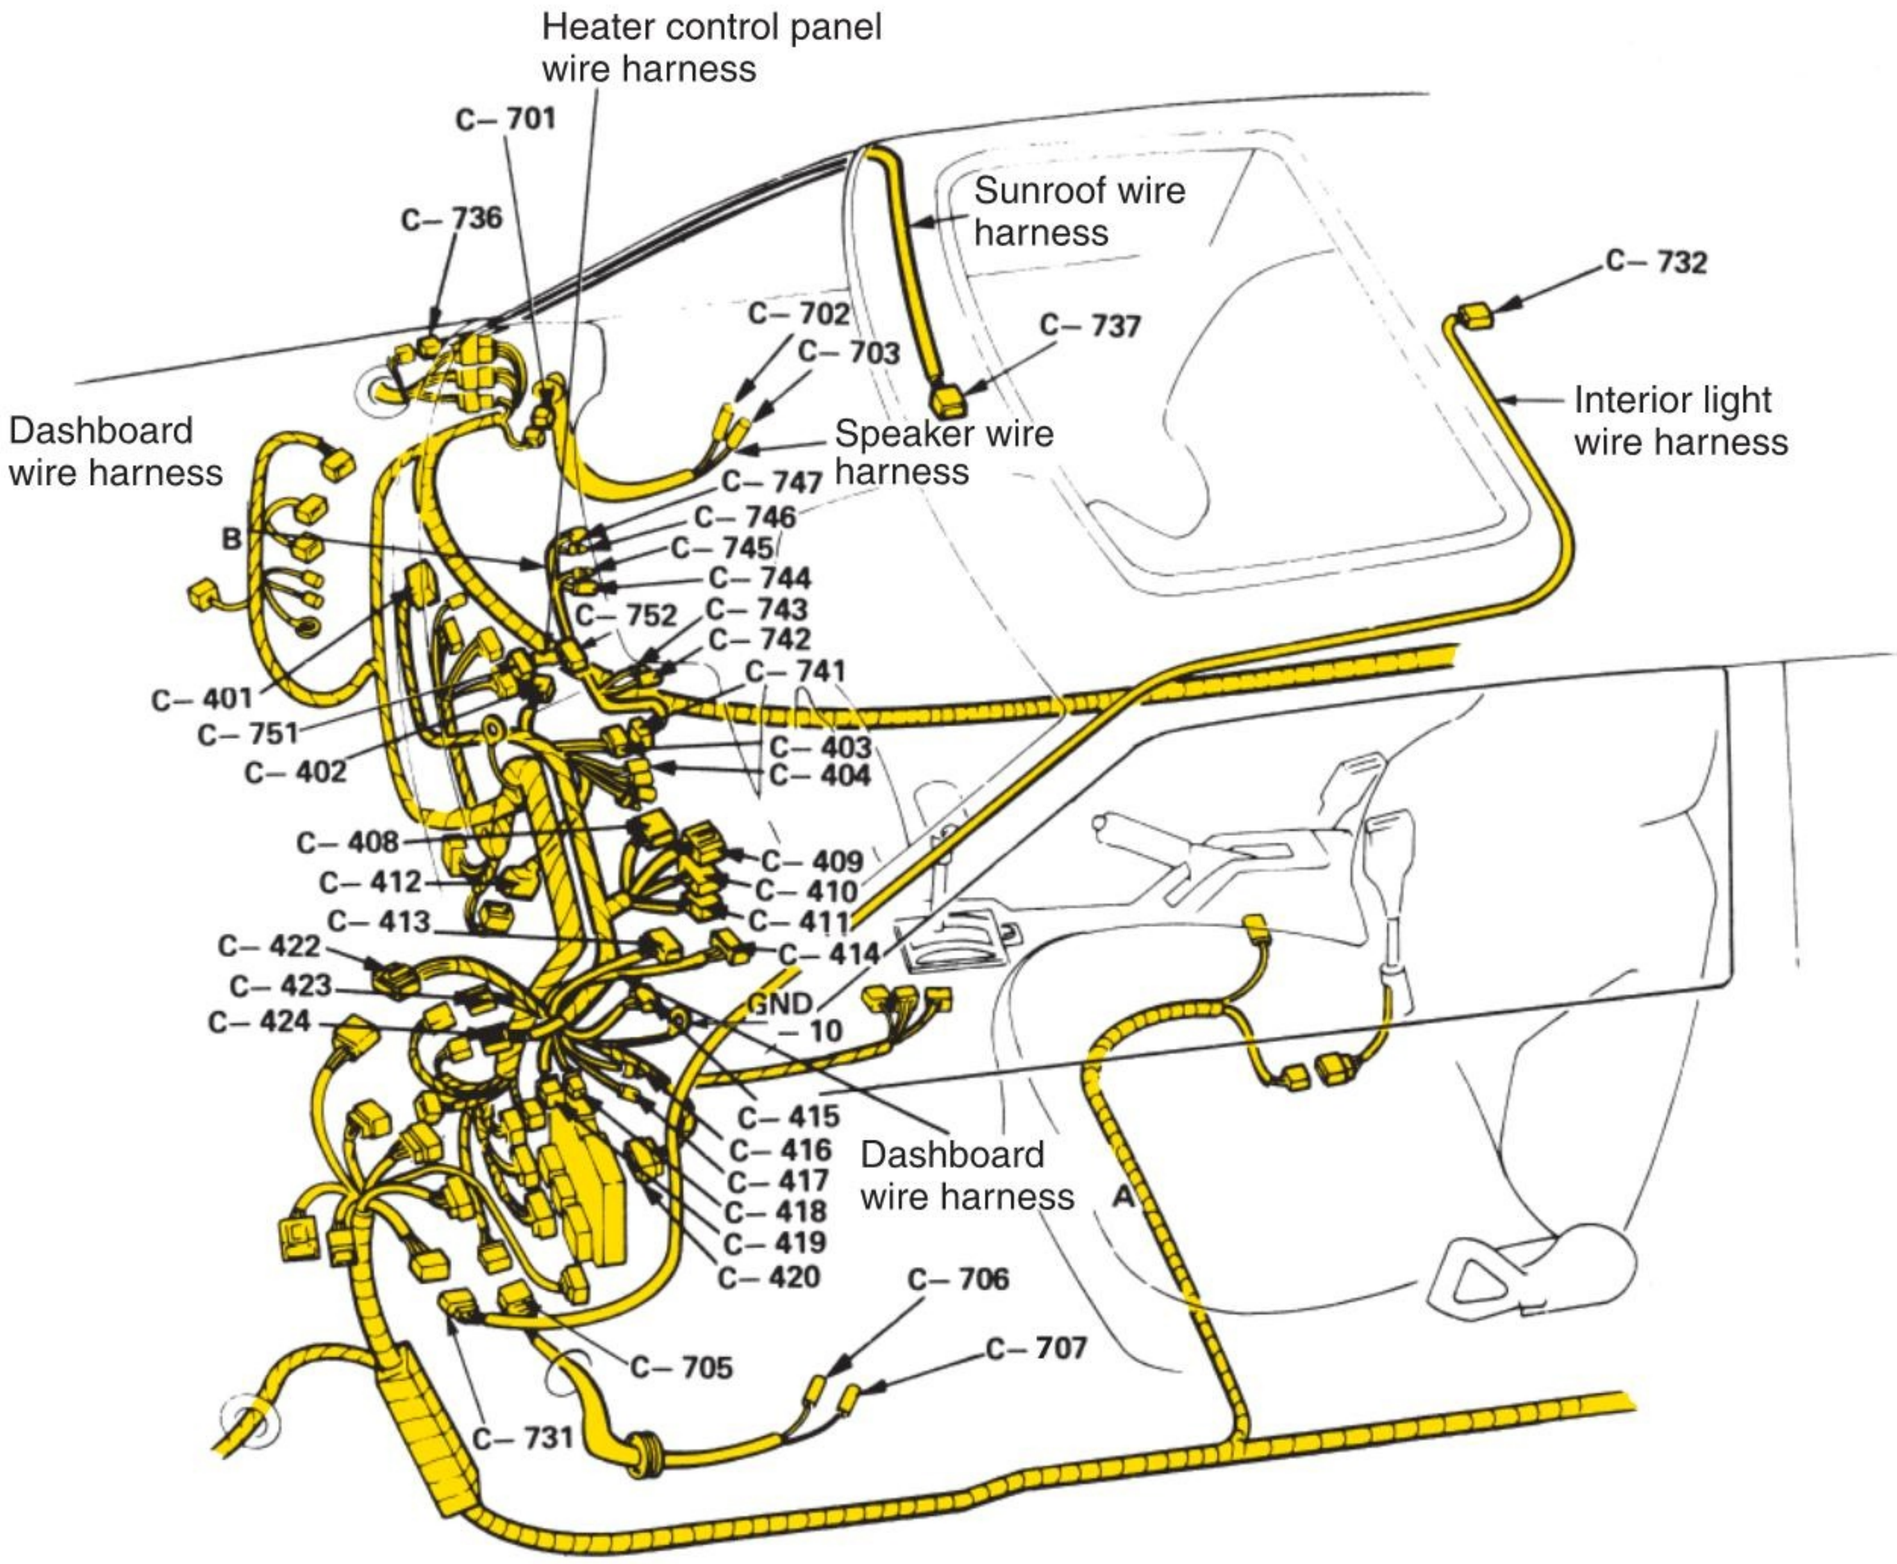
Connector diagrams show the location of connectors and identify each terminal in a connector. These diagrams are very important when you are trying to diagnose electrical problems. Connector diagrams show which connector terminals should be tested when troubleshooting. Connectors are indicated by a capital "C." **Figure 21-50** shows the location of connector C401. The chart tells you the number of pins or terminals in the C401 connector and its destination (to the clock). An example of another type of connector diagram is shown in **Figure 21-51**.

Power Distribution Diagram

A ***power distribution diagram*** shows how 12-volt battery current feeds to the main components or sections of the vehicle's electrical system. You might use this type of diagram if major systems are dead. An example of a power distribution diagram is shown in **Figure 21-52**.

Copyright Goodheart-Willcox Co., Inc.

In this diagram, note how the 12-volt battery cable is connected to the starter solenoid. Fuse links protect the circuitry before the fuse panel. Large wires feed off the solenoid terminal to the light switch, fuse panel, alternator, and other components. If fuse link B were to blow, power would not be fed to the light switch and fuse panel. However, power would still go to the alternator and to wire "5red."



Connector, Terminal Number	Number of Pins	Location	Destination	Remarks
C401	6	Center dashboard	To clock	
C402	9	Behind right gauge panel	To hazard/rear defroster switch	
C403	3	Center dashboard	To dashboard wire harness B(C741)

Location Grid

As discussed earlier, the locations of components in electric and electronic circuits may be given in illustrations, charts, or wiring diagrams. If you are not sure where to find a potentially faulty relay, for example, you can refer to the service information.

A ***location grid*** is used to locate components or connections quickly on a large wiring diagram. It is an alphanumeric system marked off around the outside of a wiring diagram. Some sources have location charts that list components as alphanumeric (letter-number) codes, as illustrated in **Figure 21-53**. To use the grid, find the intersection of the number and letter given. For example, the service information might refer to 3C as the location of a coil pack. Align the intersection of 3 on one grid line with the C on the other grid line. This produces a small area on the large wiring diagram to help you find the coil pack.

What components are located in the area 3C in the wiring diagram in **Figure 21-54**?

Main Wiring Diagram

A ***main wiring diagram*** is a large diagram that contains symbols for all major wiring and electric/electronic components on a vehicle. The main wiring diagram may vary, depending on the manufacturer. Different symbols may be used, and the diagram may or may not have a location grid. The method of indicating color codes and wire sizes may also vary. Always refer to the service information, **Figure 21-55**.

System Wiring Diagram

A ***system wiring diagram*** contains only the components and wires for a particular circuit. It contains a section of the main wiring diagram. For example, the service information might include an ignition system wiring diagram, fuel injection system wiring diagram, and computer control system wiring diagram.

A system wiring diagram is useful when you have narrowed down a possible problem to a specific circuit. You can then analyze the circuit to locate the problem. Refer to **Figure 21-56**.

Block Diagram

A ***block diagram*** uses boxes and symbols to illustrate components. It uses lines to represent wires and hoses. A block diagram simplifies a system or circuit so you can easily understand how an area of the system operates and how major components interact. By studying a block diagram, you can make a mental image of how the circuit functions. Then you can think about the symptoms to help arrive at a possible solution for any circuit trouble. See **Figure 21-57**.

Workplace Skills

A comeback is a vehicle that is returned to the shop by a dissatisfied customer. To satisfy the unhappy customer, the shop may need to repair the vehicle again, free of charge. An excessive number of comebacks will damage a shop's reputation and reduce its profits. A shop may take disciplinary action against technicians who create comebacks through careless work. Therefore, it is important to perform all repairs carefully.

Summary

- Most automotive circuits use stranded wire because it withstands vibration and movement better than solid wire.
- Wire size is commonly given as a gage number. A smaller gage number represents a larger diameter conductor, and vice versa.
- Wire resistance depends on the diameter of the conductor, wire length, the type of conductor, and temperature.
- Wire color codes allow you to trace wire from one location to the next, even when some of the wire is hidden from view.
- A wiring harness is a set of several wires enclosed in tape or a plastic protection device. Connectors branch out from the harness and link to electric components or other harness connectors.
- Use wire stripping pliers to remove insulation from wires. Avoid using cutters to strip wires.
- Soldering is the best way to join one wire to another or to join a wire to a terminal.
- Electrical tape is commonly used to cover a metal joint after soldering. Liquid electrical tape is useful when the joint must be protected from moisture. Heat shrink tubing also covers and protects a soldered joint.
- Crimp connectors provide a quick and easy method of joining wires or terminals to wires. Crimping pliers are used to form the metal part of the connector around the wire conductor. When possible, you should solder crimp connectors to ensure a permanent electrical connection.
- Factory connectors usually have a locking feature that keeps the connectors from pulling apart with vibration. Use the correct procedure to release a connector without damage.
- When replacing a fuse link, use the correct replacement wire gage size. Always solder the new link in place to prevent unwanted resistance.
- Wiring diagrams show how wires connect to electric/electronic components.
- Wire splices are usually shown with a dot where the two wires connect.
- A remote ground has an extra wire running to ground. A chassis ground uses the metal part of the component to serve as the ground.
- An alternate circuit is a possible circuit variation. An optional circuit is one that is shown on the diagram but may not be in use.
- Connector diagrams show connector locations and detail the terminals inside the connector.
- A power distribution diagram shows how battery current is fed to major components.
- A location grid can help you find the location of components or connections quickly on a large wiring diagram.
- A main wiring diagram shows all electric components and wires. A system diagram only shows part of the main diagram. A block diagram uses blocks and symbols to represent components and is used for visualizing system operation.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

Activities

1. Search for an engine wiring diagram in a service manual or on the Internet. Study the diagram and then write a paragraph explaining what components are illustrated in the diagram.
2. Use the Internet to search for a wiring diagram for an electric door wiring harness. Make a list of the components included in the schematic, and compare the symbols used to those shown in **Figure 21-36**.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Why is most automotive wire stranded?
2. Why is copper wire considered a better choice than aluminum for a wire conductor?
3. What type of wiring has copper foil conductor strips mounted on a plastic or fiber base?
4. Is a 10 gage wire smaller or larger than a 12 gage wire?
5. What is the difference between metric wire sizes and AWG wires sizes?
6. Why are wires color coded?
7. Name four characteristics that affect the resistance in a wire.
8. What is the purpose of a wiring harness?
9. Why is it important to cut all the way through a wire on the first try?
10. Name at least five types of wire protection devices.
11. In your own words, describe the proper way to solder a wire onto a terminal.
12. When is liquid electrical tape a better choice than conventional electrical tape for covering exposed conductors?
13. Explain the procedure for installing a crimp connector.
14. What must you do to disconnect a factory harness connector without damaging the connector?
15. Briefly explain how to bypass a wire.
16. A wiring diagram shows a dot where two lines on the diagram intersect. What does this mean?
17. Explain the two types of grounds.
18. What wiring component allows several wires to make a common connection?
19. How would you use a connector diagram that gives electrical values?
20. What type of wiring diagram would you use to find out why major electric circuits fail to have voltage?

    Use **Figure 21-58** to answer questions 21 through 23.

21. What components are located in grid area 1B?
22. What color wires connect to the ignition system pickup coil?
23. What is the grid location for the choke control relay?

ASE-Type Questions

1. Technician A says stranded wire is normally used to connect an automobile's electronic components. Technician B says solid wire is generally more flexible than stranded wire. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says automotive wiring is usually between 4 and 12 gage. Technician B says automotive wire size must be matched to the circuit load. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says wire resistance increases as conductor diameter decreases. Technician B says wire resistance increases as conductor length increases. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says wire resistance depends on the type of material used for the conductor. Technician B says wire resistance depends on the temperature of the conductor. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. A wire has come loose from an automotive component. Technician A says the tip of the soldering gun should be tinned before the wire is soldered. Technician B says the wire and the component lead should be preheated before melting solder onto the joint. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. All of the following are wire protection devices *except:*
   (A) heat shrink tubing.
   (B) flux.
   (C) liquid electrical tape.
   (D) wiring harness.
7. A crimp connector must be replaced. Technician A twists the wire strands before inserting the wire into the connector. Technician B fastens the new connector to the wire by squeezing the connector's plastic cover. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. One of an automobile's fuse links is burned. Technician A says the circuit problem should be identified and corrected before the link is replaced. Technician B says the battery cable should be disconnected before the link is replaced. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. A vehicle's fuel injection control unit is difficult to locate. Technician A checks a wiring diagram in the service information to help locate this component. Technician B checks a component location table in the service information to locate the vehicle's fuel injection control unit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says the term "left side of the vehicle" is sometimes abbreviated in an automotive wiring diagram as LH. Technician B says the term "left side of the vehicle" refers to the passenger side of the vehicle. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. Technician A says wire code identification systems provide information about the appearance, location, and size of wire in a given circuit. Technician B says wire code identification systems vary from manufacturer to manufacturer. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Chapter 22
Basic Electrical Tests

After studying this chapter, you will be able to:

- Use a systematic approach to find and correct electrical problems.
- Explain causes of basic circuit problems given their symptoms.
- Use testing devices to check component operation.
- Use a multimeter to measure circuit voltage, voltage drop, resistance, and amperage.
- Test basic electric and electronic components.

Basic circuit testing procedures are essential to today's automotive technicians. Knowing how to analyze circuit problems and use basic test instruments are fundamental skills. This chapter introduces basic circuit problems, explains their causes, and summarizes the tests needed to find and correct malfunctions.

Basic Circuit Problems

Almost all electrical and electronic problems are caused by something in the circuit that increases or decreases current, resistance, or voltage. For example, a broken wire could stop or decrease current, or a charging system problem could increase output voltage and current.

Unfortunately, when a basic circuit problem occurs in a complex circuit, such as a computer control system, it may not seem so simple. For example, a poor electrical connection in a feed wire to a sensor can cause a false signal to return to the computer. The computer, reacting to this signal, might then alter the operation of the fuel injection system, emission control system, or ignition system. A technician might think that any of these systems or the computer itself is at fault. Several systems may appear to have a problem. In reality, all of the problem symptoms are caused by a poor electrical connection in one wire.

As you can see, it is important to keep an open mind when diagnosing electrical problems. If analyzed properly, problems can usually be found and corrected easily.

Copyright Goodheart-Willcox Co., Inc.

Electrical Diagnosis and Repair

Electrical diagnosis involves using a logical sequence of steps to find the source of an electrical problem. Before you begin troubleshooting, verify the symptoms and problem to be sure that the customer has described the trouble accurately. Frequently, the vehicle owner or service writer may not completely describe what is wrong with the vehicle. Verifying the problem may give you added information when determining what to do next. See **Figure 22-1**.

Systematic Approach

The systematic approach to troubleshooting involves using the theory of system operation and logical thought processes to find the source of the problem quickly. A well-planned procedure must be followed to find the source of a malfunction. **Figure 22-2** shows a mnemonic (memory-jogging phrase) that may help you remember the steps in using a systematic approach to troubleshooting.

Tech Tip

With the on-board computers, sensors, actuators, and complex circuits used in late-model vehicles, a systematic approach to problem diagnosis is essential. Never use trial and error when trying to find and correct electrical problems.

Goodheart-Willcox Publisher

Figure 22-1. Verify the problem before you begin the troubleshooting process.

Veronica	***Verify*** the symptoms and problem.
Never	***Narrow*** down the problem sources.
Touches	***Test*** to find the cause.
Much	***Make*** the repair.
Voltage	***Verify*** the repair.

Goodheart-Willcox Publisher

Figure 22-2. Use this mnemonic to remember the steps in the troubleshooting process.

Verify the Symptoms

Check the vehicle carefully to find out which components are not working. Note any unusual noise, blown fuses, trouble codes, or other conditions. Try to determine which parts might be capable of causing these symptoms. Also, think of the parts that cannot be causing the symptoms. Ask yourself the following questions:

- What could be causing the specific symptoms? Picture the parts in the circuit and how they function. Mentally trace through the circuit or use a wiring diagram to find out what wires, connections, and components are in the circuit to find potential trouble sources.
- How many components are affected? If several components are not functioning normally, you know that something close to the power source is probably at fault. If only one or two sections of the circuit are faulty, you know to begin your tests at these sections of the circuit.
- Is the problem always present, or does it only occur some of the time? If the trouble only occurs some of the time, the conditions causing the problem must be simulated. For example, a loose electrical connection might open and close with vibration or movement. By wiggling wires in the circuit, you can simulate the driving conditions and try to make the problem occur.
- Is the problem affected by heat or cold? If the problem only occurs on a hot day or with the engine warmed to full operating temperature, heat may be activating the problem. Many electronic

Copyright Goodheart-Willcox Co., Inc.

circuits are greatly affected by heat. In fact, too much heat can ruin an electronic component. This might tell you which component is at fault.

- Is the problem affected by moisture? If you discover that the trouble only occurs on a wet day, you again have more information to use when analyzing the source of a problem. Moisture cannot enter a sealed electronic circuit, but it can enter and affect wire connections and components exposed to the environment. This type of thinking might help you in the troubleshooting process.

Narrow down the Cause

After verifying the symptoms, narrow down the cause to one system or circuit, if possible. Use the symptoms to visualize what is happening inside the circuit. Use your knowledge of the specific system and basic rules of electricity to determine what might be wrong.

If you are not familiar with the circuit, use a diagram to trace the circuit with the malfunction. For example, if the right headlight is not working, but the left one is, you could narrow down the problem to the circuit feeding current to the right headlight. You have, through logical thought, narrowed down the source of the electrical problem to one section of the circuit. If both headlights fail to function, then anything in the complete headlight circuit could be the cause. Further tests, probably at the power source to the circuit, would be needed to narrow down the cause.

Perform the Proper Tests

The next step is to perform the tests needed to check the specific section of the electrical system. If one headlight does not work, you might check the bulb first. If the bulb is good, you might test for power to the bulb socket. Again, you must think of how the circuit operates to select the next most logical test.

Use proper testing methods to verify your assumption about what might be wrong in the circuit. If tests prove that your first assumption is not causing the trouble, proceed to the second most logical place to test. When you are testing circuits, remember the following:

- If only one component does not work, start your tests at that component. Chances are the problem is in the inoperative component or in the section of the circuit leading to the component.
- If more than one component does not work, start your tests at the power source for the circuit. A blown fuse or loose power feed wire could be preventing current in the whole circuit.

If you have difficulty finding a problem, refer to the troubleshooting charts and circuit diagrams found in the service information. These diagrams are specific to the vehicle's make and model and will give you ideas for finding the source of the problem. Always think about the symptoms and problems while working. Visualize current through the circuit, as well as each connection and each component. A new testing method or another potential problem source may occur to you at any time.

Make and Verify the Repair

Following the steps described in this section should help you determine exactly what the problem is. After you have found the source of the problem, make the repair. This might involve replacing a bad component, soldering a broken wire, or repairing a faulty connector.

Finally, verify the repair by making sure the circuit is operating normally. If needed, test-drive the vehicle to make sure road shock and vibration do not affect the repair. Then you can be confident that the problem will not recur after the owner drives away.

Types of Circuit Problems

The four basic types of circuit problems are open circuit, high resistance, intermittent trouble, and short circuit. This section of the chapter defines these problems, lists their causes, and explains how each can cause different symptoms depending on the circuit configuration.

Open Circuit

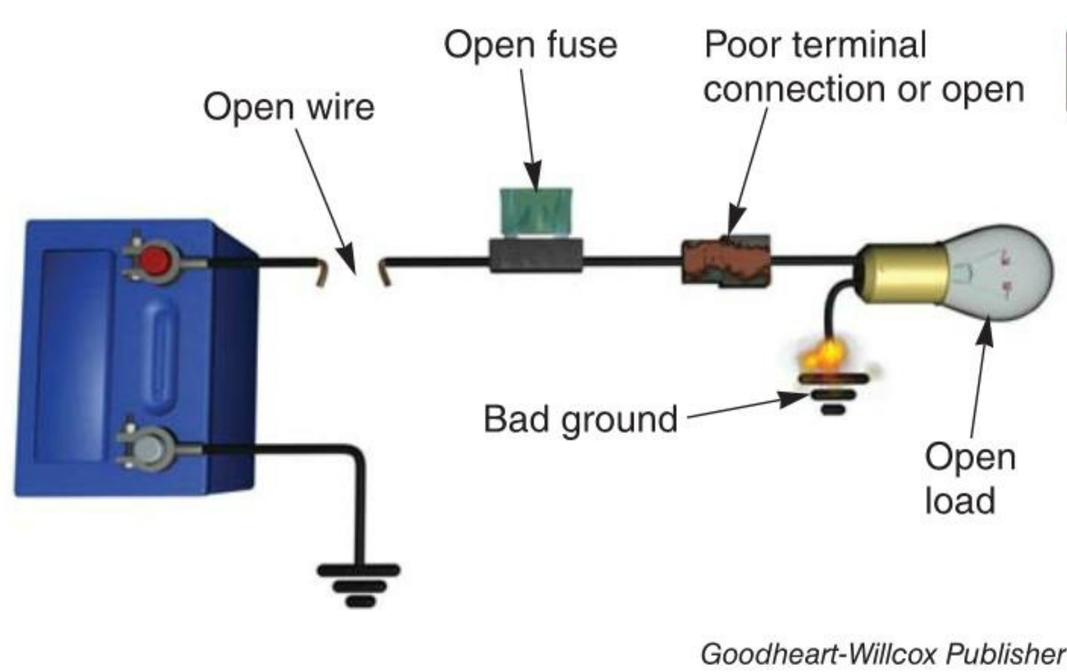
An ***open circuit*** is a complete break or disconnection in the circuit. An open circuit, or "open," stops current through a section of the circuit. See **Figure 22-3**.

An open circuit can be caused by a:

- Broken wire conductor.
- Blown fuse.
- Burned switch contacts.
- Loose connection.
- Burned or corroded connector terminals.
- Failed electric component.

When current is not reaching a component, find out which of these potential problems is present in the circuit. As shown in **Figure 22-4**, the open can occur before the load, after the load, or in the load. If the

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 22-3. These are some of the sources of opens or breaks in a circuit. In a series circuit, everything after break is "dead."

open occurs in series with a component, the component will not function. However, if the open occurs in a parallel branch, the branches that do not contain the open circuit will still function. Refer to **Figure 22-5**.

High Circuit Resistance

High circuit resistance reduces current, but it does not stop all current like an open circuit. A high resistance might make a bulb glow dimly or a motor turn too slowly. See **Figure 22-6**. High circuit resistance is usually caused by a poor electrical connection. A corroded or burned connector terminal is the most common cause. Faulty components can also have high internal resistance. See **Figure 22-7**.

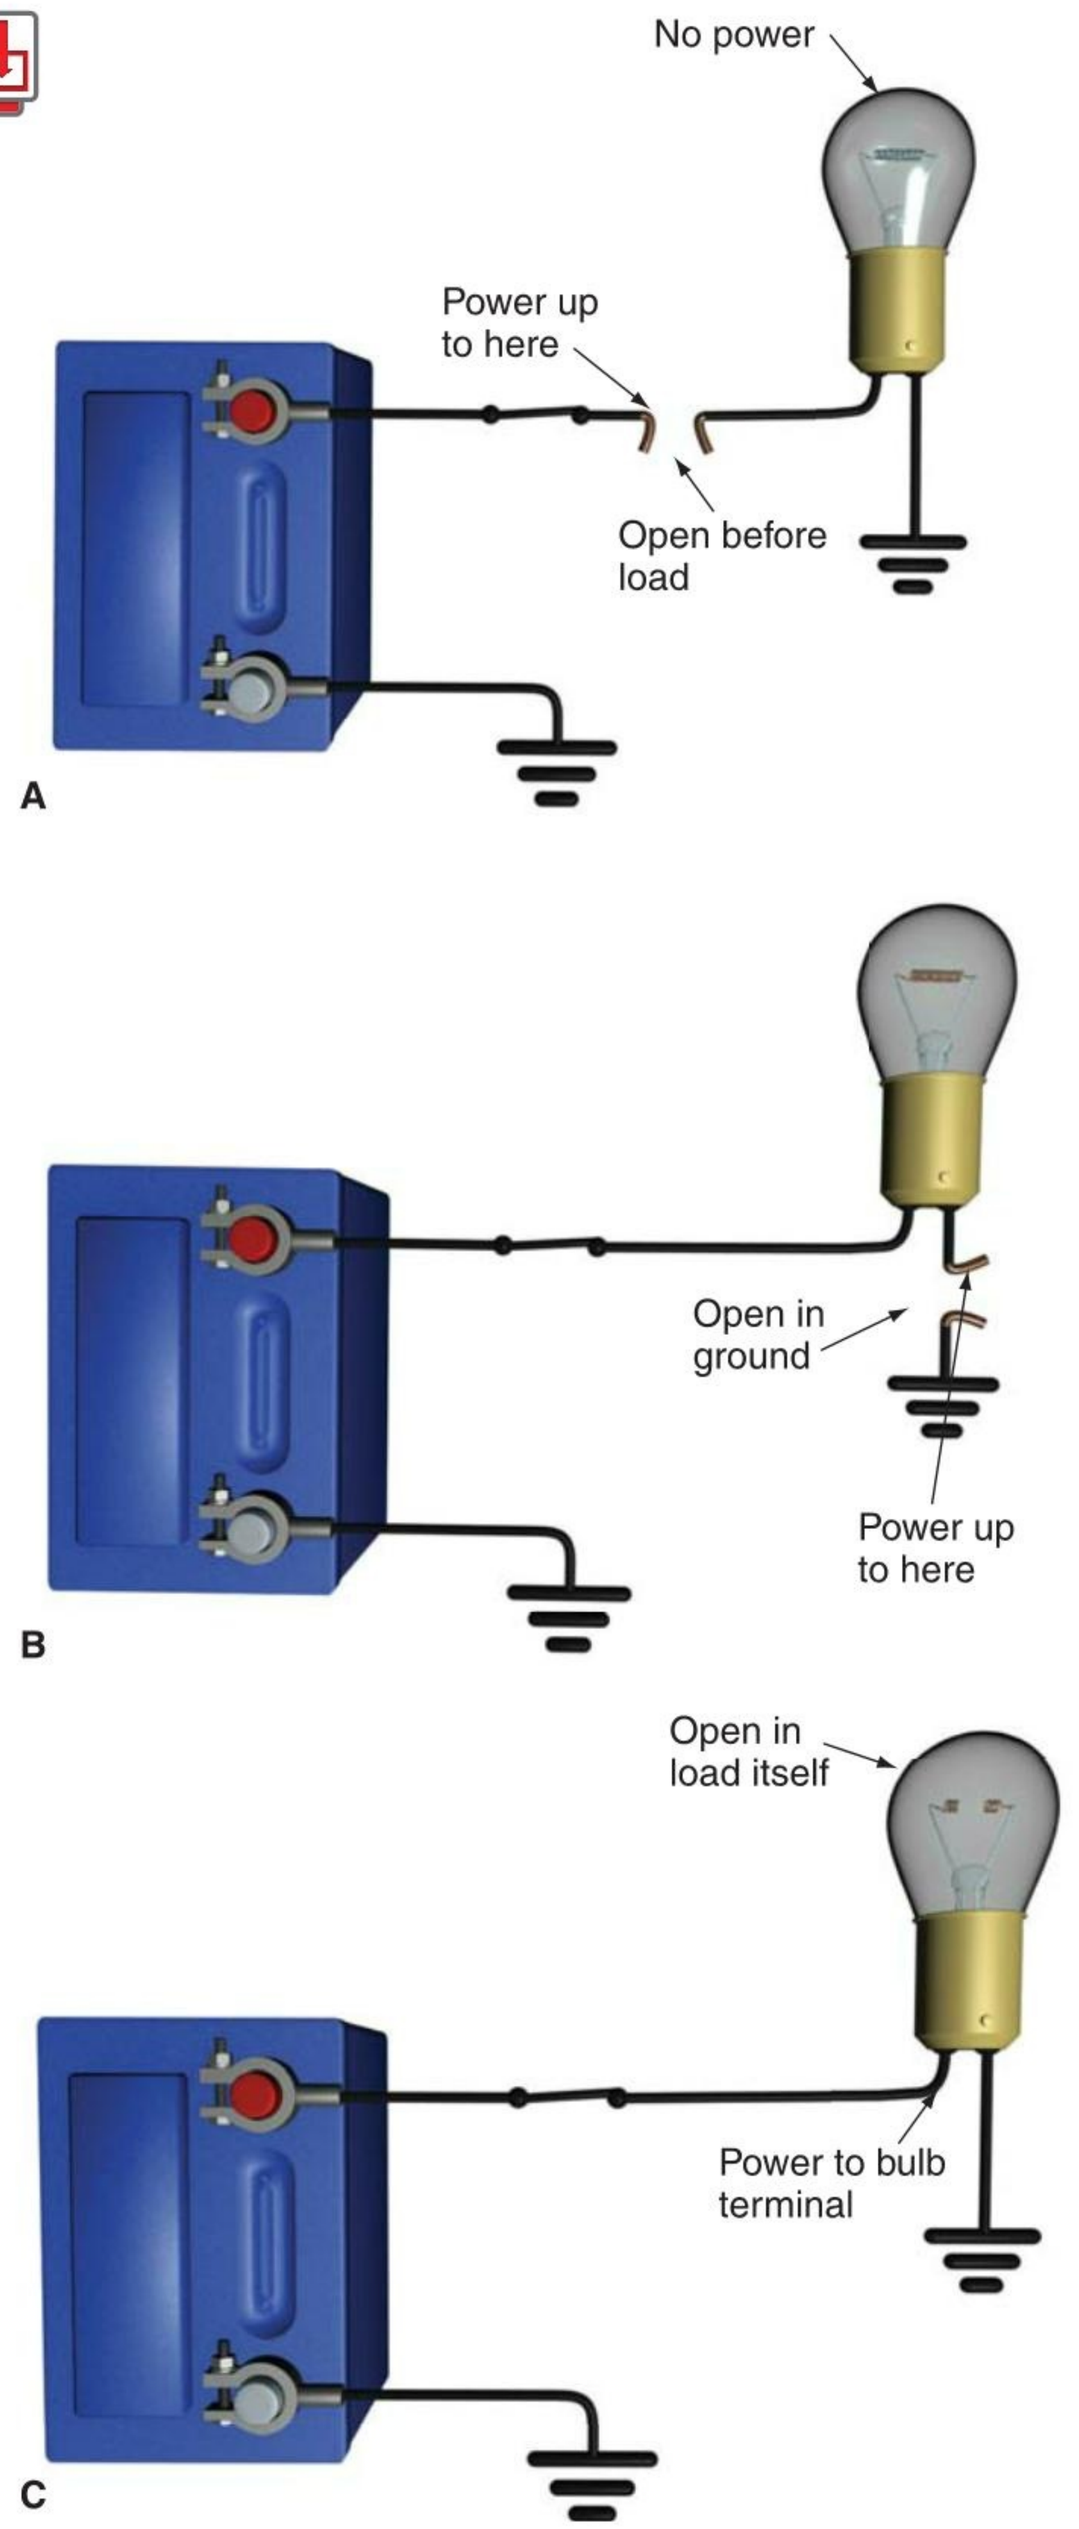
Short Circuit

A ***short circuit*** is caused by a conductor accidentally touching ground or another conductor. Shorts are caused by wire insulation damage. There are several classifications of shorts, and each causes different symptoms.

A ***hot wire short to ground*** produces low circuit resistance and extremely high current. This usually blows the fuse or circuit breaker. The fuse or circuit breaker protects the circuit from excess current damage caused by the hot wire short. See **Figure 22-8A**.

A short in an unprotected section of a circuit can cause an electrical fire when excess current overheats a conductor and melts its insulation. The melted insulation then allows other conductors to come into contact. As a result, several wires can begin to burn. This can happen in a matter of seconds.

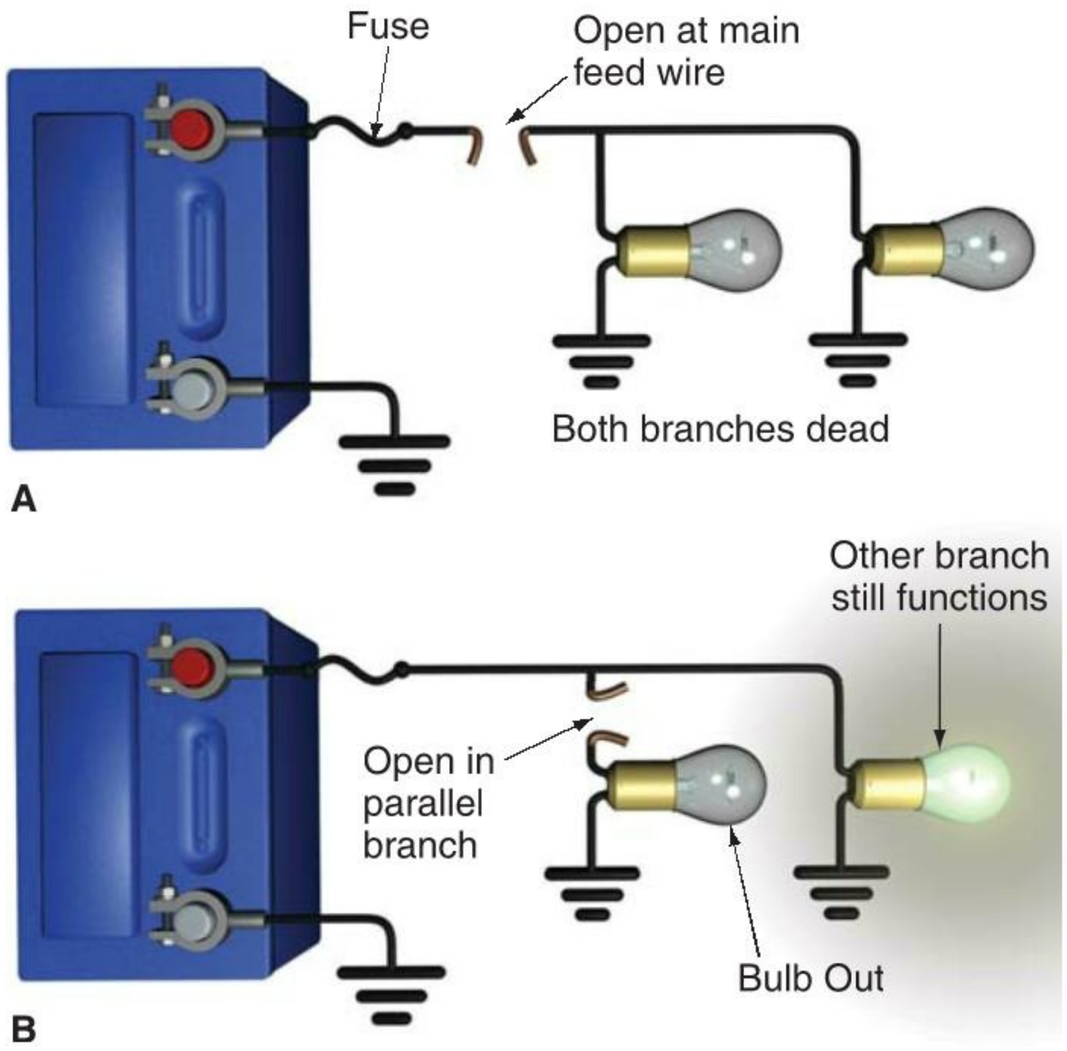
A ***grounded circuit*** is caused by a ground wire shorted to ground. This usually has no noticeable



Goodheart-Willcox Publisher

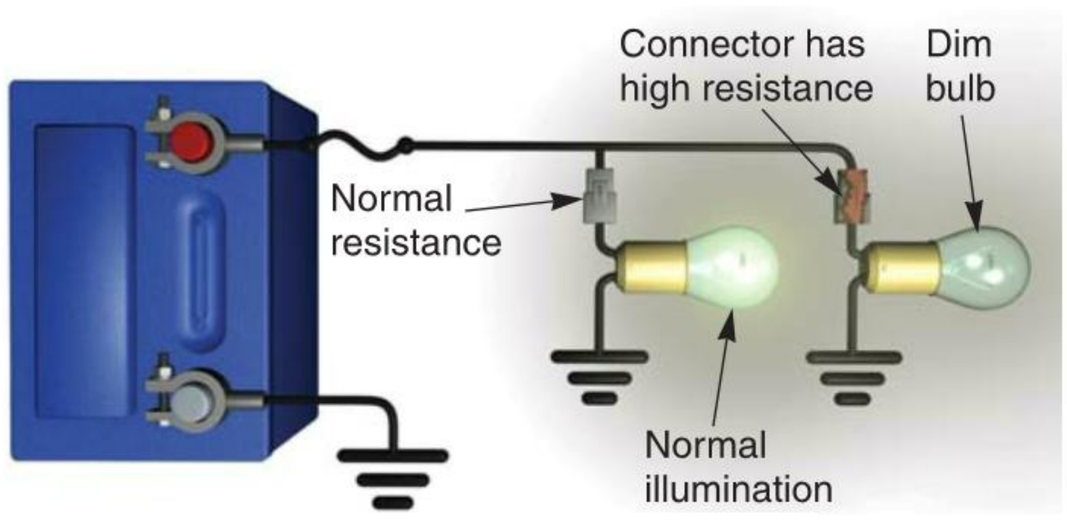
Figure 22-4. See the action of a basic light circuit. A—If the open occurs before the load, voltage cannot travel to the bulb socket. B—If the open occurs after the load, the socket does not have a return ground circuit path. C—An open in the bulb itself is a common example of an open inside the load.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 22-5. Opens in a parallel circuit may cause different symptoms, depending on where in the circuit they occur. A—An open in the main wire feeding the parallel branches disrupts power to both branches. B—If the open is on one of the parallel branches, the other branches still function normally.



Goodheart-Willcox Publisher

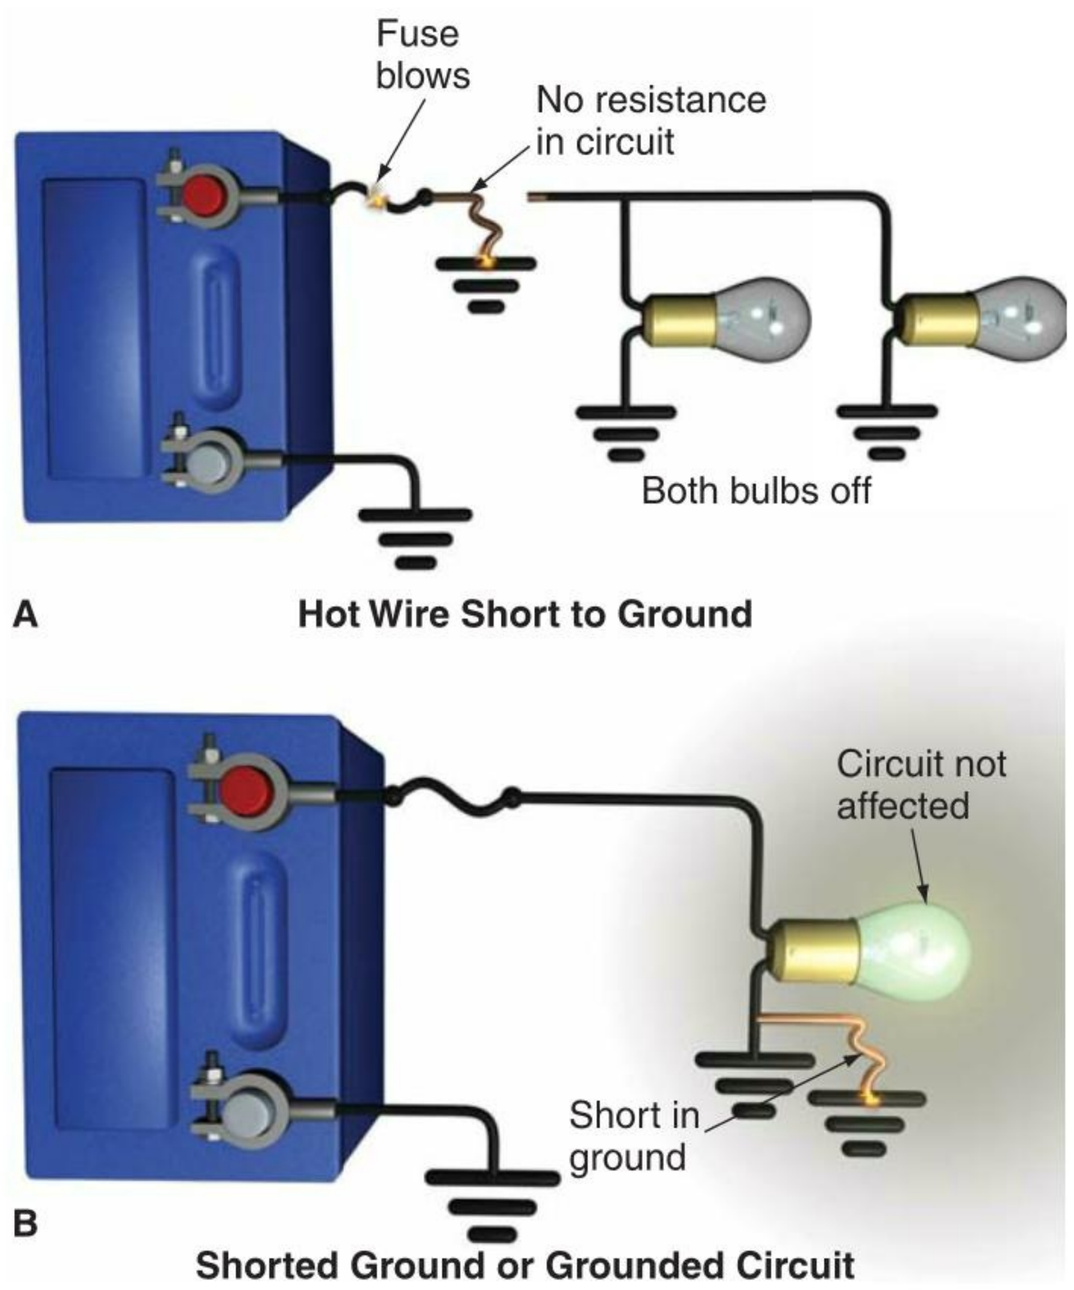
Figure 22-6. A high circuit resistance is similar to an open, but some current can still exist in the circuit. In this example, high resistance in the top connector reduces current through that branch. Therefore, the bulb in that branch burns dimly.

effect. The short just provides another path to ground. See **Figure 22-8B**.

Figure 22-9 shows how a short in different locations in a circuit can cause different symptoms. As shown in **Figure 22-9A**, a short after a load does not blow the fuse. There is still a resistance unit (bulb) between the power source and short to limit current. However, since the short is between two loads, it

Goodheart-Willcox Publisher

Figure 22-7. Some sensors, such as this oxygen sensor, produce an output of less than one volt. Any resistance in the circuit leading to the sensor could produce false signals for the computer and upset engine or other system operation.



Goodheart-Willcox Publisher

Figure 22-8. These are examples of short circuits. A—When a hot wire is shorted to ground, it causes very high current that blows the fuse. Both bulbs fail to function because of the open fuse. B—When a ground wire is shorted to ground, it does not affect the circuit. The short just provides a second path for ground.

Copyright Goodheart-Willcox Co., Inc.

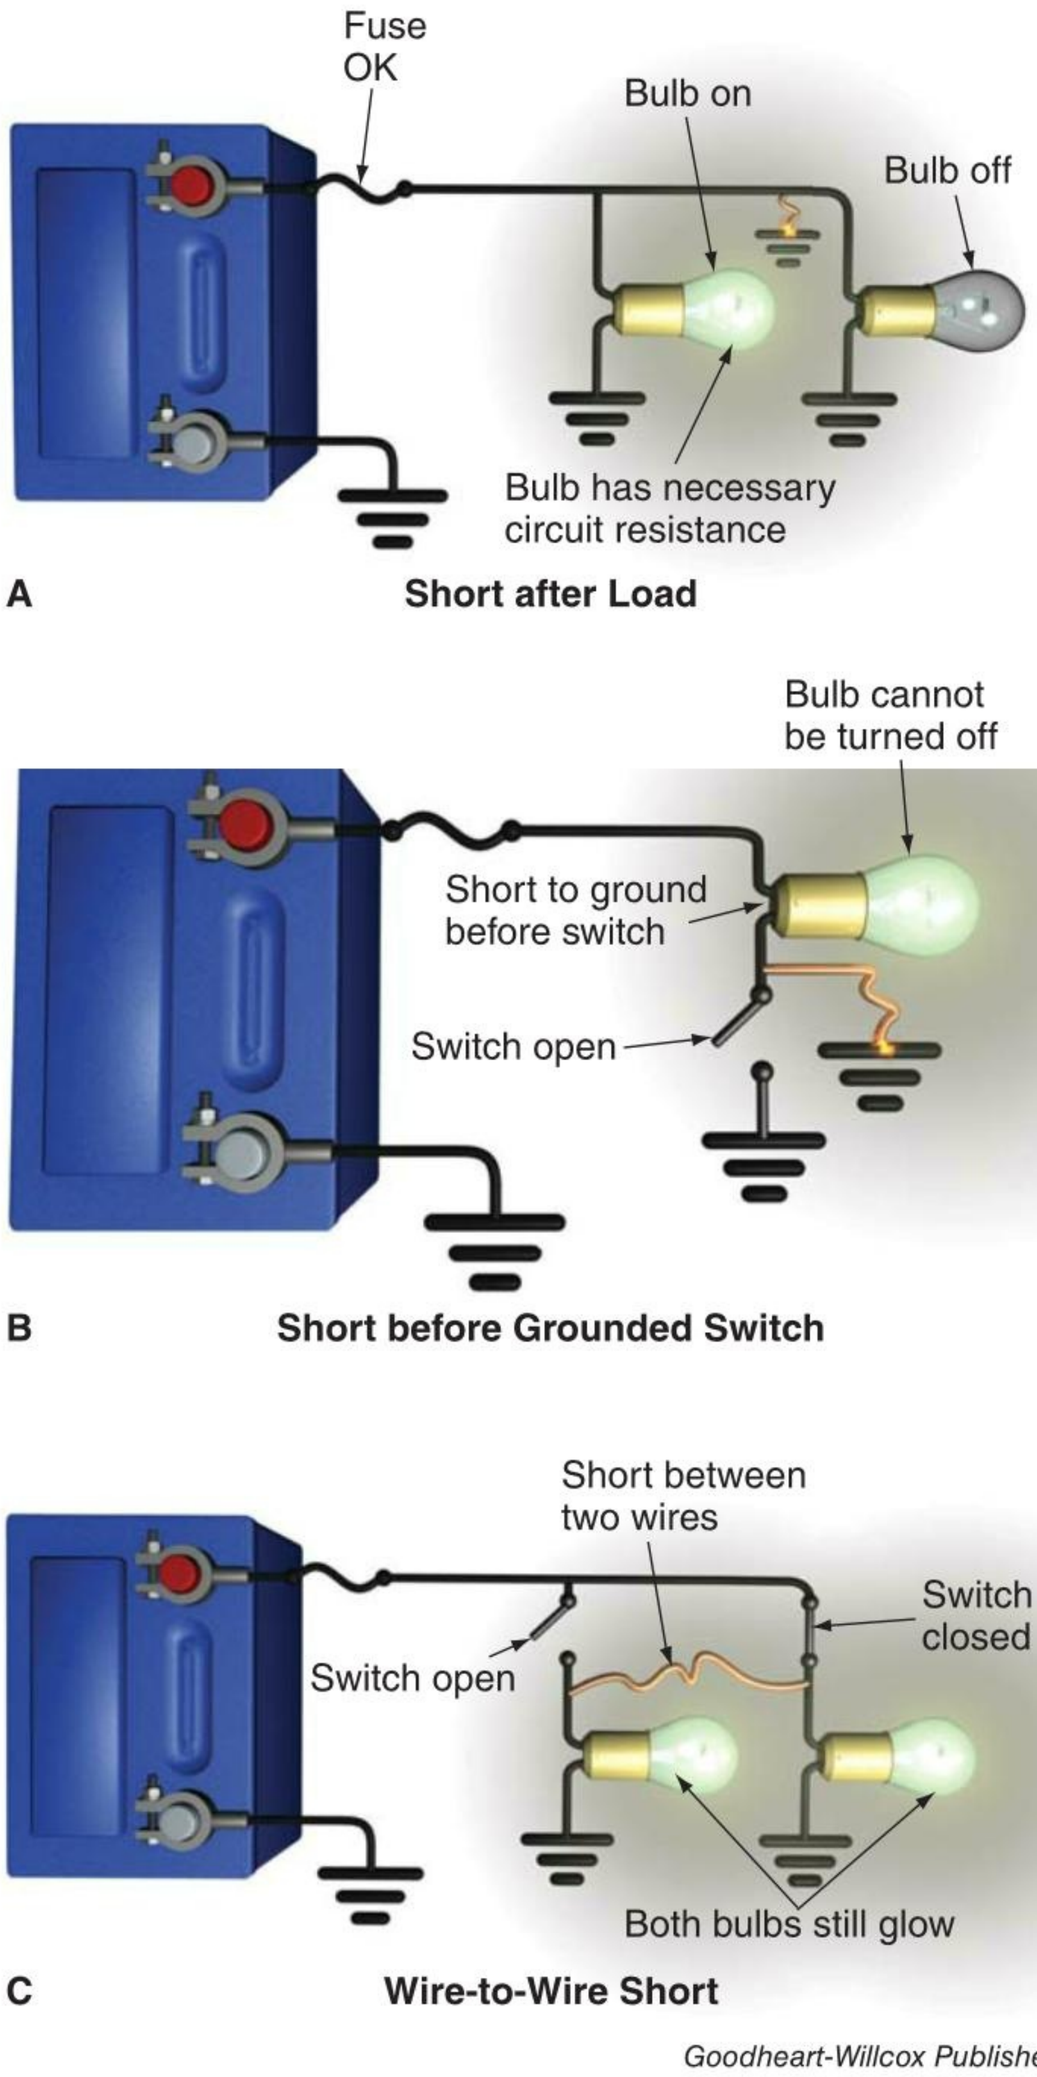


Figure 22-9. The location of the short in a circuit affects the symptoms that appear. A—A short after a load cuts power to the second load. However, the first load still works. Current increases slightly because of less resistance in the circuit. However, current may not increase enough to blow the fuse because of the resistance of the first load. B—Short before a grounded switch. The load stays on all the time, even with the switch open. Current bypasses the switch to ground. C—In this wire-to-wire short, the short feeds current across two branches. Even with one switch off, current leaks over to the other branch. Only when both switches are off will the bulbs turn off.

shunts current away from the second load. The second load (bulb) will not function. The current seeks the path of least resistance through the short to ground.

Figure 22-9B shows how a short before a switch can prevent a circuit from being shut off. A short before the grounded switch allows current in the circuit, even with the switch off.

Figure 22-9C shows an example of a wire-to-wire short. The conductors in two wires are touching because of damaged insulation. In this case, the short could make both loads (bulbs) function even when the switch to one of the loads is turned off.

Intermittent Problems

An ***intermittent problem*** is one that occurs only under certain conditions. The problem may be present one time but may not show up later. This makes testing difficult because the symptoms may not occur when you are troubleshooting.

Many intermittent problems are caused by poor electrical connections. For example, two terminals in a connector may be loose. Most of the time, the two terminals make contact and the circuit functions normally. However, when the vehicle hits a bump, the jolt may separate the loose terminals, causing the circuit to malfunction temporarily. An intermittent failure can result.

Using Testing Devices

This section of the chapter summarizes the use of electrical testing devices, including jumper wires, test lights, and multimeters. To be an effective technician, you must know how to use this equipment.

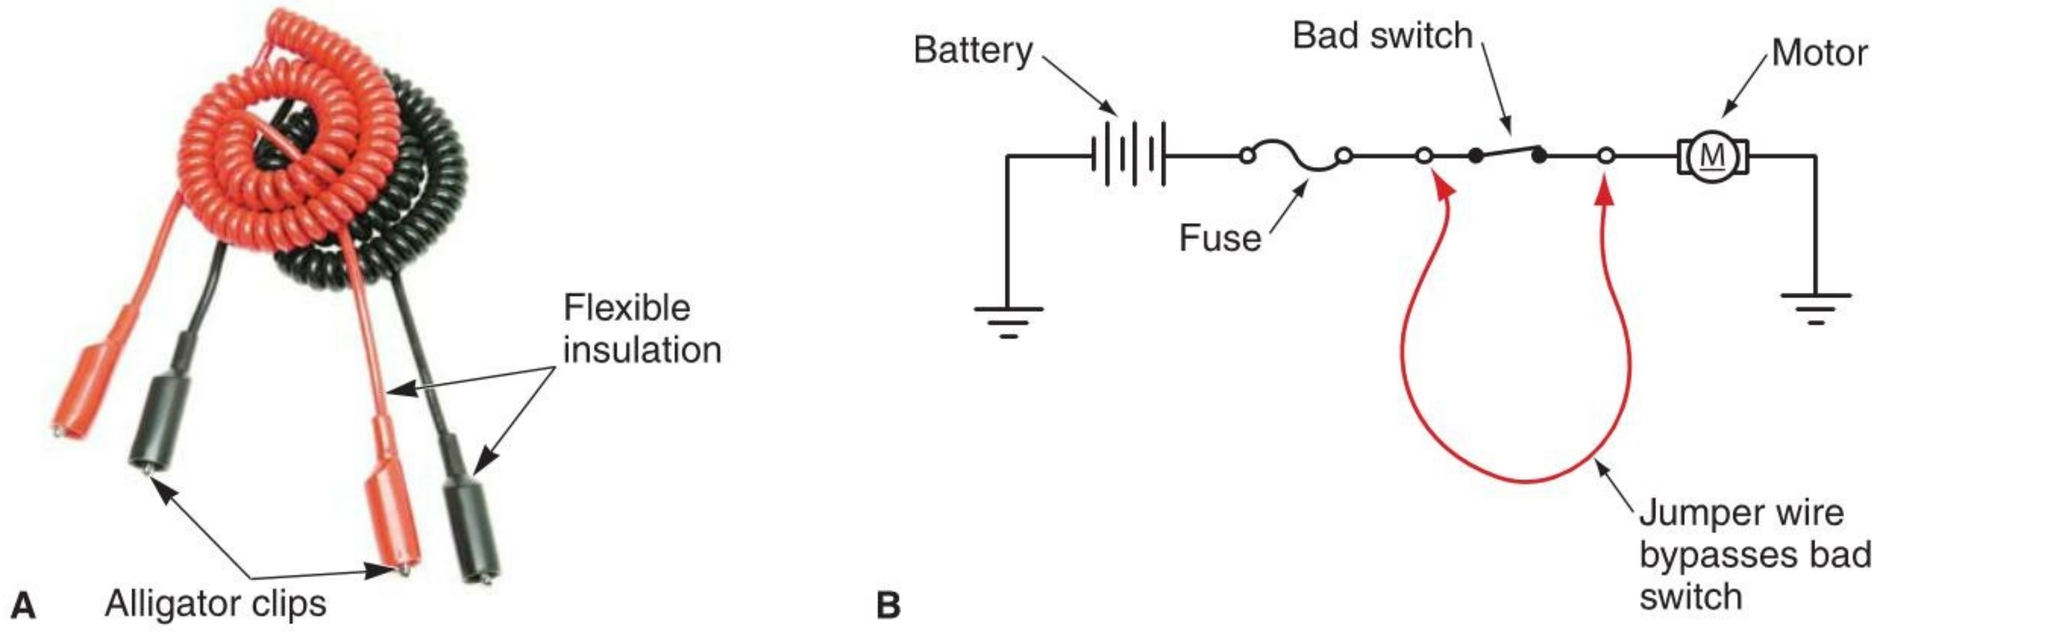
Tech Tip

When you are looking for shorts or opens, wiggle or move the wires while you are testing. This might move the conductor enough to produce the problem. It might also correct a problem temporarily so you can detect the trouble. Always look for wire damage. Check for cut or smashed wire insulation and loose connections. Any of these can cause a malfunction.

Using Jumper Wires

A ***jumper wire*** is a piece of wire with alligator clips on both ends, as shown in **Figure 22-10A**. It is commonly used to bypass components or to apply voltage

Copyright Goodheart-Willcox Co., Inc.



Snap-on Tool Corp.

Figure 22-10. Jumper wires allow you to bypass a section of the circuit for testing. Be careful not to connect the battery voltage to any ground. A—Jumper wires can be used to bypass a component or connect power to a circuit for testing. B—A jumper wire provides an easy way to bypass a component or connect power directly to a component or section of circuit. In this example, if bypassing the switch makes the motor run, the switch is bad.

to a component or section of a circuit. **Figure 22-10B** shows a good example of how a jumper wire can be used to check a switch. You might use the jumper wires to bypass the switch if symptoms point to an open switch; for example, if turning the switch on does not feed current to the load (motor). If attaching the jumper around the switch turns the motor on, the switch is bad.

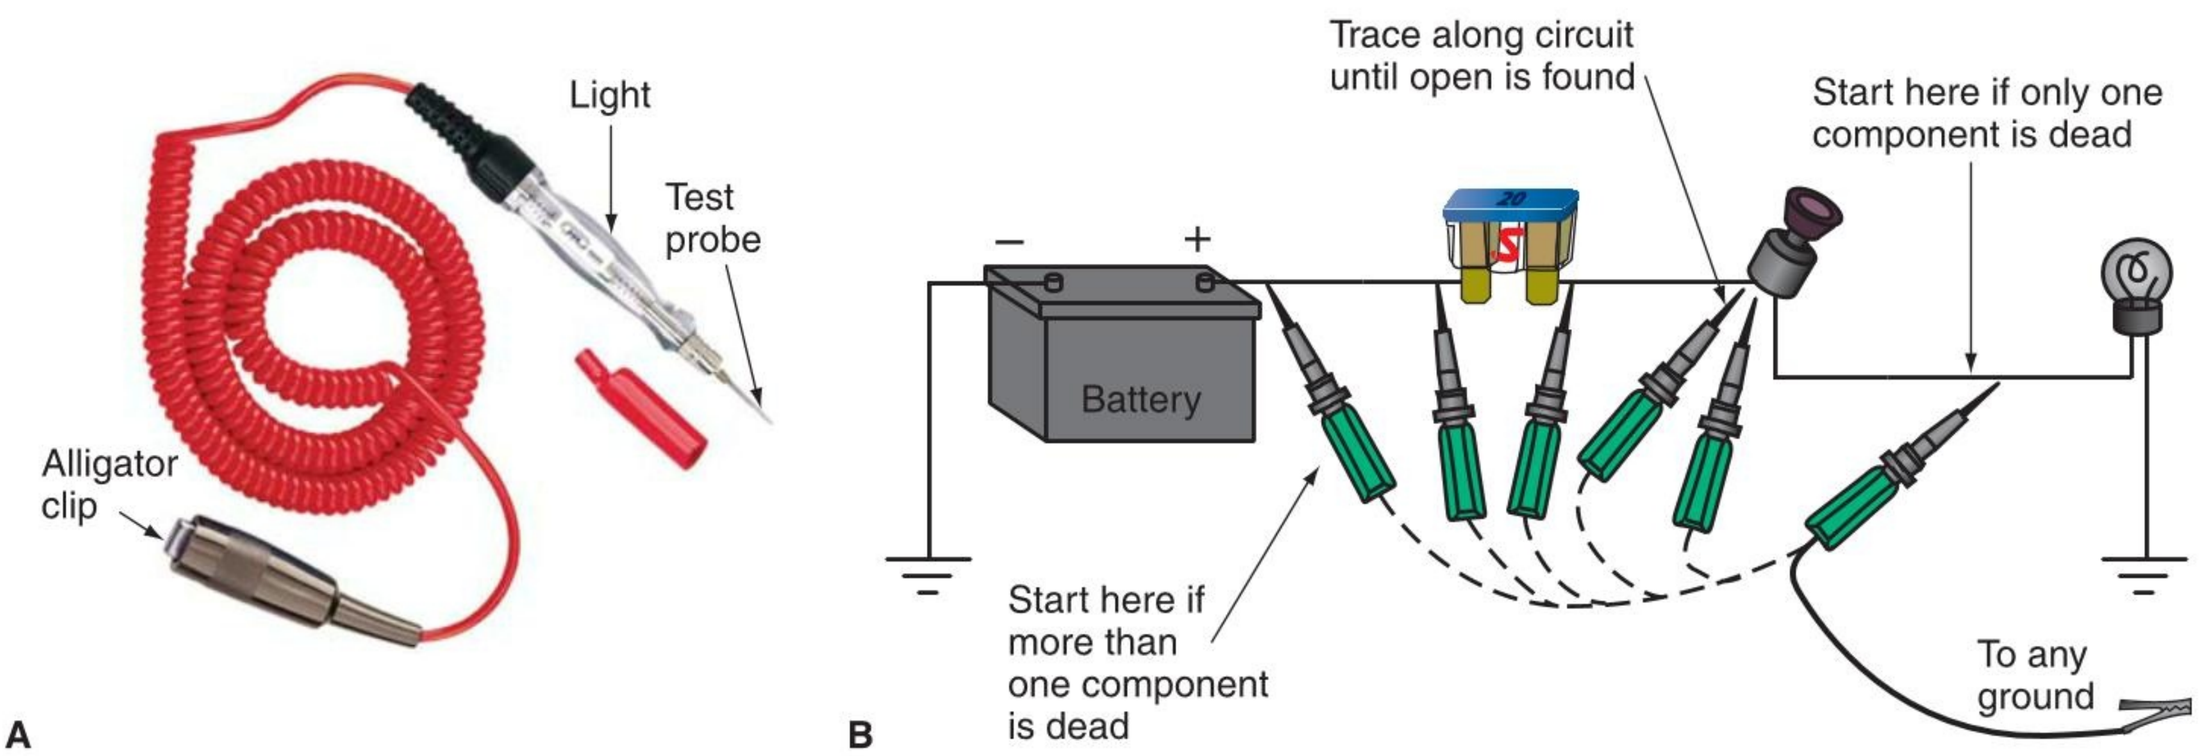
Warning

Never use a jumper wire to bypass a high-resistance component, a fuse, or a circuit breaker. This could allow excess current and cause an electrical fire.

A jumper can also be used to connect voltage directly to the load. If the load begins to work, something is wrong in the circuit leading to the load. If jumping directly to the load does not make it work, the load itself or the ground may be at fault.

Using a Test Light

A ***test light*** provides a quick and easy way of checking a circuit for power or continuity. See **Figure 22-11A**. Most test lights have a sharp probe for touching conductors and an alligator clip for grounding. As previously discussed, test lights can be either circuit-powered or self-powered. Circuit-powered test lights are more commonly used in auto repair.



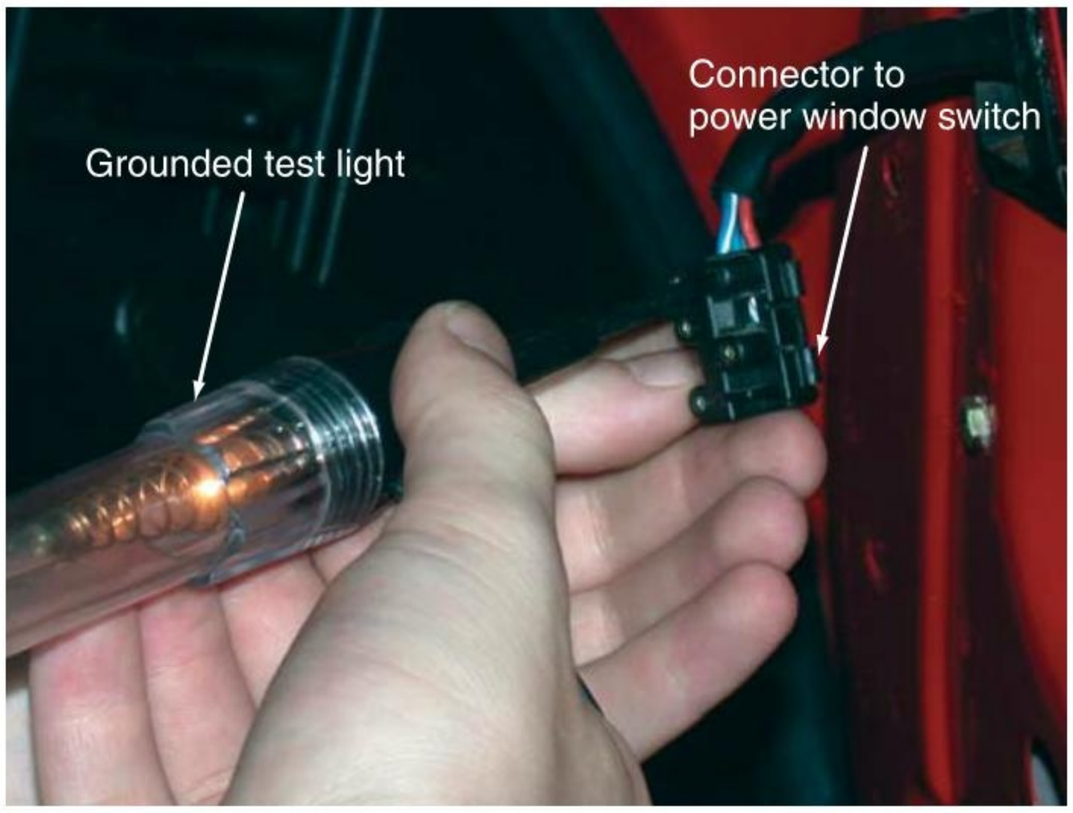
Snap-on Tool Corp.

Figure 22-11. A test light is a quick way to check for battery voltage in a wire or component. A—A test light provides a way to check for power or voltage in a circuit. B—With the circuit-powered type, the alligator clip is grounded. Then the test probe is touched to the circuit at different locations to find breaks in the circuit.

Copyright Goodheart-Willcox Co., Inc.

A circuit-powered test light uses the circuit voltage to illuminate the tester bulb. **Figure 22-11B** shows how to use a circuit-powered test light to check for power. The alligator clip is connected to any good ground. Then the test probe is touched on different points in the circuit. If the test light glows, the circuit is good up to that point. See **Figure 22-12A**. As soon as the test light fails to glow, you have found the problem area.

Sharp test light probes can be used to puncture wire insulation to check for power in the conductor. See **Figure 22-12B**. This is useful when you cannot access a connector for your tests. The test light can also be inserted into the back of a connector so that the probe touches one of the metal terminals in the connector. The connector can also be unplugged to check for voltage.



A

B

Goodheart-Willcox Publisher

Figure 22-12. If the test light glows dimly, you have a high resistance or poor electrical connection in the circuit. A—A test light is being used to check for power to the power window switch. B—The test light has a sharp, pointed tip. It can be touched on a terminal or pushed through wire insulation to touch the conductor.

Tech Tip

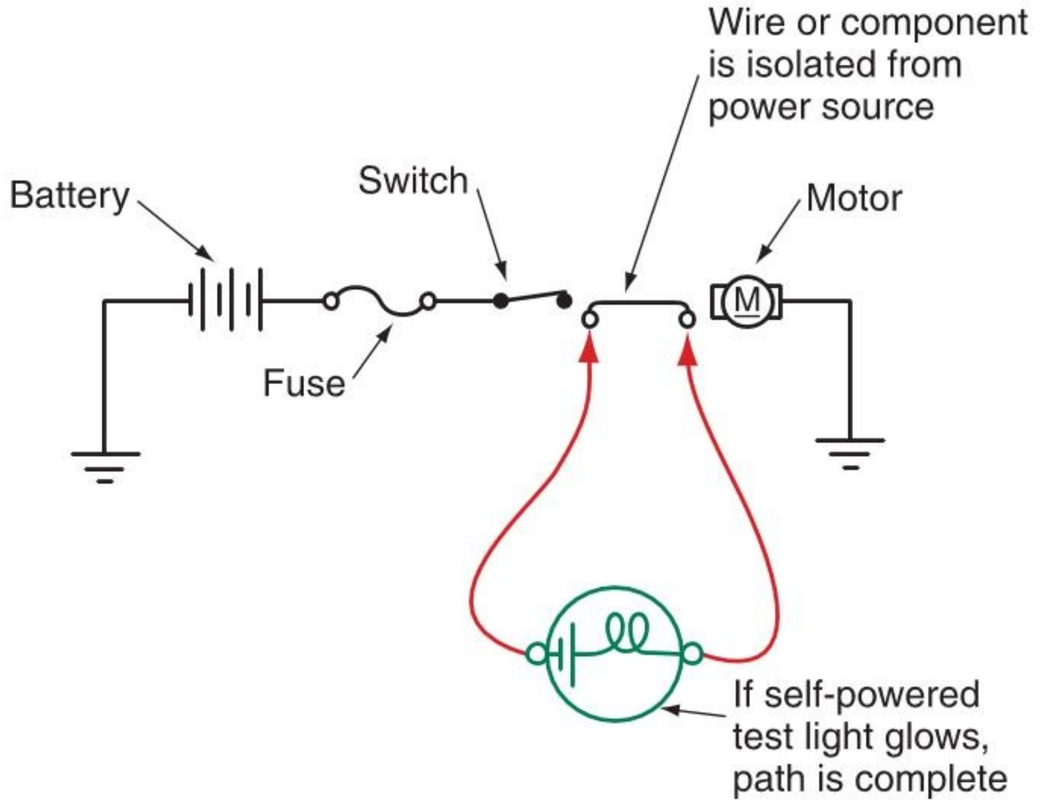
Avoid using a test light probe to puncture the insulation on wires in a computer or sensor circuit. Moisture can enter through the hole in the insulation. If the wire is to a sensor with a weak or low voltage signal, this can upset the small signal going to the computer, and a computer system malfunction may result.

A self-powered test light, or continuity tester, has an internal battery. It uses its own power source to check for a complete electrical path, so the circuit's power source must be disconnected for testing. **Figure 22-13** shows how a self-powered test light can be used to check for continuity.

Figure 22-14 shows how a test light can be used to help find shorts. The test light is substituted for the fuse in the affected circuit. As long as the circuit is complete, the test light glows. Wiggle the wires or disconnect components or wires until the test light goes out. When the test light does not glow, you have found the source of the short.

Warning

Test light probes are very sharp. It is easy to jab the probe through your skin when trying to penetrate the wire insulation. Do not place your fingers behind the probe when testing.



Goodheart-Willcox Publisher

Figure 22-14. Using a test light to help find a short circuit. Remember to disconnect the circuit before testing if you are using a self-powered test light.

Using an Inductive Wire Tracer

An inductive wire tracer uses a signal generator and an inductive pickup to find shorts. See **Figure 22-15A**. The signal generator is connected to the vehicle battery as shown in **Figure 22-15B** or to the battery and to the affected circuit. This produces a weak, fluctuating voltage in the wiring. The pickup, or detector, can then be moved along the outside of the wiring as shown in **Figure 22-15C**. It senses the fluctuating magnetic field around the outside of the wire. If you move the sensor over a short in the wire, the audible tone changes or the tracer makes a beeping sound, depending on the particular tracer.

Using a Multimeter

A multimeter is a voltmeter, ammeter, and ohmmeter combined in one housing. Also called a VOM (volt-ohm-milliammeter), it is an essential tool for automotive technicians. It can make accurate measurements of circuit values, which you can compare to known good values. If the measured values are high or low, you know a problem exists in the circuit.

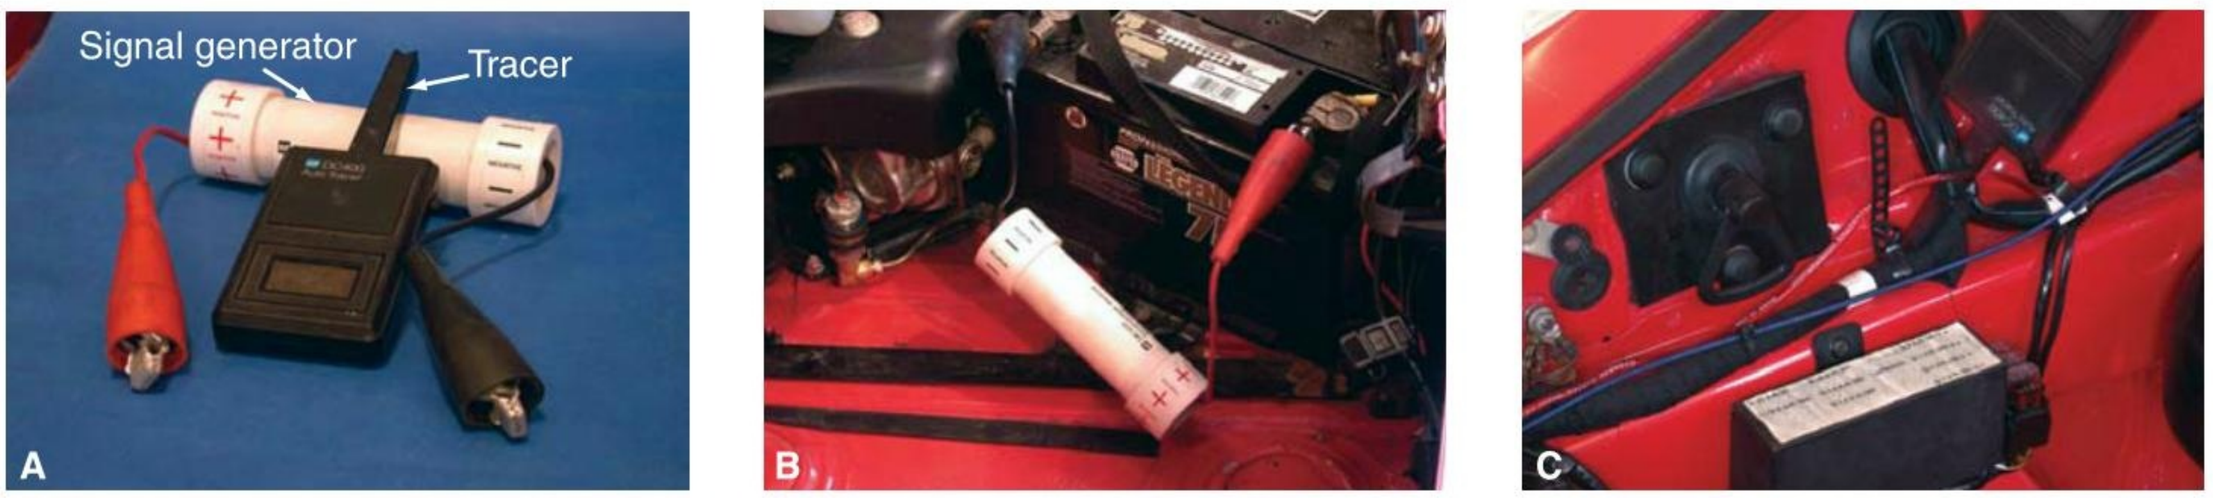
Meter Connections

As you may recall, a ***voltmeter*** measures electrical pressure, or voltage (V). A voltmeter is connected in parallel with the circuit being tested. The circuit's power source must operate the voltmeter. See **Figure 22-16A**.

Caution

Many hybrid drive systems operate on high voltage. Use *only* test instruments rated for high voltage when testing high-voltage hybrid drive trains. High-voltage test equipment has thicker internal insulation to prevent internal electric arcs that would damage a low-voltage test instrument.

An ***ohmmeter*** measures the resistance to current in ohms (Ω). Power must be disconnected from the component or portion of the circuit being tested. Then the ohmmeter can be connected to each end of a wire



Goodheart-Willcox Publisher

Figure 22-15. This is an inductive circuit tracer. A—A circuit tracer consists of a signal generator and an inductive pickup. B—The signal generator must be connected to the battery to generate an ac signal in the vehicle wiring. C—Move the tracer along the wires. The tone changes or the unit beeps when you move the tracer over a break or bad connection in the wiring.

Copyright Goodheart-Willcox Co., Inc.

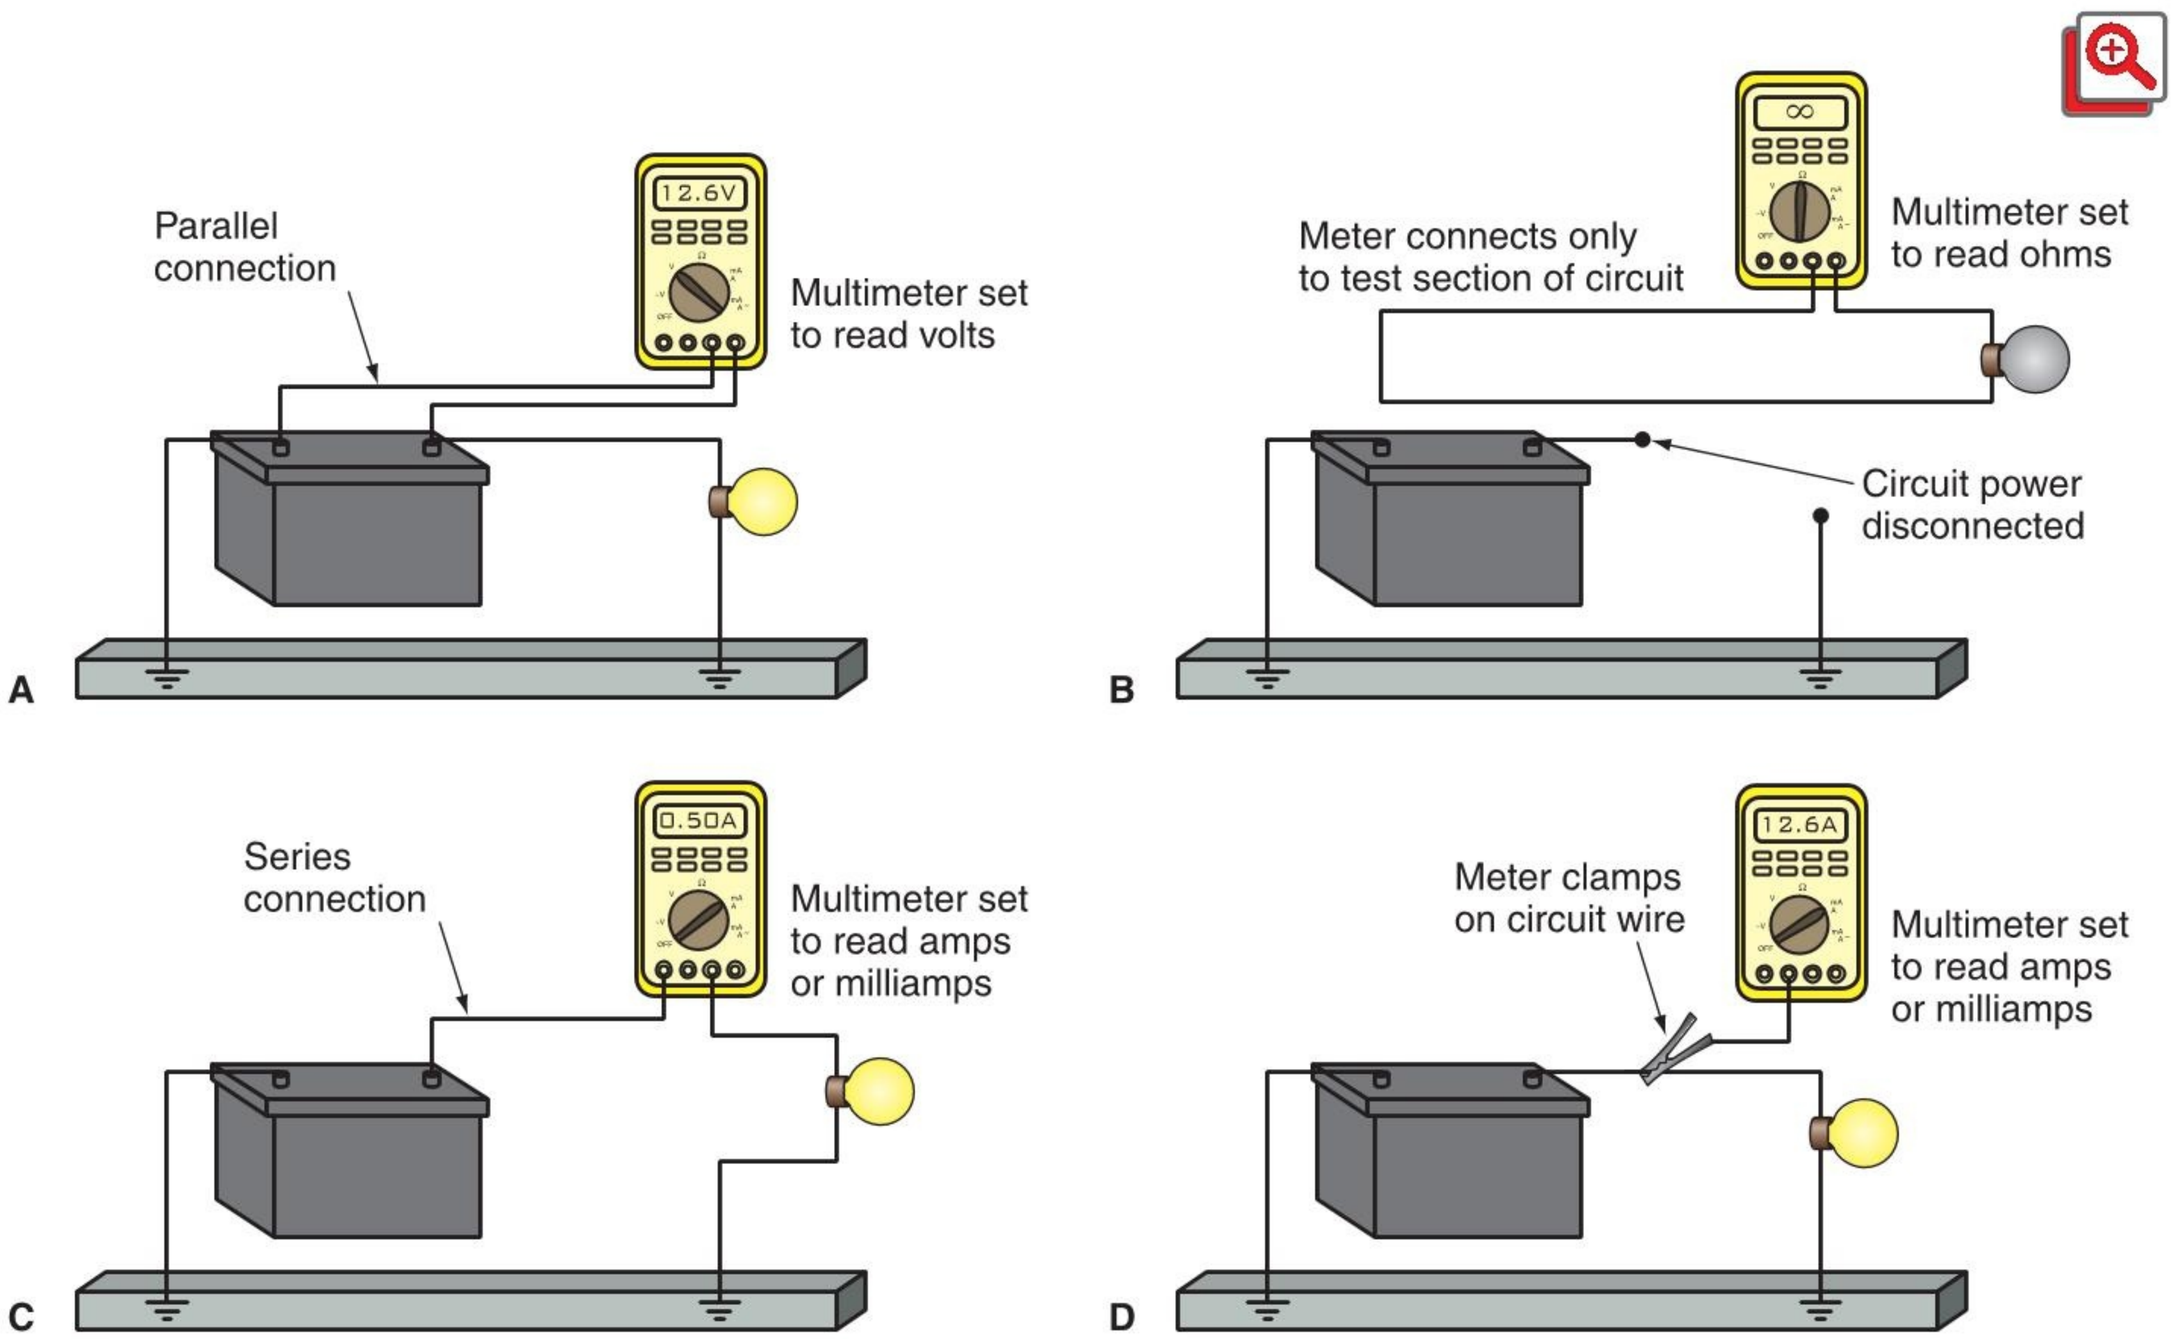
or component to check its internal resistance. This is shown in **Figure 22-16B**.

An ***ammeter*** measures current in amps (A). A conventional ammeter must be connected in series with the circuit being tested. All circuit current must pass through the ammeter. See **Figure 22-16C**. However, inductive ammeters have a clip-on pickup that fits over the wire insulation, as shown in **Figure 22-16D**. The pickup senses and measures the magnetic field around the wire, which is proportional to the current in the wire. The ammeter calculates and displays the reading in amps. An inductive pickup is a handy meter attachment for analyzing charging systems and hybrid power system operation. Most meters connected in series will not read more than a few amps without an inductive pickup.

Meter Controls

Most digital and digital-analog multimeters have a large function knob that can be rotated to select the type of electrical reading to be taken. The function knob can select a reading in volts dc or ac, amps dc or ac, and ohms. It may also have other settings, such as rpm and diode testing. See **Figure 22-17**. Meter control buttons are usually provided to allow you to select other function variables: zero meter, minimum/maximum readings during the test, range, hold, duty cycle (percent on and off), and sound alert. Most multimeters also have different test lead sockets or holes, as shown in **Figure 22-17**. Each socket is for a different type or range of measurement.

Most digital meters are ***auto ranging***—they automatically change to the correct scale. All you have to do is set the meter knob for volts, amps, or ohms, and the meter adjusts itself automatically to the correct range. For example, a digital meter might display a "k" next to the number readout when you are measuring a high resistance, as shown in **Figure 22-18**. This means the meter is displaying the value in kilohms. A reading of 9.27 kΩ equals 9270 ohms. An "M" next to the readout means the value is displayed in megohms. If no prefix is shown, the reading is in ohms.



Goodheart-Willcox Publisher

Figure 22-16. These are the methods normally used to connect a voltmeter, ammeter, and ohmmeter to a circuit. A—A voltmeter is normally connected in parallel with the circuit. B—Power must be disconnected from the component being tested so the ohmmeter can use its battery power to measure resistance. C—A conventional ammeter is wired in series with the circuit to measure current. D—An inductive ammeter clamps onto the outside of the wire and reads the magnetic field around the wire.

Tech Tip

To read a meter correctly, you must understand the electrical multipliers shown on the meter display. The prefixes used on digital multimeters are standard for electrical units.

Figure 22-19 shows a few voltmeter readings. This meter has function settings for dc volts and ac volts. The volts setting is used for most measurements in a

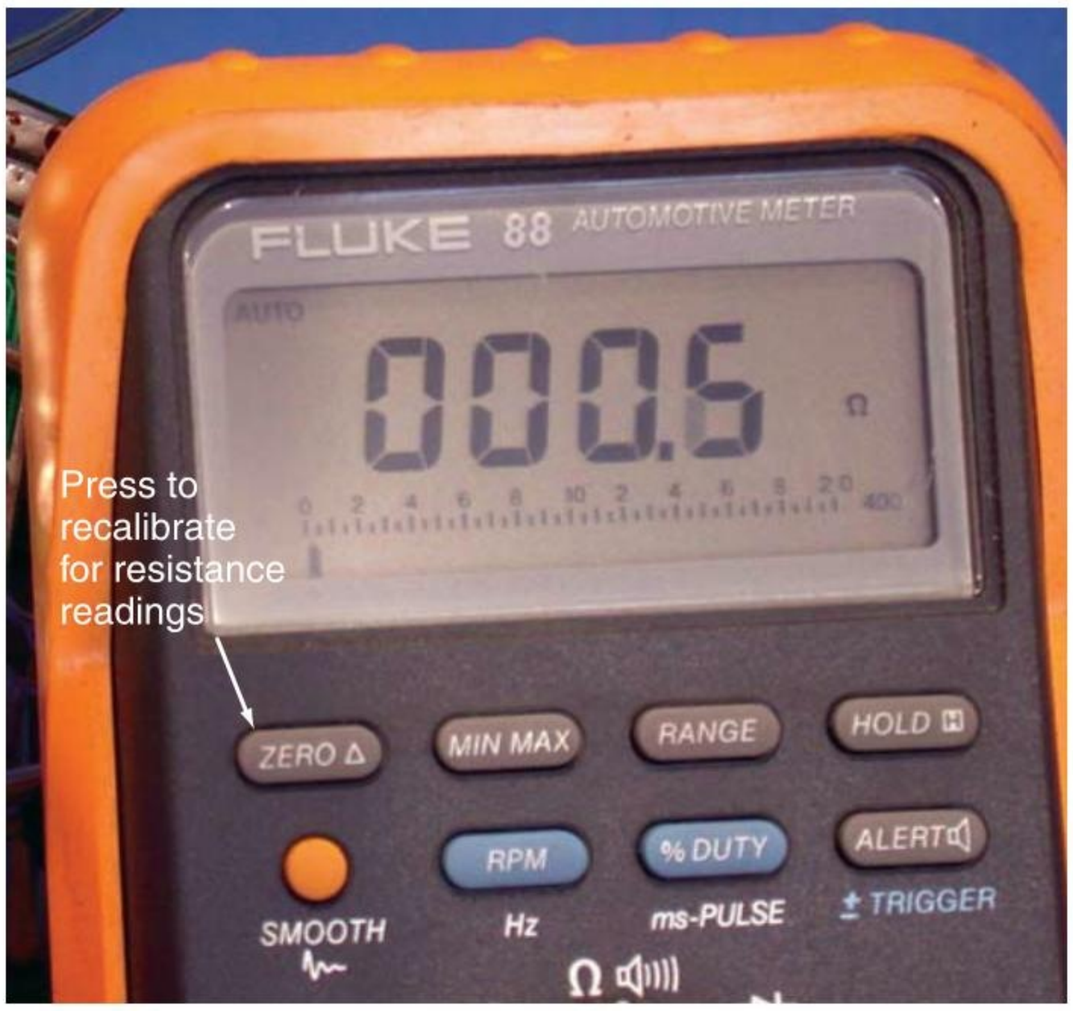
vehicle's electrical systems. The volts might be used to check the signals from speed or position sensors that generate a small ac signal indicating engine or driveline speed.

Figure 22-20 shows some ohmmeter readings from a digital multimeter. Note the multiplier shown on the far right of the display screen. Some ohmmeters must be calibrated to zero before you can make accurate resistance measurements. The calibrate function compensates for battery condition and provides accurate measurements. To calibrate the ohmmeter, touch the two meter leads together. The meter should display a reading of zero ohms. If it does not, press the Zero button to recalibrate the meter to zero. See **Figure 22-21**.

Figure 22-22 shows a multimeter set to make current (amp) readings. To avoid blowing a fuse in the ammeter, make sure the possible amp reading is below the rating of the ammeter. Meter damage can occur if you accidentally send too much current through a meter. Use an inductive pickup for higher amp readings.

The bar graph on a digital-analog multimeter serves as an analog display that can show rapid changes in readings. The bar graph functions much



Goodheart-Willcox Publisher

Figure 22-21. Press the Zero button while touching the two leads together to recalibrate the meter to zero before taking resistance readings.

like the needle on an analog meter. If a circuit or component has an intermittent open or bad connection, the bar graph display moves back and forth to display this rapid change in the reading. The digital display changes as well, but it may not be able to keep up with the reading changes. See **Figure 22-23**.

Some older meters are not auto ranging and must be switched to the correct range. For example, the meter might have a kilohms setting, which means each reading must be multiplied by 100 to find the value in ohms. If the reading is in megohms, you must multiply the reading by 100,000. Various voltage and current settings are also provided on some meters that are not auto ranging.

Voltage Measurements

Voltage measurements are also useful in determining the condition of a circuit or components. By checking the voltage, you can gather more information about the electrical problem. For example, by measuring battery voltage, you can check the charge or condition of a vehicle's battery. A fully charged 12-volt battery should have 12.6 volts. If your voltmeter reads only 11 volts, the battery either needs to be recharged, or it has an internal problem, such as low electrolyte, deteriorated plates, or shorts in cells.

As another example, imagine your engine cranks very slowly and will not start. You might measure the voltage across your positive and negative battery terminals to measure the battery's state of charge. A fully charged 12-volt battery will have 12.6 volts. As it is drained of

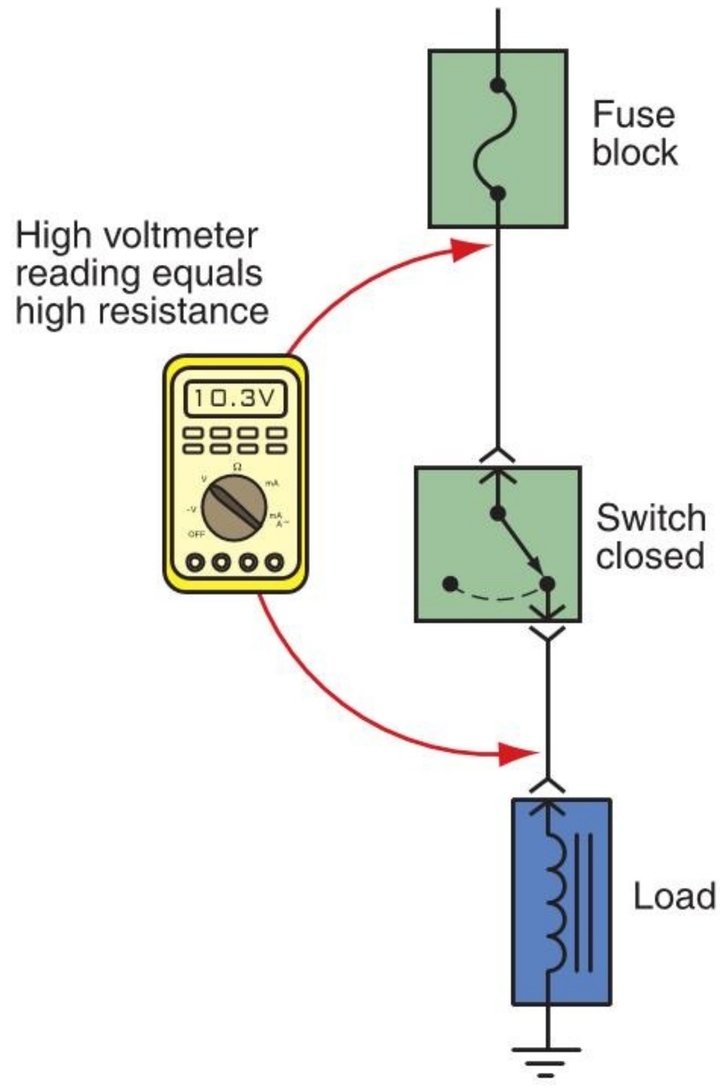
electrical energy, this voltage goes down to 11.5 volts, 10 volts, until the battery is "dead" at zero volts.

Voltage Drop Measurements

A ***voltage drop measurement*** determines the internal resistance of a wire or component. Instead of disconnecting the power source and using an ohmmeter, you can check voltage drops to find resistance for each circuit section without disconnecting the circuit. This is a much faster way of checking a circuit for high resistance.

For example, suppose you suspect a switch of having a poor internal connection and high resistance. To measure the voltage drop, connect the voltmeter across the input and output leads of the switch, as shown in **Figure 22-24**. If the voltage drop across the closed switch is too high (more than about one volt for most switches), then the switch has a poor internal connection. A good switch, when closed, has little or no voltage drop.

Figure 22-25 further illustrates the principle of voltage drop measurements. If the load resistances are equal, the voltage drop is equal across these components. As you may recall from Chapter 3, the sum of all voltage drops equals the supply voltage in a series circuit. **Figure 22-26** shows how voltage drops vary with resistance.



Goodheart-Willcox Publisher

Figure 22-24. Voltage drop measurements check resistance without requiring you to disconnect components. If the closed switch has a high voltage drop, the circuit has a high resistance problem.

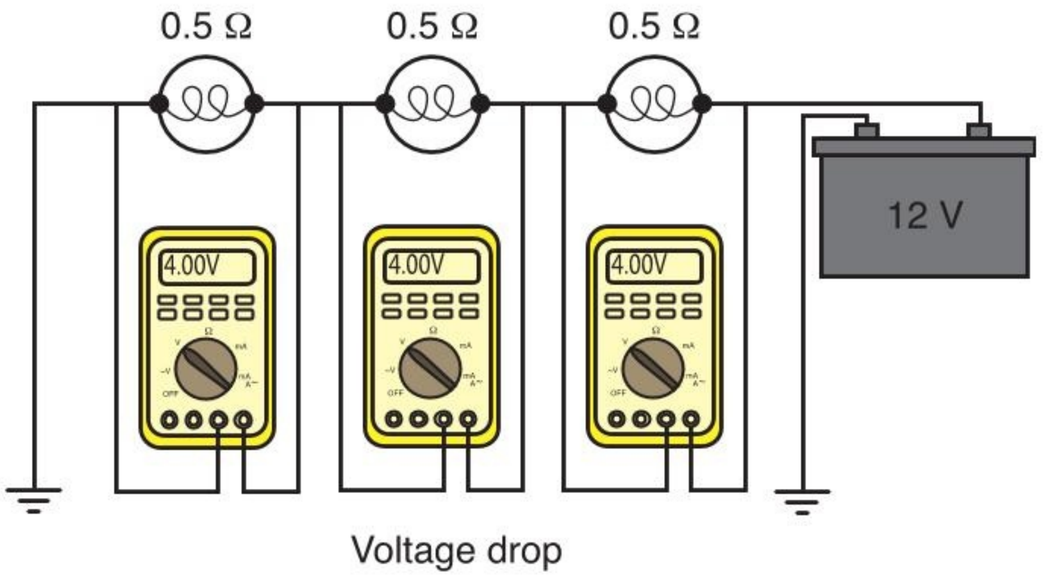
Resistance Measurements

Resistance measurements are commonly taken when the circuit or component is disconnected or when very accurate resistance readings are needed. **Figure 22-27** illustrates some examples of resistance measurements.

Infinite resistance, shown with an ∞ (infinity) symbol, means the circuit path is not complete. Something is preventing current through the tested circuit or component. There is no continuity with an infinite resistance reading. ***Zero resistance***, or no resistance, means a perfect electrical path exists between the two test points. This shows that there is continuity and a resistance of 0 in the tested circuit or component.

Amperage Measurements

Amperage measurements are needed to check the condition of various components. **Figure 22-28** illustrates how an ammeter reading might be used to check the condition of a motor. The measured values can be compared to known good readings. A high current draw might point to a problem producing a drag on the motor, such as bad armature bearings or a short in a winding. A low current measurement might point to a problem that is preventing normal current, such as burned motor brushes, poor terminal connections, or a bad ground.



Total resistance = 0.5 Ω + 0.5 Ω + 0.5 Ω = 1.5 Ω
Total voltage = 4 V + 4 V + 4 V = 12 V

Goodheart-Willcox Publisher

Figure 22-25. A component's resistance determines its voltage drop, so components that have equal resistance have equal voltage drops. Total circuit voltage drop equal voltage applied.

Goodheart-Willcox Publisher

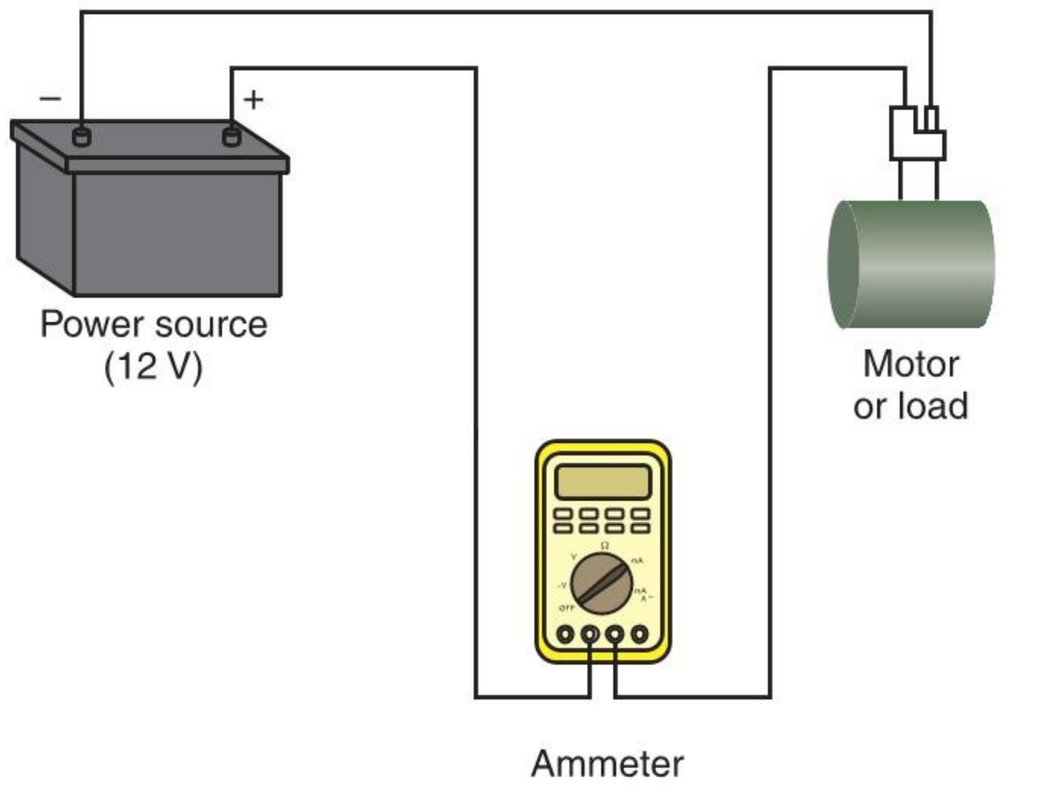
Figure 22-27. These are some examples of resistance measurements. A—A wire conductor should have low resistance. B—A coil is basically a conductor wound in a spiral. It should have very low resistance. C—The ohmmeter should show a high resistance when connected in one direction across a diode. It should show low resistance in the other direction. This shows that the diode is functioning as a one-way electric check valve.



Goodheart-Willcox Publisher

Figure 22-28. Using an ammeter to check a circuit. If current is too high, a low resistance or high voltage is indicated. If current is low, a high resistance or low supply voltage is indicated.

Rules for Using Multimeters

As you work with multimeters to diagnose electric or electronic circuit problems, keep these rules in mind:

- Make sure the test leads are connected properly. An incorrect connection may damage electronic components or the meter itself.
- Set the meter to read a high enough value. If you have the meter set on 0 to 10 amps, for example, and you try to measure 100 amps, you might burn up the meter or blow its fuse.
- Use a digital or digital-analog meter to check computer circuits.
- Place the meter in a secure location. Multimeters are expensive, and they can be ruined if they are dropped. Also keep them away from moving or hot engine parts.
- Keep the test leads away from hot or moving parts to ensure that they do not get caught in engine fans, burned on hot exhaust manifolds, or suffer other physical damage.
- Use the specifications in the service manual to determine whether a circuit or component is faulty. Component and circuit resistance, voltage, and current values vary from model to model.
- If needed, zero or calibrate the ohmmeter before use to ensure accuracy.
- To help find intermittent problems, wiggle wires and carefully use a heat gun or freeze spray on electronic components. This can help change the reading to indicate the problem.

Caution

A heat gun produces enough heat to damage sensitive electronic components. Use the heat gun sparingly and avoid generating very high temperatures around these components.

Basic Component Tests

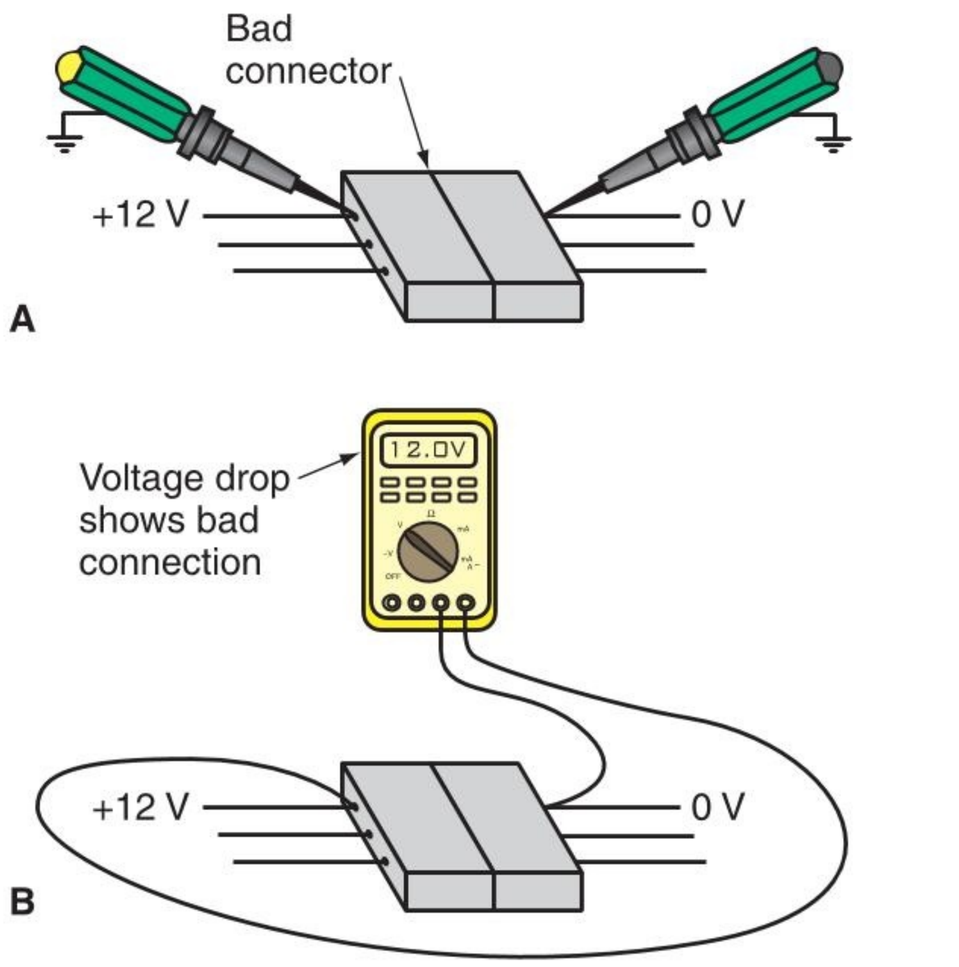
This section of the chapter briefly explains how to test basic electric and electronic components. Understanding these test procedures will help you later when you study other, more specific tests.

Testing Connectors

A good connector has little or no resistance across its terminals. A bad connector has resistance that decreases current through the connector. This reduced current can upset or stop the operation of the circuit that contains the connector.

A test light can be used to check for power on both sides of a connector. See **Figure 22-29**. This test might be used when a circuit is completely dead, indicating that power is not reaching a component or section of a circuit. First, check for power going into the connector. See **Figure 22-30A**. Then check for power on the other side of the connector. Make sure you check the same wire or terminal. Unless you are testing a weather-pack connector, you can touch the test probe on the terminals through the outside of the connector. If the test light does not glow on both sides of the connector, you have found a high resistance or poor electrical connection.

A voltage drop test can also be used to check a connector. See **Figure 22-30B**. A good connector has little voltage drop. A high voltage drop indicates poor terminal contact.



Goodheart-Willcox Publisher

Figure 22-30. Testing a connector. A—Using a test light, you can quickly check for power on both sides of a connector. If the test light glows on one side only, a bad terminal connection is indicated. B—Use a voltmeter to check the voltage drop across a connector. A high drop shows a high resistance problem.

Testing Resistors

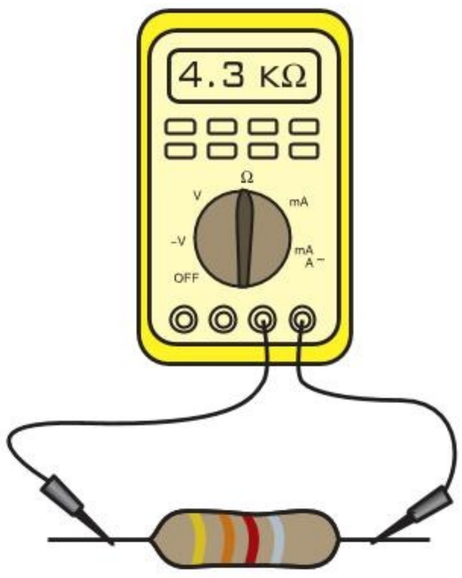
Various types of resistors are used in various automobile circuits. After a period of use, resistors can break down and change resistance. This can upset the operation of the circuit. An ohmmeter can be used to test actual resistance. See **Figure 22-31**. A voltmeter can also be used to check the resistor's voltage drop. If the resistor is not within specifications, it should be replaced.

Testing Variable Resistors

A good variable resistor should exhibit a gradual change in resistance as you turn its shaft or move its

OTC/SPX Corp.

Figure 22-29. A good set of test leads makes it possible to probe all types of electrical connectors without damaging them. To prevent damage, never insert a large test probe into a small connector terminal.



Goodheart-Willcox Publisher

Figure 22-31. The resistance of all resistors in a vehicle must be within specifications. After a period of service, resistor values can change enough to upset circuit operation.

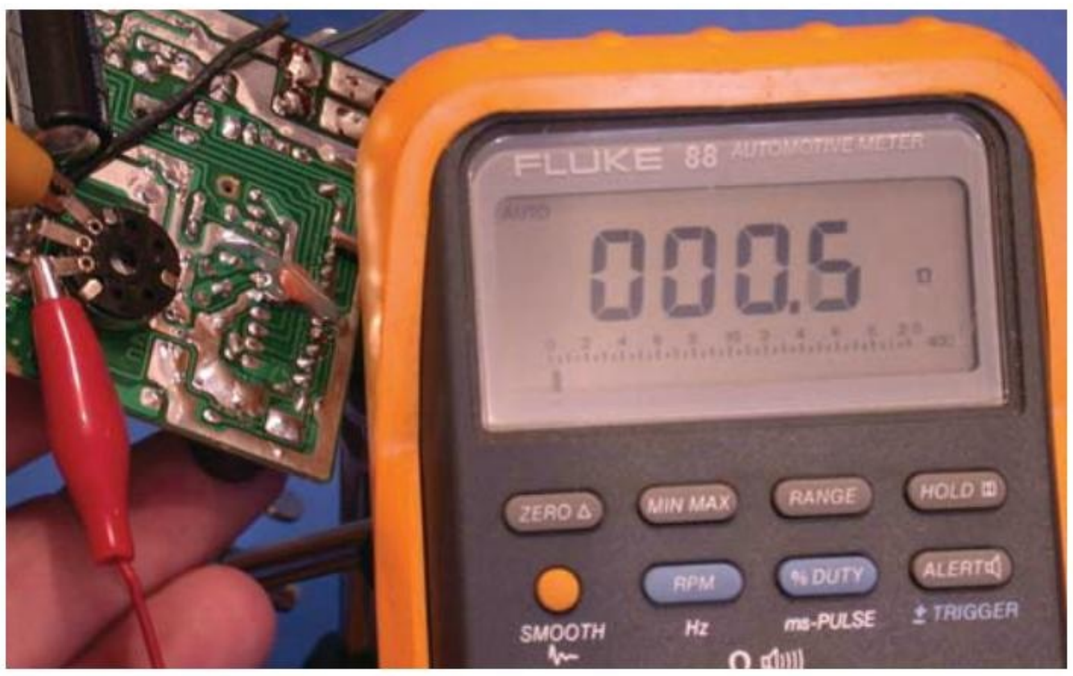
Copyright Goodheart-Willcox Co., Inc.

slide. A bad variable resistor might be open (infinite resistance) or shorted (zero resistance). It may also be stuck at a specific resistance value, or its resistance may not vary properly with shaft or slide movement.

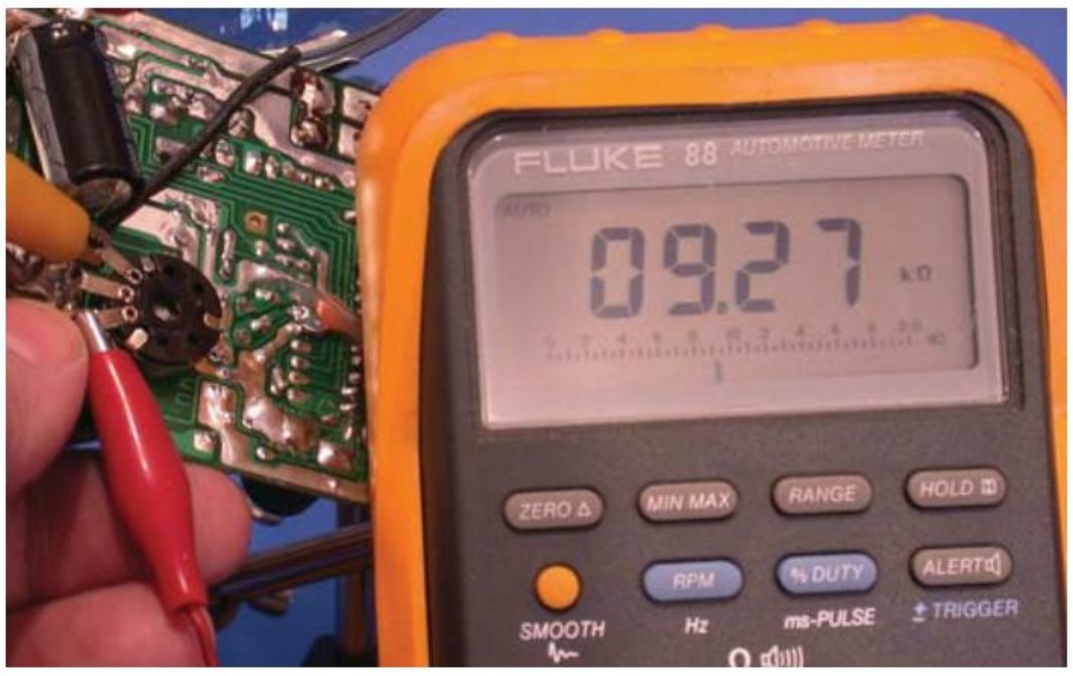
In most conditions, an ohmmeter is the most accurate way of checking a variable resistor. The service manual usually gives resistance specifications for different variable resistor positions. If test values differ from specifications, the variable resistor is bad. See **Figure 22-32**. You can also check a variable resistor by testing voltage drops, but specifications are not given this way.

Testing Switches

A good switch blocks current in one position and passes current freely in the other position. A bad switch may not turn on and off, or it may have high resistance when on. A switch can be tested using a test light, voltmeter, or ohmmeter.



Variable Resistor at a Low-Resistance Position



Variable Resistor at a High-Resistance Position

Union Electronics

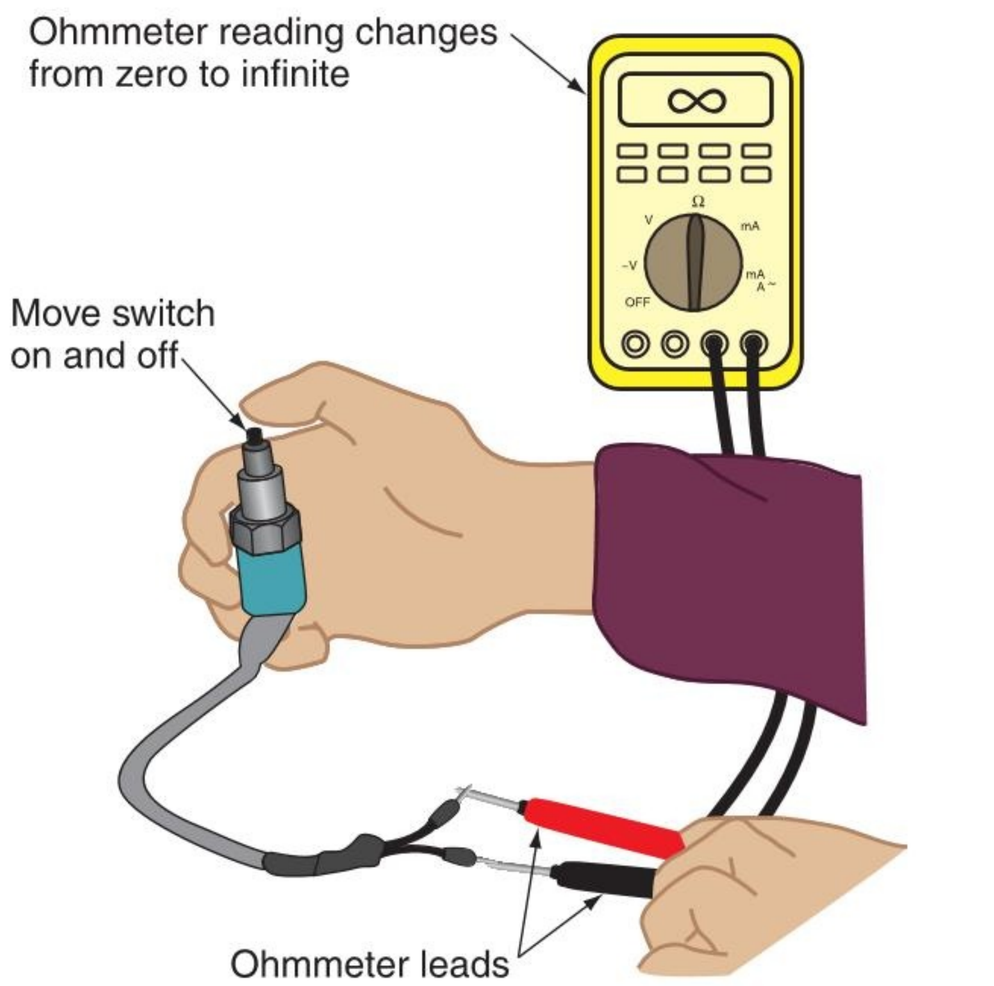
Figure 22-32. A variable resistor, or potentiometer, should have a specific resistance reading at each position. Compare your readings with those given in the service manual.

If the switch is still installed, a test light can be used to check for power in the two positions. A voltmeter can also be connected across the switch. It should show full voltage drop when the switch is off and little or no voltage drop when the switch is on. An ohmmeter can be used if the switch is removed or isolated from the circuit. The switch should have zero resistance when on and infinite resistance when off. See **Figure 22-33**.

Testing a Transducer Switch

The internal resistance of a ***transducer switch*** changes with a change in a condition. Examples include temperature switches, position switches, and pressure switches. When a transducer switch fails, it usually stays in the same position (on or off) even though conditions change.

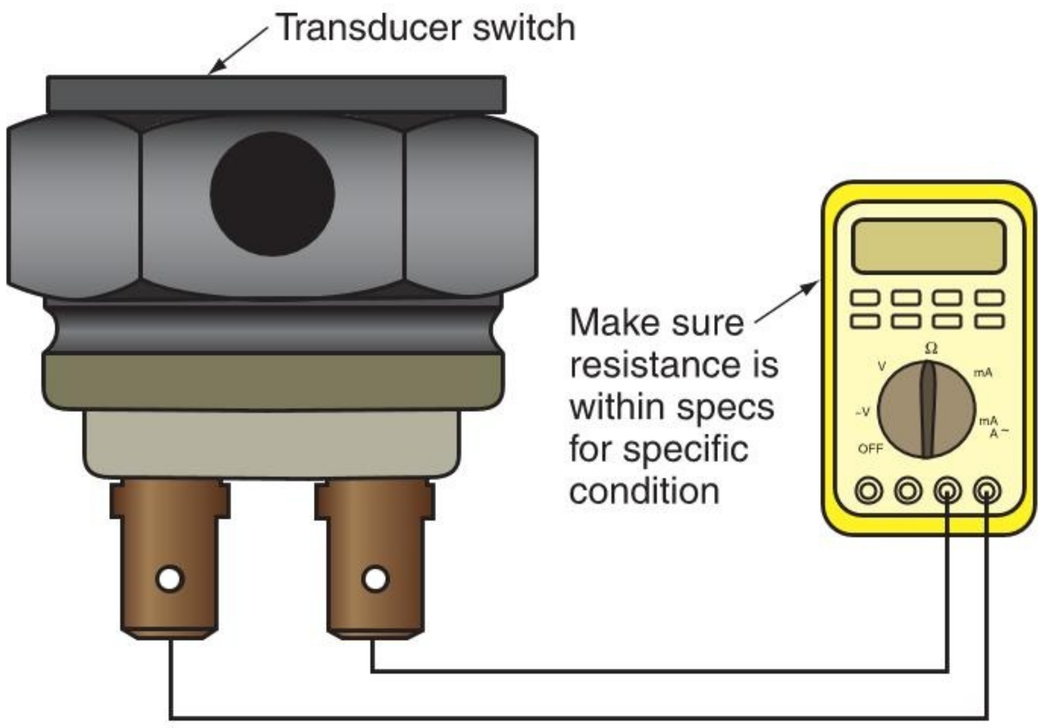
An ohmmeter is normally used to check a temperature switch because the leads to the switch can be disconnected easily. See **Figure 22-34**. Measure the unit's internal resistance when cold and hot (two conditions). You may have to remove the unit so you can control its temperature using a hot plate or a heat gun. You can also use a thermometer to measure the temperature of the switch while it is installed in the engine. If the resistance values are not within specifications for specific temperatures, the temperature switch has failed.



Goodheart-Willcox Publisher

Figure 22-33. A bad switch may be shorted closed or burned open. Resistance should be zero when the switch is closed and infinite when the switch is open.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 22-34. A transducer switch may be open or shorted closed, or its resistance may be higher than normal. It is normally easy to remove the wires and measure the transducer's resistance. You can also use a jumper wire to bypass the transducer switch to see if the circuit begins to function.

A quick way of checking a temperature switch and its circuit is to bypass it. Use a jumper to connect the two leads that go to the temperature switch. This should make the temperature light glow or temperature gauge read fully hot or cold, depending on gauge design.

Caution

Never bypass a sensor switch unless you are sure the switch is designed to have almost zero resistance when closed. If a normally operating sensor is designed to have some resistance, even when closed, you could short out the circuit and cause circuit damage when testing.

Testing Relays

Relay problems usually result from worn, burned, or sticking contact points that prevent normal circuit operation. The small coil windings in a relay can also break, preventing the points from closing.

Many circuits are controlled by relays. Always look for relays in wiring diagrams and check them if power is not reaching a circuit on the output side of a relay.

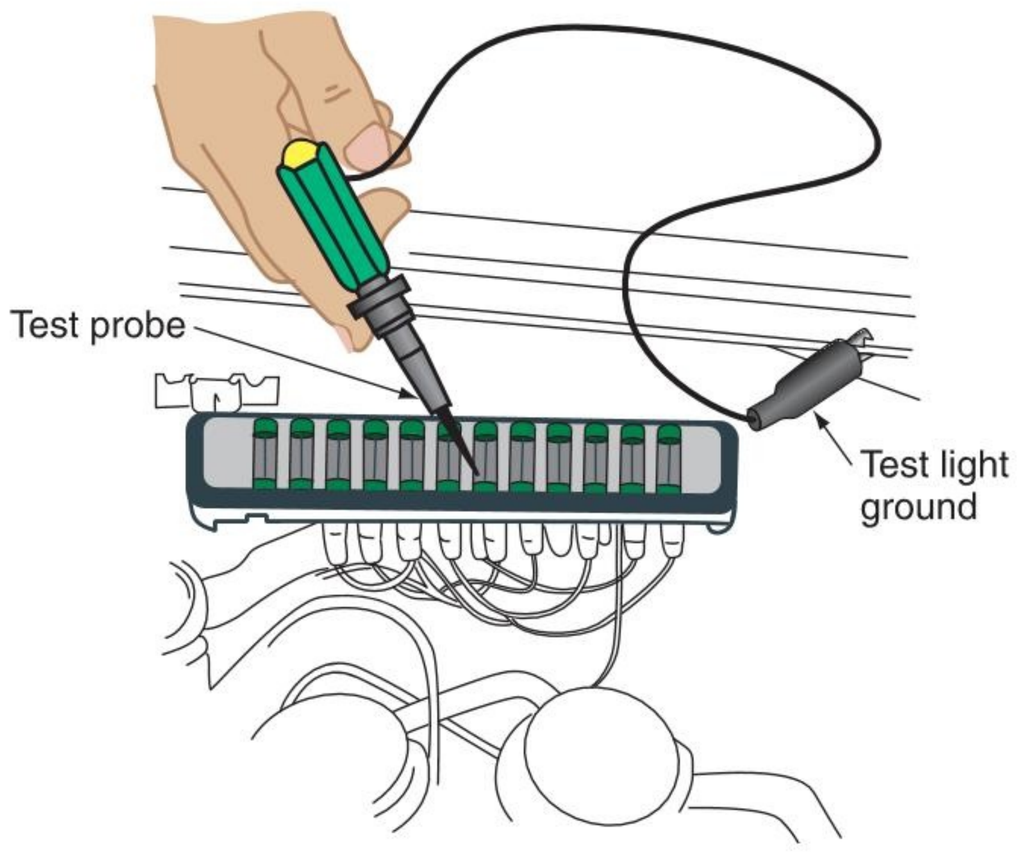
Relays can be located almost anywhere on a vehicle—in the engine compartment, under the dash, on a fuse box, or under the rear seat cushion. The service manual will give relay locations for the vehicle being repaired.

To test a relay, first make sure a voltage signal is being fed to the relay windings. You can check this with a test light or voltmeter. If power is reaching the relay, check that the relay points are closing. Check for voltage leaving the closed relay points. If not, replace the relay.

Testing Fuses

A fuse can be checked quickly using a test light. See **Figure 22-35**. The test light should glow when connected to either side of the fuse. If the light glows only on the feed side, the fuse is blown. If you find that the fuse is blown, you should check for a short that may have caused the fuse to blow. However, sometimes fuses fail after prolonged service, even if there is no short in the circuit.

A voltmeter can also be used to check a fuse, but it is not as handy as a test light. If the meter is digital and makes an audible signal when the voltage changes, you can check the fuse without too much trouble. Again, voltage should be present on both sides of the fuse.



Goodheart-Willcox Publisher

Figure 22-35. Using a test light is the easiest way to check for a blown fuse. A blown fuse will light the tester on the feed side, but it will not light the tester on the output side.

Copyright Goodheart-Willcox Co., Inc.

Testing Capacitors

Capacitors are commonly used to absorb fluctuating voltage or current in a vehicle's electrical system. They can be used to prevent interference in the radio caused by unsmooth dc current or switches opening and closing. Capacitors were also used in older contact point ignition systems to prevent contact point burning.

Warning

A capacitor can store an electric charge. You should always ground the capacitor lead before testing the capacitor. A capacitor cannot hurt you, but it can startle you enough to make you jump and be injured. You also do not want a capacitor to discharge into and damage your ohmmeter.

To test a capacitor, you can use either an ohmmeter or a capacitor tester. To use a capacitor tester, follow the manufacturer's directions. To use an ohmmeter, disconnect and ground the capacitor's lead. Connect the ohmmeter leads across the capacitor as shown in **Figure 22-36**. At first, the ohmmeter should show low resistance as the capacitor takes a charge from the ohmmeter batteries. As the capacitor approaches its full charge, the ohmmeter reading should increase to infinite resistance. This shows that it is blocking dc current but storing voltage.

Testing Diodes

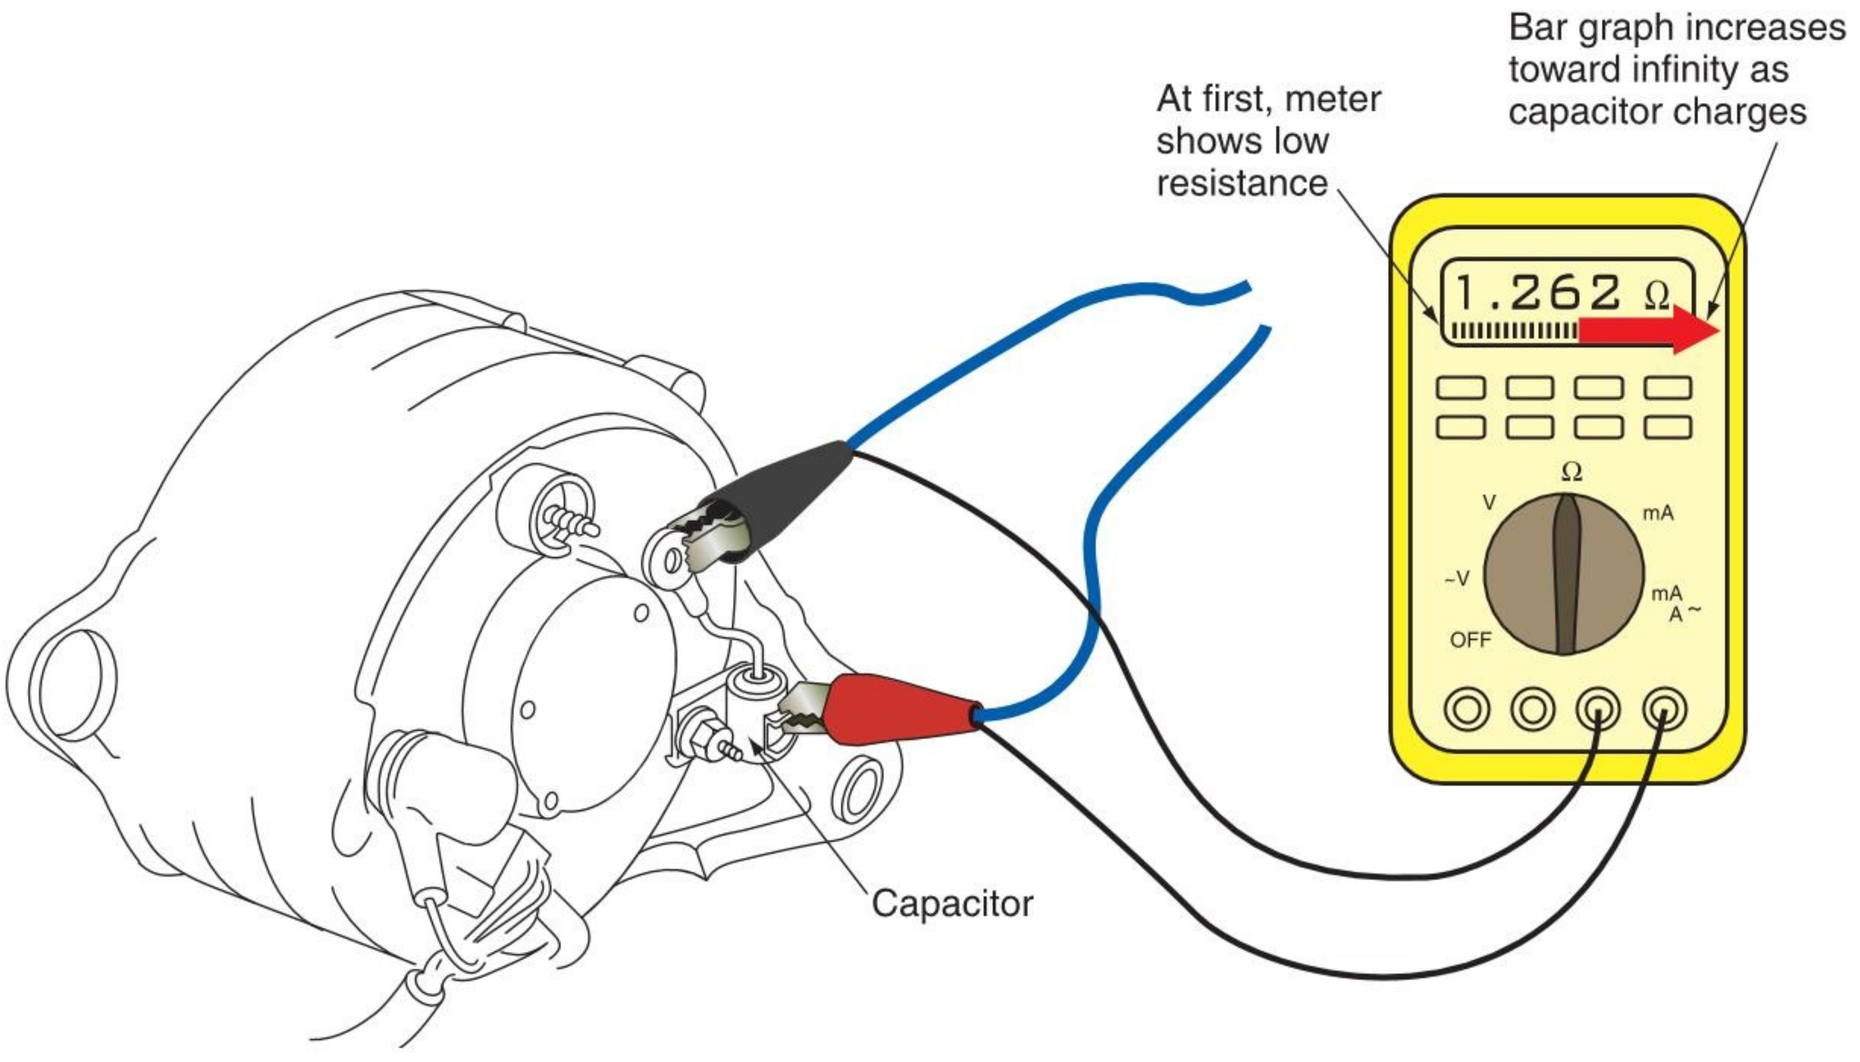
An ohmmeter is normally used to check diodes. A bad diode may have an internal open (PN junction burned and separated), or it may be shorted (PN junction burned and fused). The diode should have infinite resistance in one direction and low resistance in the other. If it does not, the diode should be replaced.

Testing other Components

Methods for testing other electric and electronic components are discussed in later chapters. **Figure 22-37** shows how an ohmmeter and voltmeter can be used to test various components. If you use common sense, your knowledge of component operation, and recommended testing practices, you should have little trouble finding problems.

Electrical Service Chemicals

Several chemicals can be helpful when you are doing electrical tests and repairs. ***Electrical solvent*** can be used to clean oil and grease from components



Goodheart-Willcox Publisher

Figure 22-36. Before using an ohmmeter to check a capacitor, be sure to ground the capacitor lead to discharge any electricity stored in the capacitor.

Goodheart-Willcox Publisher

Figure 22-37. You must use common sense and the basic rules given in this chapter when making electrical measurements. By thinking about the circuit and specific components, you should be able to use logical steps to find circuit problems.

before soldering. It can also be used to remove soldering flux from a component. ***Contact cleaner*** is a chemical for cleaning deposits from contacts, switches, and other components.

Freeze spray can be used to find intermittent problems in electronic components. Electronic components are very sensitive to temperature. When you spray the freeze solution on a component, the component's temperature lowers instantly. This may cause a change in the component's output, helping you find some internal problems.

Green Tech

Fluorescent Shop Lights

To keep your shop energy efficient, one step you can take is to replace any high-power lights with fluorescent lights. There are varying levels of efficiency in fluorescent lights as well. The T system designates the tube diameter for fluorescent lamps. Older fluorescent lights may be T12 lights. To be more efficient, these should be replaced with T8 lights. The lights with smaller diameters will give off more light and use less power.

Copyright Goodheart-Willcox Co., Inc.

Summary

- Most circuit problems are caused by something very simple, such as a broken wire or loose terminal connection. However, when this basic trouble is in a complex circuit, it can be very difficult to locate and repair. Correct techniques must be used to find electrical problems in a modern vehicle.
- Use a systematic approach to diagnose electrical trouble. First verify a problem and analyze the symptoms. Then narrow down the possible causes of the problem. Perform the proper tests to find the exact trouble. After making the repair, recheck to be sure the problem has been corrected before releasing the vehicle to the customer.
- If only one component does not work, start your tests at that component. If several components in the same circuit are not working, start your tests at the power source to the circuit.
- Common circuit problems include an open circuit, high circuit resistance, short circuit, and intermittent circuit problems.
- Jumper wires, test lights, inductive circuit tracers, and multimeters are important testing devices and can be used to find most types of circuit trouble.
- A voltmeter must be connected in parallel with the circuit. A conventional ammeter must be connected in series with the circuit. An inductive ammeter has a lead that clips over the outside of the wire. An ohmmeter must not be connected to a source of power. It uses internal batteries to measure circuit or component resistance.
- Voltage drop measurements provide an easy way of checking for high resistance. You do not have to disconnect the power source and isolate the component, as with an ohmmeter. A high voltage drop indicates a high resistance. A low voltage drop indicates a low resistance.
- Learning how to perform basic tests on connectors, resistors, switches, fuses, and other basic components will help you understand how to test more complex components.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

ammeter
auto ranging
contact cleaner
electrical diagnosis
electrical solvent
freeze spray
grounded circuit
hot wire short to ground
infinite resistance
intermittent problem
jumper wire
ohmmeter
open circuit
short circuit
test light
transducer switch
voltage drop measurement
voltmeter
zero resistance

Activities

1. While wearing rubber gloves and eye protection, measure the voltage of two old car batteries. Write down the voltage reading for each. Charge both batteries for 15 minutes, then recheck the voltage. Do both batteries charge up at the same rate? Recharge both batteries for two hours and repeat your voltage measurements. Write a short paragraph on your findings.
2. While wearing safety gear, measure the resistance of a temperature sensor at room temperature. Record your resistance reading. Using a heat gun, heat the sensor to 100°F, and record the sensor resistance reading. Does the sensor seem to be working? Write a paragraph on your findings.

Review Questions

Answer the following questions using the information provided in this chapter.

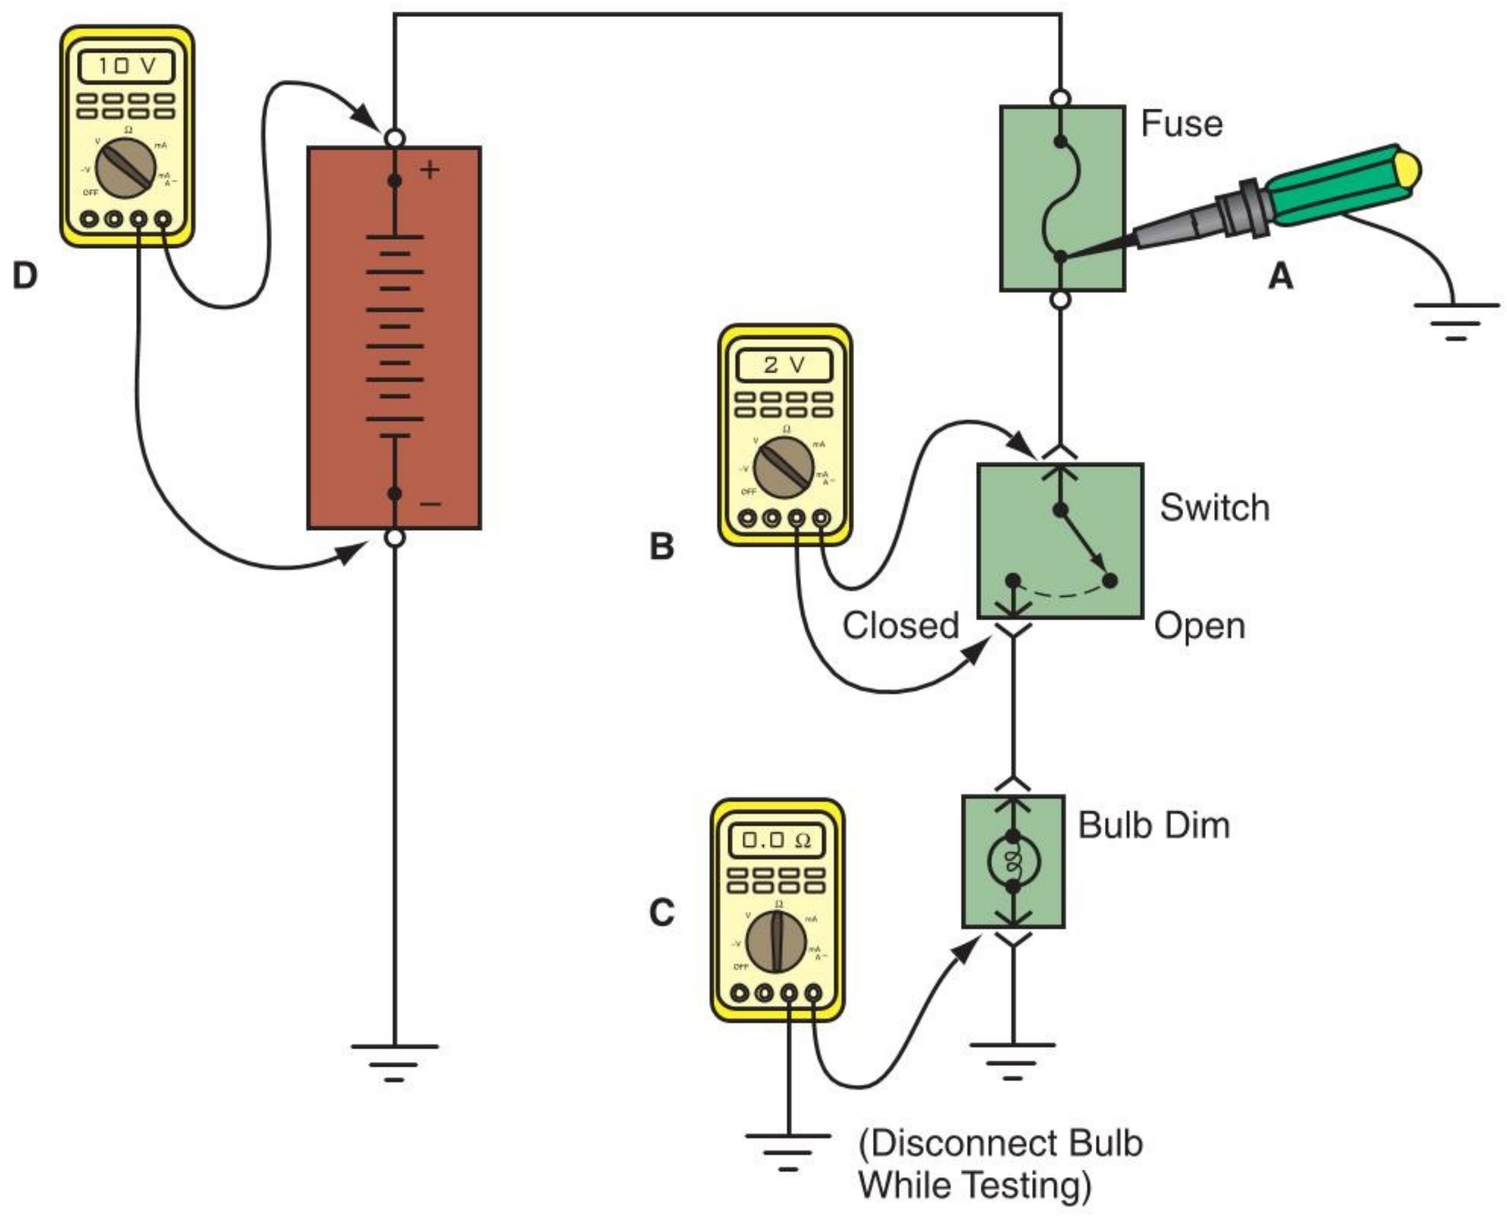
1. What are five questions you might ask yourself when trying to find a problem?
2. If only one component does not work, where should you start your tests?
3. If more than one component does not work, where should you start your tests?

Copyright Goodheart-Willcox Co., Inc.

4. What effect does an open circuit have on current?
5. What six conditions may cause an open circuit?
6. What might make a bulb glow dimly or a motor run slowly?
7. Explain how a short might cause an electrical fire.
8. What is an intermittent problem?
9. How would you use a jumper wire to check a switch?
10. Which testing device usually provides the quickest and easiest way to check a circuit for continuity?
11. Which testing device uses a signal generator and inductive pickup to find shorts and opens in wires?
12. Explain how to connect a conventional ammeter and an inductive ammeter to test a circuit.
13. An ohmmeter shows a reading of 2.500 kΩ. What is the meter reading in ohms?
14. Explain how you can use voltage drop measurements to determine whether a switch is functioning correctly.
15. List eight rules for using multimeters.
16. Which type of multimeter should be used to check for voltage in a computer circuit?
17. Explain how to use a test light to check a connector.
18. What three testing devices might be used to test a switch?
19. What is the most accurate way to check a variable resistor?

Use the circuit drawing in **Figure 22-38** to answer questions 20 through 24. The battery produces 12.6 volts (6 cells at 2.1 volts each). The bulb burns very dimly with the switch on.

20. Would test A be needed with these symptoms or conditions?
21. What does test B tell you?
22. Test C would verify:
    (A) That electricity is not leaking through the bulb socket.
    (B) That the ground does not have low resistance.
    (C) That the ground does not have high resistance.
    (D) All of the above.
    (E) None of the above.
23. What would you learn from test D?
24. How would you repair the circuit problem?



Goodheart-Willcox Publisher

Figure 22-38. Use this circuit illustration to answer review questions 20 through 24.

ASE-Type Questions

1. Technician A says a basic circuit problem can be caused by something in the circuit that increases voltage. Technician B says a basic circuit problem can be caused by something in the circuit that decreases resistance. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. An automobile is brought into the shop with an engine electrical problem. Technician A says the first step to electrical diagnosis is to verify the symptoms and the problem. Technician B says electrical diagnosis involves using a logical sequence of steps to find the source of the problem. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. More than one component in a particular automotive electric circuit is not working. Technician A starts testing the circuit at the power source. Technician B starts testing the circuit at its load. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. There is an open in an automobile's headlight circuit. Technician A says this problem can be caused by a blown fuse. Technician B says the problem may be caused by burned switch contacts. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Technician A says an open will always stop current in a circuit. Technician B says high circuit resistance will normally reduce current in a circuit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says a short circuit can be caused by a conductor touching ground. Technician B says a short circuit can be caused by a conductor touching another conductor. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says intermittent problems occur only under certain conditions. Technician B says intermittent problems are often caused by poor electrical connections. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Test light use is being discussed. Technician A says that self-powered test lights are the most common type of test light used in automotive repair. Technician B says that you should avoid using a test light probe to puncture wire insulation whenever possible. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. The current in an automotive taillight circuit needs to be checked. Technician A connects a conventional ammeter in parallel with the circuit being tested. Technician B connects a conventional voltmeter in series with the circuit being tested. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. A particular diode has a reading of infinite ohms in both directions. Technician A says this indicates the diode is in good condition. Technician B says this indicates that the diode has an internal short. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Section 4

Computer Control Technology

Chapter 23
Computer System Fundamentals

Chapter 24
On-Board Diagnostics and Scan Tools

Chapter 25
Computer System Service

Today's vehicles are as much electronic as they are mechanical. Computers control and monitor every major system in a modern car or light truck. It is virtually impossible to work on almost any vehicle without a basic knowledge of computers.

Section 4 details the theory and operation of computer systems, explains how to use a scan tool to find problems in computerized systems, and describes the use of pinpoint tests to verify the basic electrical/electronic faults identified by the scan tool.

This important section will prepare you for almost every other chapter in this textbook. Study it carefully! This section will also help you pass several ASE Certification Tests that require an understanding of computers, sensors, actuators, scan tools, and related topics, including Test A6, Electrical/Electronic Systems and Test A8, Engine Performance.

Chapter 23
Computer System Fundamentals

After studying this chapter, you will be able to:

- Compare computer systems to the human body's nervous system.
- Describe the input, processing, and output sections of a basic computer system.
- Summarize computer system signal classifications.
- Sketch a block diagram for a computer system.
- Explain input sensor and output device classifications and operation.
- Summarize where computers, sensors, and actuators are typically located.
- Explain how a computer uses sensor inputs to determine correct outputs.
- Correctly answer ASE certification test questions that require a knowledge of automotive computer system fundamentals.

An automotive ***computer*** is a complex set of electronic circuits. An automotive computer will produce programmed electrical control currents for actuators after receiving specific input signals from sensors. Computers now monitor and control all major systems of a modern vehicle.

It is almost impossible to work on almost any automotive system without having a sound knowledge of vehicle computers. In the past, automotive systems (ignition, cooling, emissions, and fuel, for example) worked independent of each other. Today, on-board computer networks work together at lightning-fast speeds to react to almost any condition, making the passenger vehicle a much safer, efficient, and powerful means of transportation.

Tech Tip

Complex sensors (oxygen sensors, MAP sensors, throttle sensors, yaw sensors, etc.) will also be studied in later textbook chapters. Refer to the index for more information on any specific type of sensor, actuator, or circuit.

Cybernetics

The term ***cybernetics*** is often used to refer to the study of how electrical-mechanical devices can duplicate the action of the human body. Comparing the human body to a computer system is an easy way to explain this subject. Just as your brain communicates with and controls parts of your body, an automotive computer system can communicate with and control parts of a vehicle. See **Figure 23-1**.

Dash graphic display output	⟷	Talk, write, draw output
Memory and processor IC circuits in computer	⟷	Brain's memory and thought

Goodheart-Willcox Publisher

Figure 23-1. Cybernetics compares the human body to a computer system. Study this chart comparing the human nervous system and an automotive computer system.

The Nervous System (Computer Input)

The human nervous system uses chemical-electrical signals to control the body. If you touch a sharp needle, nerve cells in your finger "fire" and send a signal through a strand of nerve cells in your hand, up your arm, and into your brain. The strand of nerve cells forms a "wire" that connects your finger and brain. The nerve cells in the tip of your finger are comparable to a sensor, or input device, in a computer system.

The Brain (Computer Processing)

The brain uses billions of cells interconnected by linking cells called neurons. Each neuron chemically-electrically connects tens of thousands of neighboring cells. When the brain "thinks," minute electrical impulses travel from neuron to neuron. One simple thought might involve electrical impulses between hundreds of thousands of cells in a specific pattern. This is not unlike the electrical action inside the circuits of a computer.

The brain is comparable to a super powerful computer. It can process the inputs from the nervous system and determine what actions should be taken.

For example, imagine you accidentally poke a sharp needle into your finger. The result is chemical-electrical signals for pain and a reaction signal to pull the needle away from your finger. First, your brain would almost instantly tell you, "my finger is being injured." Your brain would then take corrective action to protect your finger.

The brain makes decisions much like computers produce logical outputs. The cells in the brain can be either chemically-electrically charged (on) or not be charged (off). By connecting all the brain cells in complex logic/memory circuits, the brain can decide what to do in almost any situation.

The Reflex Action (Computer Output)

The needle prick signal from the nerve endings in your hand activates specific brain cells to fire and produce a chemical/electrical reaction (pain). A reflex output (voltage) is then produced by your brain (computer) and sent back down the nerves (wires) in your arms. This chemical-electrical output signal stimulates the muscles in your arm and hand to pull back, protecting your finger from the sharp object. The reflex action of your muscles is similar to the action of an actuator, or output device, in a car's computer system.

Computer Circuit Advantages

There are several reasons that computers are being used in modern vehicles. Computers provide several advantages.

- Computer systems can compensate for mechanical wear. Also, they do not have as many mechanical parts to wear and go out of calibration.
- Computers "think" very quickly and can alter outputs in milliseconds (thousandths of a second). This lets a computer alter outputs almost instantly as inputs and operating conditions change.
- Computers reduce fuel consumption and lower emissions by precisely metering fuel into the engine. The computer sensor circuit "sniffs" the exhaust gases to find out if too much or too little fuel is entering the engine.
- Computers also increase engine power by accurately controlling ignition timing, fuel injection, emission control system operation, etc.
- Computers reduce vehicle weight because they are much lighter than mechanical control mechanisms.

Copyright Goodheart-Willcox Co., Inc.

- Most computers have on-board diagnostics that can detect and record system problems. The on-board computer can produce and store an output code that tells the technician where a fault might be located.
- Computers can increase driver convenience by better control of the passenger compartment environment and dash displays.
- Computers can improve passenger safety by controlling the anti-lock brakes, air bags, suspension, and other systems.
- Computers can compensate for component wear and failure to keep the car driveable.

Digital Electronics

Digital electronics is a field of study dealing with the ways a computer uses on-off signals to produce "artificial intelligence." A computer analyzes input signals from sensors. It has memory in which fixed and semi-fixed data is stored, using small integrated circuits (ICs). The computer can make logical choices on how to control specific outputs by comparing the input signals from sensors to known signals.

Binary Numbering System

The ***binary numbering system*** uses only two numbers, zero and one, and is the key to how computers operate. The numbers zero (0) and one (1) can be arranged in different sequences to represent other numbers, letters, words, a computer input, a computer output, or a condition.

To use the binary system, a computer turns switches (transistors, for example) either *on* or *off*. *Off* would represent a zero (0) and *on* would represent one (1) in the binary system, **Figure 23-2**.

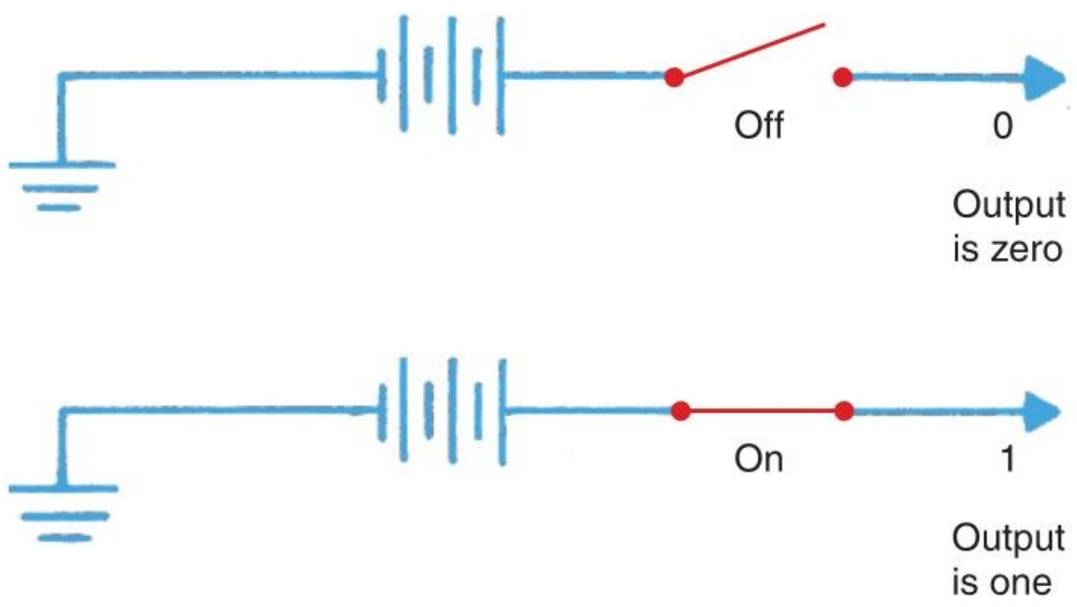
Note that a 0011 in binary would equal a three (3) in the base 10 decimal system. A 0110 in binary would equal a six (6) in the base 10 system. Study the conversion chart in **Figure 23-3**.

In binary language, a zero or a one is called a bit. A pattern of four bits is a nibble. A pattern of eight bits is called a byte, (pronounced "bite"). One or more bytes are referred to as a word. You are more likely to hear this terminology when you work with home or personal computers.

Gating Circuits

A ***gate*** is an electronic circuit that produces a specific output voltage for given input voltages. Just as a diode will pass current when forward biased (output lead would have voltage representing one) and stop current when reverse biased (output would be zero or no voltage), gates have programmed (previously known) outputs. Shown in **Figure 23-4**, the most common computer gates are:

- NOT gate—Also called an inverter gate, a NOT gate will reverse its input. If the input has voltage applied (1), the output terminals will not have voltage (0) or vice versa. A NOT gate can be used to make other gates.
- AND gate—An AND gate requires voltage (1) at both inputs to produce a voltage (1) at the output. If pins A and B are both one (1), the output will be 1. If only pin A or pin B is one, the output will be 0.



Goodheart-Willcox Publisher

Figure 23-2. Since electronic components can be either on or off, the binary numbering system is ideal for digital logic and computer circuits. The binary system has only two numbers, zero and one, which represent off and on conditions.

Decimal number	Binary number code 8 4 2 1	Binary to decimal conversion
0	0 0 0 0	= 0 + 0 + 0 + 0 = 0
1	0 0 0 1	= 0 + 0 + 0 + 1 = 1
2	0 0 1 0	= 0 + 0 + 2 + 0 = 2
3	0 0 1 1	= 0 + 0 + 2 + 1 = 3
4	0 1 0 0	= 0 + 4 + 0 + 0 = 4
5	0 1 0 1	= 0 + 4 + 0 + 1 = 5
6	0 1 1 0	= 0 + 4 + 2 + 0 = 6
7	0 1 1 1	= 0 + 4 + 2 + 1 = 7
8	1 0 0 0	= 8 + 0 + 0 + 0 = 8

Goodheart-Willcox Publisher

Figure 23-3. Binary numbers can be converted into decimal (base ten) numbers. Note how the right-hand binary number equals one and the left-hand number equals eight.

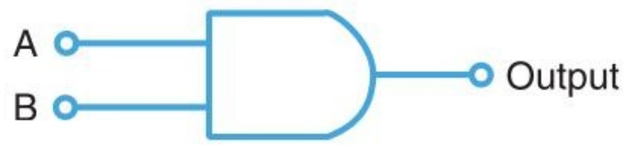
1	0
0	1

A—Inverter simply reverses its input.

AND



A	B	A • B
0	0	0
0	1	0
1	0	0
1	1	1

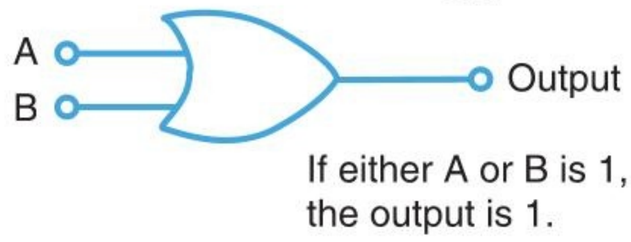
B—AND gate requires both inputs to be on for an output.

NAND

A	B	A • B
0	0	1
0	1	1
1	0	1
1	1	0

C—NAND gate is an inverted AND gate; there is no output when both inputs are on.

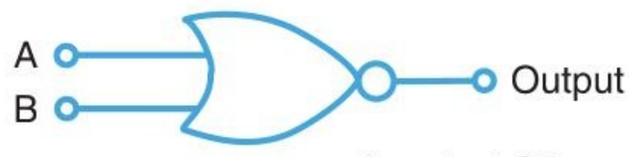
OR



A	B	A + B
0	0	0
0	1	1
1	0	1
1	1	1

D—OR gate only needs input voltage on either terminal to get an output voltage.

NOR



A	B	A + B
0	0	1
0	1	0
1	0	0
1	1	0

E—NOR gate is an inverted OR gate; no input voltage will produce an output voltage.

Goodheart-Willcox Publisher

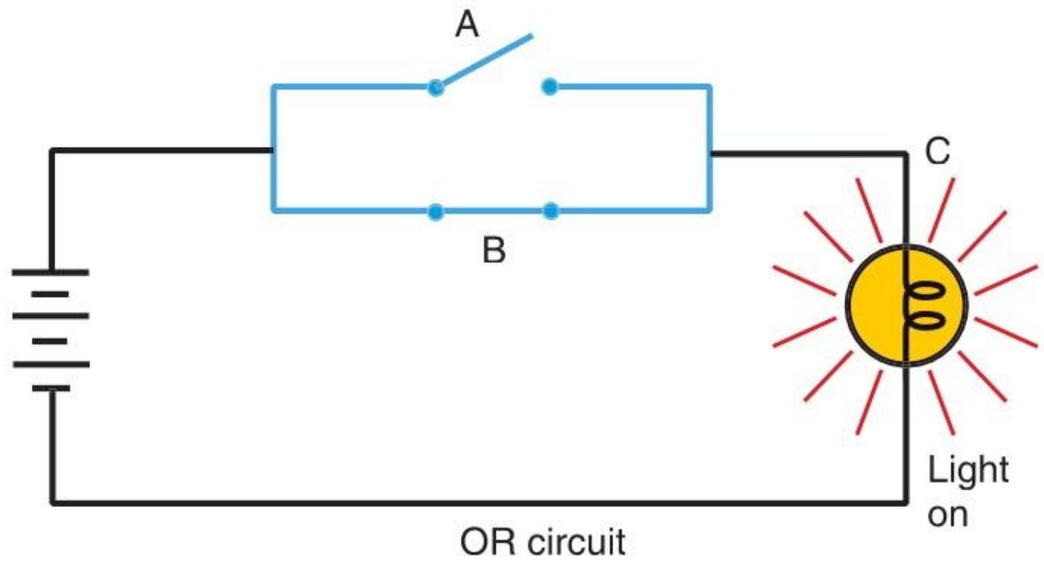
Figure 23-4. Study the basic types of computer gates. Truth tables on the right show what the output of each gate will be with different inputs.

- A NAND gate—An inverted AND gate is a NAND gate. Its output will be opposite that of an AND gate. Note the small circle or dot on the output lead of the gate. The small circle represents an inverter.
- OR gate—An OR gate will produce an output (one or on) if either input is energized (1). A or B input voltage (1) will result in voltage (1) at the output lead.

OR gate

A	B	A or B
0	0	0
0	1	1
1	0	1
1	1	1

A or B on = C on



Goodheart-Willcox Publisher

Figure 23-5. Compare the OR gate and the switch setup in this simple circuit. Either A or B will turn on the light and produce a one, or on, output.

- NOR gate—An inverted OR gate is a NOR gate. Note the small circle that represents an inverter. The output is inverted to produce an output opposite that of an OR gate.

Truth Tables

A truth table is a chart that shows what the output of a gate will be with different inputs. Look at the truth table for an OR gate shown in **Figure 23-5**. Note that if two switches are wired in parallel, either switch A or switch B (OR gate) will turn the light *on* (output 1). The output will be *on* (1) with A or B or both energized. Only when neither input is *on* will the output be *off* (0). A truth table graphically shows how a gate functions.

Gates are often called *logic devices* because they make logical decisions (outputs) based on specific inputs (facts). If an AND gate was compared with two switches wired in series, both switches (A and B) must be *on* to activate the starter motor, **Figure 23-6**. Compare these circuits to the action of the gates and the truth tables.

Logic gates can be connected together to form super-complex circuits. Millions of gates can be interconnected to produce thousands of preprogrammed outputs (decisions) from numerous inputs (facts). This is how a computer works, or thinks. Its circuitry and software are designed to make the correct output signals based on various input signals. In this way, a

Goodheart-Willcox Publisher

Figure 23-6. Compare this starting circuit with the computer gate circuit and truth table. It shows how a computer gate can make a decision. Two input conditions (A and B) must be satisfied in both circuits to produce an output to the starting motor. The same principle, only with thousands of gates and dozens of inputs and outputs, is used inside an automotive computer.

computer knows what to do to keep the vehicle operating efficiently with many different variables.

Integrated Circuits

An ***integrated circuit (IC)*** is an electronic circuit that has been reduced in size and etched on the surface of a tiny semiconductor chip, **Figure 23-7**. Metal conductors on the top of the chip connect these various electronic components to form the circuit. Wire leads allow for input and output connections to and from the IC chip. Technicians often have to reprogram the integrated circuits in a vehicle's computers to rectify problems.

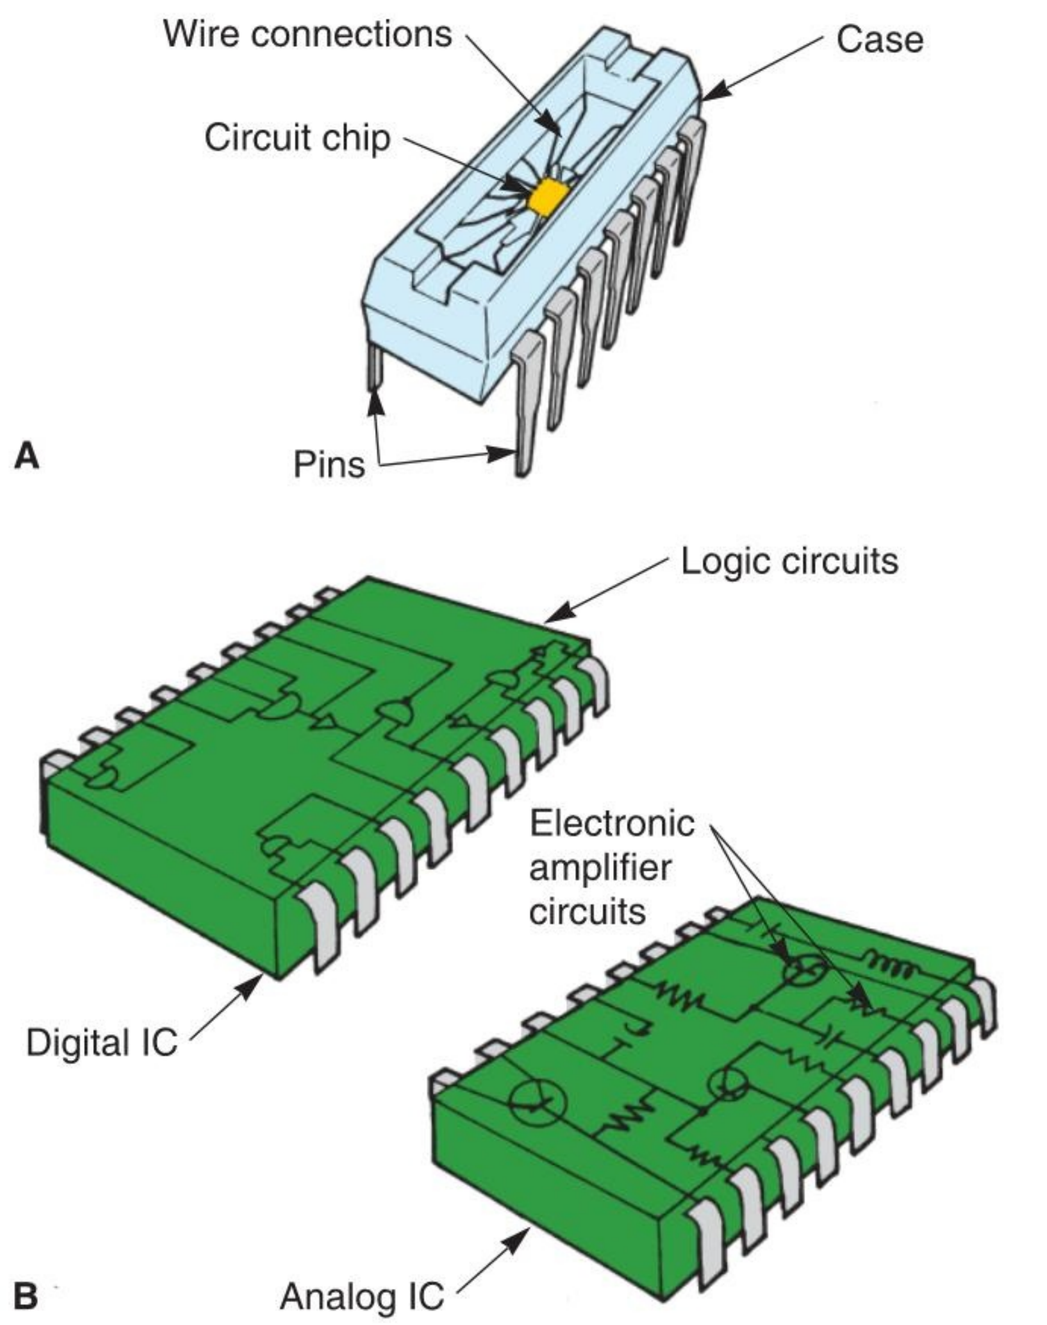
Computer Signals

A ***computer signal*** is a voltage variation over short periods of time. It is a specific arrangement of pulses or waves used to carry electronic data, or information. You must be familiar with computer signals to understand the operation and service computer systems.

Computer signals can be digital (square or on/off scope waveform) or analog (smooth, gradual change in current and voltage), as in **Figure 23-8**.

Digital signals are on-off signals, like those produced by a rapidly flipping switch. Voltage output goes from maximum to minimum. A digital signal basically produces a square wave. See **Figure 23-9**.

An example of a sensor providing a digital signal is a Hall effect-type crankshaft position sensor, which shows engine RPM using a 12 V signal. Compare crankshaft and camshaft signals in **Figure 23-10**.



Goodheart-Willcox Publisher

Figure 23-7. An integrated circuit has been photographically reduced in size, etched on a silicon chip, and placed inside a protective case. A—Note how a tiny chip is installed inside this plastic case. Tiny wires connect the chip to each metal pin. The pins then plug in or are soldered to other parts of the circuit. B—These are two broad classifications of integrated circuits. Digital circuits use gates to produce logic circuits for computers. An analog IC is a small amplifier circuit for increasing output strength or altering output.

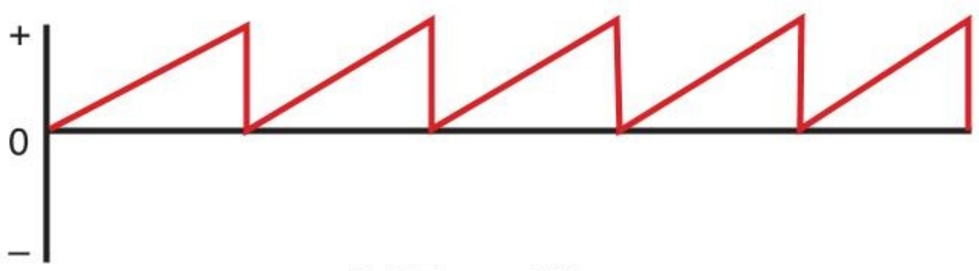
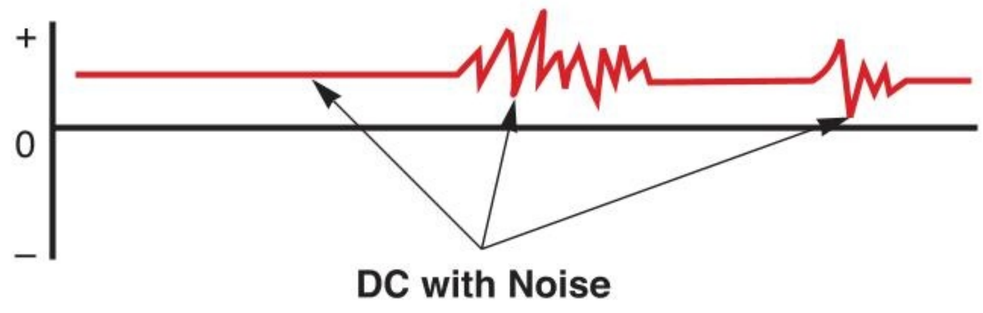
Voice Waves



DC Ramp Wave



DC with Noise

Goodheart-Willcox Publisher

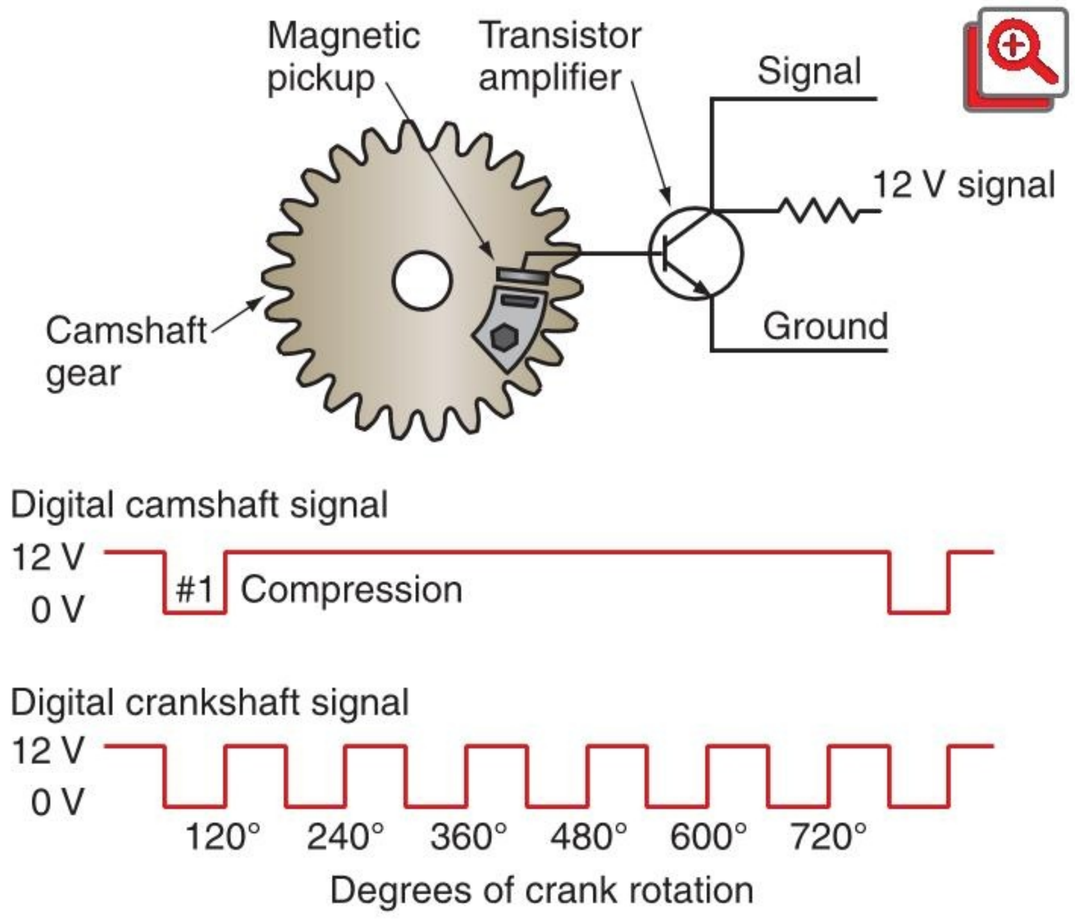
Figure 23-9. These are the basic signals found in computer system circuits. Voltage is shown vertically and time is shown horizontally. An oscilloscope can be used to measure computer signals.

An ***analog signal*** gradually changes in strength. For example, a sensor's internal resistance (and resulting voltage signal) may smoothly increase or decrease with changes in temperature, pressure, or part position. The change in resistance will cause a change in the resulting voltage signal. An analog signal will produce a curved wave or an irregular wave. Refer to **Figure 23-9**.

Computer signals can be measured with an oscilloscope or a scan tool with a scope function. If a scope is connected to a sensor that generates a signal voltage, a trace of the signal, or ***waveform***, can be viewed on the scope. A speed sensor waveform is illustrated in **Figure 23-11**.

There are many types of electrical waveforms within the analog-digital categories. A few of the most common waveforms include:

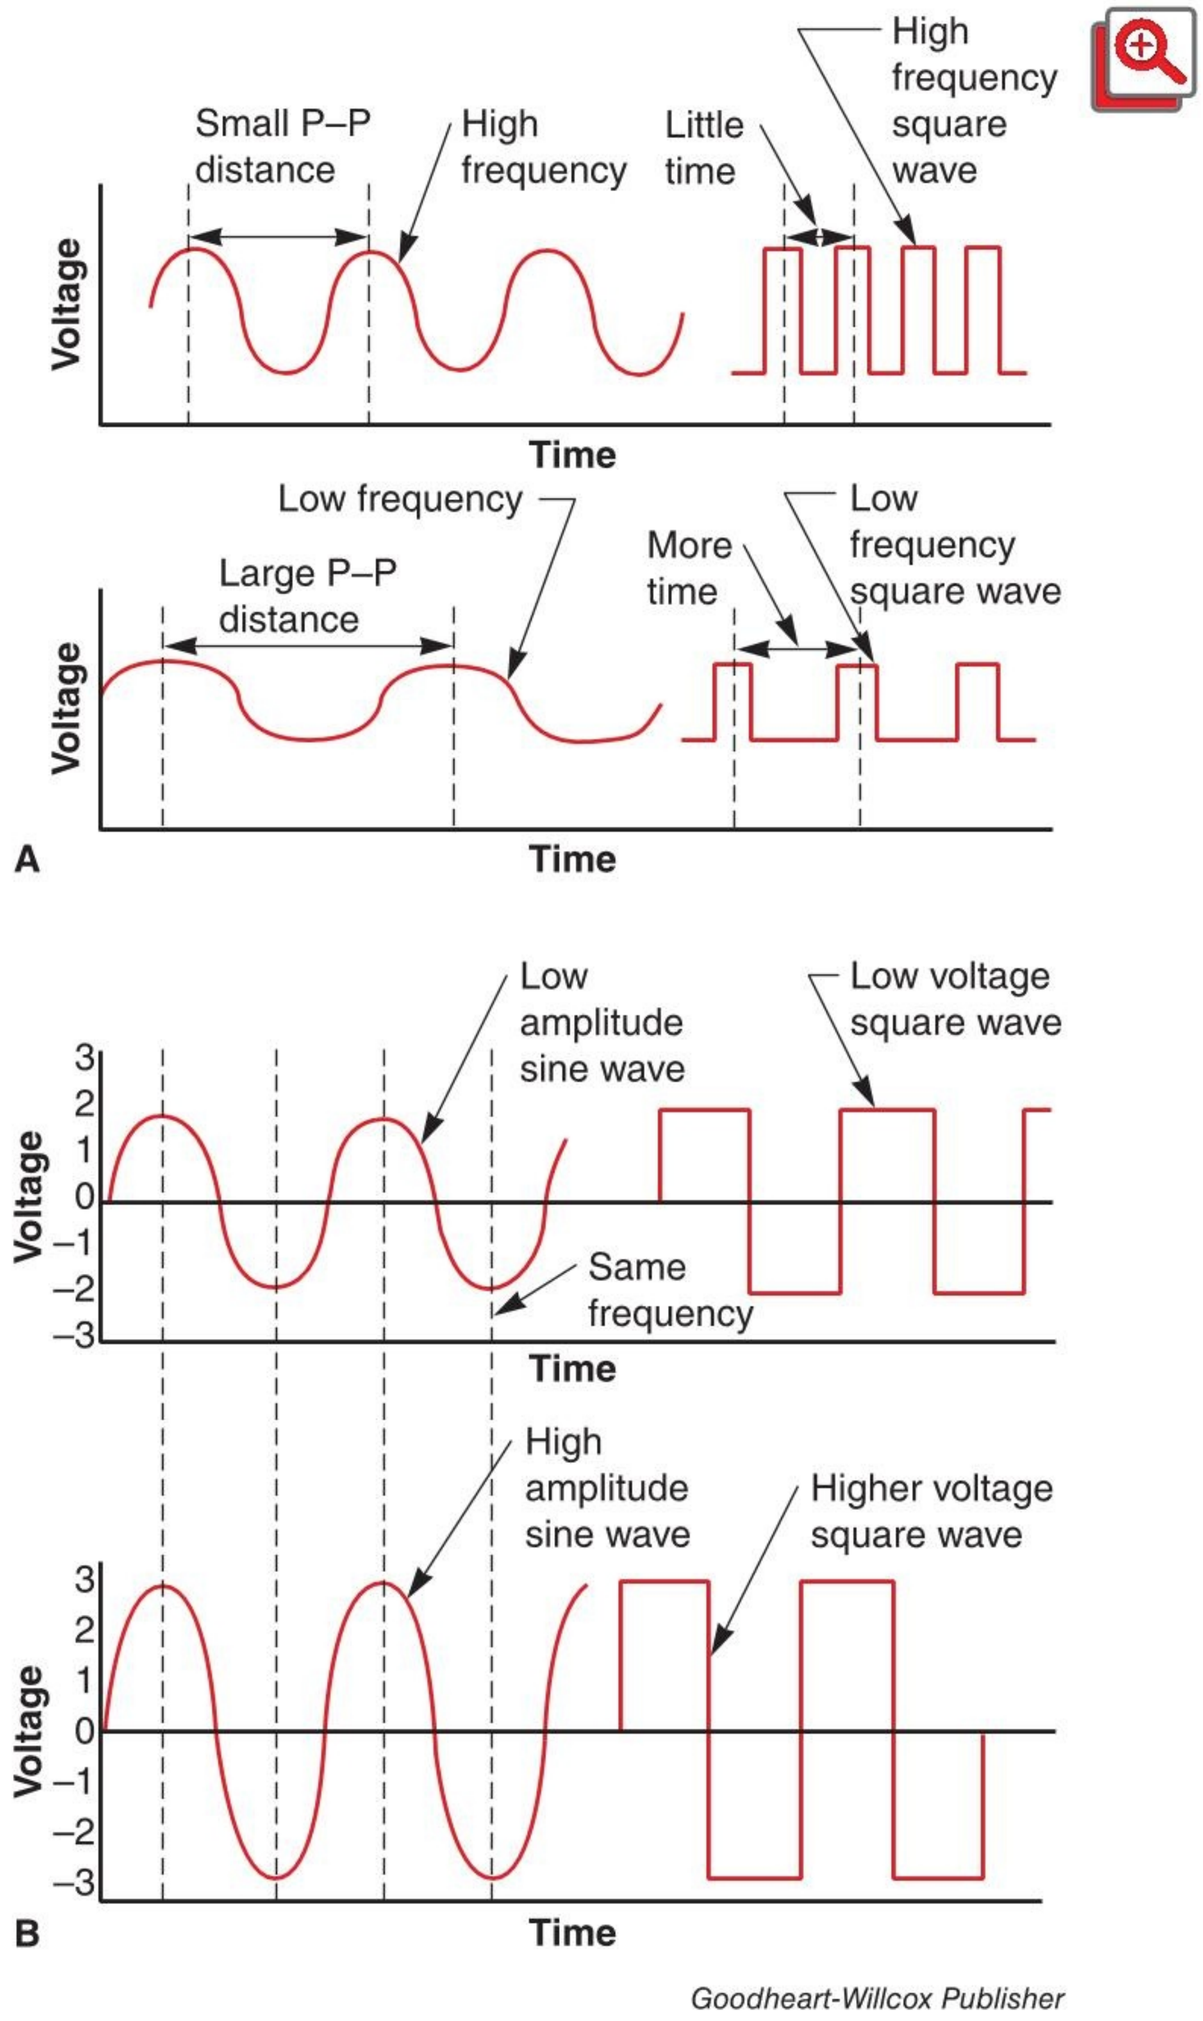
Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 23-10. Note how the speed sensors are operated by a crankshaft and camshaft trigger wheel. This lets the computer compare and adjust ignition timing and cam timing for maximum engine efficiency.

- AC sine wave—This wave is a curving signal that smoothly fluctuates above and below zero volts. The electricity in your home or inside an alternator would produce an alternating current (ac) sine wave at 120 V.
- DC sine wave—This type of wave is a curving, fluctuating signal that stays at or above zero volts. Most magnetic speed sensors produce a low-voltage sine wave on a test scope.
- DC square wave—This digital, on-off signal stays at or above zero volts. The computer converts dc sine waves from sensors into dc square waves for logic chips inside the computer.
- DC ramp wave—A wave that moves steadily up from zero and then switches off almost instantly is a dc ramp wave.
- Pulse wave—A pulse wave is a signal that rises progressively from zero and then almost instantly returns to zero.
- Complex sine wave—This signal voltage moves up and down erratically but gradually.
- Voice wave—A voice wave is an irregular wave that corresponds to the frequency of the human voice's airwaves. A microphone produces a weak analog wave proportional to the airwaves hitting the microphone.



Goodheart-Willcox Publisher

Figure 23-11. Scope patterns give you much more information about circuit operation than conventional voltmeter readings. A—Compare the differences in waveform frequencies. B—Note how the waveform amplitude, or voltage level, is denoted.

- DC noise wave—A dc noise wave is a straight line (dc) with some voltage fluctuations (noise). Noise is usually unwanted voltage spikes in a circuit and is caused by induced voltage from an outside source.

Computer Signal Terminology

There are several terms used to describe computer signals. Signal frequency, or ***pulse width***,

Copyright Goodheart-Willcox Co., Inc.

generally refers to how fast a voltage signal changes over time. The signal frequency from a sensor might be measured in milliseconds, or thousandths of a second.

A high-frequency signal would be very short (narrow), or have a short pulse width. A low-frequency signal would be longer (wider), or would have a long pulse width.

Signal amplitude refers to how much voltage is present in the wave. A high-amplitude signal would have more voltage than a low-amplitude signal. Most automotive computer systems use a signal amplitude of about 3–5 V.

Duty cycle is the percentage of *on* time compared to total cycle time. Along with pulse width, it can be used to measure a signal or pulse as a percentage. For example, if a solenoid is sent a 50% duty cycle, it will be turned on half the time and off half the time.

Computer System Operation

There are three stages of computer system operation:

- ***Input***—Vehicle sensors convert a condition into an electrical signal that can be used by the computer.
- ***Processing*** and ***storage***—The computer compares sensor inputs to data and operating parameters in its memory to determine what action should be taken to control the vehicle's control circuits. The computer can remember programming, as well as store trouble codes in its memory chips.
- ***Output***—The computer produces electrical outputs that are used to control solenoids, servo motors, relays, and other actuators. These actuators perform physical actions to alter component operation for maximum vehicle efficiency.

Computer System Block Diagram

A ***computer system block diagram*** is a simple service manual drawing that shows how the sensors, the actuators, and the computers interact. It uses basic squares or rectangles to represent components and lines to represent wires. A computer block diagram is handy when trying to find out what types of sensors are used and what conditions are controlled by a specific computer system. A block diagram for one computer control system is shown in **Figure 23-12**.

Sensors

Most ***vehicle sensors***, or transducers, change a physical condition into an electrical signal. ***Transduce*** means to change from one form to another. Just as our eyes, ears, nose, fingers, etc., can sense conditions, vehicle sensors can detect the operating conditions of a car or truck. The computers use the voltage signals from sensors to control the actuators.

Sensors can be found almost anywhere on a vehicle. Many are mounted on the engine. Others can be located on or in the transmission or transaxle, in the exhaust system, on the wheel hubs, on and in the fuel tank, on the suspension, or even in the trunk (impact sensor). If in doubt, refer to the service manual for the specific vehicle to find sensor types and locations, **Figure 23-13**.

Sensor Classifications

An automobile uses several types of sensors to provide electrical data to its many computers. There are dozens of specific names for vehicle sensors. However, they can all be classified into two general categories: active sensors and passive sensors.

An ***active sensor*** produces its own voltage signal internally. This very weak signal is fed back to the computer for analysis. ***Shielded wire***, which has a flexible metal tube around the conductor to block induced voltage and interference, is often used with active sensors.

A ***passive sensor*** is a variable resistance sensor. Voltage is fed to the sensor from the computer. The passive sensor's resistance varies with changes in a condition (temperature, pressure, motion, etc.). The computer can detect the resulting change in voltage caused by the change in resistance. Within these two categories are several sensor types:

- Variable resistor sensor—This type of sensor changes its internal resistance with a change in a condition; its ohms value may change with temperature, pressure, etc. It is an analog sensor. Examples of variable resistance sensors are throttle position and temperature sensors. A ***potentiometer*** is a variation of a variable resistor sensor. It has three external connections instead of two. One lead connects to each end of the resistor, and the remaining lead connects to a wiping arm that slides over the fixed resistor. This arrangement more precisely controls the current throughout than a two-connection variable resistor sensor.

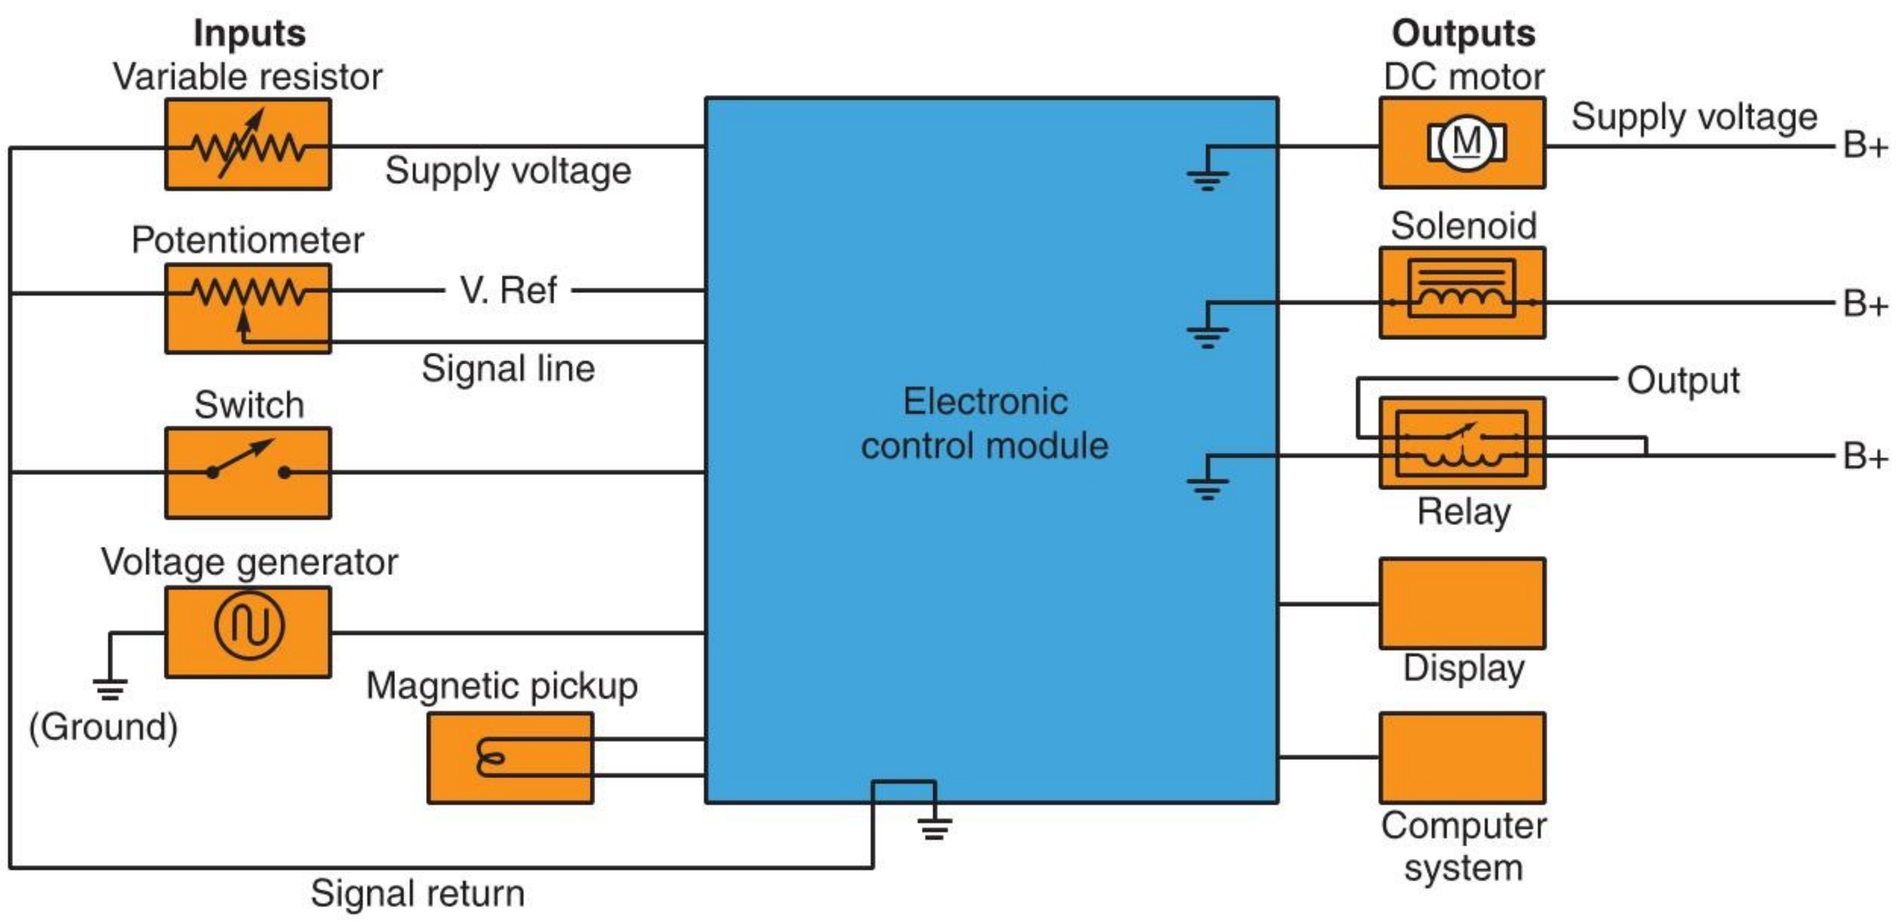
Figure 23-12. Study the block diagram for this computer system. Note the different modules and the various input and output devices.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 23-13. These are the basic classifications of input sensors and actuators. Each sensor feeds a different type of signal to the computer.

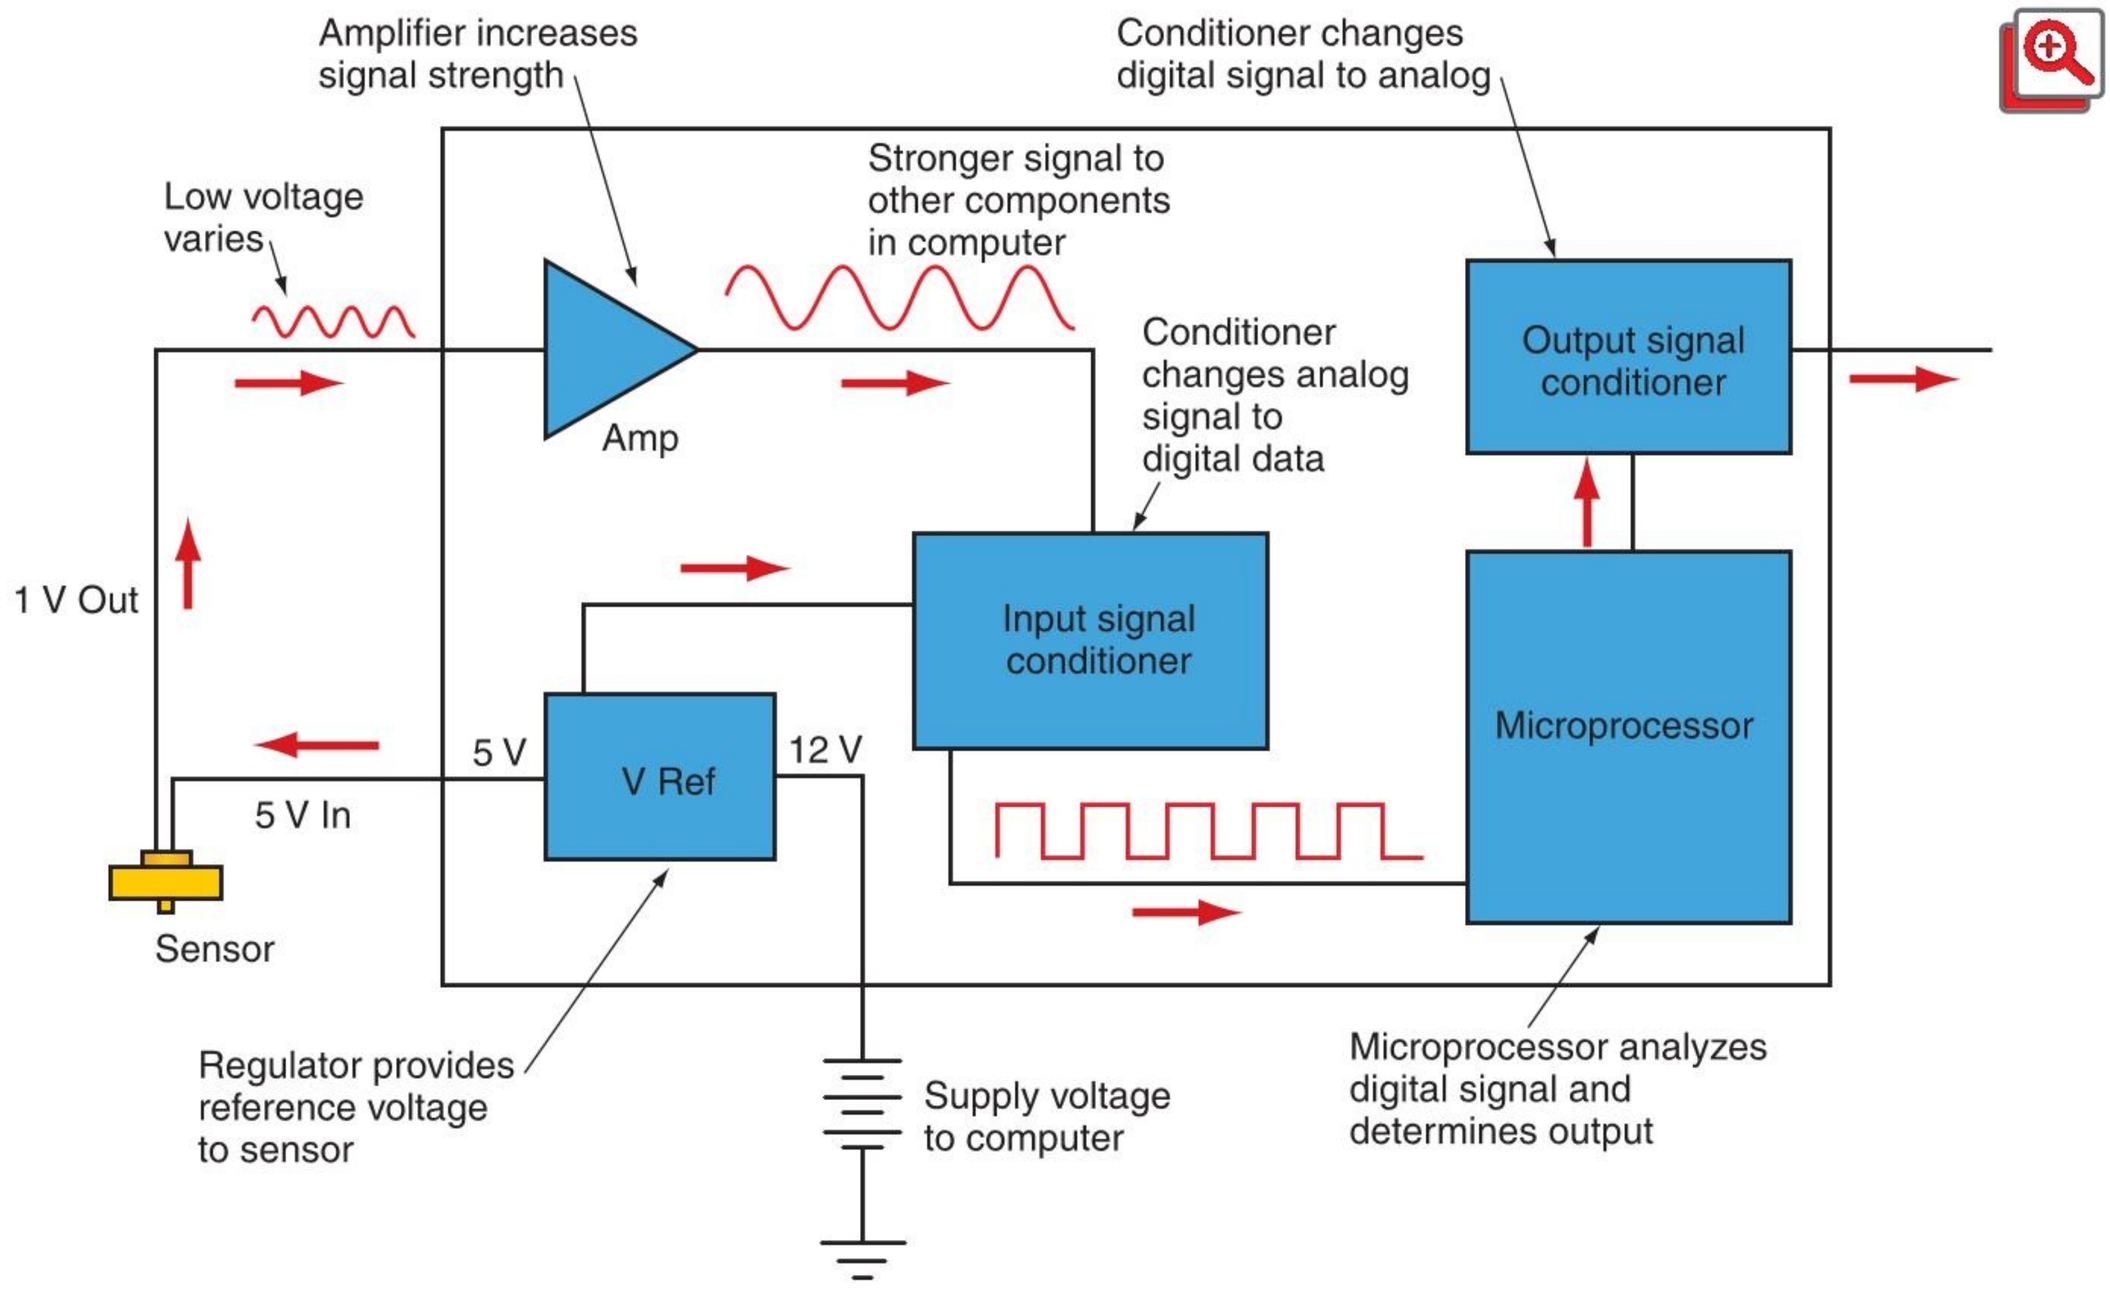
- Switching sensor—This type of sensor opens or closes the sensor circuit to provide an electrical signal for the computer. Transmission pressure switches are examples of this type of sensor. A switching sensor can detect almost any condition and produces a digital signal (either *on* or *off*).
- Magnetic sensor—A magnetic sensor uses part movement and induced current to produce a signal for the computer. This type of sensor is commonly used to monitor speed (vehicle speed sensor) or part rotation. It usually produces an analog signal. Magnetic sensors are also referred to as permanent magnet (PM) generators.
- Hall-effect sensor—This type of sensor uses a special semiconductor chip to sense part movement and speed. It produces a digital signal. These sensors are used as crankshaft and camshaft position sensors, as well as pickup devices in some electronic ignition distributors.
- Optical sensor—This type of sensor uses light-emitting diodes and photo diodes to produce a digital signal. Optical sensors may be used to sense part rotation and speed. These sensors are used in some distributors and as speed sensors mounted outside the speedometer.
- Knock sensor—This type of sensor generates voltage from a physical shock or motion on a crystal. It is sometimes used to listen to a condition, such as engine pinging upon rapid acceleration.
- Solar sensor—This sensor converts sunlight directly into an electrical signal. It is made of a semiconductor material that converts photons (light energy) into direct current.
- Direction sensor—This type of sensor detects the polarity of a moving magnet. This is a variation of a magnetic sensor. Unlike a magnetic sensor, it can signal which direction a part is rotating. It can produce signals for North, South, East, and West and is used in some navigation systems.

Reference Voltage

Reference voltage, sometimes abbreviated Vref, is the base voltage used to carry a computer signal. The computer sends a reference voltage to a passive sensor so a signal can be fed back for processing. A reference voltage is needed so a change in sensor resistance can be read by the computer as a change in current and voltage, **Figure 23-14**.

The reference voltage is typically around 5 volts. The computer steps down battery voltage so that a smooth, constant supply of dc voltage is fed to the passive sensors. The sensor alters the reference voltage by changing its internal resistance. This change in reference voltage is interpreted by the computer as a change in condition or state.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 23-14. A reference voltage of about 5 volts dc is sent out to the sensor. By varying the amount of voltage/current returning to the computer, the sensor gives data about an operating condition. Small amplifiers and conditioners treat this signal so it can be used by a microprocessor.

Sensor Types

The most common sensors used in late-model vehicles include the following:

- Intake air temperature (IAT) sensor—This sensor measures the temperature of intake air as it enters the intake manifold. The IAT is also called a manifold air temperature (MAT) or an inlet air temperature sensor.
- Engine coolant temperature (ECT) sensor—This sensor measures the temperature of engine coolant. In most cases, it is simply referred to as a coolant temperature sensor.
- Oxygen (O_2) sensors—These sensors measure the amount of oxygen in the engine's exhaust gases before and after the catalytic converter. Most newer sensors contain heaters and are referred to as heated oxygen sensors (HO_2S).
- Manifold absolute pressure (MAP) sensor—This sensor measures intake manifold vacuum in relation to a reference pressure (usually a vacuum).
- Barometric pressure (BARO) sensor—This type of sensor measures the outside air pressure around the engine. It is combined with the MAP sensor on most newer vehicles.
- Throttle position sensor (TPS)—This sensor measures the opening angle of the throttle valves to detect how much power is requested by the driver.
- Fuel pressure sensor (FPS)—A modern fuel pressure sensor threads into the fuel rail to monitor the amount of gasoline pressure available at the inlet of the fuel injectors. Some measure fuel pressure over time and can detect a leaking or clogged injector automatically.
- Engine speed sensor (ESS)—This sensor measures engine speed. It is often located next to a trigger wheel on the engine crankshaft snout. In older vehicles, it is located inside the distributor.
- Crankshaft position sensor—This type of sensor measures crankshaft position, rotation, and speed.

Copyright Goodheart-Willcox Co., Inc.

- Camshaft sensor (CS)—This sensor measures camshaft position, rotation, and speed so the computer knows the stroke of the engine (intake, compression, power, or exhaust).
- Mass airflow (MAF) sensor—This sensor sometimes measures the amount of intake air flowing into the engine. It is often referred to as an airflow sensor or an airflow meter.
- Knock sensor (KS)—A knock sensor is usually a piezoelectric sensor that detects engine pinging, preignition, or detonation so the ECM can retard ignition timing or reduce turbocharger boost pressure.
- Transaxle/transmission sensor—This sensor checks transaxle or transmission gear selection, oil pressures, part speeds, loads, and other functions. A neutral safety switch is a part of a safety circuit to keep the engine from starting when the transaxle/transmission is not in *Park* or *Neutral*.
- Brake switch—This type of sensor detects brake pedal application.
- Wheel speed sensors—These sensors measure wheel rotational speed for anti-lock brake, traction control, and hybrid drive systems.
- Oil level sensor—This sensor measures the amount of oil in the engine oil pan.
- EGR sensor—This type of sensor measures the position of the exhaust gas recirculation valve pintle.
- Impact sensors—These sensors detect a collision to shut off the fuel pump and engine. A similar type of impact sensor is used to deploy the air bag system.
- Vehicle speed sensor—This type of sensor measures the vehicle's road speed so the ECM can adjust fuel, ignition, transmission, suspension, and other system operations. It is located in the transmission/transaxle housing or as part of the electric drive train.
- Fuel tank pressure sensor (FTPS)—This sensor measures the pressure or vacuum inside the closed evaporative monitoring system. It is similar in construction and operation to a MAP sensor. If someone leaves the gas cap off the vehicle, the system will detect a pressure leakage to inform the driver with a trouble code.
- Battery temperature sensor—This type of sensor monitors battery temperature so the computer can adjust vehicle operation to affect charging system output as needed.
- Computer-mounted sensors—These sensors are tiny sensors wired inside a vehicle's computer. Yaw sensors, direction sensors, interior temperature sensors, and others can be located inside the computer itself.
- Hybrid drive circuit sensors—These sensors monitor HV battery temperature, generator output, HV battery charge, power control module output, motor-generator torque/speed, and other conditions.

Circuit Sensing

Circuit sensing involves using the computer itself instead of dedicated sensors to monitor component and circuit operation. The computer monitors current flow through various components and circuits. For example, some circuit sensing systems can monitor fuel injector operation (injector coil winding current), ignition coil action (current through ignition coil windings), and computer operation (current through computer circuits). The windings and the wires in the circuits serve as the sensors.

Tech Tip

For more information on computer system sensors and other components, refer to the index. More details of specific kinds of vehicle sensors are given in later chapters where this information is relevant.

Computers

The term *computer* is a general term that refers to any electronic circuit configuration that can use multiple inputs to find preprogrammed outputs.

Automobile manufacturers use many names for their computers, including:

- Central processing unit (CPU).
- Electronic control unit (ECU).
- Electronic control module (ECM).
- Engine control module (ECM).
- Electronic control assembly (ECA).

Copyright Goodheart-Willcox Co., Inc.

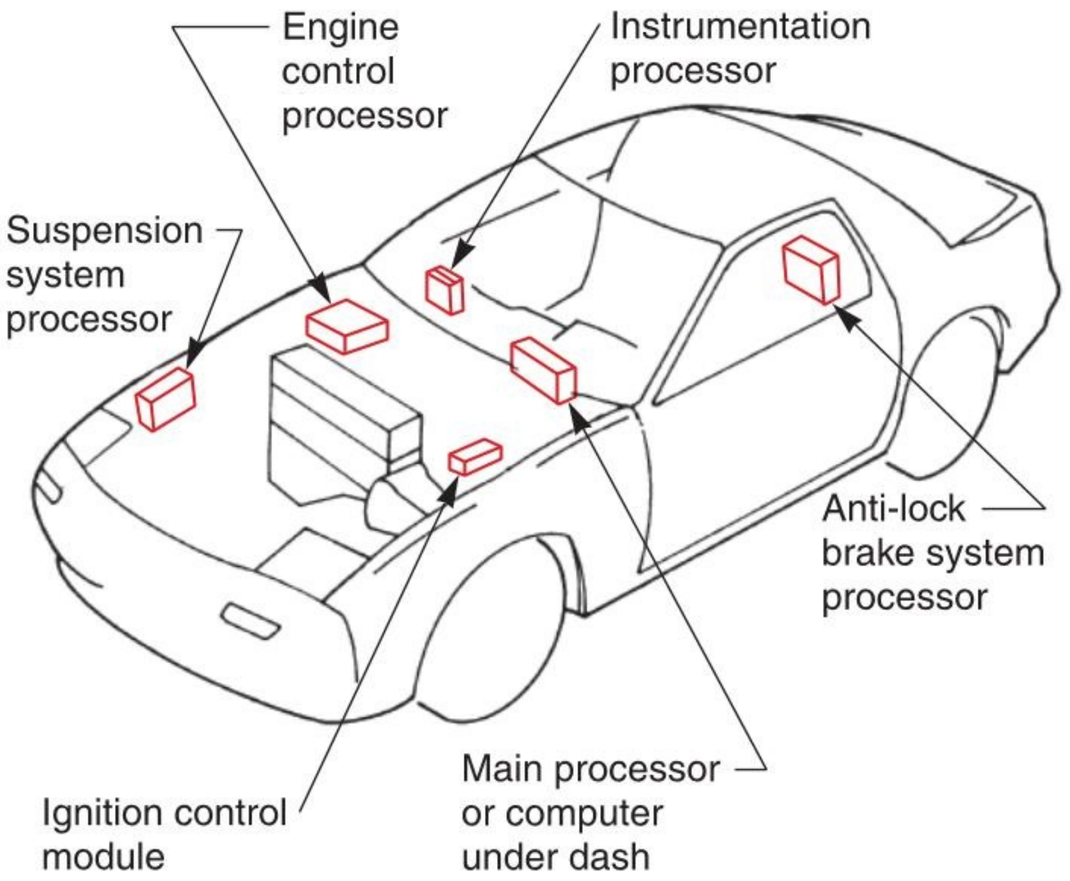
- Powertrain control module (PCM).
- Vehicle control module (VCM).
- Microprocessor.
- Logic module.

Keep these names in mind when reading service manuals. To prevent confusion, this textbook will use the term *control module* when referring to automotive computers in general.

Computer Locations

Automotive computers may be located under the dash on the passenger side of the vehicle. This protects the delicate circuits and components in the computer from engine heat, vibration, and moisture. However, computers, like the high-temperate electric drive train controller, can also be located in the engine compartment, in the trunk, or under the seats. See **Figure 23-15**.

When located in the engine compartment, the computer is closer to most sensors and actuators. Less wiring and fewer connectors are needed to tie the system together. Computers used to operate the anti-lock brakes and other systems are often found anywhere in the vehicle. Engine and powertrain control modules are located under the dash, in the engine compartment, or in another central location. Computers used with specific systems, such as the ignition or air conditioning systems, are close to, in, or under the system components.



Goodheart-Willcox Publisher

Figure 23-15. One or more computers can be used on the same car. Note the potential locations.

Computer Types

Several types of computers can be used in a car. The number and types of computers will vary with the manufacturer. The most common types are:

- Vehicle control module—This large, powerful computer processes data from sensors and other, less powerful control units. It coordinates engine, transmission, traction control, and anti-lock brake functions, and instrumentation, for example.
- Powertrain control module—This module is a powerful computer used to monitor and control the engine, transmission, and other systems.
- Engine control module—This computer uses sensor inputs to control engine idle speed, fuel injection, ignition timing, emission control devices, and other operating parameters.
- Anti-lock brake module—This small computer uses wheel speed sensor inputs and other inputs to control anti-lock brake application.
- Instrumentation module—This small computer uses sensor inputs to operate a digital dash display.
- Ignition module—This small computer uses sensor inputs to control ignition timing, spark plug firing, or ignition coil pack operation.
- Suspension system module—This small computer uses vehicle speed, suspension, and steering sensor inputs to control ride stiffness or shock absorber action.
- Climate control module—This small computer used to control the operation of the heating, ventilation, and air conditioning systems.
- Air bag module—This small computer controls the vehicle's air bag system. This electronic circuit also stores power to deploy the air bags in the event that battery power is severed and lost in a collision.
- HV power control module—This module consists of a set of electrical and electronic circuits that alter current and route it between the battery pack and motor-generator in a hybrid vehicle.
- Hybrid control module—This module controls the power control module and motor-generator to keep the battery pack operating at the optimum temperature and state of charge.
- Body module—This computer provides memory and other functions for the radio, driver's information center, electronic compass, trip computer, navigation, exterior and interior lights, etc.

Copyright Goodheart-Willcox Co., Inc.

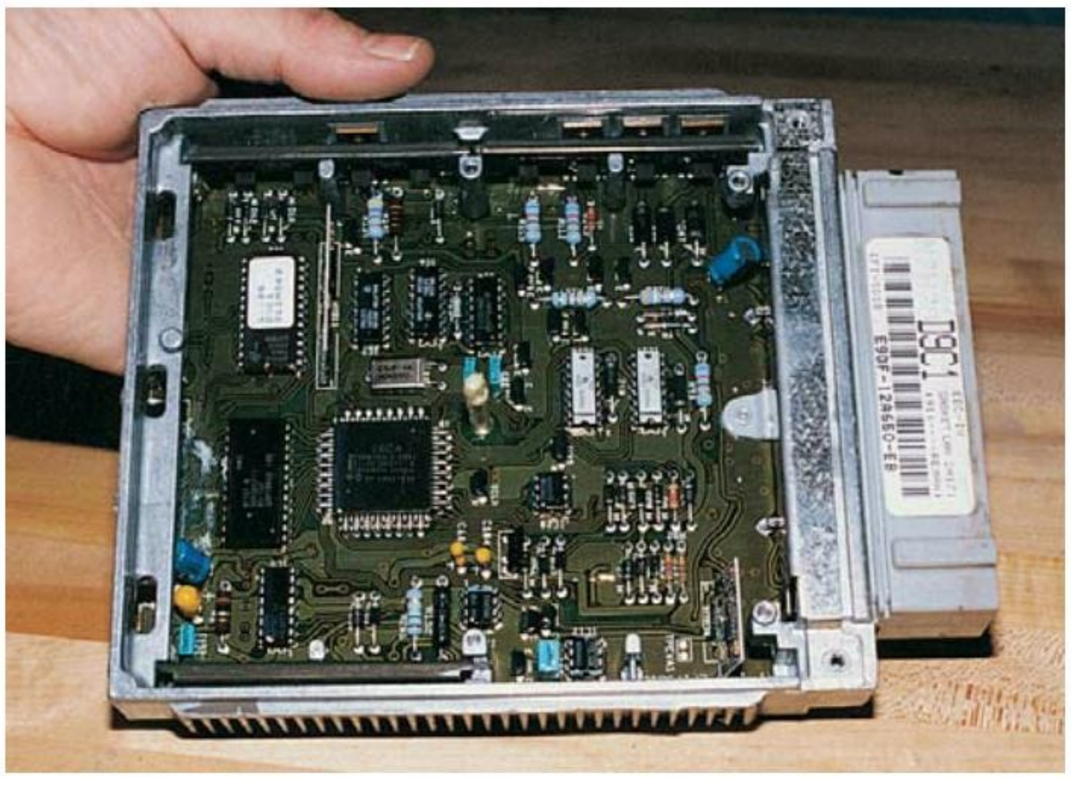
Again, the number and types of computers used will vary with the year, make, and model of vehicle. The trend is to use a body ECM and an engine control module ECM to process most of the input data and control most outputs for the vehicle. In conjunction with these computers, smaller computer modules are used for the brake system, suspension system, ignition, hybrid drive, and other circuits. Refer to the service manual to find out what types of computers are used on a specific vehicle and what each computer is called.

Tech Tip

A computer used to be nicknamed a "black box." This is because its mysterious electronic circuitry was enclosed in a box-shaped housing, sometimes made of black plastic or metal. Modern computers are still a mysterious marvel of electronic circuit complexity.

Computer Operation

This section will summarize the operation of a computer. Even though you will probably never repair a computer, it will be helpful to you as a technician to understand how a computer uses sensor inputs and produces actuator outputs using complex electronic circuits.



Goodheart-Willcox Publisher

Figure 23-16. This photo shows the inside of a computer. Note that it uses integrated circuits attached to a printed circuit board.

Figure 23-16 shows the inside of an automotive computer. It is composed of printed circuit boards, integrated circuits, capacitors, resistors, power transistors, and many other basic electronic components.

Parts of a Computer

Even though you may never see the inside of an ECM when you repair cars, this information will help you understand what is happening when you troubleshoot and reprogram automotive computers. All computers can be divided into sections that have specific functions.

The computer housing is a metal or plastic enclosure that protects electronic components from unwanted induced currents, moisture, and physical damage.

A circuit board is a plastic or fiberboard insulator with flat metal conductors printed on its surface to connect and hold components. A computer harness connector is a multi-pin terminal that attaches to the vehicle's wiring harness.

The computer's clock is an integrated circuit that uses a constant pulse rate to coordinate when or how quickly signals are sent throughout the complex circuits.

The microprocessor is usually the largest integrated circuit in a computer. The microprocessor analyzes data from sensors and compares it to known good operating values in memory. Memory chips store digital data. The microprocessor chip can then produce decisions or calculations for the proper output for actuators (fuel injector pulse width, ignition timing, throttle valve position, and other functions).

A ***voltage regulator*** converts battery and generator voltage into lower, cleaner dc voltage that can be safely used by the ECM circuits, dash displays, and sensors.

A computer amplifier simply strengthens various signals inside the computer. An amplifier might increase the voltage signal from the oxygen sensor, which is less than one volt. Then, the signal is strong enough to be used by circuits in the computer.

Conditioners, also called converters or interfaces, alter signals for use by other chips and circuits in the computer. An input conditioner alters the input from some sensors. It filters incoming data (voltage and current changes). For example, many sensor signals are analog. The conditioner can convert an analog signal into a comparable digital, square wave signal that the computer can understand. An output conditioner is needed to change digital signals back into analog signals for use by power transistors energizing actuators or other computers.

Copyright Goodheart-Willcox Co., Inc.

Both input and output conditioners protect the computer from shorted or grounded circuits. If a sensor, output device, or related circuit is shorted or grounded, the conditioner will not accept the signal and will open the circuit to protect the ECM circuitry from damage.

A ***buffer*** is a device that can serve as a temporary storage area for data. It can also protect internal computer chips from improper data. For example, if data is fed into the computer too quickly, the buffer can hold the data and then feed it into the other devices at a controlled rate. In many cases, the buffer is built into the input conditioners.

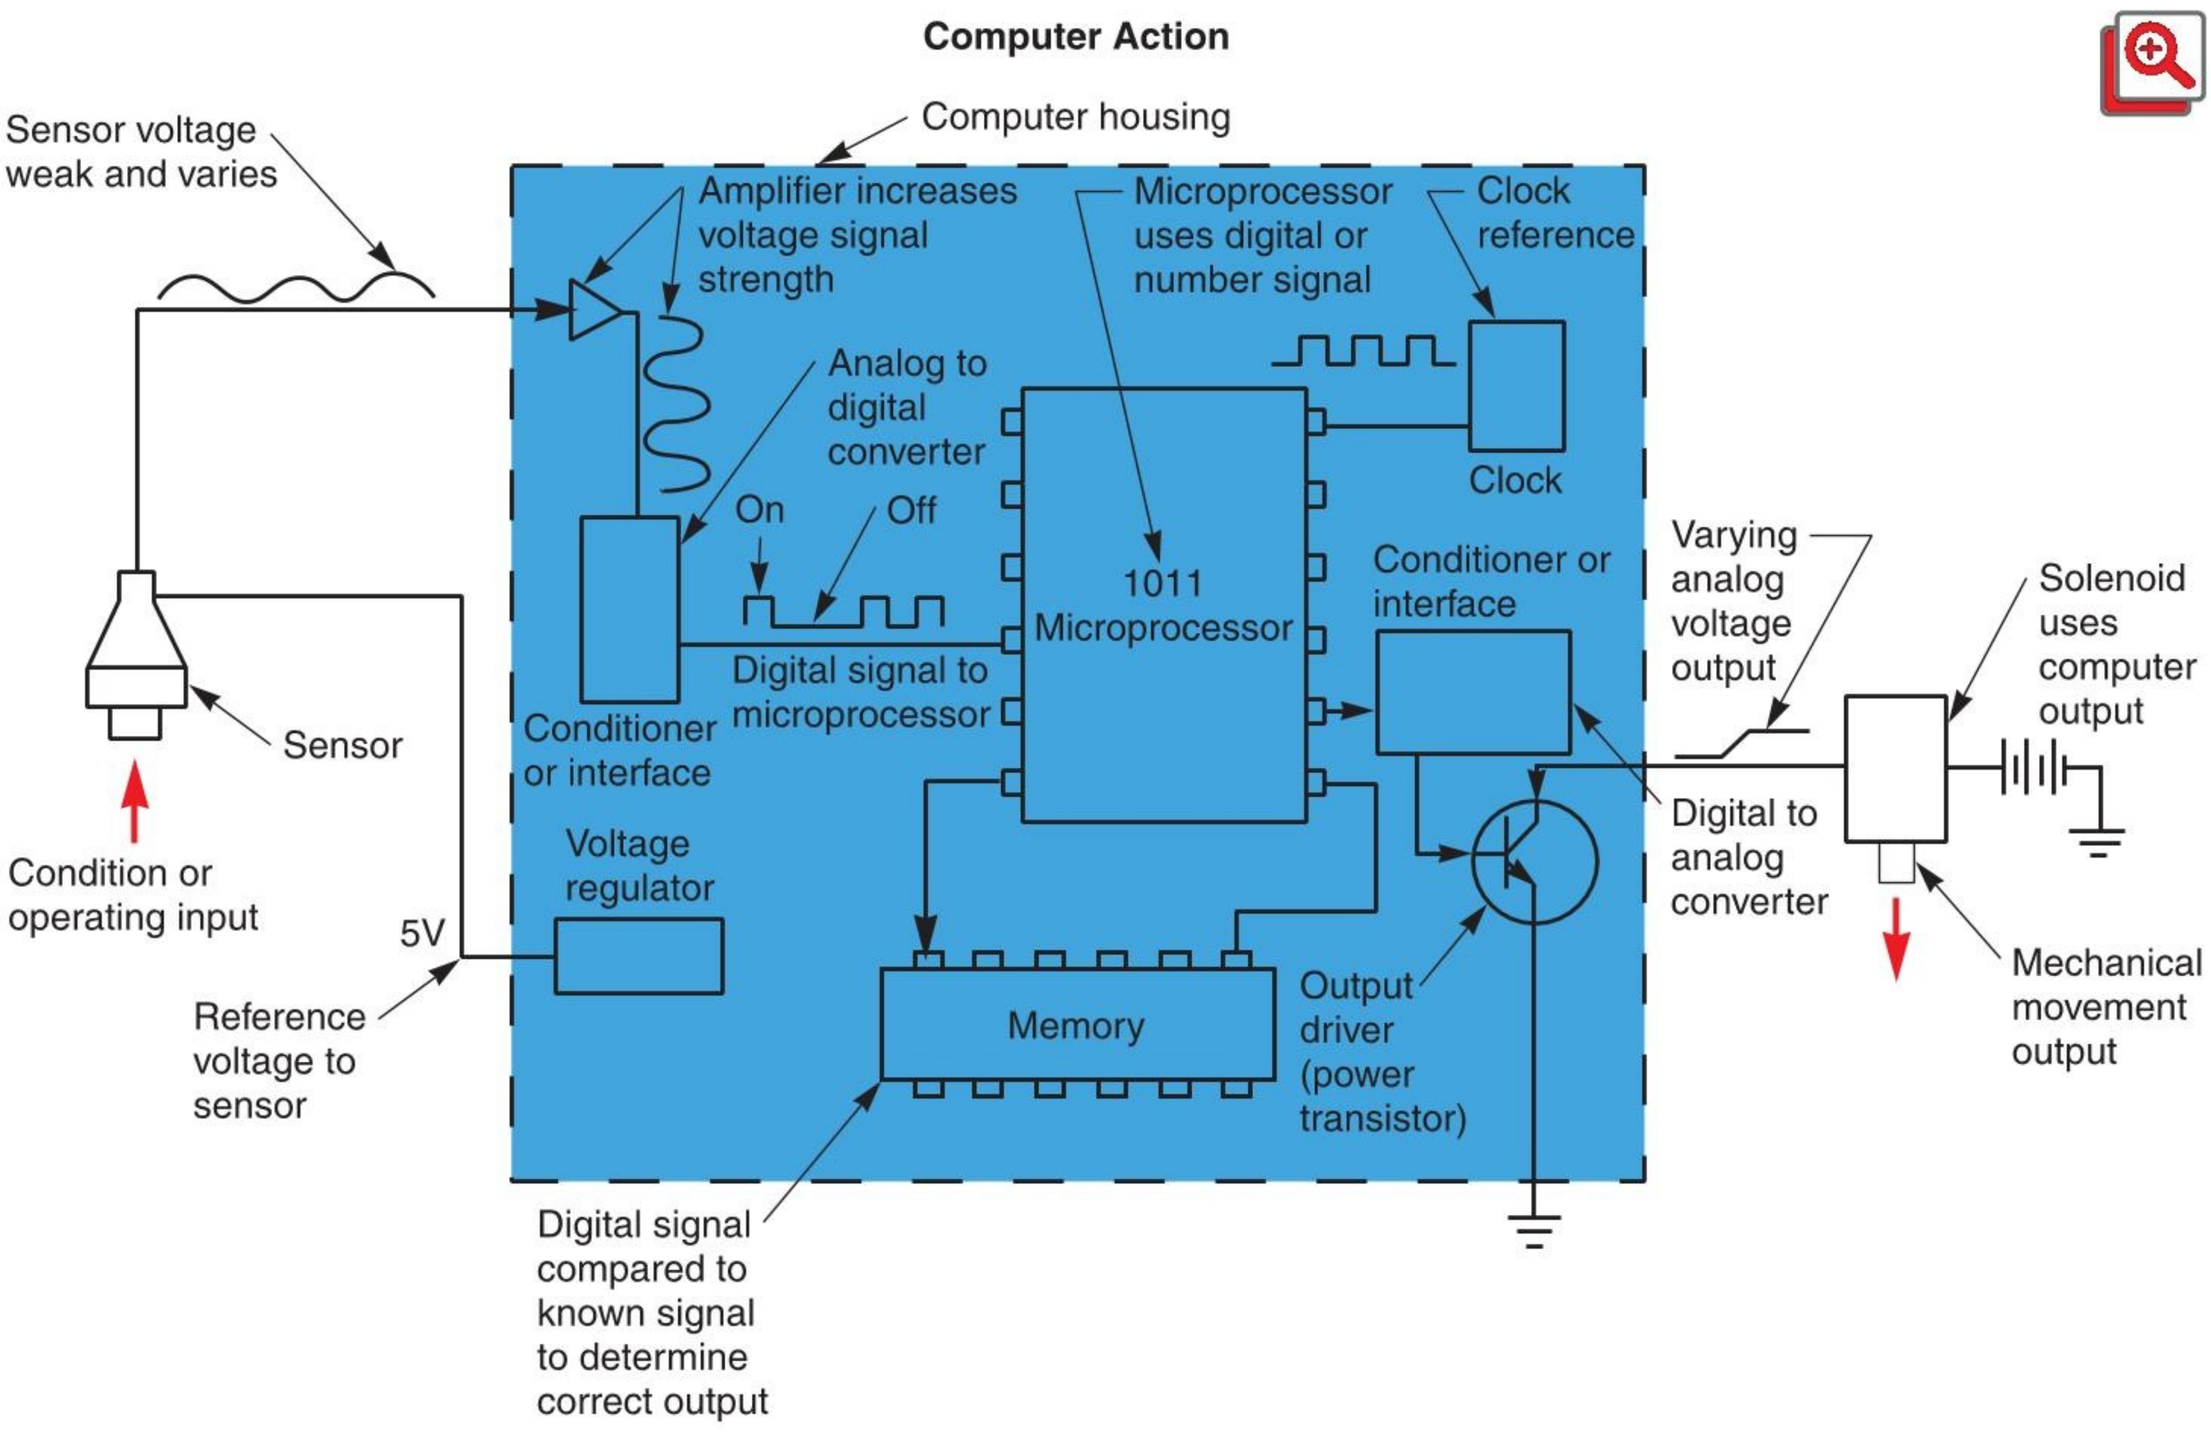
Computer memory stores data for the microprocessor. Trouble codes and vehicle-operating data are stored in memory.

Output drivers are power transistors that step up current by providing a ground path to operate actuators (fuel injectors, solenoids, servo motors, and other high-current devices).

Computer Microprocessor Operation

The term *microprocessor* means small (micro) computer (processor). A microprocessor is an integrated circuit capable of analyzing data and calculating appropriate outputs. It is the brain of a computer. See **Figure 23-17**.

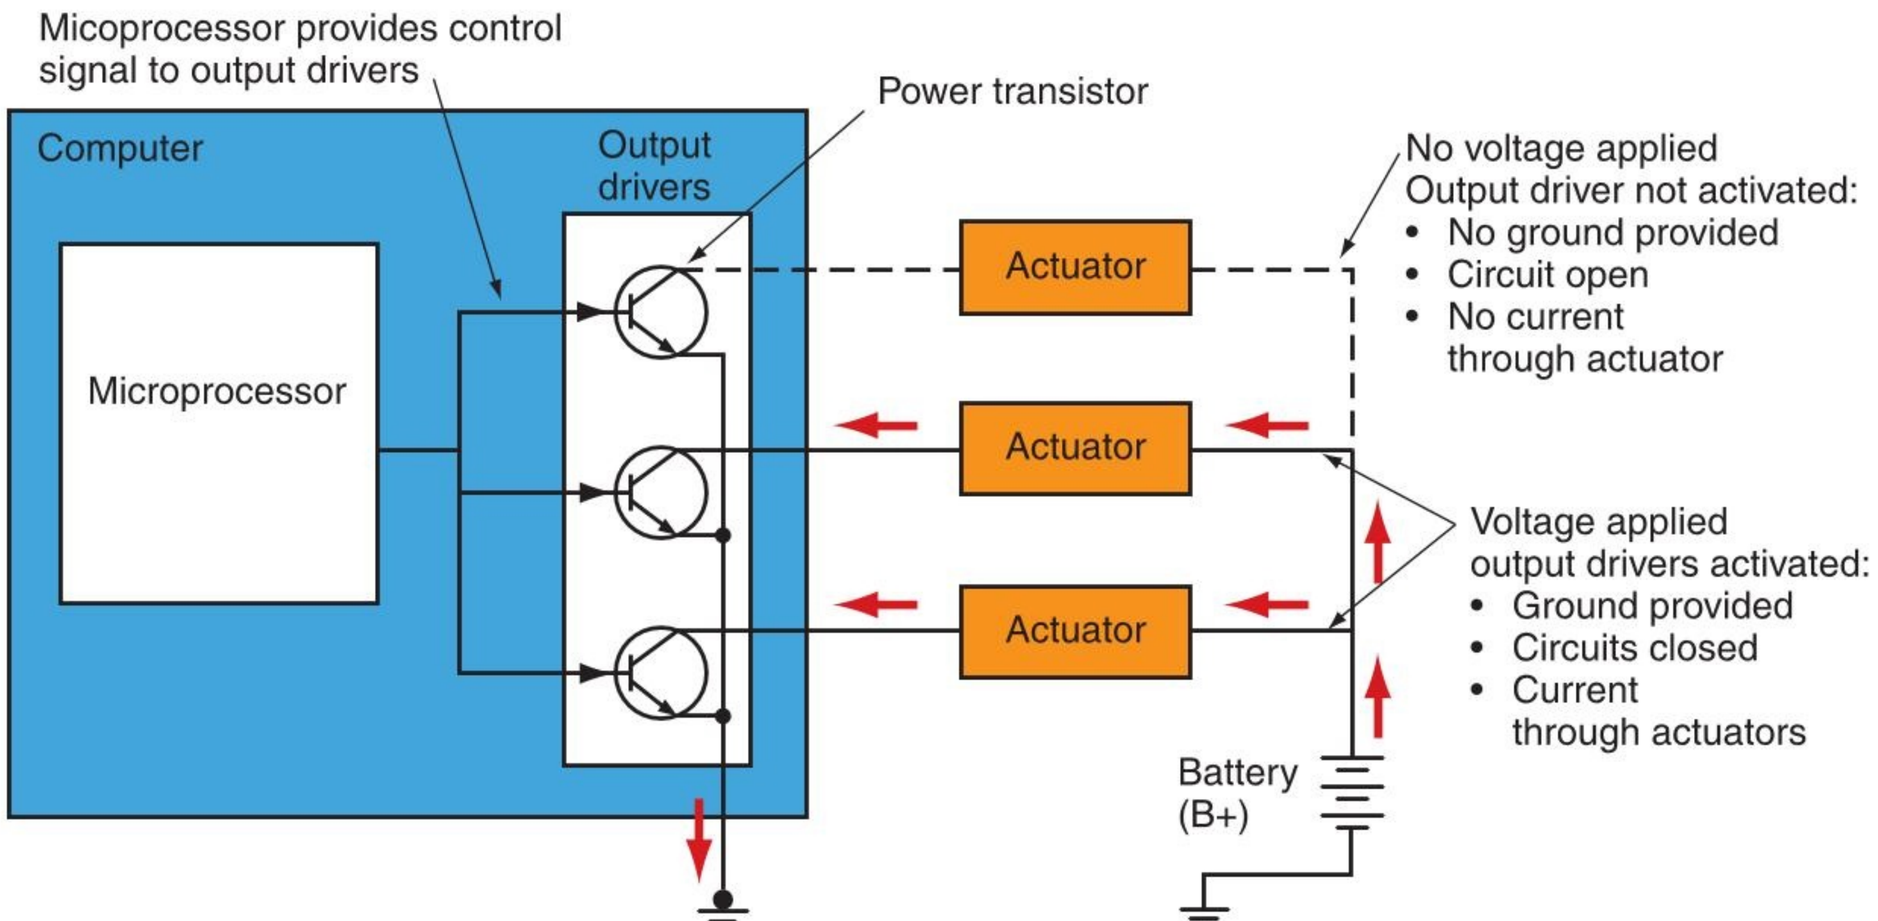
A microprocessor uses the binary number system to make decisions, comparisons, or calculations. Digital pulses from the conditioners are fed into the microprocessor. Since these inputs are off (0) or on (1) voltages, they can be used by the logic gates in the processor. A microprocessor also uses data stored in the computer's memory. It compares input signals to memory data to decide what the outputs should be for maximum efficiency. Refer to **Figure 23-18**.



Goodheart-Willcox Publisher

Figure 23-17. Trace the flow of data through this simplified computer system. Can you explain the purpose of each component?

Copyright Goodheart-Willcox Co., Inc.



Ford

Figure 23-18. A computer will normally activate each output by grounding its circuit. Power is present at the output devices at all times, but there is not a complete circuit path. When a computer's output drivers, or power transistors, are turned on, they will conduct current through ground to energize the output devices.

Tech Tip

The computers used on late-model vehicles have more computing power and memory than their predecessors. For example, computers used in late-model vehicles have 16- to 64-bit processors and large read only memory chips. The computers found in older vehicles contain 8-bit processors and smaller memory chips and are not powerful enough to monitor and control present-day vehicle systems.

Computer Memory Operation

Computer memory uses gates that are capable of storing data as voltage charges. The integrated circuits inside the memory chips will hold the data (*on* or *off* charges) until it is needed by the microprocessor. There are several basic types of computer memories:

- ***Random access memory (RAM)***—Random access memory is a memory chip used by the computer to store information or data temporarily. This data is erased if battery power to the computer is removed.
- ***Read only memory (ROM)***—Read only memory stores permanent data that cannot be removed from memory. This memory chip contains calibration tables and look-up tables for the general make and model car.
- ***Programmable read only memory (PROM)***—Programmable read only memory contains permanent data that is more specific than the data stored in ROM. The microprocessor can read from the PROM, but it cannot write to the PROM. A laptop computer with factory software is required to reset PROM chips. The PROM contains specific information about the vehicle's engine (number of cylinders, valve sizes, compression ratio, fuel system type), transaxle (shift points, gear ratios, etc.), weight, tire size, optional accessories, and any unique features. There are three types of PROM used in late-model vehicles:
  - ***Erasable programmable read only memory (EPROM)***—Erasable programmable read only memory can be changed. However, in most cases, the changes can only be made by the manufacturer using special equipment. This type of memory is also responsible for storing semipermanent data, such as odometer or mileage readings for an electronic dash display.
  - ***Electrically erasable programmable read only memory (EEPROM)***—Electrically erasable programmable read only memory can be altered by the technician in the field. This allows the manufacturer to easily change operating parameters if a performance or driveability problem is discovered.

Copyright Goodheart-Willcox Co., Inc.

- ***Flash erasable programmable read only memory (FEPROM)***—Flash erasable programmable read only memory is similar to EEPROMs in all respects. FEPROM is simply another name for an EEPROM.

Another type of memory found in some computers is known as ***keep alive memory (KAM)***. KAM allows the computer to have an adaptive strategy. An ***adaptive strategy*** is needed as parts wear and components deteriorate. The information stored in KAM allows the computer to maintain normal vehicle performance with abnormal inputs from sensors. It gives the computer the ability to also ignore false inputs to maintain good driveability.

The ECMs used on late-model vehicles use modified flash PROMs (high-speed programmable read only memory) that is permanently fixed to the circuit board but can be erased and reprogrammed quickly with a laptop.

On older vehicles, the PROM chip is removable. During computer replacement, the chip can be removed from the old computer and reused in the new computer. Data is retained in the PROM even when the chip is removed from the computer.

Output Drivers

Output drivers, sometimes referred to as quad drivers or power transistors, control current flow through the actuators. When energized by the computer, the drivers ground the actuator circuits. The actuators can then produce movement, such as turning the electric cooling fans.

Actuators

Mentioned earlier, ***actuators*** are the hands and arms of a computer system. They allow computers to do work and alter the operation of other components and systems.

Actuator Locations

Actuators can be found almost anywhere on a vehicle. They can be located on the engine, in the doors or dash, under the hood, and in the trunk. Check an appropriate service manual for exact actuator locations.

Actuator Classifications

A computer system uses several types of output devices, or actuators, to control part operation. All actuators can be grouped into the following categories:

- Solenoid
- Relay
- Servo motor
- Display devices
- Control module

A ***solenoid*** has tiny wire windings that form an electromagnet that moves a metal core or plunger when energized. The core movement can then act on other components, such as a fuel injector valve, throttle valve, or door locks.

A ***relay*** is another actuator that reacts to a small control signal from the computer to control a much higher current flow to large components or systems, such as the starting motor, air conditioning, or headlights.

A ***servo motor*** is a very small dc motor actuator that can produce a rapid spinning motor when energized by a relay or main computer. A common use for a servo motor is to control engine idle speed by opening or closing a small air passage into the engine intake manifold.

Electronic ***display devices*** include vacuum-fluorescent, liquid-crystal, and plasma displays to provide output information in the dash instrument cluster(s).

A control module is a small, specialized computer that reacts to input data to control other devices or circuits. The control module often amplifies and/or modifies the input signal to operate actuators by grounding their circuits. An ignition control module is a very common type. An ignition control module operates the ignition coils so high-voltage pulses are sent to the spark plug electrodes. When the hot electric arcs jump across the air gap at each spark plug, combustion begins to operate the engine.

Actuator Operation

When a computer turns on an actuator, it normally provides the device with a ground circuit. Then, current flows through the actuator itself, and the frame ground can operate the actuator. The following sections detail the operation of the three most common actuator types: solenoids, relays, and servo motors.

Figure 23-19 shows how the computer can use a solenoid to lock the vehicle's doors once a certain road speed is achieved. Input from the vehicle speed sensor enters the computer. When the computer detects vehicle travel or forward motion, it grounds the solenoid circuits and current flows through the solenoid windings. This produces a magnetic field in the windings. The magnetic field moves the plunger mounted in the solenoid windings. This plunger move-

Figure 23-19. Simplified illustration of how sensor inputs can be used by the computer to operate solenoids. When the vehicle speed sensor produces a signal, the computer grounds the door lock solenoid. The solenoid movement is used to lock the car doors automatically.

ment locks the doors.

A relay is often used as an actuator when a high-current load must be controlled by the ECM. The ECM will simply ground the relay coil windings. Then, the relay coil field will pull the mechanical contacts closed, allowing a large current to flow to the load, **Figure 23-20**.

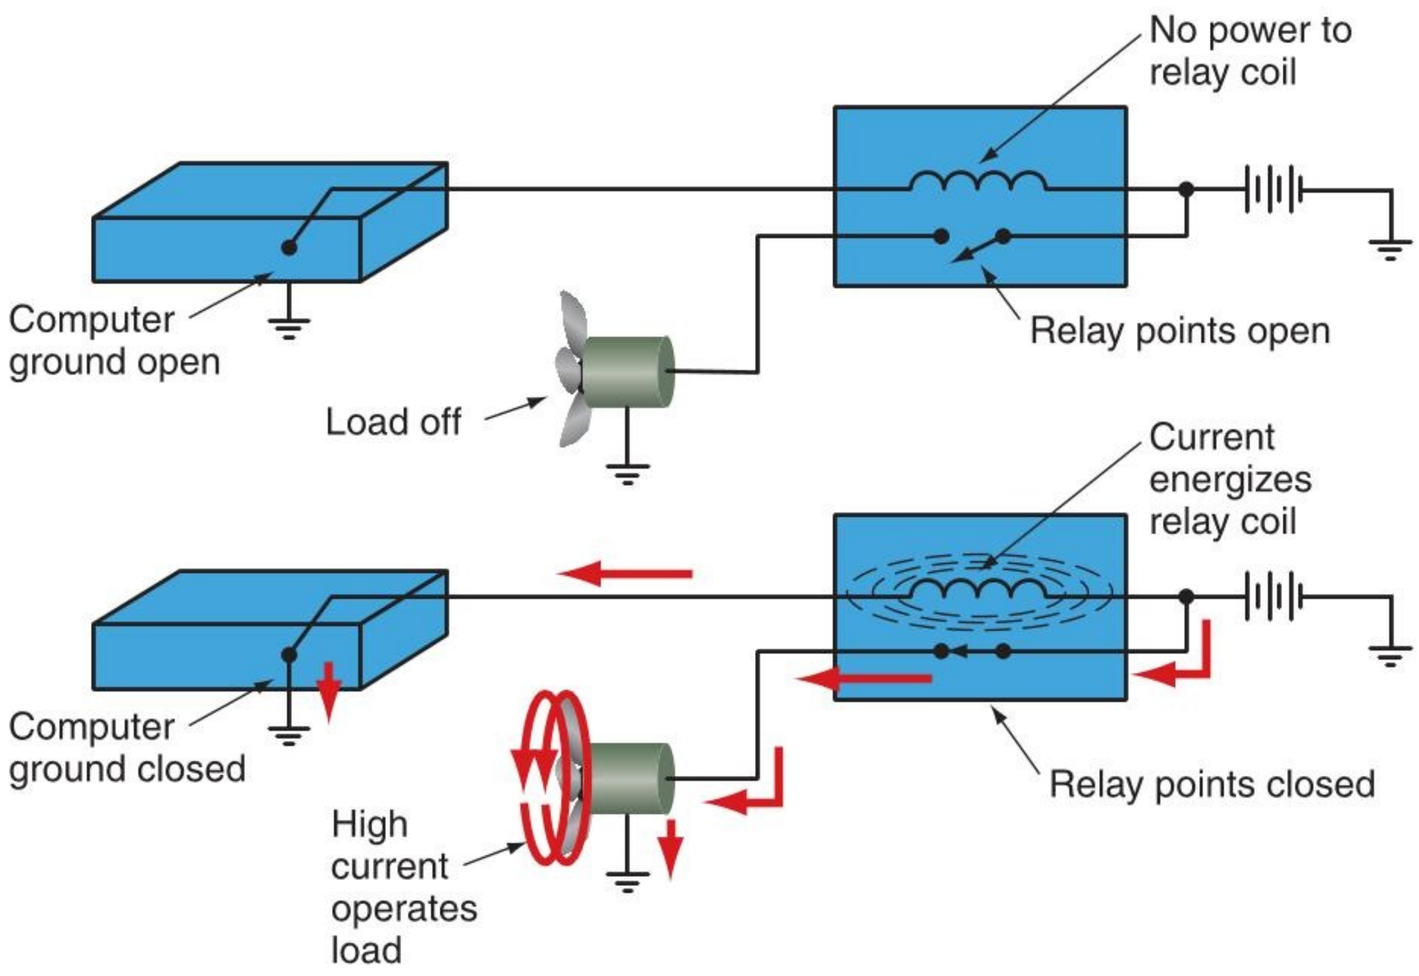
A servo motor provides another way for the ECM to produce an output. The ECM can ground the motor circuit, turning the motor on or off or reversing motor rotation as needed.

Sometimes, the servo motor is simply a reversible dc motor. The motor will turn a threaded mechanism to produce a controlled movement of a part. A good example would be an idle speed motor. Note that some motors also serve as sensors for the computer. They can inform the computer as to their positions. Look at **Figure 23-21**.

Specific Actuators

Some common actuators used on late-model vehicles include the following:

- Fuel injectors—A fuel injector is basically a solenoid valve that controls fuel flow into the engine.
- Fuel pump—An electric fuel pump is a small motor and impeller that forces fuel out of the gas tank and to the engine.
- Idle air solenoid—An idle air solenoid controls airflow into the engine to help control idle speed.
- Idle speed motor—An idle speed motor is a small



Goodheart-Willcox Publisher

Figure 23-20. A relay can also serve as an actuator to control high current. Low-voltage computer control current is used to close the relay points. Then, high current flows to the load.

Figure 23-21. A servo, or stepper, motor can be stopped in an exact position. The computer can energize specific coils to attract and stop the armature next to the energized coils.

reversible dc motor that opens and closes the engine throttle valve to control idle speed.

- EGR solenoids—EGR solenoids open and close small ports to control exhaust gas flow back into the engine to control emissions.
- Canister purge solenoids—Canister purge solenoids control vacuum flow to draw fuel vapors into the engine for burning to reduce emissions.
- Door lock motors or solenoids—Door lock motors or solenoids move latch mechanisms to lock or unlock the car doors.
- Electric seat motors—Electric seat motors are reversible dc motors that move the seat into the desired position.
- Ignition coil—An ignition coil uses high current flow to change low voltage into the high voltage that operates the spark plugs.
- Ignition module—An ignition module is an electronic circuit that uses computer signals to control the operation of the ignition coils and spark plugs.

Computer Networks

A ***computer network*** is a series of computers that control different systems but work together to improve overall vehicle efficiency. Also called an integrated computer system, the network allows all the on-board computers to use feedback data from several systems (engine, transmission, braking, suspension, and traction control, for example) to better control all vehicle systems. The term used to describe this computer interaction in vehicles is ***multiplexing***. Multiplexing binary signals between computers avoids the duplication of components, it speeds electronic communication, and it reduces the amount of wiring needed in the vehicle's wiring harnesses.

The computers in the network share common parts, such as wires, input signals, and output signals. They exchange data from sensors to prevent duplication of parts and to reduce wiring.

The wiring used for the network is often referred to as a ***data bus***. The signals traveling through the data bus are coded to indicate which computers the signals are being sent to, and in what order the signals should be processed. This prevents the signals from being processed by the wrong computer or in the wrong order.

Each computer and system needed for vehicle operation has its own default operating or limp-in mode, so the vehicle can be driven home or to a shop for service.

In the near future, fiber optics, which uses light to transmit data, may form the network connections. This will allow faster and simultaneous transmission of data from each computer.

Serial/Parallel Network Communication

Communication between ECMs in a network can be classified as either serial or parallel. ***Serial communication*** uses only one wire to exchange digital data. In this setup, data is transferred one bit at a time. ***Parallel communication*** involves the use of several wires to exchange multiple bits of data simultaneously. See **Figure 23-22**.

ECM Information Flow

There are several ways that vehicle ECMs communicate or talk with one another. In a ***star configuration***, one main processing ECM and several less complex ECMs work as a network. The smaller ECMs cannot communicate with each other unless data is first sent through the main processing ECM.

The ***bus configuration*** has several of the vehicle's ECMs wired to a single conductor, or bus. No main processing ECM is used.

A ***ring configuration*** has each ECM wired in series, or in a loop. The signal-transmitting ECM's data flows through each ECM and then back to the source ECM. Again, no main processing ECM is needed. Refer to **Figure 23-23**.

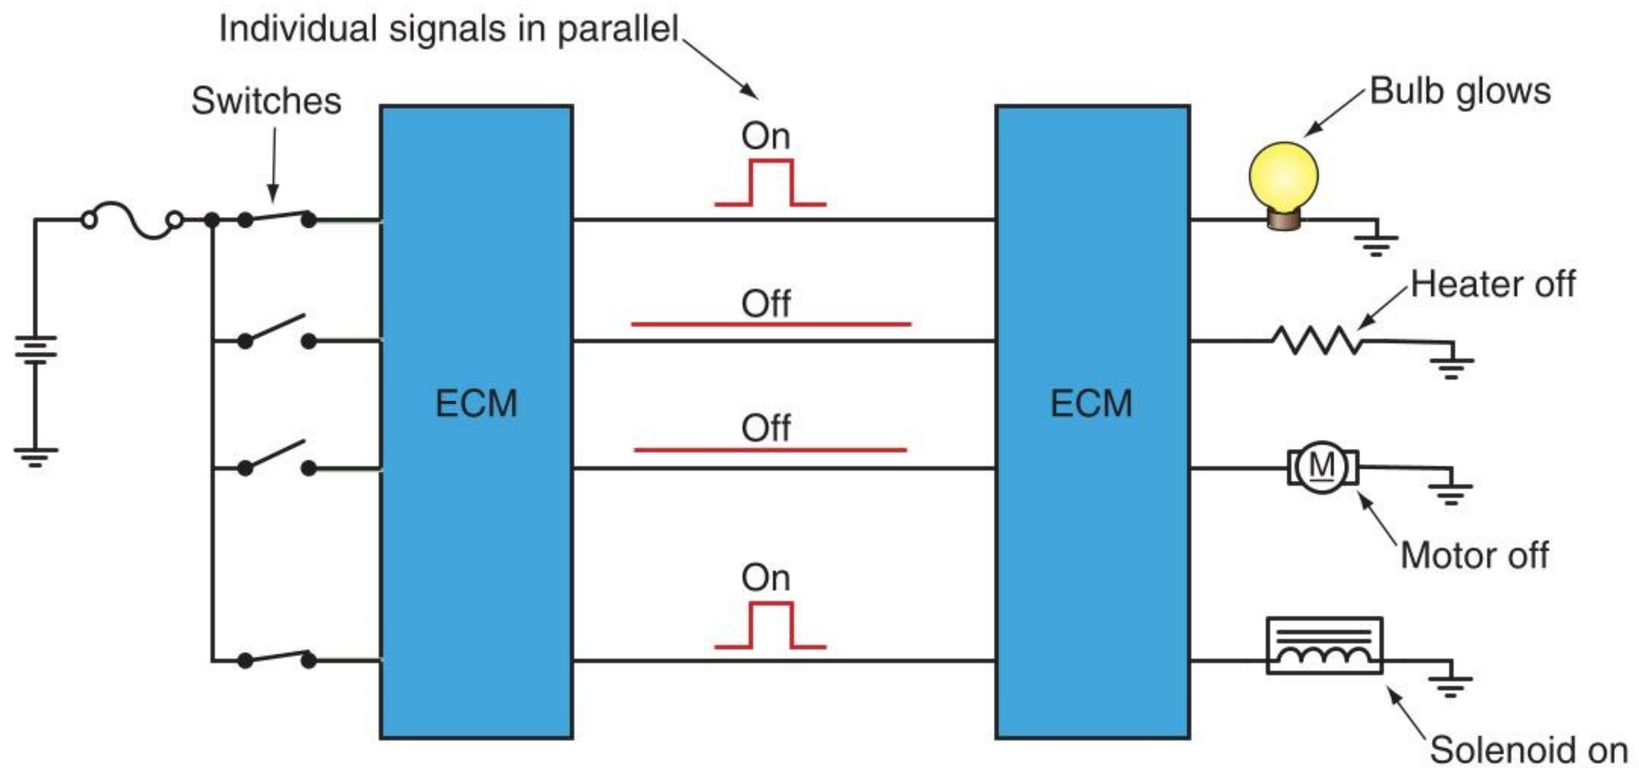
A **Serial (Multiplexed) Communication**



B **Parallel Communication**

Goodheart-Willcox Publisher

Figure 23-22. A multiplex communication system has several computers working together to improve overall vehicle efficiency. The computers in the network share a common wire or wires that carry digital data through the network or multiplex.

Network Wiring

There are two basic types of conductors used in a vehicle ECM network to carry data between different components: single-wire conductors and twisted-pair conductors.

A ***single-wire conductor*** is a conventional insulated wire that carries data signals between computers. The insulation in a single-wire conductor may be covered by a braided metal shield to protect the conductor from electromagnetic interference.

A single-wire conductor is the smallest, lightest type of conductor used to provide communication between computers in different vehicle systems. It is adequate for vehicle systems that do not affect vehicle performance and safety, such as the accessory system.

Twisted-pair conductors consist of two insulated wires that are wound, or twisted, into a spiral. Twisting the wires together helps cancel out electromagnetic interference from external sources. Twisted-pair conductors can carry computer data faster than single-wire conductors.

Twisted-pair conductors can be unshielded or shielded. Unshielded twisted-pair conductors are ideal for high-speed communication between computers when the conductor is away from strong sources of electromagnetic interference or when it is located inside a metal body structure of the vehicle.

A ***shielded twisted-pair conductor*** is encased in a metal shield to further reduce electromagnetic interference. Shielded twisted-pair conductors must be used near high-voltage sources in the vehicle, such as the ignition coils or hybrid power cables. If an unshielded conductor is routed near a high-voltage source, current can be induced in the conductor and affect computer communication.

A ***differential voltage signal*** is used with twisted-pair conductors. A differential voltage signal consists of two complementary digital signals with opposing polarities. One of these signals is sent through each wire

Goodheart-Willcox Publisher

Figure 23-23. Study network styles.

of the twisted pair. The differential voltage signals are synchronized to strengthen the low-voltage communication signals flowing between computers. The signals are combined when they reach their destination.

CAN and LIN Systems

A ***CAN***, or ***controller area network***, is a specific type of high-speed computer data bus. Several computers and sensors can use CAN bus wiring at the same time. Each computer in a CAN system has the ability to send and receive signals. Each CAN signal carries markers that denote where the signal originated, what type of information it contains, the priority of the information in the signal, and the actual information or message.

The signal from one computer in a CAN system is sent to all other computers in the network. Each computer decides whether or not to process the signal based on its marker.

Tech Tip

Starting with the 2008 model year, the diagnostic systems in all new vehicles are CAN compliant.

A ***LIN***, or ***local interconnect network***, is a data bus system that is designed to work in conjunction with CAN. It operates at a relatively low speed and is less expensive to manufacture than CAN. LIN is ideally suited for sensor and actuator networking applications for body control systems, such as climate control, lighting, and door control (power windows, locks, and mirrors). While CAN may be used throughout the vehicle, LIN would be used in one section, such as inside a door. A special CAN-LIN bridge must be used to connect the LIN to the CAN system.

In the Rearview Mirror

In response to the Clean Air Act of 1977, manufacturers began producing "self-adjusting" engines. These engines, which were introduced in 1981, were equipped with feedback fuel-control systems. Early feedback systems consisted of an oxygen sensor to measure the oxygen content in the exhaust gases (an indication of air-fuel ratio), a small computer to analyze the oxygen sensor signal, and a mixture control device to make air-fuel ratio adjustments based on the computer's output signals. These simple systems were the predecessors to the powerful, complex computer systems found on today's vehicles.

Summary

- A computer is a complex electronic circuit that will produce programmed electrical outputs after receiving specific electrical input signals.
- The term *cybernetics* refers to the study of how electrical-mechanical devices can duplicate the action of the human body.
- The binary numbering system uses only two numbers, zero and one, and is the key to how computers and ECMs operate.
- A gate is an electronic circuit that produces a specific output voltage for given input voltages.
- An integrated circuit is an electronic circuit that has been reduced in size and placed on the surface of a tiny semiconductor chip.
- Digital signals are on-off signals, like those produced by a rapidly flipping switch.
- An analog signal changes in strength (voltage, current, and/or resistance).
- A computer signal, waveform, or wave is a voltage variation over short periods of time.
- A vehicle sensor is a transducer that changes a condition into an electrical signal.
- The computer sends a reference voltage to passive sensors so that a signal can be fed back for processing.
- Circuit sensing involves using the computer itself instead of dedicated sensors to monitor component and circuit operation.
- Output drivers control current flow through the actuators.
- A microprocessor is an integrated circuit capable of analyzing data and calculating appropriate outputs.
- Computer memory uses gates that are capable of storing data as voltage charges.
- The three basic types of computer memory are RAM, ROM, and PROM.
- Actuators allow the computer to alter the operation of other components.
- A computer network is a series of computers that control different systems but work together to improve overall vehicle efficiency.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

Activities

1. Use the Internet to research CAN systems in modern cars.
2. Look up a specific make and model vehicle with our shop's computer service software. Research the number and names of the electronic control units (ECUs) used on this vehicle. Note their locations and wiring diagrams.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Define the term *cybernetics*.
2. The binary numbering system uses only _____ and _____ and is the key to _____.
3. Describe the five basic types of computer gates.
4. Name and describe the two general sensor classifications.
5. An active sensor requires a reference voltage. True or False?
6. Typically, a reference voltage is about _____.
7. Explain seven types of computers used on a car.
8. What is an EPROM?
9. What is meant by the term *adaptive strategy*?
10. _____ are the hand and arms of a computer network.

ASE-Type Questions

1. Technician A says the term "cybernetics" refers to the study of how chemical-mechanical devices can duplicate the action of the human body. Technician B says the term "cybernetics" refers to the study of how electrical-mechanical devices can duplicate the action of the human body. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Which of the following are known as the "linking cells" of the human brain?
   (A) Neutrons.
   (B) Neurons.
   (C) Protons.
   (D) None of the above.
3. The advantages of computers in late-model vehicles are being discussed. Technician A says computers can compensate for mechanical wear. Technician B says computer systems have on-board diagnostic systems that can detect and record system problems. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says digital electronics deals with the way an alternator charges a battery. Technician B says digital electronics deals with the way a computer system uses discrete on and off signals to produce artificial intelligence. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Technician A says the numbers 1 and 2 are used in the binary numbering system. Technician B says the numbers 0 and 1 are used in the binary numbering system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says in computer language a 0 or 1 is called a byte. Technician B says in computer language a 0 or 1 is called a bit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says the term "gate" refers to an electronic circuit that stops current from flowing in a particular direction. Technician B says the term "gate" refers to an electronic circuit that produces a specific output voltage for given input voltages. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

8. Technician A says an AND gate requires voltage at both inputs to produce a voltage at the output. Technician B says an AND gate requires voltage at only one input to produce a voltage at the output. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says both inputs of a NAND gate must be *on* to produce an output. Technician B says both inputs of a NAND gate must be *off* to produce an output. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says an IC is an electronic circuit that has been reduced in size and etched on the surface of a semiconductor chip. Technician B says an IC is a small power transistor, amplifier circuit for increasing output strength. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
11. Technician A says a variable resistor sensor opens or closes the sensor circuit to provide an electrical signal for the computer. Technician B says a variable resistor sensor changes its internal resistance with a change in a condition. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
12. Which of the following is another name for an automotive computer?
   (A) Electronic control unit.
   (B) Electronic control module.
   (C) Electronic control assembly.
   (D) All of the above.
13. Technician A says an automotive computer can be located under the dash. Technician B says an automotive computer can be located in the automobile's engine compartment. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
14. Which of the following memories can be altered in the field to adjust for operating parameters?
   (A) EEPROM.
   (B) XPROM.
   (C) KAM.
   (D) RAM.
15. Technician A says a servo motor is one type of output device used in an automotive computer system. Technician B says a solenoid is one type of output device used in an automotive computer system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Chapter 24
On-Board Diagnostics and Scan Tools

After studying this chapter, you will be able to:

- Discuss the purpose and operation of on-board diagnostic systems.
- Explain the use of scan tools to simplify reading of trouble codes.
- Locate the data link connector on most makes and models of cars.
- Activate on-board diagnostics and read trouble codes with a scan tool.
- Erase diagnostic trouble codes.
- Correctly answer ASE certification test questions concerning late-model on-board diagnostics and scan tool use.

No longer can the untrained "shade tree mechanic" hope to repair modern vehicles. It takes the skill of a well-trained technician versed in on-board diagnostics to troubleshoot and repair today's vehicles. Today, the first thing a technician often does when diagnosing a problem in a computerized system is check for diagnostic trouble codes with a scan tool.

On-board diagnostics refers to a vehicle computer's ability to analyze the operation of its circuits, and to store and output data showing any problems. All late-model cars and light trucks have this self-monitoring feature. To save time and effort finding problems, it is critical that you know how to use this vital troubleshooting aid.

A ***scan tool*** is used to communicate with the vehicle's computers to retrieve trouble codes, display circuit and sensor electrical values, run tests, and give helpful hints for finding problems. This can all be done quickly and easily, without disconnecting wires or removing parts.

This chapter will summarize on-board diagnostic capabilities and explain the fundamental use of any make of scan tool. It will prepare you for other text chapters on troubleshooting and servicing vehicle systems.

Tech Tip

This chapter provides the basics of using scan tools and reading trouble codes. More advanced scan tool functions are explained at the beginning of most service chapters and are covered in detail in later chapters.

On-Board Diagnostic Systems

Modern automotive computer systems are designed to detect problems and indicate where they might be located. The computer is programmed to detect abnormal operating conditions. It actually scans its input and output circuits to detect an incorrect voltage, resistance, or current.

Today's on-board diagnostics will check the operation of almost every electrical-electronic part in every major vehicle system. A vehicle's engine control module can detect engine misfiring and air-fuel mixture problems. It monitors the operation of the fuel injectors, ignition coils, fuel pump, catalytic converter, and other major components that affect vehicle performance and emissions.

You can scan for problems in the engine and its support systems, the transmission, the suspension system, the anti-lock brake system, and other vehicle systems. This has greatly simplified the troubleshooting of complex automotive systems.

If the on-board computer finds any abnormal values, it will store a trouble code and light a malfunction indicator light on the instrument panel. This will inform the driver and the technician that something is wrong and must be fixed.

Early On-Board Diagnostic Systems

Most early on-board diagnostic systems could check only a limited number of items. Although these older systems are able to detect a major problem in a circuit, they are unable to detect weak or partially failed circuits and components. Also, there was little or no standardization among these early systems. A wide range of connectors and methods were used to retrieve stored trouble codes.

Early diagnostic systems are called ***OBD I (on-board diagnostics generation one) systems***. There are still millions of vehicles on the road that use OBD I systems.

OBD II Systems

A malfunctioning automobile engine can be a significant source of air pollution. For this reason, the Environmental Protection Agency (EPA) recommended and passed vehicle pollution laws. They require on-board diagnostic systems to detect potential problems *before* they result in the production of harmful exhaust emissions. These regulations also require auto manufacturers to standardize the monitoring systems on their cars and light trucks.

OBD II (on-board diagnostics generation two) systems are designed to more efficiently monitor the condition of hardware and software that affect driveability emissions. OBD II systems detect part deterioration (changes in performance), not just complete part failure. For example, if a sensor becomes lazy or remains in the low end of its normal operating range, this problem is stored as a trouble code in the computer memory for retrieval at a later date. Refer to **Figure 24-1**.

OBD II systems are designed to keep the vehicle running efficiently for at least 100,000 miles (160,000 km). The on-board computers used in OBD II systems have greater processing speed, more memory, and more complex programming than computers used in OBD I systems.

OBD II systems can produce over 500 engine-performance-related trouble codes. They check the operation of switches, sensors, actuators, in-system components, wiring, and the computer itself. OBD II systems also have standardized data link connections, trouble codes, sensor and output device terminology, and scan tool capabilities.

Malfunction Indicator Light (MIL)

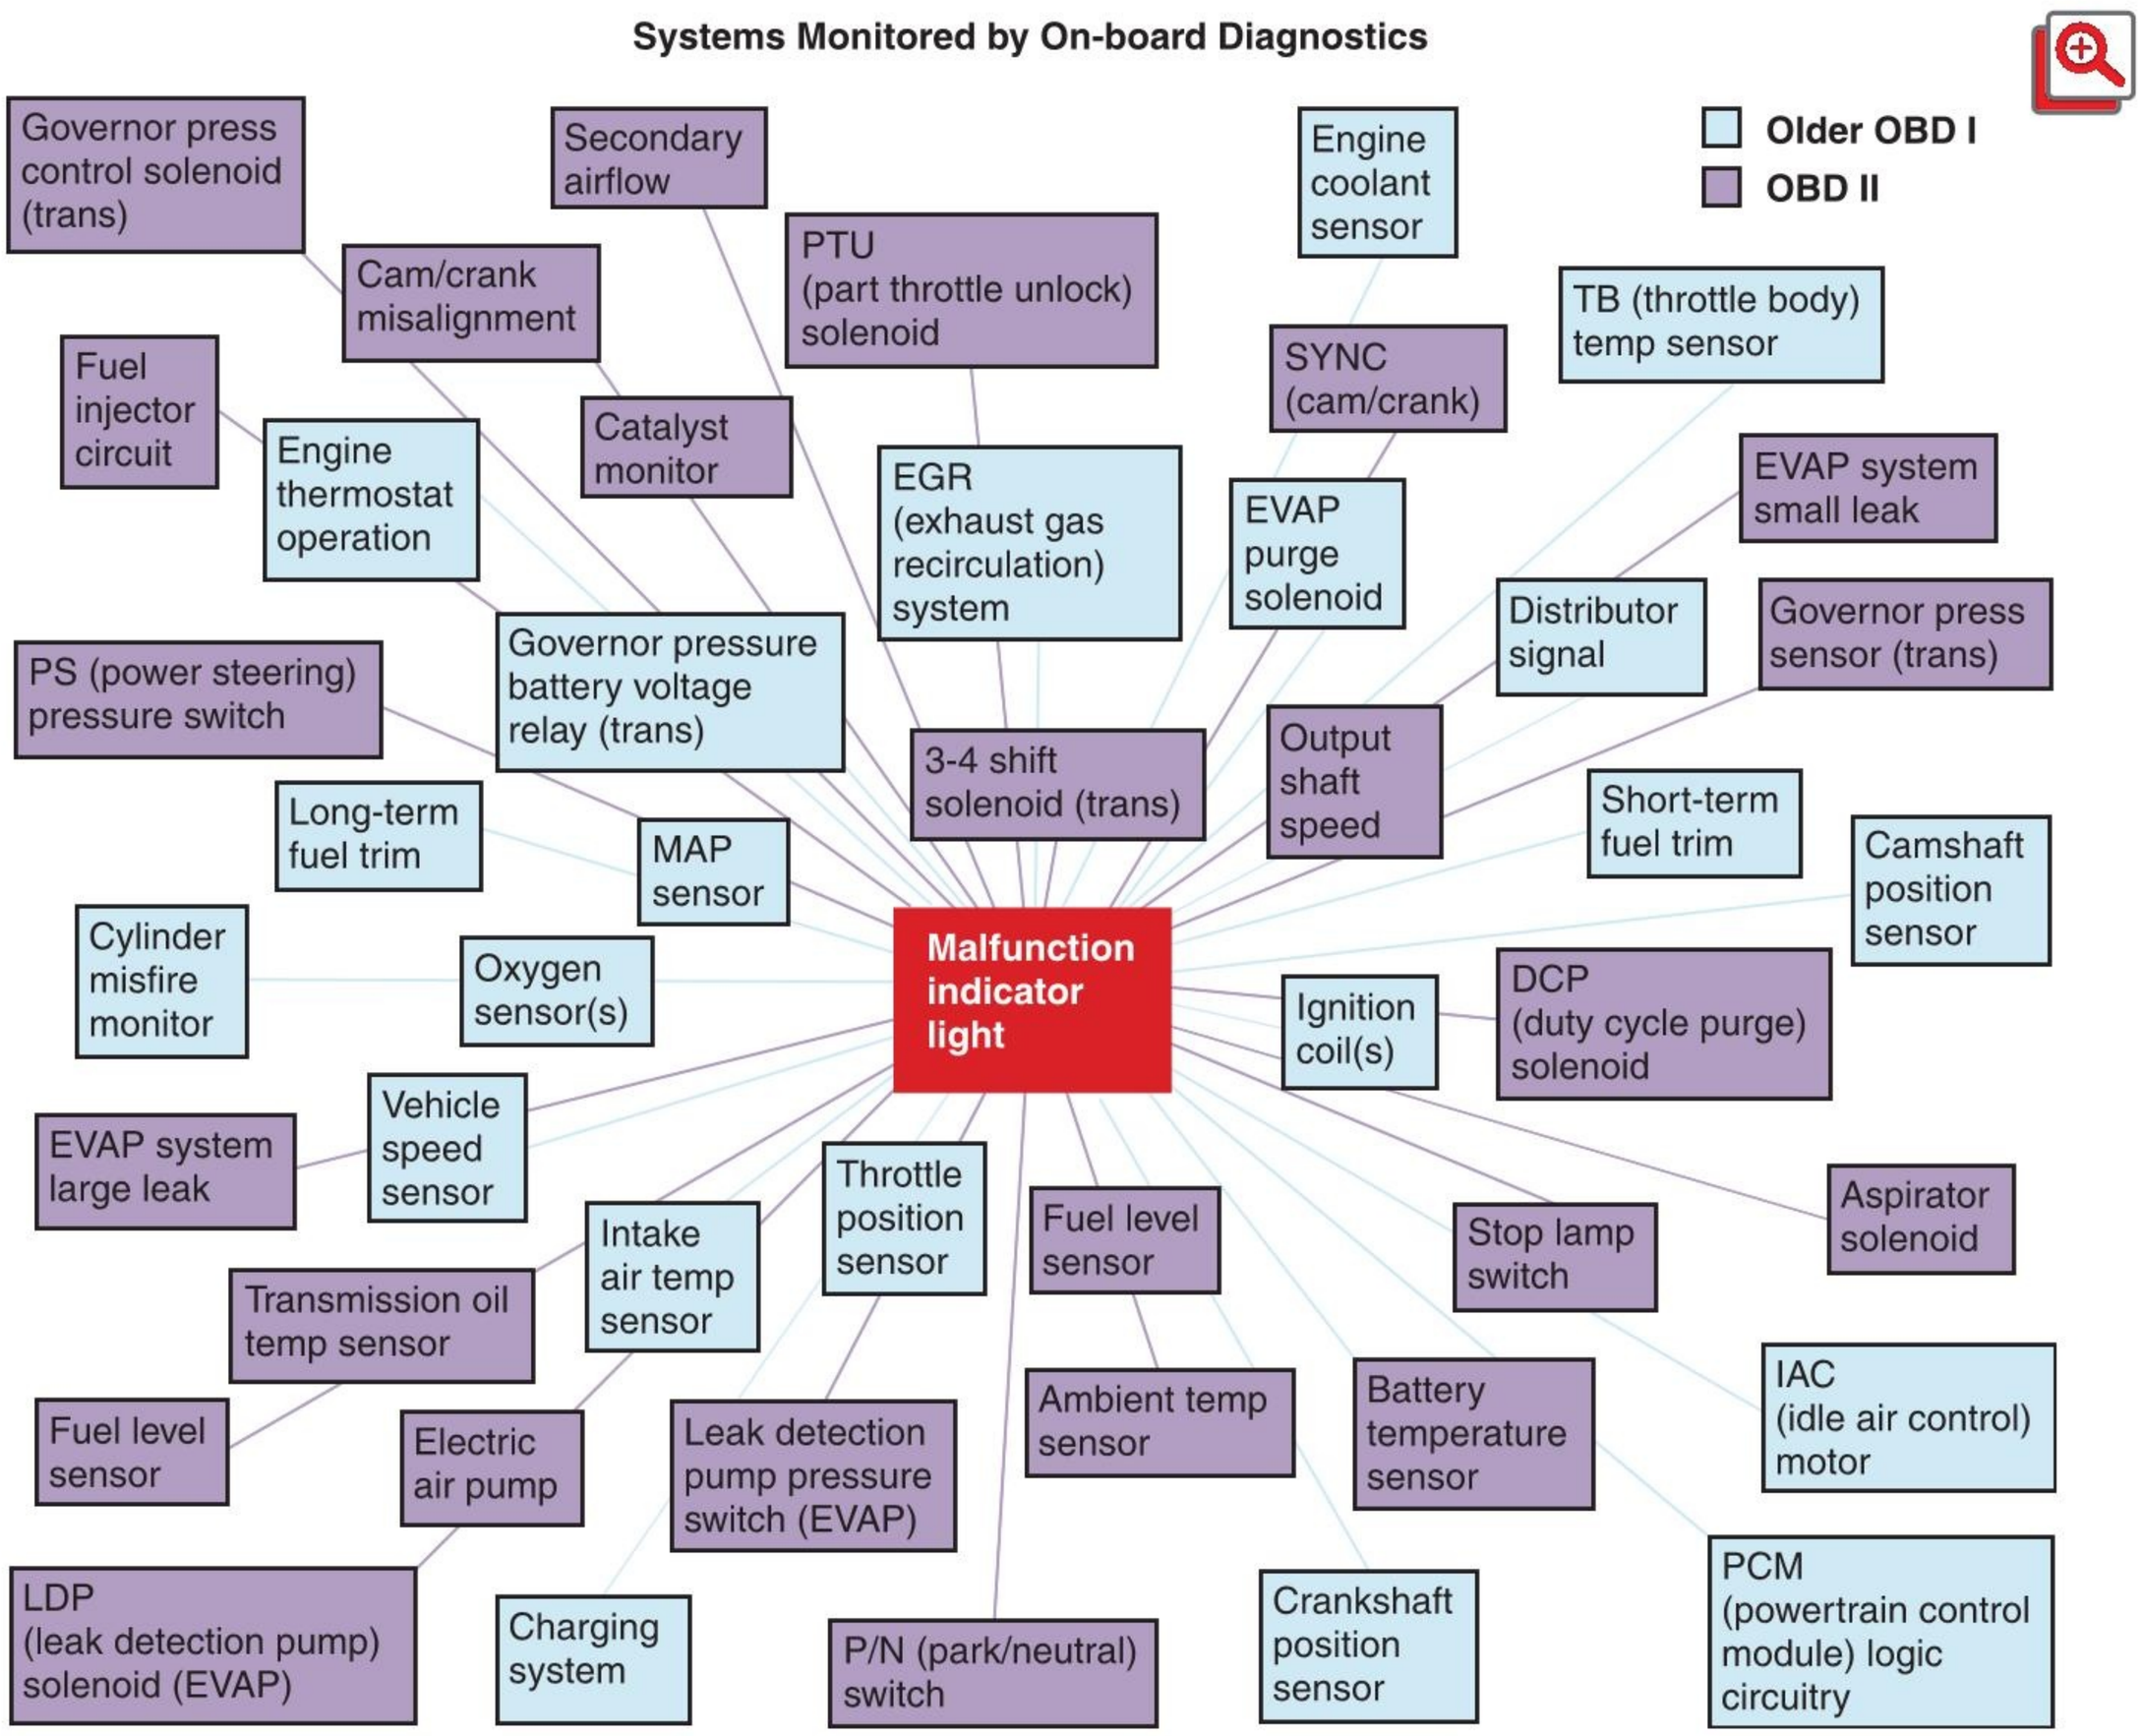
If an unusual condition or electrical value is detected, the computer will turn on a warning light in the instrument panel or the driver information center. The warning light will notify the driver that the vehicle needs service. Some vehicles have a silhouette of an engine on their warning lights.

In OBD II systems, the engine warning light is referred to as a ***malfunction indicator light (MIL)***. If the MIL glows continuously, the trouble is not critical but should be repaired at the vehicle owner's convenience. If the MIL light comes on and then goes out, the problem may be intermittent.

A flashing MIL in an OBD II equipped vehicle means that the trouble could damage the catalytic converter and is, therefore, considered critical. For example, an engine misfire (engine not completely burning fuel mixture) or a fuel system malfunction will generally cause the malfunction indicator light to flash on and off. This warns the driver that the catalytic converter may be overheated and burned if the vehicle is not serviced immediately.

Whenever the MIL is illuminated, drivers should be advised to bring the vehicle in for service as soon as

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 24-1. Compare the OBD I diagnostic system's capabilities with the OBD II system's abilities.

possible. The technician can then use a scan tool to retrieve information about the problem.

A ***trouble code chart*** in a service manual will state what each number code represents. However, most modern scan tools can perform trouble code conversion. ***Trouble code conversion*** means the scan tool is programmed to automatically convert the number code into abbreviated words that explain the potential problem. The technician can then use service information to further isolate the problem.

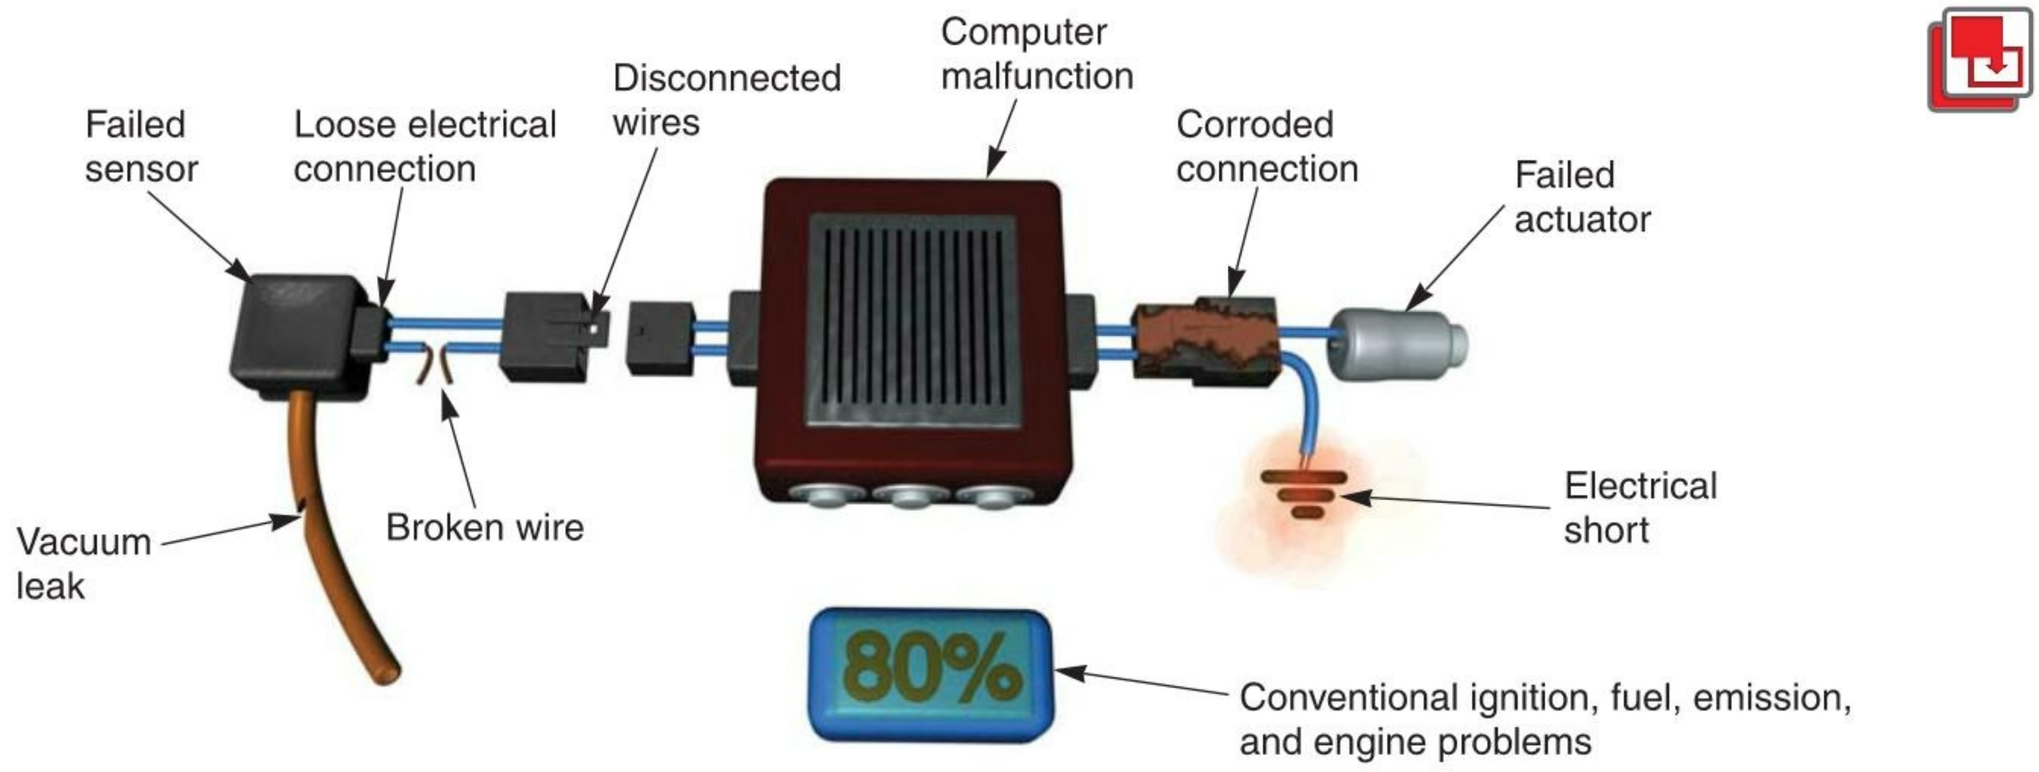
Diagnostic Trouble Codes

Diagnostic trouble codes (DTC) are digital signals produced and stored by the vehicle's computer when an operating parameter is exceeded. An ***operating parameter*** is an acceptable minimum and maximum value. The operating parameter might be an acceptable voltage range from the oxygen sensor, a resistance range for a temperature sensor, current draw from a fuel injector coil winding, or an operational state from a monitored device. In any case, the computer "knows" the operating parameters for most inputs and outputs. This information is stored in its permanent memory chips.

Computer System Problems

Common problems that can affect vehicle performance and cause the computer system to set a code and light the MIL in the dash are shown in **Figure 24-2**. These problems include:

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 24-2. Always remember that about 80% of all performance problems are not caused by the computer, its sensors, or its actuators. Most problems are the result of conventional problems, such as loose connections, broken wires, vacuum leaks, mechanical problems, etc.

- Loose electrical connection—This problem can cause an input signal from a sensor to not reach the computer properly, or an actuator may not respond to the computer's output control current.
- Corroded electrical connection—This problem can result in high resistance in a wiring connector, upsetting sensor input or actuator output.
- Failed sensor—This problem occurs when an opened or shorted sensor or other sensor malfunction prevents normal computer system operation.
- Failed actuator—This involves a solenoid, servo motor, relay, or display that shorted, is open, or does not react to computer signals.
- Vacuum leak—This problem is an engine vacuum leak that reduces engine or system performance.
- Electrical short—This problem occurs when wires touching ground or each other cause a current increase or incorrect current path.
- Ignition system problems—Problems include fouled spark plugs, weak ignition coil voltage, a bad crankshaft sensor, etc. For example, a spark plug misfire causing unburned fuel to enter the exhaust can trick the oxygen sensor into trying to create a leaner mixture. The misfire upsets computer system operation and can be detected in OBD II systems by variations in the crankshaft sensor signal.
- Fuel system problems—Problems include leaking or clogged injectors, bad pressure regulator, faulty fuel pump, or other problems.
- Emission system problems—These are problems with the catalytic converter, EGR valve, vapor storage system, etc. Many emission components are monitored electronically and will set a trouble code if a malfunction occurs.
- Engine problems—These are mechanical problems that cannot be compensated for by the computer modifying system operation. Engine misfire due to mechanical wear will also trip a trouble code on OBD II systems.
- Computer malfunction—This problem results from an faulty or incorrect internal programming, failure of an integrated circuit, or failure of other computer components can disable the computer and alter the operation of related systems.
- Weak or lazy component—This includes any sensor, actuator, or computer that is working slowly or inefficiently. In some cases, a sensor's current, voltage, or resistance values are within specs, but the component is sending weak or incorrect signals to the ECM. A lazy oxygen sensor, for example, can trick the computer system into compensating for an artificial lean or rich condition; it will trip codes on OBD II-equipped vehicles.
- Transmission problems—Electronically controlled transmissions and transaxles are monitored and will trip trouble codes if a problem is detected. Transmission problems include a bad vehicle speed sensor, a faulty shift sensor or shift solenoid, or faulty wiring.

Copyright Goodheart-Willcox Co., Inc.

- Anti-lock brake system problems—Problems include bad wheel speed sensors, faulty wiring, worn brake pad sensor, or a malfunctioning hydraulic unit.
- Air conditioning problems—These problems include faulty pressure and temperature sensors, a loss of refrigerant, or compressor clutch failure.
- Air bag problems—Problems include faulty impact sensors, a malfunctioning arming sensor, or a damaged air bag module.
- Hybrid electric drive train part and circuit malfunctions—These types of problems include an HV battery malfunction, a failed power control module, or faulty HV power cables.

OTC/SPX Corp.

Figure 24-3. A scan tool is now the most important tool of the automotive technician. It will tell you where problems are located.

Tech Tip

Most computer system problems are conventional (loose electrical connection, mechanical problem, etc.). Only about 20% of all performance problems are caused by an actual fault in the computer or one of its sensors. For this reason, always check for the most common problems before testing more complex computer-controlled components.

Scanning Computer Problems

A scan tool is an electronic test instrument designed to retrieve trouble codes from the computer's memory and display these codes as a number and words identifying the problem. It is now the most important tool used by the automobile technician, **Figure 24-3**.

A basic scan tool is designed to read and erase vehicle trouble codes. An advanced scan tool is commonly a wireless, touch screen tablet that has more functions than a basic scan tool, including troubleshooting guides, manufacturer-specific tests, and circuit values. An advanced scan tool can communicate with the vehicle and the internet at the same time.

To use any scan tool, read the operating instructions for the tool at hand. Operating procedures vary slightly. Most scan tools have simple buttons, a scroll wheel, or a touch screen that allow the technician to choose various test functions. With modern scan tools, plug the cord or wireless sending unit into the connector under the dash and follow scanner on-screen instructions.

A wireless sending unit for a diagnostic tablet plugs into the vehicle's diagnostic connector and can send and receive radio signals to and from the tablet. This allows you to take the diagnostic tablet anywhere in the shop while monitoring vehicle operation, data stream values, and trouble codes. **See Figure 24-4**.

Goodheart-Willcox Publisher

Figure 24-4. Wireless touch screen diagnostic tablets are replacing scan tools. There is no hard wire needed between the vehicle and the tablet. The wireless sending unit is plugged into the vehicle's diagnostic connector.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

Late-model vehicles are equipped with CAN-compliant computer systems. While the diagnostic techniques for these systems are similar to those for conventional computer systems, a CAN-compliant scan tool must be used to retrieve diagnostic information from CAN-equipped vehicles.

Data Link Connector (Diagnostic Connector)

The ***data link connector (DLC)*** is a standardized multipin terminal used to link the scan tool to the computer. In the past, this connector was identified by a variety of names, including ***diagnostic connector*** and ***assembly line diagnostic link (ALDL)***.

OBD I data link connectors came in various shapes and sizes, and were equipped with a varying number of pins or terminals. With OBD II, the DLC is a standardized 16-pin connector. The female half of the connector is on the vehicle, and the male half is on the scan tool cable.

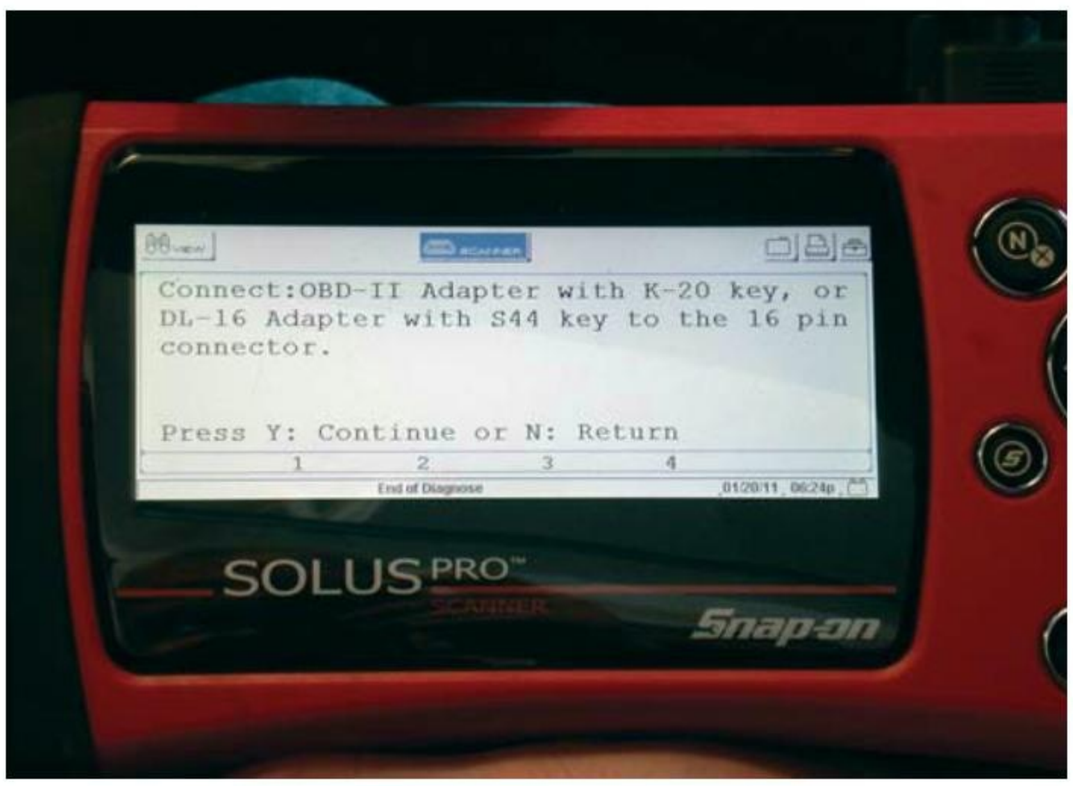
With OBD II diagnostic systems, you should be able to connect a scan tool to the vehicle's data link connector with one hand while sitting in the driver's seat or kneeling outside the vehicle.

Connecting the Scan Tool

In late-model vehicles, the data link connector is mounted under the dash in a location that is easy to access from the driver's seat. The scan tool cable should slide easily into the data link connector, **Figure 24-5**. If not, something is wrong. Never force the two together or you could damage the pins on the tool cable or the data link connector. With an older vehicle, you will need an ***adapter*** so the scan tool connector will fit the vehicle's pre-OBD II pin configurations.

Using Scan Tools

Modern scan tools will give ***prompts***, or step-by-step instructions, in their display windows. The prompts tell you how to input specific vehicle information and run diagnostic tests. These procedures and specifications are programmed into the scan tool circuitry. See **Figures 24-6** and **24-7**.



Snap-on Tool Corp.

Figure 24-6. This advanced scan tool is prompting the user to install an OBD II connector and a specific key adapter.

Figure 24-5. The OBD II test connector is under the dash. It should be visible as you lean down and look under the dash. A—The OBD II connector has 16 male pins and a power plug to the power scan tool. B—The OBD II connector under the dash has a 16-pin female plug. C—Slide scan tool connector straight into the vehicle data link connector so the pins slide smoothly together.

Copyright Goodheart-Willcox Co., Inc.

Controls vary by manufacturer. This scan tool uses simple yes–no buttons.

Snap-on Tool Corp.

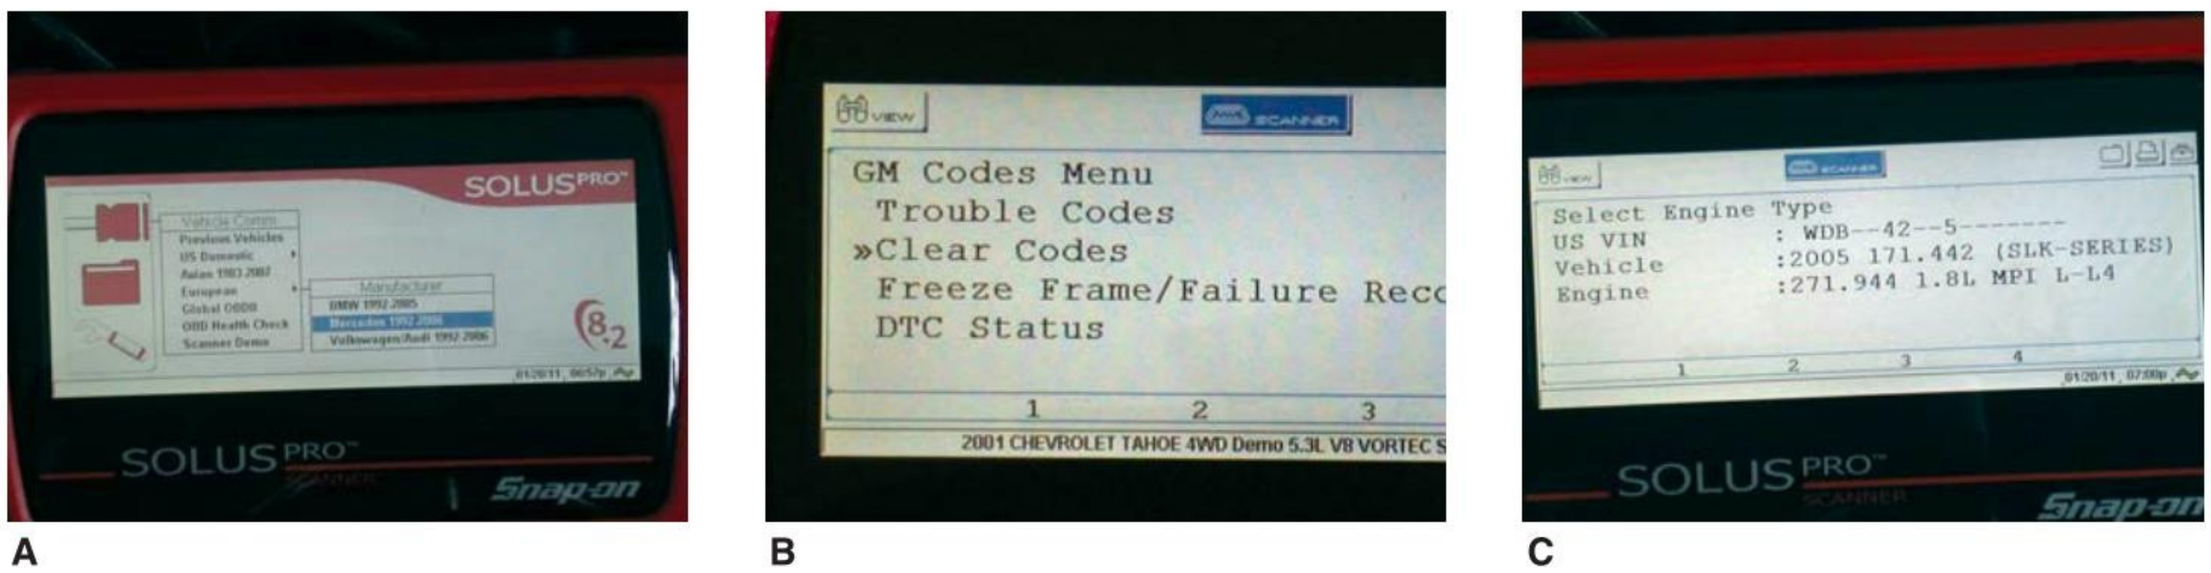
Figure 24-7. Always read the operating manual fully before attempting to use any model of scan tool. A—Scan tool controls vary from one manufacturer to another. B—Note the simple yes-no buttons that allow the user to quickly respond to the scan tool's prompts.

The scan tool may ask you to input VIN information (numbers or letters) from the plate on the top of the dash.

The VIN data lets the scan tool know which engine, transmission, and options are installed on that car or truck. With some makes, however, the on-board computer will contain this data and will automatically download it into the scan tool. Then, you will be able to select the information that you would like the scan tool to give you, **Figure 24-8**.

Some of the information a scan tool can request includes:

- Stored diagnostic trouble codes—This is a number that represents the general area (body, chassis, power train, network) and specific system or part that is not functioning normally in the vehicle.
- Fault description—This explains what each stored diagnostic trouble code means by pinpointing specific fuel injectors, ignition coils, sensors, actuators, or other parts and circuits that are operating out of specification.
- Datastream information—This displays the operating values of all monitored circuits and sensors (engine speed, engine temperature, ignition timing, injector pulse width, and other values).
- Run tests—These read datastream circuit values for sensors and actuators while they are operating. If an actuator fails to move or fire during the run tests, the scan tool will inform you of any problem.



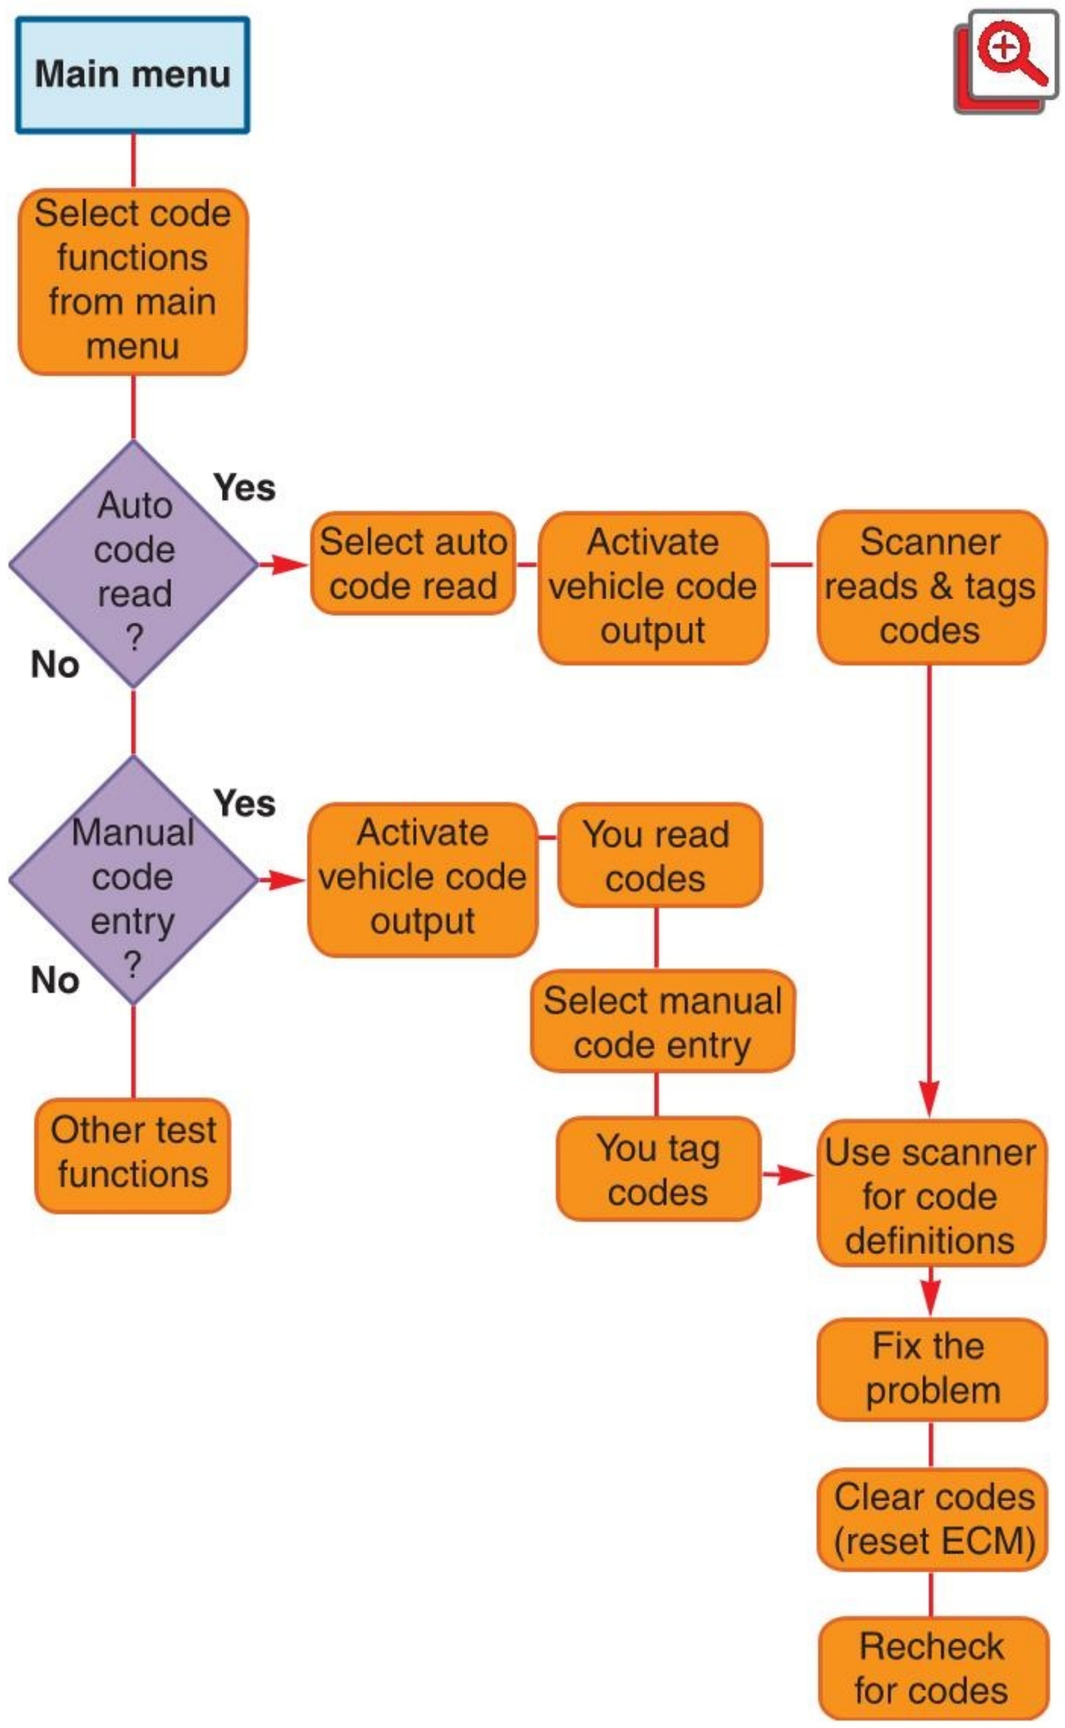
Snap-on Tool Corp.

Figure 24-8. A full-featured scan tool can perform complex testing and troubleshooting procedures. A—This advanced scan tool does not require cartridges. You can quickly navigate to the exact make, model, and year car to be tested. B—Here the scan tool is asking the technician to input VIN information. This lets the tool know how the vehicle is equipped—engine type, transmission type, computer configuration, etc. C—You can then proceed to read stored trouble codes, or erase codes by scrolling through the menu.

Copyright Goodheart-Willcox Co., Inc.

- Oxygen sensor monitoring—This performs detailed tests of the O_2 sensors signals under normal operating conditions. This helps find a weak or sluggish oxygen sensor.
- Failure record—This lists the number of times a particular trouble code has occurred by keystarts or warm-ups. This will help you find intermittent or irregular problems.
- ***Freeze frame***—This takes a snapshot of sensor and actuator values when a problem occurs or when triggered during a test drive. This also helps find problems that do not set hard trouble codes. This records the values from all monitored components so they can be further evaluated, letting you locate and correct intermittent problems more easily.
- Troubleshooting—This feature provides help and instructions for diagnosing faults once you have read a trouble code.

Figure 24-9 gives the general sequence for using a scan tool. You can ask the scan tool to give more information on a trouble code, and the tool will display words that give sensor resistance values, identify common problems, and provide other useful repair information.



Snap-on Tool Corp.

Figure 24-9. This flowchart shows the basic steps for using a scan tool.

Tech Tip

Most technicians check for stored diagnostic trouble codes before performing tests on specific components. This is a quick way to pinpoint any hard failures, so they can be repaired first.

Always correct the cause of the lowest number diagnostic trouble code first. Sometimes, fixing the cause of the lowest code will clear other codes because of component interaction. A trouble code does not mean that a certain component is bad. It simply indicates that a possible problem has been detected in that particular device or its circuit.

Most ECMs count the number of times a trouble code has occurred. This information is stored in a ***failure record***, or failure recorder. The failure recorder in OBD II systems counts the number of times the engine reached operating temperature since the last time the trouble code was set.

Diagnostic Trouble Code Identification

To simplify troubleshooting, OBD II requires all auto manufacturers to use a set of standardized alphanumeric trouble codes. Each trouble code identifies the same problem in all vehicles, regardless of the manufacturer.

OBD II codes contain a letter and a four-digit number. The letter in all OBD II codes indicates the general function of the affected system (power train, chassis, etc.).

The first digit of the number indicates whether the code is a standard trouble code or a nonuniform code. Standard trouble codes, or SAE codes, are indicated by the number *0*. Nonuniform codes (nonstandard OBD II codes that are assigned by the auto manufacturers) have the number *1* after the system letter. The second digit of the OBD II code number indicates the specific function of the system where the fault is located, such as fuel, computer, etc.

Copyright Goodheart-Willcox Co., Inc.

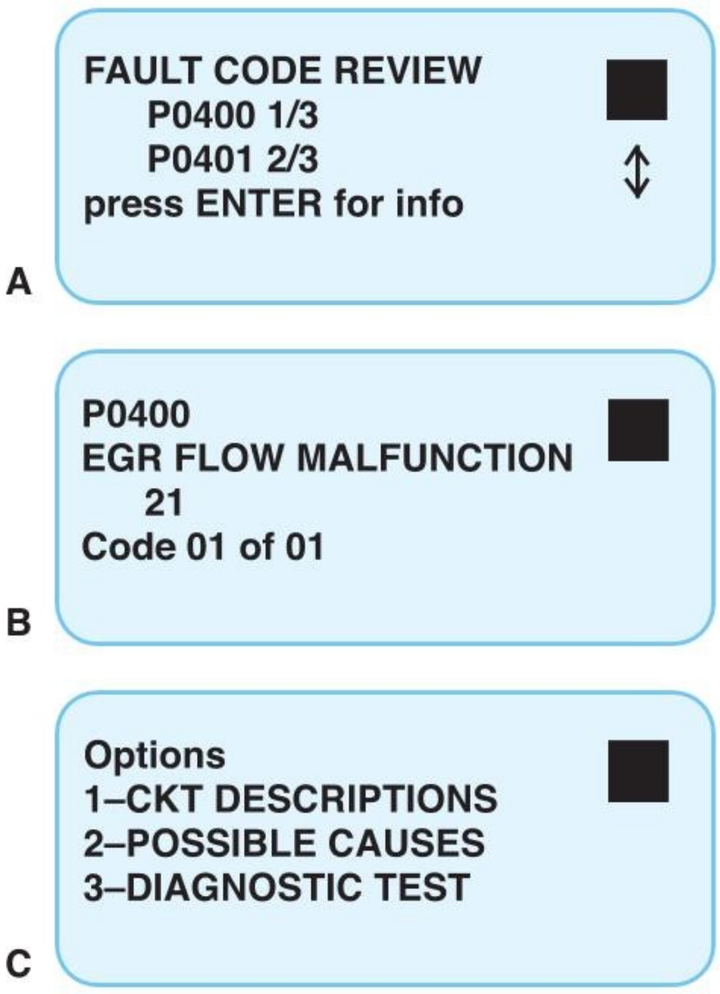
The code's last two digits refer to the specific fault designation. The ***fault designation*** pinpoints exactly which component or circuit of the system might be at fault, as well as the type of problem. Regardless of the type of vehicle being serviced, the standard trouble code numbers will be the same. The scan tool explains the code and, in some cases, describes how to fix the problem.

Figure 24-10 gives a breakdown of the OBD II diagnostic code. Study it carefully. **Figure 24-11** shows the display of a scan tool that has found a stored trouble code.

Failure Types

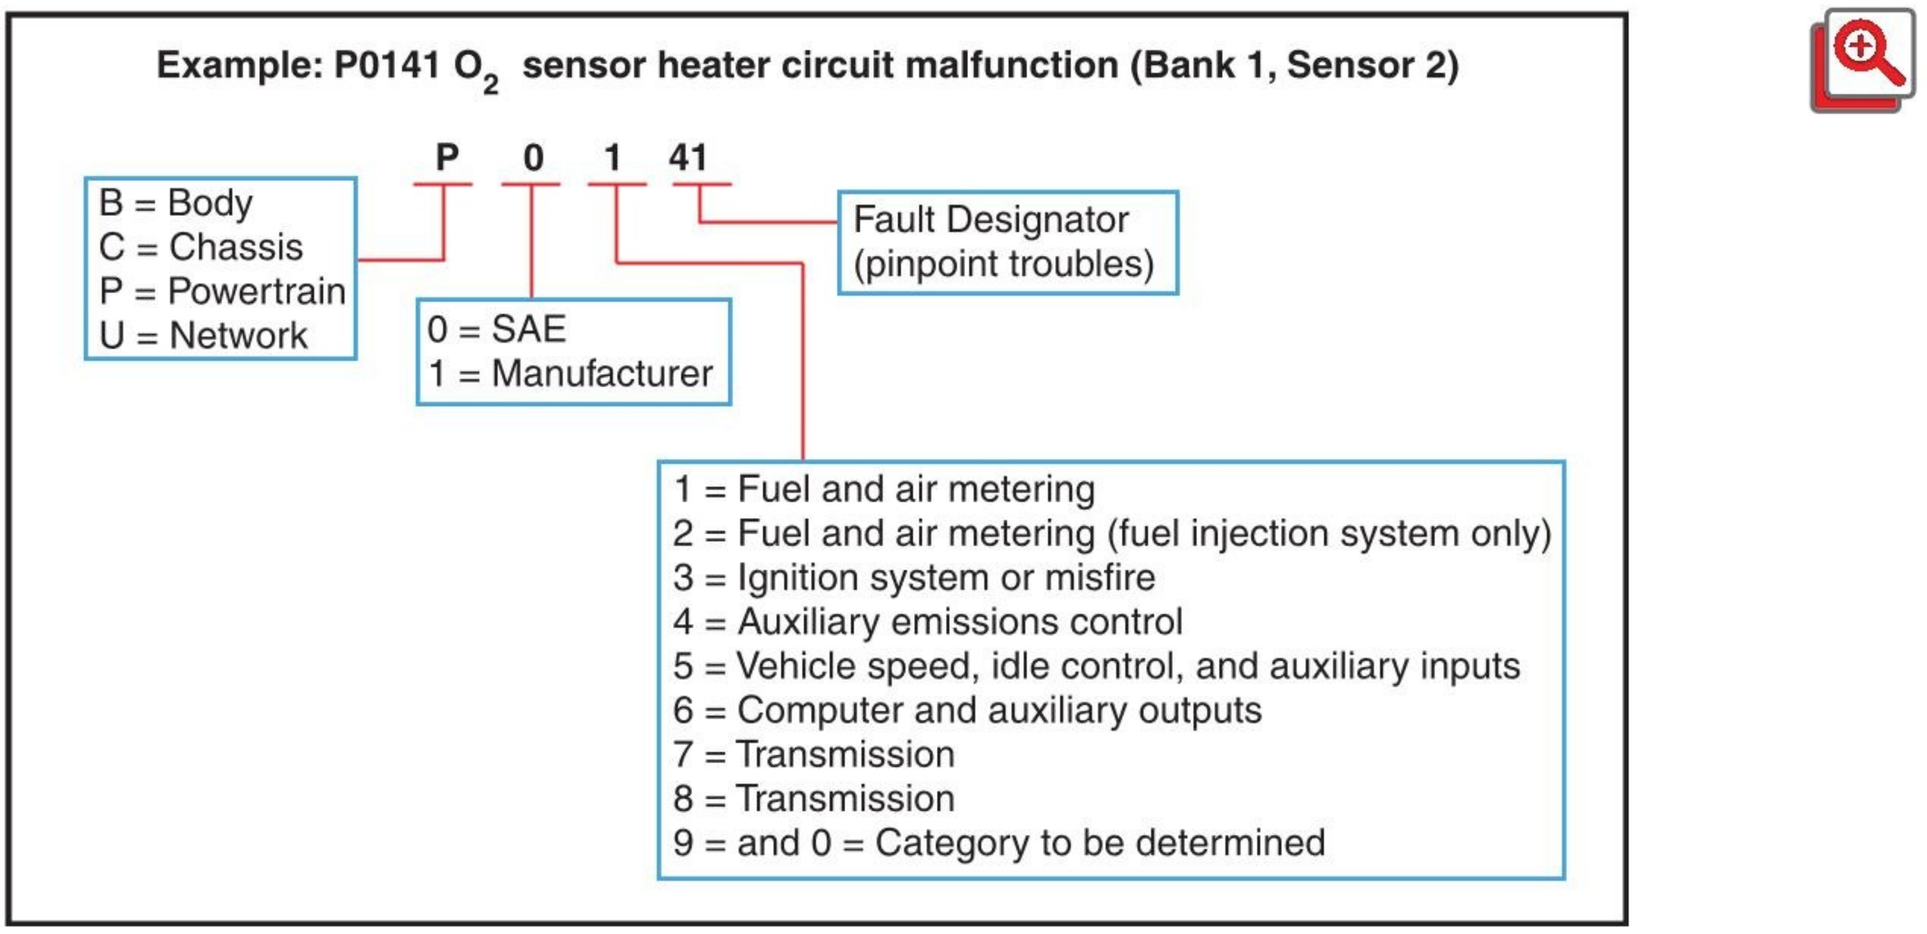
There are two general types of computer system failures: hard failures and soft failures. A ***hard failure*** is a problem that is always present in a computer system. An example of a hard failure is a disconnected wire or another problem that would cause a general circuit failure. A hard failure does not come and go with varying conditions. After the computer memory is cleared, any hard failures will usually reset as soon as the engine is started or the affected system is energized.

A ***soft failure***, or intermittent failure, is a problem that only occurs when certain conditions are present. It might be present one minute and gone the next. Soft failures will usually be stored in memory for 30–50 keystarts or engine warm-ups. An example of a soft failure is a loose terminal that connects and disconnects as the vehicle travels over bumps in the road. Low-input, high-input, and improper range failures are usually classified as soft failures.



OTC/SPX Corp.

Figure 24-11. This is an example of what you might see on the display of a scan tool. A—The scan tool will give you the trouble code numbers. B—If you request information on the stored trouble codes, the tool will explain what each code means. C—Options will allow you to use the scan tool to get detailed descriptions of each code, list possible causes, or perform diagnostic tests.



Goodheart-Willcox Publisher

Figure 24-10. OBD II trouble codes are alphanumeric. Note what each part of the trouble code means. The first part of the code tells you which system is having problems. The last part of the code identifies the specific problem circuit or component.

Copyright Goodheart-Willcox Co., Inc.

Computer system failure types can be further broken down into four general categories:

- ***General circuit failure***—The circuit or component has a fixed value, no output, or an output that is out of specifications. This is the most severe fault, but it is the easiest to locate. It is caused by disconnected wires, high-resistance connections, shorts, or a component constantly operating out of parameter.
- ***Low-input failure***—A failure that produces a voltage, current, or signal frequency below normal operating parameters. A weak or abnormally low signal is being sent to the on-board computer. This type of failure is often caused by high circuit resistance, a poor electrical connection, a contaminated or failed sensor, or a similar problem.
- ***High-input failure***—This results when the signal reaching the on-board computer has a much higher voltage, current, or frequency than normal. This type of failure is often caused by a faulty sensor, a high charging voltage, or a mechanical fault that is "fooling" the computer system.
- ***Improper range/performance failure***—This occurs when a sensor or actuator is producing values slightly lower or higher than normal. The circuit is still functioning, but not as well as it should under normal conditions. This type of failure can be caused by a contaminated sensor, a partial sensor failure, a poor electrical connection, and similar problems. Improper range/performance failures were not detected in OBD I systems and were often difficult to find. OBD II systems can detect improper range/performance failures.

Datastream Values

Datastream values, or diagnostic scan values, produced by the vehicle's computer give electrical operating values of sensors, actuators, and circuits. These values can be read on a scan tool's digital display and compared to known normal values in the service manual. Datastream values give additional troubleshooting information when trying to locate a problem.

Key-On/Engine-Off Diagnostics

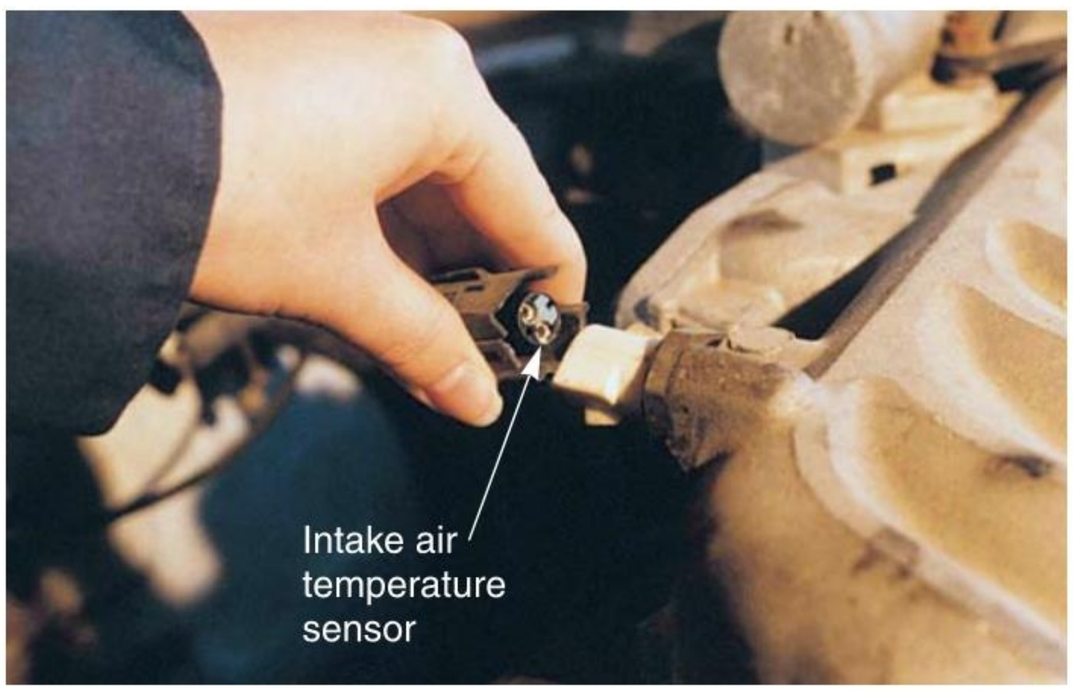
In order to access the ECM data on most vehicles, it is necessary to turn the ignition key on. ***Key-on/engine-off diagnostics*** are performed by triggering the ECM's on-board diagnostic system with the ignition key in the *on* position but without the engine running. This allows you to access any stored trouble codes in the computer's memory chips. Key-on/engine-off diagnostics are usually performed before key-on/engine-on diagnostics. Look at **Figure 24-12**.

If you anticipate working in the key-on/engine-off diagnostic mode for over 30 minutes, connect a battery charger to the vehicle. This will prevent the extended current draw from draining the battery and upsetting the operation of the computer while in the diagnostic mode. False trouble codes could result from a partially drained battery.

Wiggle Test

Many computer system failures, especially intermittent failures, are caused by loose, dirty, or corroded connections, **Figure 24-13**. These failures can be found by performing a ***wiggle test***, or "flex" test.

A



B

Snap-on Tool Corp.

Figure 24-12. Most technicians check for stored trouble codes first. A—This scan tool readout shows a problem with the intake air (air charge) temperature sensor. B—You would then know to check that sensor and its wiring for problems.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 24-13. The wiggle test involves moving wires and connectors while scanning for trouble codes. If wiggling a wire trips a code, you found the location of the problem.

Service Procedure

To perform a wiggle test:

1. Connect a scan tool to the vehicle and choose the appropriate test options. Refer to the instructions provided with the scan tool.
2. Place the vehicle in the key-on/engine-off diagnostic mode.
3. Flex wires and wiggle harness connectors while scanning for problems.
4. If wiggling a wire or connector produces a new diagnostic trouble code, check the wire or electrical connection more closely. It may be loose, corroded, or damaged.

Some technicians perform a wiggle test while the engine is running. If engine operation changes suddenly (stalls or idles high, for example) when a connector or wire is flexed, the problem is located at or near that point. Be careful when performing a wiggle test on a running vehicle.

You might also want to use a heat gun to heat potentially faulty components during a wiggle test. For example, electronic amplifiers and modules tend to malfunction when hot. This could help find an intermittent problem.

Caution

Exercise care when using a heat gun. The heat generated by the gun can easily melt most plastics and damage electronic components.

Key-On/Engine-On Diagnostics

Key-on/engine-on diagnostics are performed with the engine running at full operating temperature. These tests check the condition of the sensors, actuators, computer, and wiring while they are operating under normal conditions.

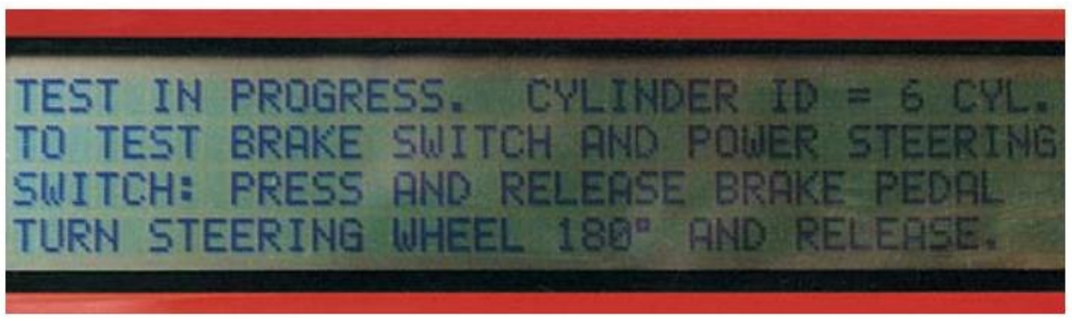
Switch Diagnostic Test

A ***switch diagnostic test*** involves activating various switches while using a scan tool. The scan tool will tell you which switch to move and will monitor its operation. The scan tool will quickly indicate if the switch is working normally, **Figure 24-14**.

For example, you might be told to shift the transmission shift lever through the gears, press on the brake pedal, and turn the air conditioning on and off. As each step is performed, the scan tool will indicate if the affected switch is okay and whether or not the ECM is reading the switch input. Refer to the service manual for details of the switch diagnostic test.

Actuator Diagnostic Test

An ***actuator diagnostic test*** uses the scan tool to order the vehicle's computer to energize specific output devices with the engine on or off. This will let you find out if the actuators are working. Most actuator diagnostic tests are considered intrusive tests, since engine or vehicle operation will be drastically affected



Snap-on Tool Corp.

Figure 24-14. Most scan tools will also perform switch and actuator tests. This is sometimes done automatically. You may be prompted to close different switches to make sure each one is working. The scan tool may also be able to perform additional actuator tests.

Copyright Goodheart-Willcox Co., Inc.

while the device is being tested. Actuator diagnostic tests might:

- Fire or prevent the firing of the ignition coil.
- Open and close the fuel injectors.
- Cycle the idle speed motor or solenoid.
- Energize the digital EGR valve solenoids.

You can then watch or listen to make sure these actuators are working. With OBD II, the scan tool will give readouts showing whether there is trouble with any actuators.

Switch and actuator diagnostic tests cannot be performed on all vehicles. Refer to the service manual or scan operating manual for details.

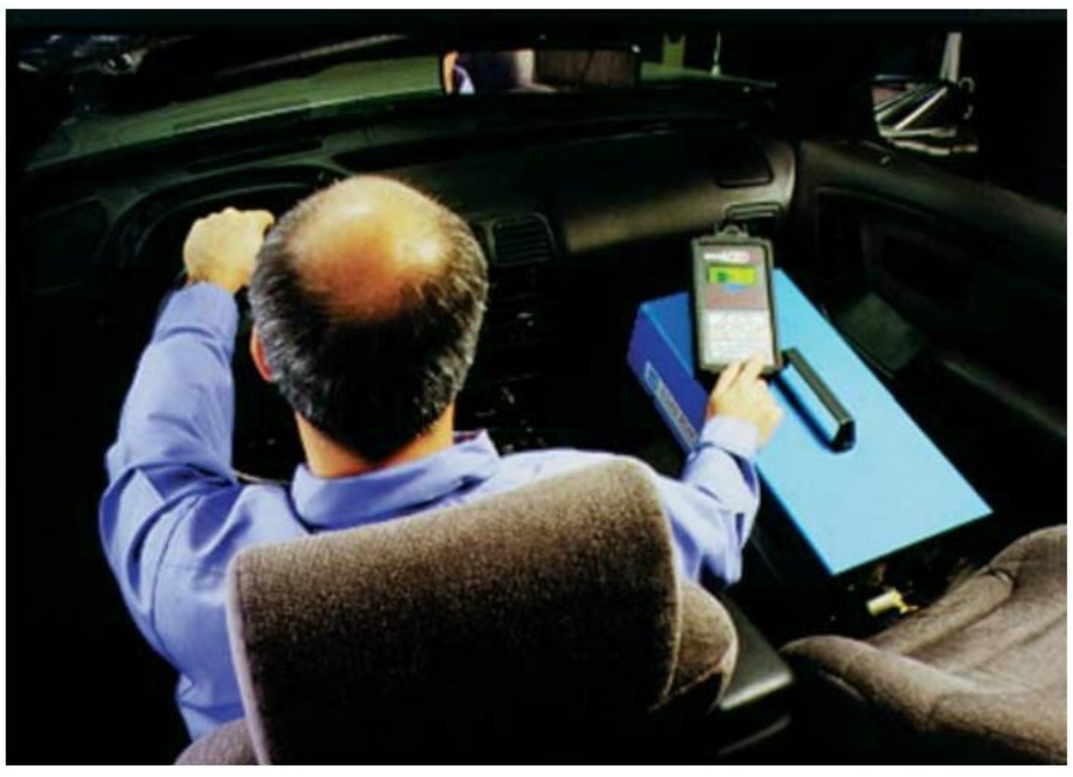
Scanning during a Test-Drive

With a modern scan tool, you can also check for problems while driving the vehicle to simulate the conditions present when the trouble happens, **Figure 24-15**. For example, if the problem occurs only while driving at a specific speed when the engine is cold, you can scan under these conditions. Start the cold engine and drive at the specified speed while scanning for problems. You can then take a snapshot (if the scan tool has this feature) when the problems occur.

Erasing Trouble Codes

Erasing trouble codes, also termed clearing diagnostic codes, removes the stored codes from computer memory after system repairs have been made. In most cases, codes will be automatically erased after 30–50 engine starts or warm-ups. However, codes should be erased after repairs are made to prevent a possible misdiagnosis by the next technician who works on the vehicle. There are various methods used to erase trouble codes from the computer:

- Use a scan tool to remove stored diagnostic codes from the on-board computer. This is the best way to remove old codes after repairs. In OBD II systems, the ECM may retain stored codes for several days without battery power. See **Figure 24-16**.
- Disconnect the battery ground cable or strap. However, this will also erase the digital clock memory, all radio presets, and any adaptive strategy information from the computer.
- Unplug the fuse to the ECM. This will also erase all other information stored in the computer's temporary memory.



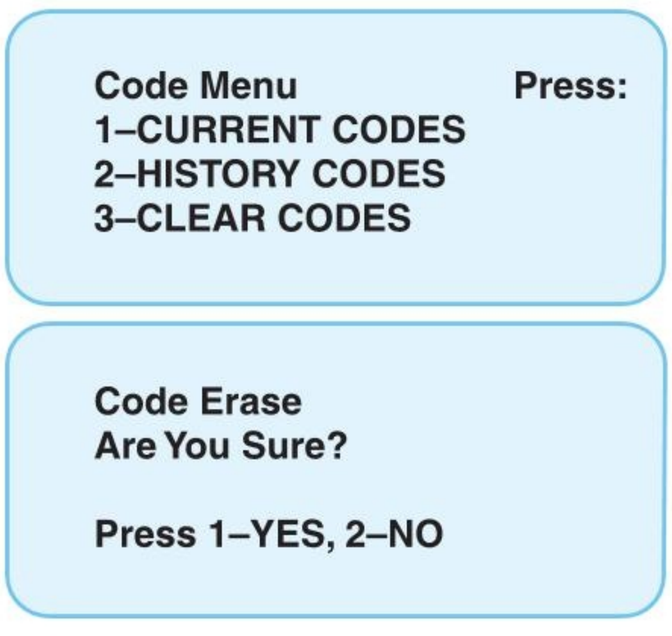
OTC/SPX Corp.

Figure 24-15. Scan tools are sometimes used while test- driving vehicles. This will allow you to check engine and vehicle operating parameters while duplicating the conditions present when the problem occurred.

Caution

Some auto manufacturers warn against unplugging or plugging in the computer harness connector with the ignition key on or the engine running. This could cause a voltage spike that could damage the computer.

After erasing trouble codes, reenergize the on-board diagnostics and check for diagnostic trouble codes. If no trouble codes are displayed, you have corrected the problem.



OTC/SPX Corp.

Figure 24-16. Using a scan tool is the fastest and easiest way to erase stored trouble codes. With most scan tools, simply choose the menu selection to clear codes and then press yes.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

The OBD II system performs a series of checks, or monitors, to verify the proper operation emissions-related components. Erasing trouble codes may also erase monitor status records stored in the computer's memory. If this occurs, the monitors must be reset before the vehicle is emission tested. This can be done by performing the appropriate OBD II drive cycle or by simply driving the vehicle until all the monitors reset. However, the vehicle may have to be driven 100 miles or more under varying conditions to reset the monitors.

Diagnostic Case Study

Concern: Ms. Figuroa says that a light is glowing in the dash of her 2013 Toyota pickup truck.

Cause: Duff questions Ms. Figuroa as to the nature of the problem, but she says she has noticed nothing wrong other than the glowing light. Duff starts the vehicle and notes that the malfunction indicator light in the dash is glowing. He test-drives the vehicle to try to find problem symptoms. He notices that the vehicle seems to miss slightly and lack normal power. He makes a note of his findings and turns the repair over to the shop's master technician.

After analyzing the symptoms, the technician connects a scan tool to the truck's data link connector. The scan tool readout indicates a misfire in cylinder number one. The technician then performs pinpoint tests to verify the scan tool findings. He first pulls the ignition coil on cylinder number one and checks for a good, "hot," high voltage spark. He finds that the direct ignition coil has a very weak spark. An ohmmeter test of the coil primary shows high resistance.

Correction: The technician installs a new ignition coil in the affected cylinder. He erases the stored trouble codes and then starts the engine and rechecks the system for codes. No problems are found and the MIL light no longer glows. He test drives the vehicle to make sure it is no longer missing and lacks normal power.

Summary

- On-board diagnostics refers to a vehicle computer's ability to analyze the operation of its circuits and output data showing any problems.
- A scan tool is used to communicate with the vehicle's computers to retrieve trouble codes, display circuit and sensor electrical values, run tests, and give helpful hints for finding problem sources.
- OBD I and earlier on-board diagnostic systems could check only a limited number of items.
- OBD II systems are designed to more efficiently monitor the condition of hardware and software that affect emissions. New vehicle diagnostics detect part deterioration and not just complete part failure.
- If an unusual condition or electrical value is detected, the computer will turn on a malfunction indicator light (MIL) in the dash instrument panel or driver information center.
- Code conversion means the scan tool is programmed to automatically convert trouble codes into abbreviated words that explain what might be wrong without referring to a service manual.
- Diagnostic trouble codes (DTCs) are digital signals produced by the computer when an operating parameter is exceeded.
- The data link connector (DLC) is a multipin terminal for reading computer trouble codes or scanning problems.
- A scan tool freeze frame is a snapshot of operating parameters at the time of a malfunction.
- OBD II codes contain a letter and a four-digit number.
- The letter in all OBD II codes indicates the general function of the affected system.
- The first digit of the number in OBD II codes indicates whether the code is a standard trouble code or a nonuniform code.
- The second digit of the number in the OBD II code indicates the specific function of the system where the fault is located.
- The last two digits in the OBD II code refer to the specific fault designation.
- A wiggle test is done by moving wires and harness connectors while scanning to find soft failures.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

actuator diagnostic test
adapter
assembly line diagnostic link (ALDL)
data link connector (DLC)
datastream values
diagnostic connector
diagnostic trouble codes (DTC)
failure record
fault designation
freeze frame
general circuit failure
hard failure
high-input failure
improper range/performance failure
key-on/engine-off diagnostics
key-on/engine-on diagnostics
low-input failure
malfunction indicator light (MIL)
on-board diagnostics
OBD I (on-board diagnostics generation one) system
OBD II (on-board diagnostics generation two) system
operating parameter
prompts
scan tool
soft failure
switch diagnostic test
trouble code chart
trouble code conversion
wiggle test

Activities

1. Demonstrate the proper method for using a scan tool or diagnostic tablet.
2. Videotape a service technician using a scan tool to "check out" an engine performance problem. Ask the technician to explain each step as he or she performs the work. Show the completed video to the class.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What is computer on-board diagnostics?
2. What is the first thing most technicians look at when diagnosing a computer system problem?
3. If an unusual condition or electrical value is detected, most computer systems will turn on a(n) _____.
4. List and summarize 17 types of problems that can affect computer system operation.
5. Only about _____ of all performance problems are caused by the computer, sensors, and actuators.
6. Where is a typical OBD II scan tool connector located?
7. Summarize the OBD II alphanumeric diagnostic code.
8. Which of the following is a standardized OBD II code for a malfunction in the computer or auxiliary outputs?
   (A) P0605.
   (B) P1600.
   (C) P0141.
   (D) P0505.
9. Name the four general types of computer system failures.
10. A(n) _____ is always present and a(n) _____ is intermittent.
11. Explain key-on/engine-off diagnostics.
12. What is a wiggle test?
13. An OBD II vehicle comes in the shop with the engine trouble light glowing. Technician A says to connect a scan tool to the vehicle first to read stored trouble codes. Technician B says to test-drive the vehicle first even with the trouble light ON. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
14. An _____ diagnostic test uses the scan tool to order the vehicle's computer to energize specific output devices with the engine on or off.

ASE-Type Questions

1. Technician A says an automotive computer can scan its input and output circuits to detect incorrect voltage problems. Technician B says an automotive computer can scan its input and output circuits to detect an incorrect resistance problem. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says if an automotive computer system detects an abnormal condition, the car's malfunction indicator light will normally be activated. Technician B says if an automotive computer system detects an abnormal condition, the car's low oil warning light will normally be activated. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. The malfunction indicator light in an OBD II system is flashing. Technician A says this means the problem could be damaging the catalytic converter. Technician B says that this simply indicates a soft problem. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says a faulty actuator can affect the operation of an automotive computer system. Technician B says a leaking vacuum hose can affect the operation of an automotive computer system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Technician A says a spark plug misfire can affect the operation of an automotive computer system. Technician B says an automotive computer system is not affected by a spark plug misfire. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. An automobile has a small fuel tank leak. Technician A says this problem may activate the car's computer system "malfunction indicator light." Technician B says this type of problem has no effect on the car's computer system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says about 50% of all automotive engine performance problems are caused by the computer system. Technician B says about 80% of all automotive engine performance problems are caused by something other than a computer system malfunction. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. A trouble code indicates that there is no activity in an oxygen sensor circuit. Technician A says to test the sensor and its circuit. Technician B says to replace the sensor. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says the term "hard failure" refers to an intermittent automotive computer problem. Technician B says the term "hard failure" refers to a constant automotive computer problem. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

10. A wiggle test is being performed on an automotive computer system. Technician A performs this test with the engine off and the ignition key off. Technician B performs this test with the engine off and the ignition key on. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. All of the following can normally be performed during an automotive computer system actuator self-test *except*:
    (A) open and close injectors.
    (B) fire the ignition coil.
    (C) operate the reed valve.
    (D) activate the idle speed motor.
12. Technician A says a switch diagnostic test involves energizing specific output devices. Technician B says an actuator diagnostic test involves the scan tool giving orders to the vehicle's computer. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
13. Which of the following is used with a wireless diagnostic tablet?
    (A) Jumper wire.
    (B) Sending unit.
    (C) Cartridge.
    (D) PROM.

Chapter 25
Computer System Service

After studying this chapter, you will be able to:

- Perform a visual inspection of the computer, its sensors, actuators, and the systems they monitor and control.
- Test sensors and their circuits.
- Remove and replace sensors.
- Test and replace actuators.
- Remove and replace a computer.
- Program an EEPROM.
- Demonstrate safe working practices when servicing automotive computers.
- Correctly answer ASE certification test questions on servicing computer system components.

Since almost all vehicle systems now use computer components, you must have a thorough knowledge of computer circuit service methods. Otherwise, you will not fully understand the chapters on the service and repair of fuel injection, ignition, and emission control systems.

This chapter will briefly summarize how to test computer components and circuits and help you develop the skills needed to verify where problems are.

After you have checked the computer for trouble codes, you can find the exact source of the problem by doing pinpoint tests. ***Pinpoint tests*** are more specific tests of individual components. The service manual will normally explain how to do each pinpoint test. It will show specific tests, as well as provide component electrical values and other critical information.

Remember that trouble codes only indicate the area of trouble and sometimes the type of problem, not what part or circuit is at fault. It is therefore imperative that you know how to do basic electrical tests on individual components.

Preliminary Visual Inspection

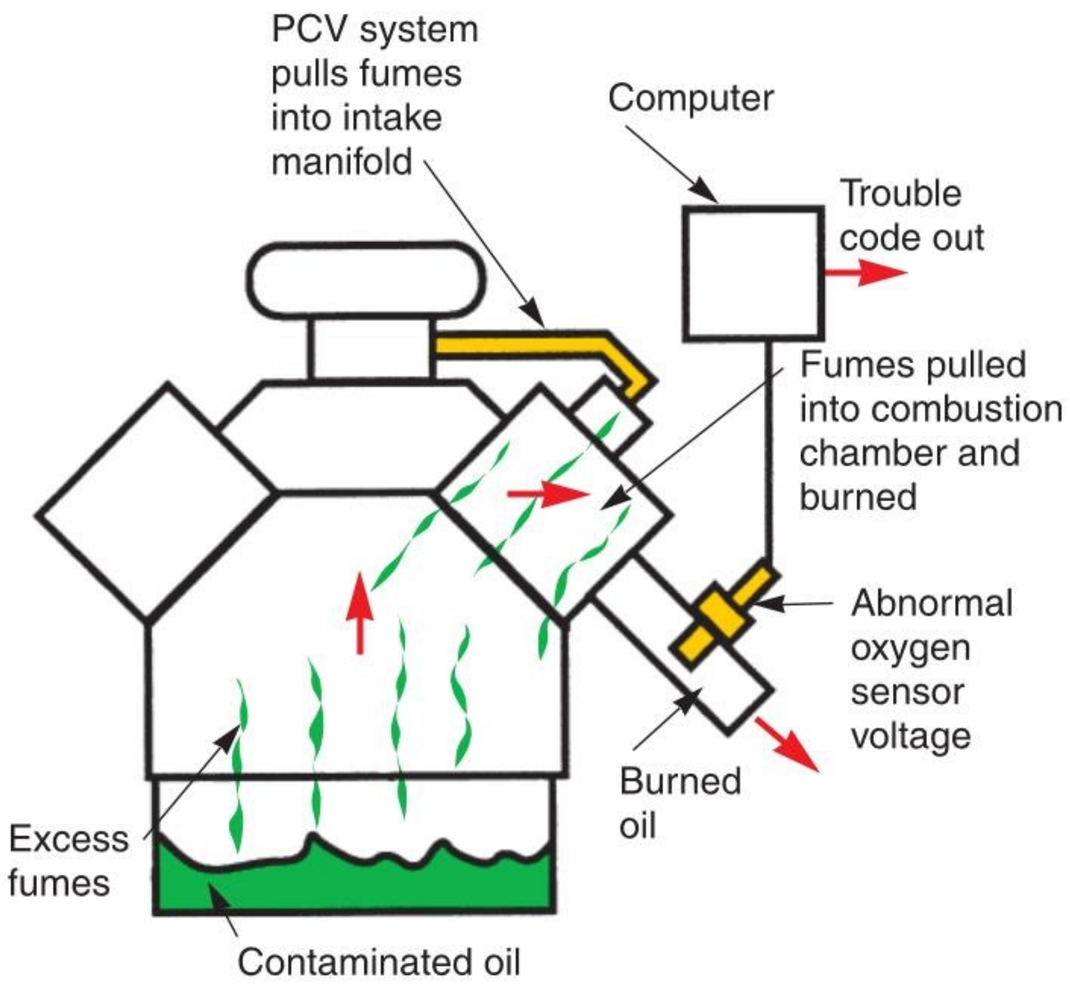
A ***preliminary visual inspection*** involves looking for signs of obvious trouble: loose wires, leaking vacuum hoses, part damage, etc. For example, if the trouble code says there is something wrong in the coolant temperature sensor circuit, you should check the sensor resistance and the wiring going to the sensor. You should also check the coolant level and the thermostat. A low coolant level or engine overheating could also set this code.

Copyright Goodheart-Willcox Co., Inc.

KISS is an acronym that could help you find the source of performance problems on a computer-controlled vehicle. KISS stands for "keep it simple, stupid." This means you should start your troubleshooting with the simple checks and tests. Then, as the common causes are eliminated as the source of the problem, you will move to more complex tests. It is easy for the untrained person to instantly think "computer problem" when an engine runs rough, fails to start properly, or exhibits some other performance problem.

For example, contaminated engine oil can trigger a computer trouble code, **Figure 25-1**. Fumes from the contaminated oil can be drawn into the engine's intake manifold from the crankcase. If these fumes are excessively strong, the oxygen sensor could be tricked into signaling a rich air-fuel mixture. The computer would then lean the mixture to compensate for the crankcase fumes. An oxygen sensor trouble code may be produced and, in some cases, an engine performance problem could result.

As this points out, it is critical that you check for conventional or simple problems first. Start checking for computer problems only after all the conventional causes have been ruled out.



Goodheart-Willcox Publisher

Figure 25-1. This example shows that a trouble code can be tripped by factors other than a computer system problem. Contaminated engine oil can cause excess fumes to be pulled into the PCV system. When burned in the combustion chambers, the fumes could trick the computer into sensing that something is wrong with the oxygen sensor circuit.

Electrical Component Damage

Semiconductor devices, such as transistors and integrated circuits, are very easy to damage. They can be damaged by static electricity, voltage spikes, heat, and impact shocks. Here are some things to remember when working with semiconductor devices and their wiring:

- When welding on any part of a vehicle, disconnect the battery ground and disarm the airbag system. If welding within 12″ (304.8 mm) of any control module, remove the electronic module from the vehicle to avoid heat and radiation damage.
- Never disconnect the battery cables while the engine is running. In the past, some technicians would do this to see if the alternator was working. This can destroy or weaken electronic circuits, causing failure in a short period of time.
- Do not disconnect or connect wiring, especially the computer wiring, with the ignition key on. This can cause a current surge that can damage the computer.
- Make sure you do not reverse the battery cable connections. This can destroy electronic components.
- Wear an anti-static wrist strap whenever you handle static-sensitive components (removable PROM chips, for example) to protect them from damage.
- Use only high-impedance test lights and meters when checking electronic circuits or their wiring. A conventional test light or meter will draw too much current and destroy electrical components.
- Do not disconnect a scan tool from the data link connector while the ignition key is on. This could create a voltage spike that can damage the computer.

Computer System Circuit Problems

Almost all electrical-electronic problems are actually basic circuit problems. A ***basic circuit problem*** is caused by a problem in a circuit that increases or decreases current, resistance, or voltage. For example, a broken wire could stop current flow or a charging system problem could decrease output voltage and current flow.

Unfortunately, when a minor problem occurs in a complex circuit like a computer control system, it may

Copyright Goodheart-Willcox Co., Inc.

not seem like a minor problem. For example, a poor electrical connection in a positive feed wire to a body ground may cause the computer system or one of the systems it controls to lose power. This can result in a shutdown of the fuel injection system, the emissions control system, the ignition system, or the entire vehicle.

You might think that any of these systems or the computer itself is at fault. Several systems could appear to have a problem. In reality, it is simply a poor electrical connection in one wire that is causing all the problems. It is important for an automotive technician to remain calm when diagnosing electrical problems. If analyzed properly, problems can usually be found and corrected easily.

Locating Computer Problems

The most difficult aspect of making computer system repairs is finding the source of the problem. To find the source of computer problems, you must ask yourself the following types of questions:

- What could be causing the specific symptoms? Mentally picture the parts in the circuit and how they function. Trace through the circuit while referencing a wiring diagram to find out which wires, connections, and components are in the circuit leading to the potential trouble source.
- How many components are affected? If several components are not working, something close to a common power source or ground point is at fault. If only one or two sections of the circuit are faulty, begin your tests at those sections of the circuit.
- Is the problem always present or is it ***intermittent*** (only occurs under some conditions)? If the problem is intermittent, the conditions causing the problem will have to be simulated. For example, a loose electrical connection could open and close with vibration or movement. You might simulate driving conditions by wiggling wires and connectors in the circuit to make the problem occur.
- Is the problem's occurrence related to heat or cold? If it occurs only on a hot day or when the engine is warmed to full operating temperature, heat is related to the problem's occurrence. Electronic circuits (transistors in particular) are greatly affected by heat. In fact, too much heat can ruin an electronic component. You can use a heat gun to simulate the heat in an engine compartment.
- Is the problem's occurrence affected by moisture? If the trouble occurs only on wet or humid days, you have information to use when analyzing the source of a problem. In most cases, moisture cannot enter a sealed electronic component, but it may enter and affect the wire connections and any components exposed to the environment.

Stress testing refers to the use of heat, cold, or moisture to simulate extreme operating conditions of components, like spark plug wires, explained in a later chapter under spark plug wire leakage.

Sensor and Actuator Problems

As with other electrical and electronic components, sensors, actuators, and their circuits can develop opens, shorts, or abnormal resistance or voltage values. When your pinpoint tests find a problem, the sensor or actuator should be replaced or the circuit repaired.

In most cases, a scan tool is used to find the problem circuit and component. A digital multimeter is sometimes used to measure the electrical signal from the component or circuit to verify problems indicated by the scan tool. Then, this value (voltage, resistance, or current) is compared to factory specifications. If the test value is too high or too low, you would know that the sensor or actuator is faulty and must be replaced.

The shop manual will also have a wiring diagram, or schematic, for the computer system. The diagram will show the color codes of the wires and the number of connectors that are used to feed signals from the sensors to the computer and from the computer to the actuators. This can be very helpful when servicing any computer system. The following paragraphs discuss the most frequent circuit problems.

Poor Electrical Connections

Poor electrical connections are the most common cause of electrical-related problems in a computer system. Discussed previously, a wiggle test will help find poor connections and intermittent problems. Always check electrical connections when diagnosing sensors and other electronic components. OBD II scan tools will help you find poor electrical connections, as shown in **Figure 25-2**.

Poor electrical connections can be due to corroded terminals, loose terminal ends, burned terminals, chafed wires, and other problems. Dirt and moisture can get into connectors, causing high resistance. Any of these conditions can prevent a normal sensor signal from returning to the computer. They can also prevent the control current from reaching an actuator.

Snap-on Tool Corp.

Figure 25-2. The scan tool will usually direct you to the area of the vehicle causing the problem. A—"Read DTC Options" allows you to select stored codes, pending codes (codes that are almost out of normal operating parameters), and manufacturer data. B—The scan tool denotes the vehicle has tripped two trouble codes. C—The scan tool readout explains that the mass or volume airflow sensor circuit is showing low voltage or current input to the computer. D—The scan tool readout shows there is no engine misfire problem, the fuel injection system is working normally, and the catalytic converter is working. E—No signal from the heated catalyst may be due to the engine not warming up completely. The evaporative emission control system is working normally. Air conditioning has no signal because it might not be turned on. F—The scan tool indicates both O_2 sensors are working normally. The EGR system may not have a signal because the engine has not warmed fully.

Vacuum Leaks

Vacuum leaks are frequently caused by deteriorated, broken, or loose vacuum hoses. Vacuum leaks often make a hissing sound. Some vacuum leaks can upset the operation of a computer system and cause a wide range of symptoms. Also, some engine sensors and actuators rely on engine vacuum for operation.

Always check for vacuum leaks when they could be causing a performance problem, **Figure 25-3**. For example, if the trouble code indicates a problem with the MAP (manifold absolute pressure) sensor, check the vacuum lines leading to the sensor. If there is a vacuum leak, the sensor cannot function normally. Also check the intake manifold gasket area, as this is a common location for vacuum leaks.

Air leaks after a mass airflow sensor can also cause problems. The sensor cannot measure the

Goodheart-Willcox Publisher

Figure 25-3. Always inspect the engine compartment for signs of trouble. A loose or corroded connection or a vacuum leak may be setting trouble codes or tricking the computer system.

Copyright Goodheart-Willcox Co., Inc.

actual amount of air being drawn into the engine, and an incorrect air-fuel mixture will result.

Sensor Service

Sensor service involves testing and, if needed, replacing computer system sensors. Since sensor designs vary and some can be damaged by incorrect testing methods, it is important for you to know the most common ways of checking sensor values.

For testing purposes, you can classify sensors into one of two categories: passive sensors or active sensors. This will help you select a testing method.

Testing Passive Sensors

Since passive sensors do not generate their own voltage, the computer must feed them a reference voltage. A passive sensor can change its internal resistance with a change in system or vehicle condition or operation. This resistance change modifies the reference voltage, which is interpreted and used by the computer to control the engine's various systems.

To test a passive sensor, either measure its internal resistance with an ohmmeter or measure the voltage drop across the sensor with its reference voltage applied. Depending on the sensor or manufacturer, both tests may be performed. You can also read computer data stream values with your scan tool. However, the scan tool cannot isolate the sensor, wiring, or computer for individual tests. Any unusual sensor readings by a scan tool should be verified using a multimeter.

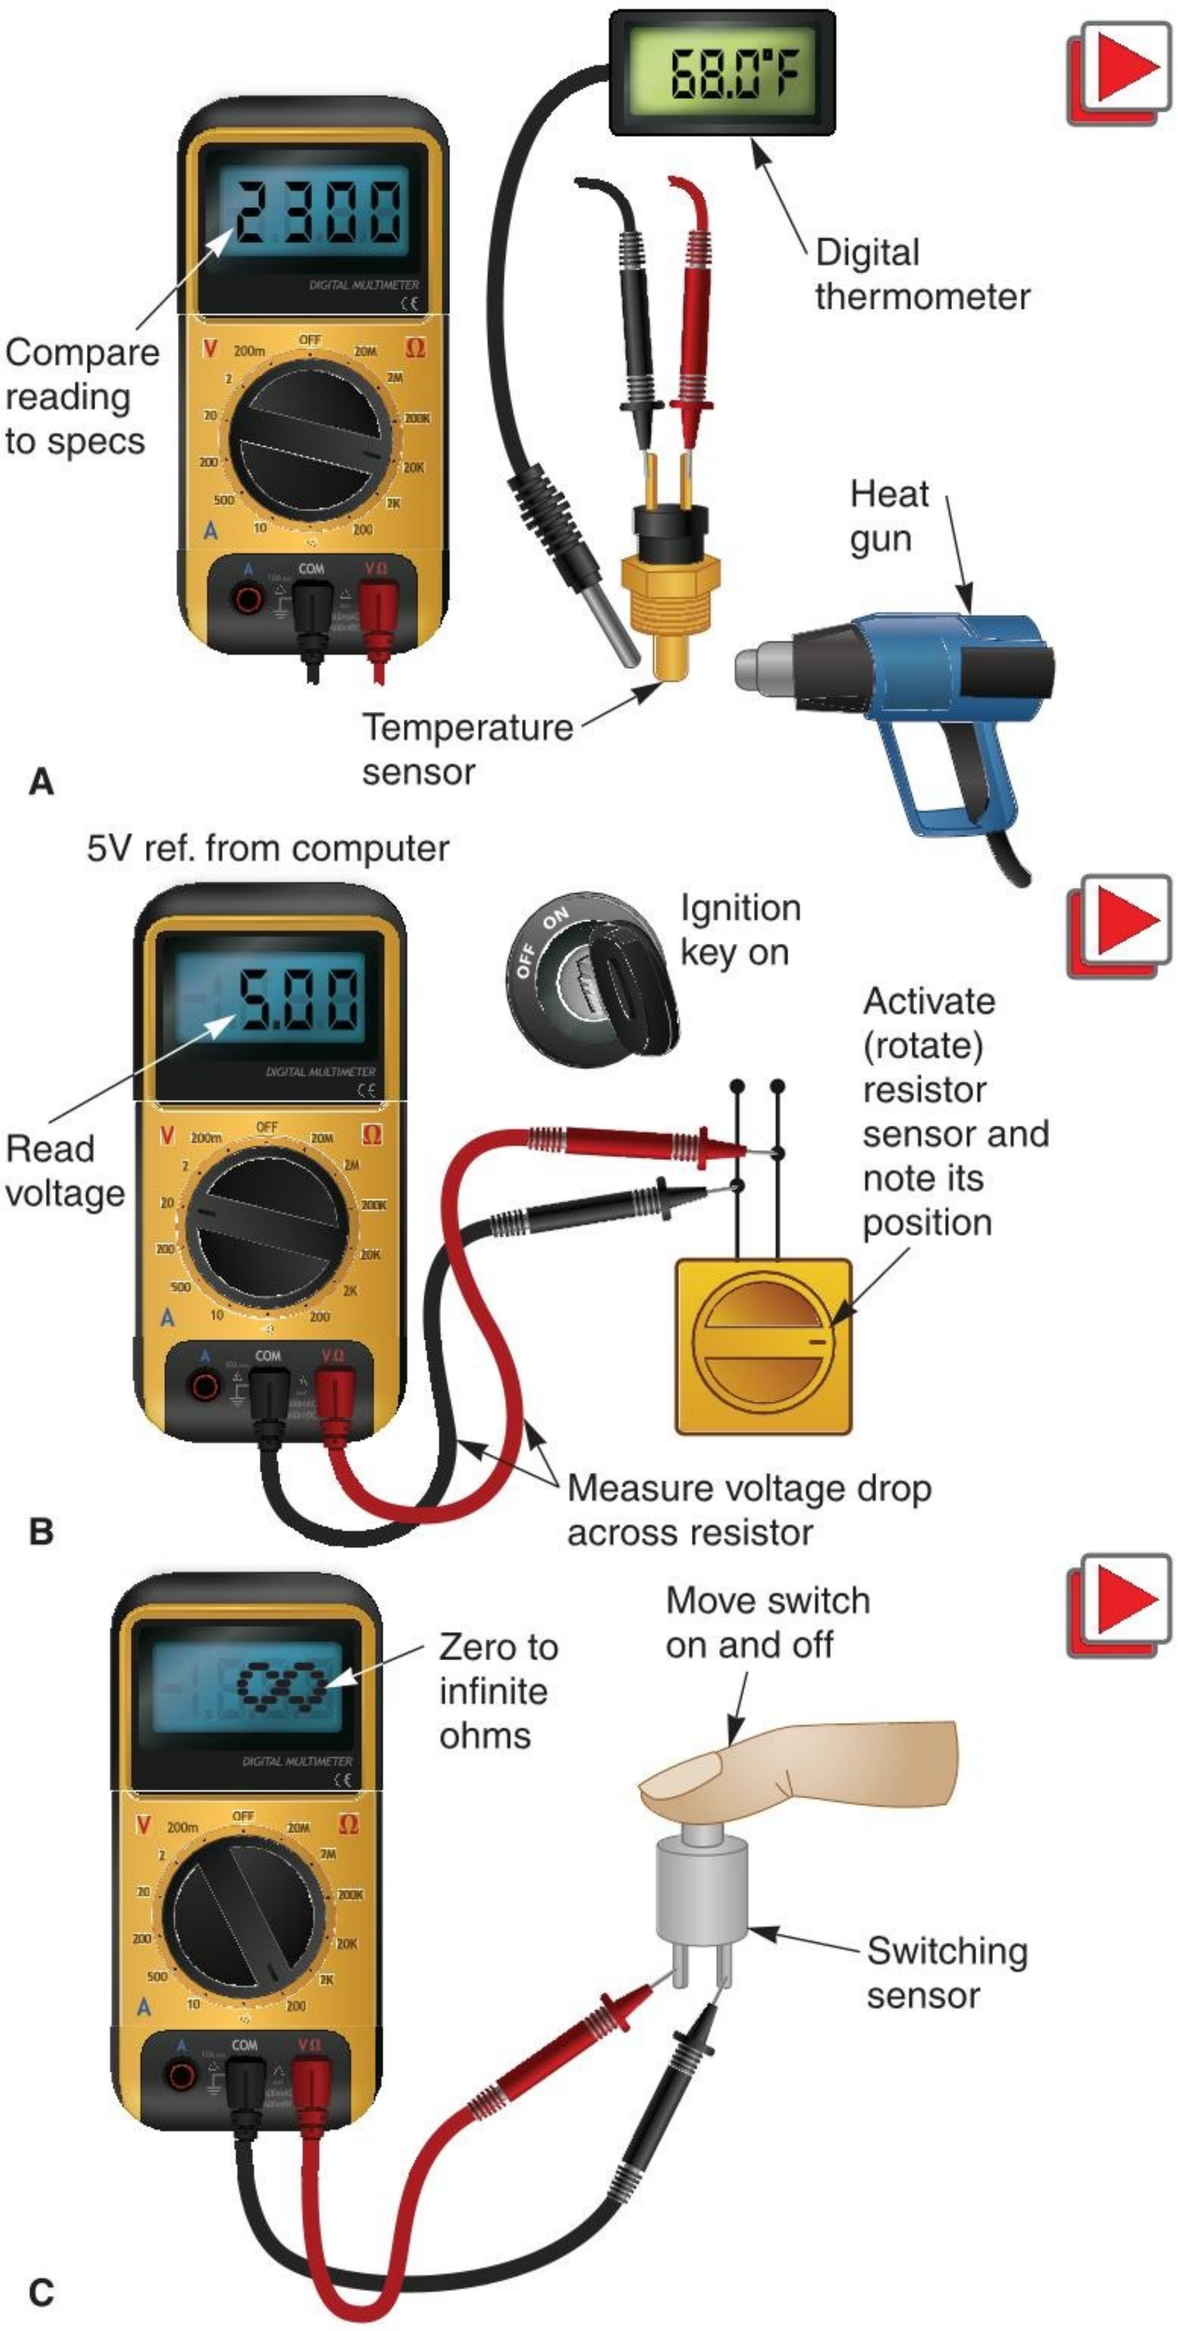
Testing Variable Resistance Sensors

Service Procedure

To test a variable resistance sensor with an ohmmeter:

1. Disconnect the sensor wires.
2. Connect the ohmmeter's test leads to the sensor terminals, **Figure 25-4A**.
3. Compare the ohmmeter reading to the manufacturer's specifications.

The sensor's resistance must be within factory specifications. For example, if you are testing a temperature sensor, connect an ohmmeter to the sensor terminals and then measure coolant temperature with



Goodheart-Willcox Publisher

Figure 25-4. There are many ways to test passive sensors. A—An ohmmeter can be used to measure internal resistance. Some sensors can be heated with a heat gun while measuring resistance. A digital thermometer may also be used to compare actual temperature with sensor resistance. B—A voltmeter can be used if sensor specifications are given only as a voltage drop. The sensor must have reference voltage while testing occurs. C—Switching sensors may be tested with an ohmmeter or a high-impedance test light. The meter or light should show a change in condition when the switch is turned on and off.

Copyright Goodheart-Willcox Co., Inc.

a digital thermometer. Note the resistance readings at various coolant temperatures and compare these readings to service manual specifications.

If the sensor's resistance is within specifications, check for opens or shorts in the wires going to the sensor. If the wires are good, suspect the computer itself. The service manual will give detailed instructions for testing the computer.

Service Procedure

To check a variable resistance sensor with a voltmeter:

1. Connect the voltmeter in parallel with the sensor. Be sure to leave the computer wires connected to the sensor, **Figure 25-4B**.
2. Measure the voltage drop across the sensor with the computer reference voltage applied.
3. Compare your measurements to specifications.

Testing Switching Sensors

With a switching sensor, such as a power steering pressure switch, you can use an ohmmeter to check that the switch is opening and closing. As shown in **Figure 25-4C**, connect your ohmmeter and move the switch opened and closed. Your meter should register infinite ohms and then zero ohms. Replace the sensor if it is defective. You could also use a high impedance test light to quickly check the operation of a switching sensor.

Note that some auto manufacturers do not give resistance specifications for passive sensors, they only give voltage drops. You may have to use a test harness to connect the meter in parallel with the sensor. You can make or purchase this type of test harness.

Testing Reference Voltage

A reference voltage (typically 5 volts) is fed to passive sensors. Then, when conditions and sensor resistance change, the amount of voltage flowing back to the computer also changes. The reference voltage is needed so a signal returns to the computer.

Service Procedure

To measure reference voltage to a passive sensor:

1. Disconnect the wires leading to the sensor.
2. Connect a digital voltmeter to the wires.
3. Turn the ignition key on and note your readings.
4. Compare your voltage readings to specifications.

Typically, the open circuit voltage should be about 5 volts. Refer to **Figure 25-5**.

If the reference voltage to the sensor is low, check the wiring harness for high resistance, as something is preventing the full reference voltage from reaching the sensor. Low reference voltage would cause a sensor to produce erroneous readings. It is possible for the reference voltage to be too high if a current-carrying wire is shorted into the circuit. High voltage may also be caused by a computer malfunction, but this is rare.

Testing Active Sensors

As mentioned, an active sensor produces its own voltage and sends it back to the computer. The voltage produced by an active sensor is very low, often under 1 volt. This makes sensor wiring harness continuity very critical. One poor electrical connection can keep the low voltage from returning to the computer.

Figure 25-6 shows several ways to test an active sensor. In **Figure 25-6A**, an ohmmeter is connected to a common magnetic sensor. The ohmmeter will measure the resistance of the coil winding. Replace the sensor if the resistance is high or low.

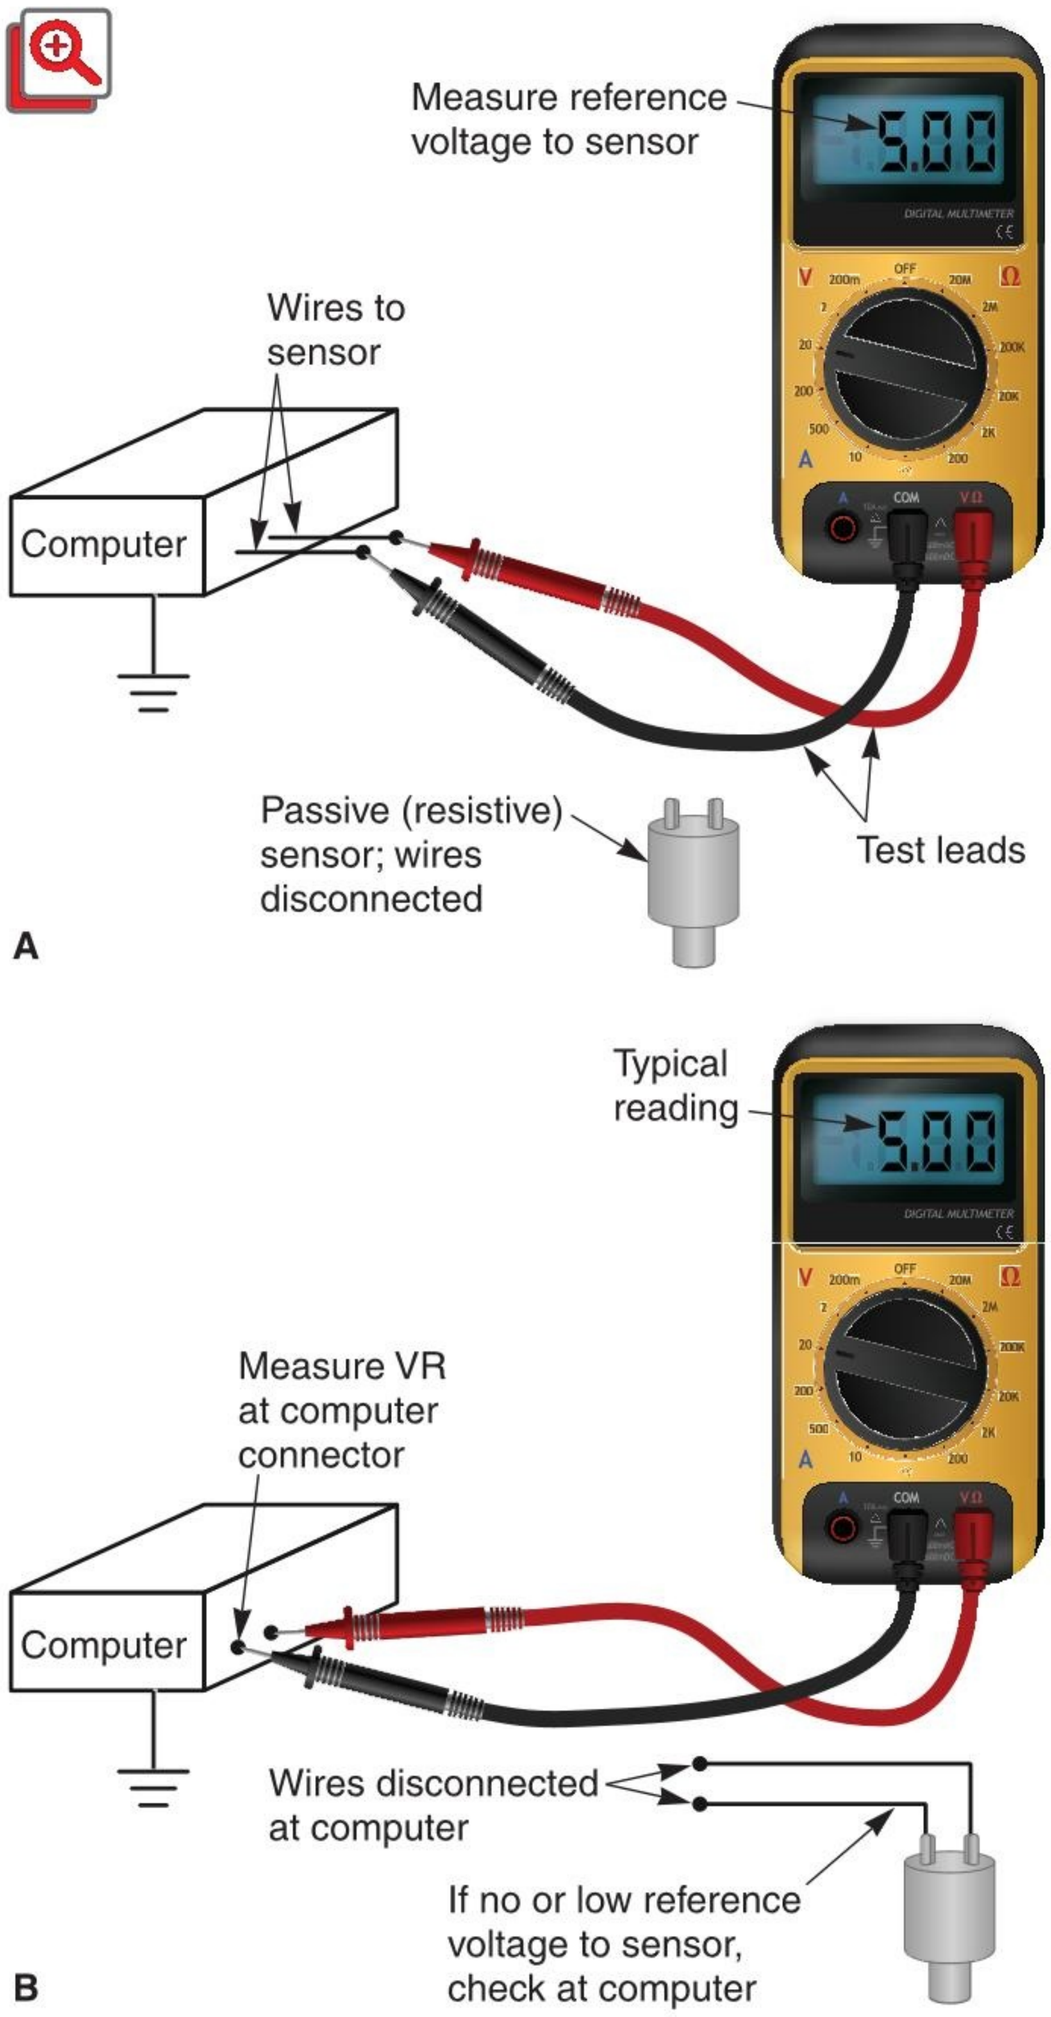
In **Figure 25-6B**, an ac voltmeter is connected to a magnetic sensor. The trigger wheel must be rotated (engine cranked over, wheel or hub in an ABS system turned, etc.) to make the sensor generate voltage. A magnetic sensor should typically produce about 1.5–3 volts ac. A magnet can also be passed by a coil to make it produce a voltage.

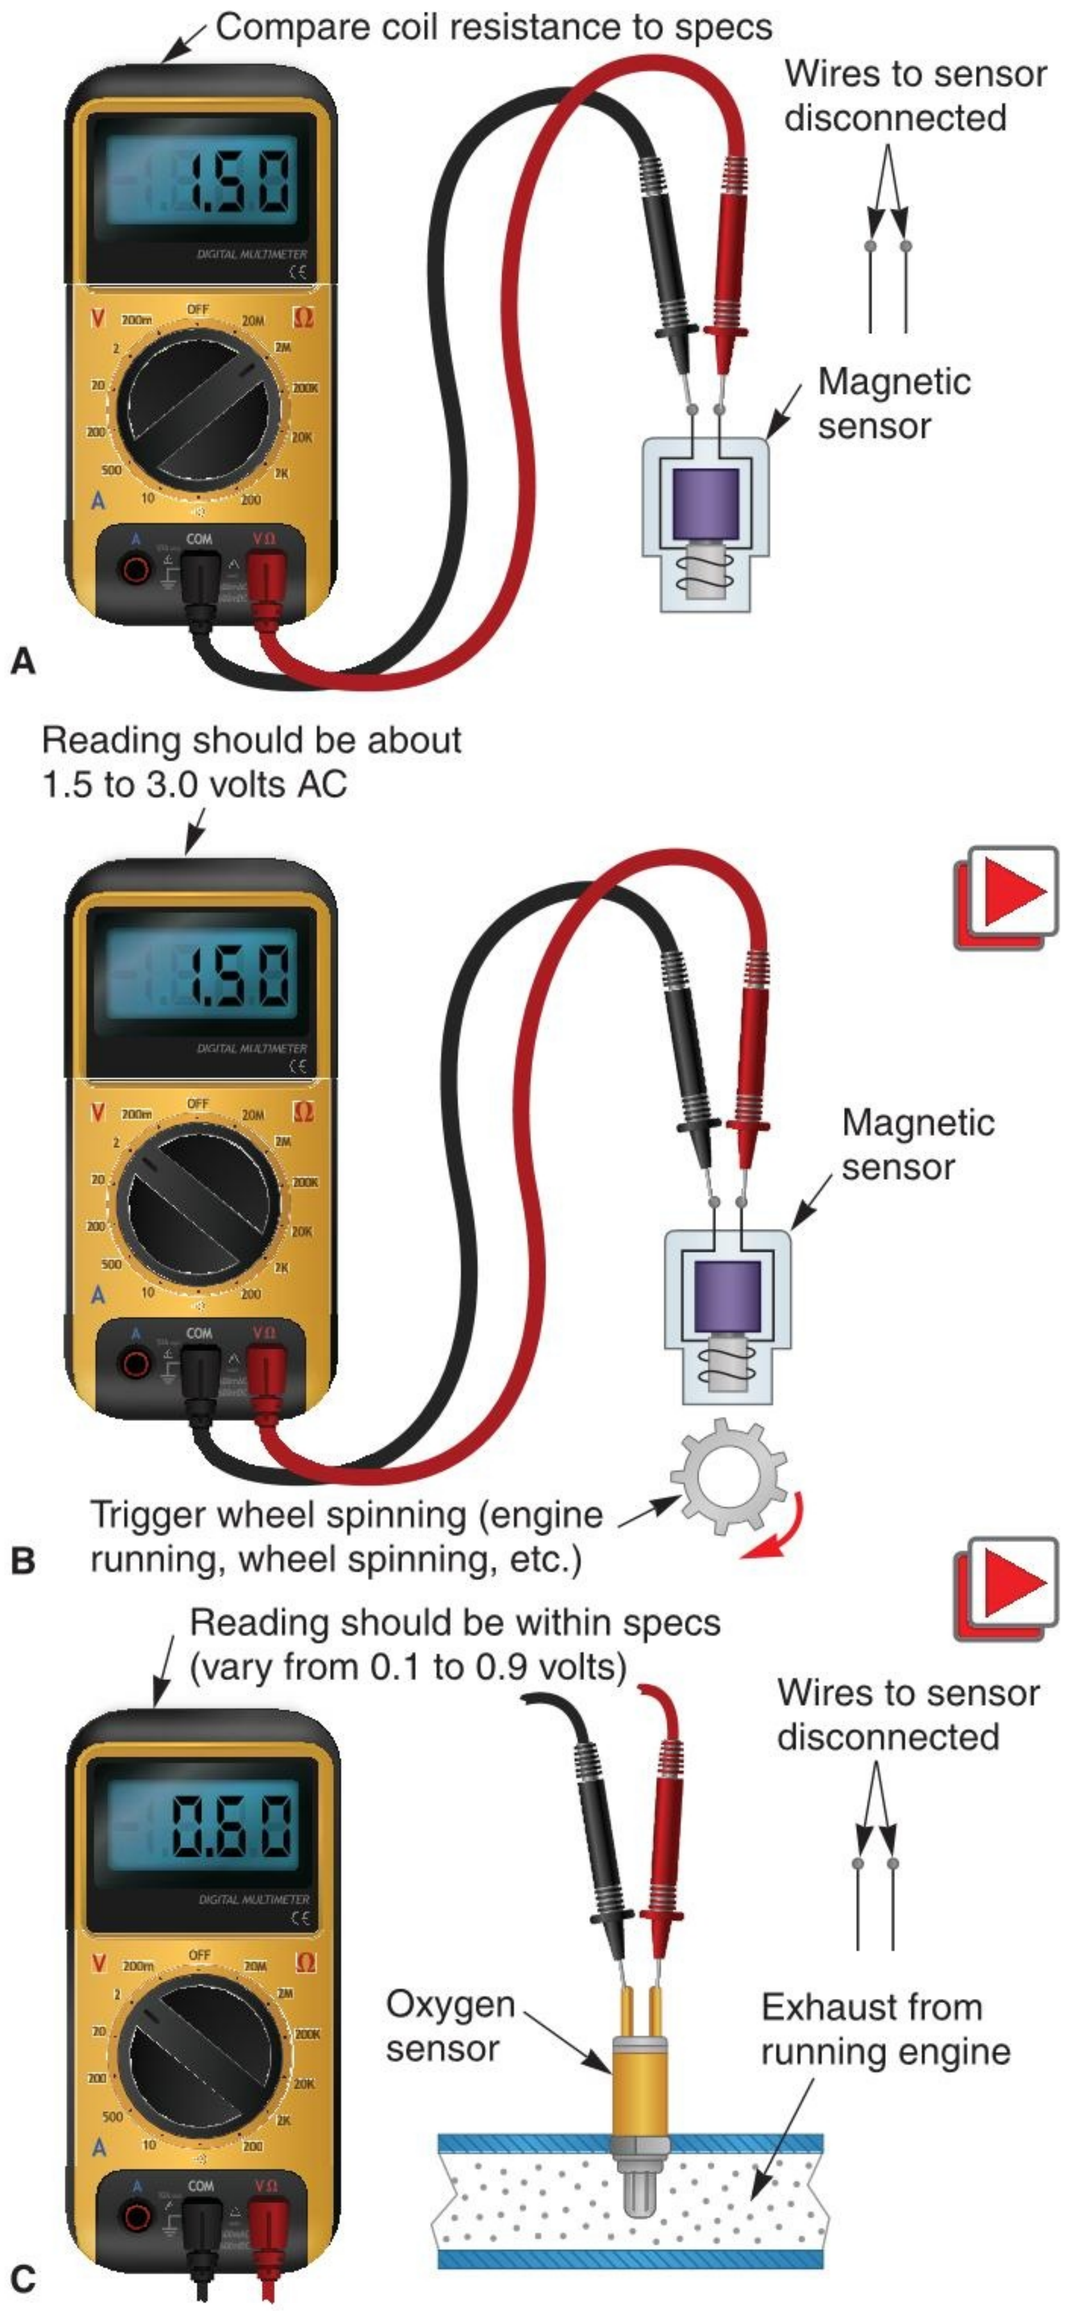
In **Figure 25-6C**, a digital voltmeter is connected to an oxygen sensor. With the engine running in closed loop, the voltmeter should show the sensor's output voltage. If the output voltage from the sensor is low or high, the sensor may require replacement. **Figure 25-7** shows how to use small jumper wires to connect a meter to check a sensor while it is still functioning in the circuit.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

Whenever a sensor tests good, check the wiring leading to the sensor. Bad wiring may be blocking current flow back to the computer.



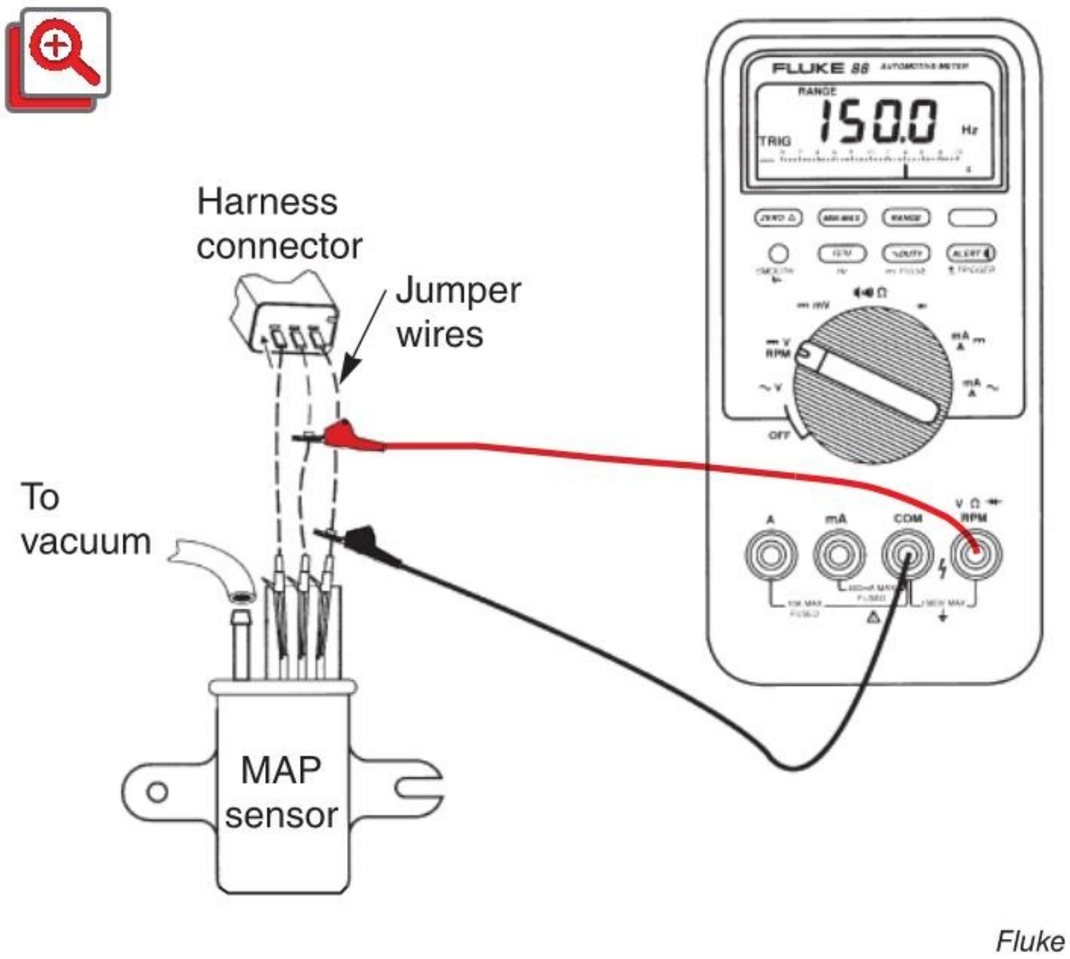


Goodheart-Willcox Publisher

Figure 25-5. Passive sensors rely on a computer reference voltage for proper operation. A—Use a digital voltmeter to measure the amount of voltage supplied to the sensor. Typical reference voltage might be 5 volts, but refer to the service manual specifications. B—If the reference voltage is not correct, test for voltage at the computer. If the reference voltage at the computer is correct, a problem with the wiring harness is indicated.

Figure 25-6. Since an active sensor generates its own output signal, testing methods for active sensors are slightly different from those for passive sensors. A—Magnetic sensor internal coil resistance can be measured with an ohmmeter. B—An ac voltmeter can be used to check a magnetic sensor while it is operating. With the triggering device moving, an ac voltage signal should be generated. C—Sometimes it is recommended to connect a meter directly to the sensor. You can compare the operating sensor's output to specifications. Be sure to test the harness leading to the sensor.

Copyright Goodheart-Willcox Co., Inc.



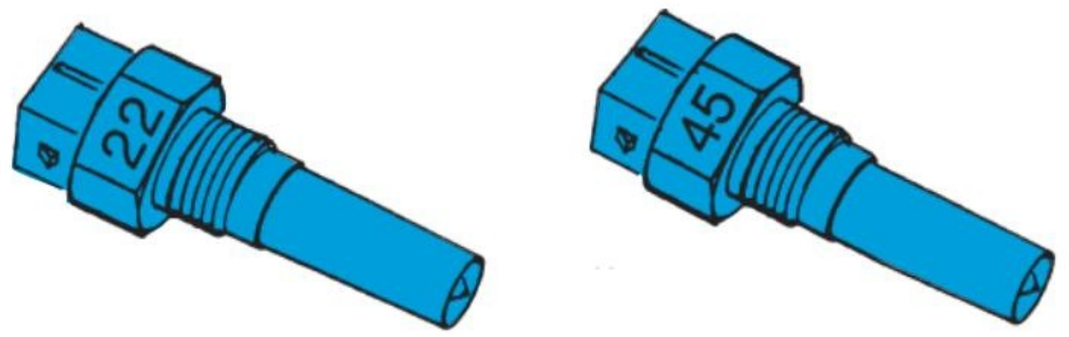
Fluke

Figure 25-7. Small jumper wires are often used when measuring sensor circuit values. Make sure you do not short the jumper wires together or to ground. This test is used to measure the frequency signal in hertz from a manifold absolute pressure sensor.

Replacing Sensors

When replacing a sensor, there are several general rules you should remember:

- Always purchase an exact sensor replacement. Even though two sensors may look identical, their internal resistance or circuitry may be different. See **Figure 25-8**.
- Release the sensor connector properly. Most connectors have positive locks that must be released. If you damage the connector, intermittent problems may result from a loose connection.
- Use special tools as needed. Some sensors, such as oxygen sensors, require the use of a ***sensor socket***. This socket has a deep pocket and a cut-out that will fit over the sensor and any wires. Conventional deep sockets may not fit over the wiring or the sensor head.
- Use thread sealant sparingly. If the sensor seals a coolant, oil, or vacuum passage, do not use too much sealant.
- Use thread and engine sealants that are safe for oxygen sensors. Some sealants can poison the oxygen sensors.
- Tighten the sensor properly. Overtightening a sensor can damage it. Undertightening can lead to leaks.



Snap-on Tool Corp.

Figure 25-8. Always make sure the replacement sensor is same as the old one. These two temperature sensors look the same but have different temperature and resistance values. If the wrong one is installed, the vehicle may not function correctly.

- Adjust the sensor, if needed. Some throttle position sensors require adjustment after installation.
- Scan for trouble codes after sensor replacement.

Actuator Service

Actuator service involves testing the actuators for possible electrical or mechanical problems and replacing them, if necessary. If an actuator fails, the computer cannot control the engine and vehicle systems properly.

Testing Actuators

Since actuators are simply relays, solenoids, and motors, they are fairly easy to test. **Figure 25-9** shows several ways to test actuators.

Testing Servo Motors

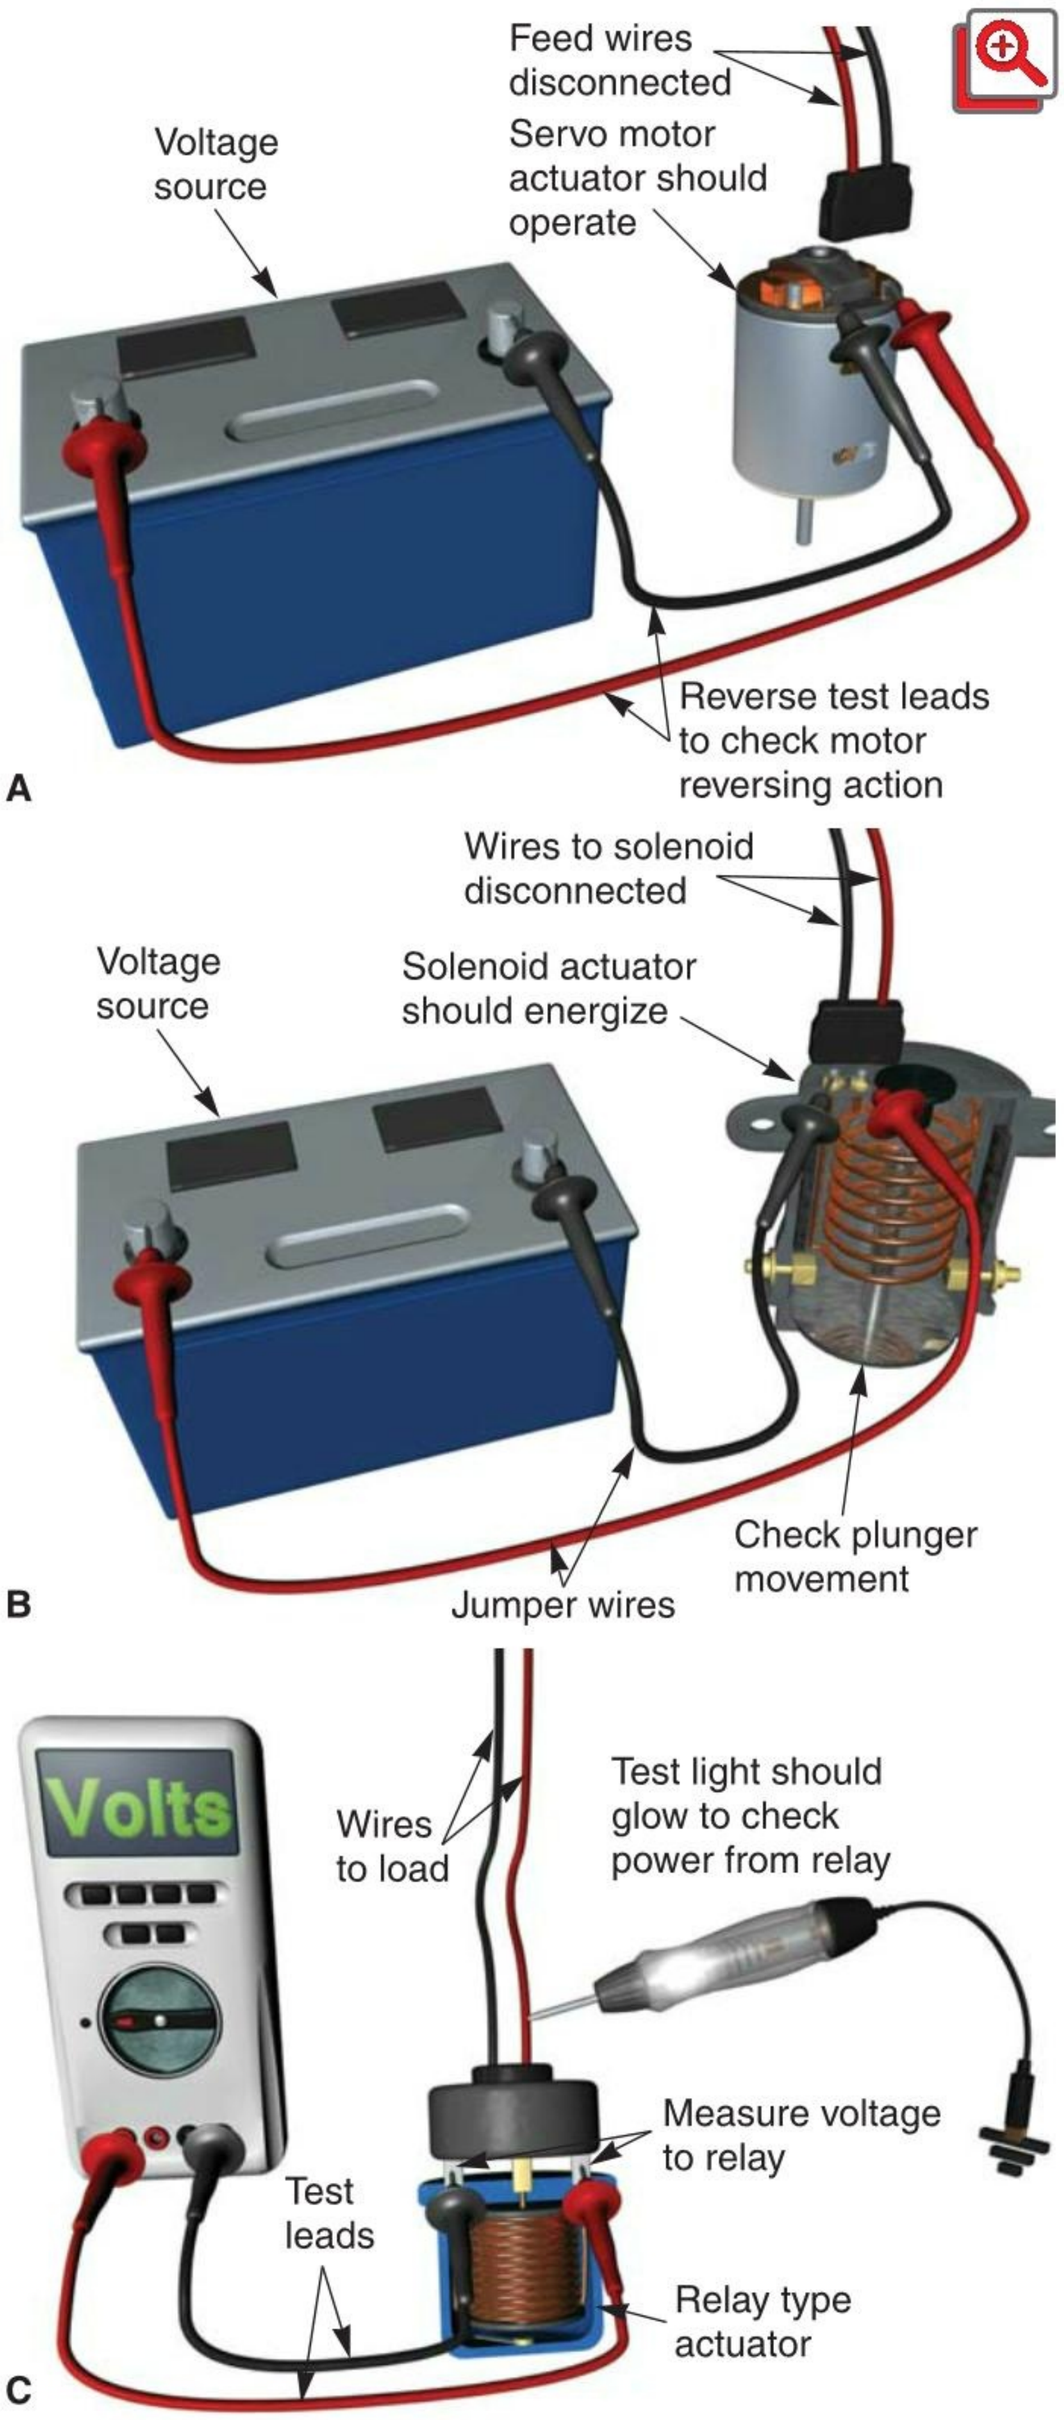
In **Figure 25-9A**, a voltage source has been connected to a servo motor. The wiring harness to the motor has been disconnected. Jumper wires feed current directly to the motor. This is a simple way to check the operation of an electric or servo motor. If the motor begins to function with an external voltage source applied, you should test the wire harness leading to the motor.

Testing Solenoids

In **Figure 25-9B**, a voltage source is being used to check a solenoid. When jumper wires are connected to the vehicle's battery and the solenoid, the solenoid should operate. If the solenoid tests good, you should check the voltage coming to the solenoid through its harness.

An ohmmeter can also be used to test a solenoid. You can use the meter to measure the internal

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 25-9. Actuator testing is straightforward. It is similar to testing a conventional motor, relay, or solenoid. A—Voltage can be jumped to a servo motor. The motor should function when energized by the power source. B—A solenoid can also be tested in the same manner as a servo motor. C—A relay is slightly more complex to test. You must make sure there is an output when voltage is supplied to its input terminals. This can be done using a voltmeter or a high-impedance test light.

resistance of the unit. By comparing resistance readings to specifications in the service manual, you can find out if the actuator must be replaced.

Testing Relays

Figure 25-9C shows how to test a relay. Check the voltage entering the relay and the voltage leaving the relay. It is possible that voltage is applied to the relay but the relay points are not sending voltage out to the controlled device.

Since relays contain movable contact points, they are a common source of computer system problems. The scan tool may indicate a problem with the circuit containing the relay. However, you must test the relay to pinpoint the problem source.

Relays can be located almost anywhere on a vehicle: in the engine compartment, under the dash, under the seat, or in the trunk. The service manual will give exact locations. See **Figure 25-10**.

An integrated ***junction block*** encloses most or all of the vehicle's mechanical relays in a single housing. Some of the relays found in this block are the fuel pump relay, cooling fan relay, wide open throttle relay, air conditioning relay, and a host of others. The junction block is usually mounted in the engine compartment.

When testing a relay, refer to the service manual wiring diagrams for pin numbers and wire color codes. Special ***relay testers*** can be used to quickly test relay operation. They plug into the relay and test the unit automatically.

For information on actuator service, refer to the index in this textbook. You can find instructions on testing fuel injectors, glow plugs, and more specialized actuators.

Replacing Actuators

Actuator replacement will vary with the type and location of the unit. Here are a few rules to follow when replacing an actuator.

- Do not damage the wire connectors when releasing them. They are made of plastic and will break if forced open improperly.
- Do not drop the actuator mounting screws during removal or installation. If a screws falls into an engine, major problems can occur.
- Make sure you have the correct replacement actuator before attempting installation. Two actuators may look the same, but they will often have different internal construction.

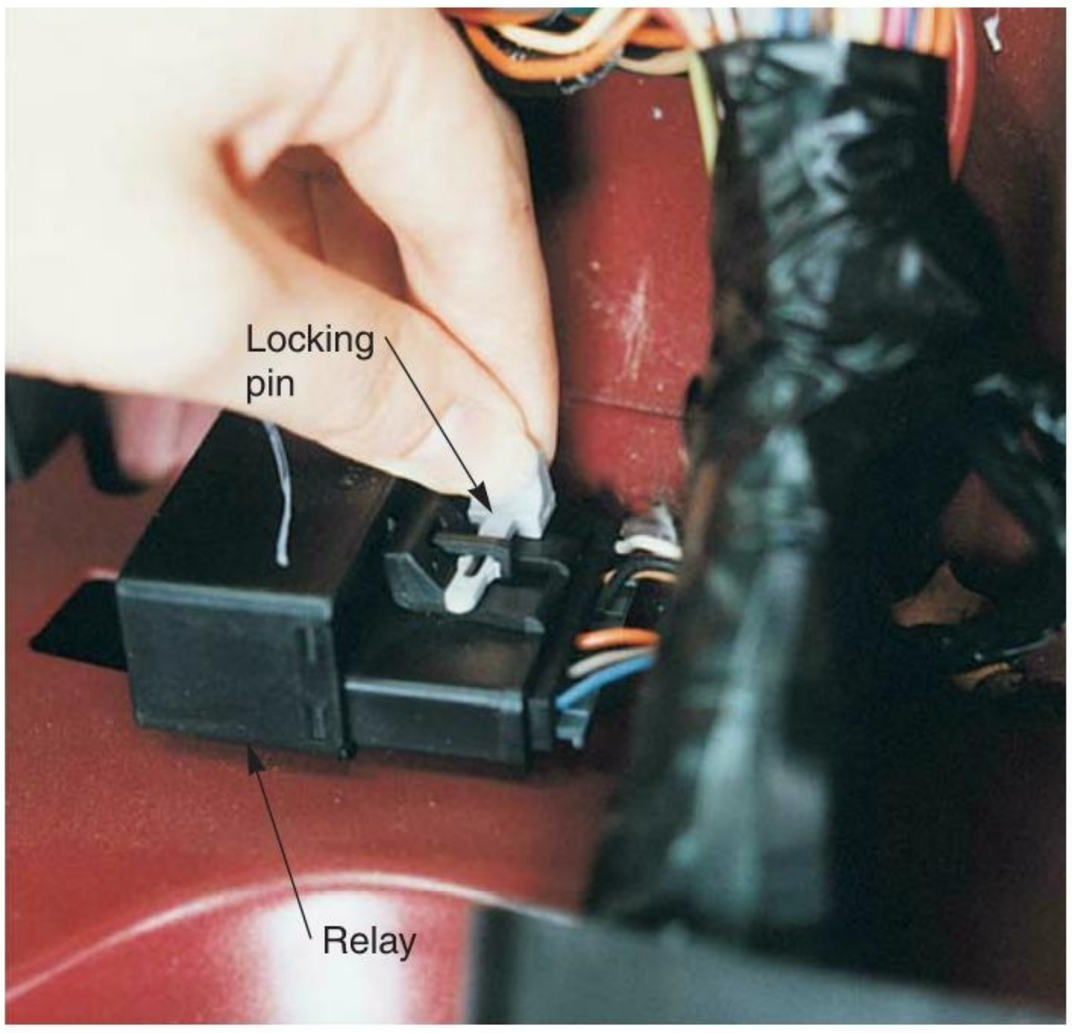
Copyright Goodheart-Willcox Co., Inc.

- Check that the actuator is fully seated before tightening the mounting screws.
- Double check actuator operation after replacement.

Computer Service

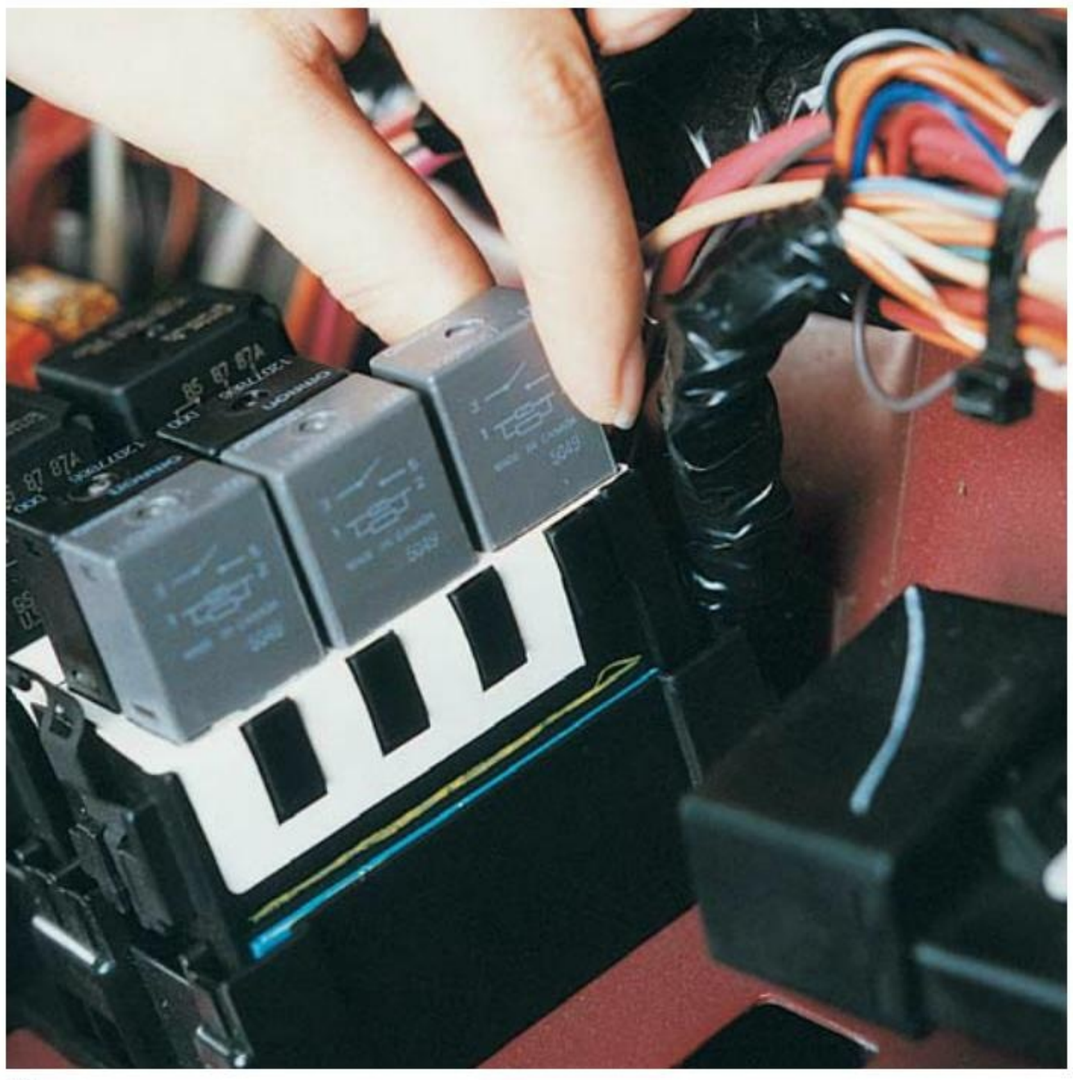
Computer service involves replacing or reprogramming the computer. The computer is the last component to be suspected of being the problem

A



B

C



D

Goodheart-Willcox Publisher

Figure 25-10. Relays have moving parts that can fail in service. Relays can be located almost anywhere on the vehicle. Copyright Goodheart-Willcox Co., Inc.

source, only after all other potential sources of trouble have been eliminated. It is sometimes possible for an integrated circuit, transistor, or other electronic part in the computer to fail and upset system operation.

Measuring Computer Output

If the computer is not tested, a defective computer is often identified through the process of eliminating the sensors, actuators, and related wiring as the cause of the problem. In the process of sensor and actuator testing, it was necessary for you to measure the computer's output. A ***computer output*** can be a reference voltage to a sensor or a supply voltage to an actuator.

Use a voltmeter to make sure the correct reference voltage is being sent to a sensor. Most computers produce a reference voltage of about 5 volts. If the reference voltage is not correct, check the wiring before condemning the computer. You can also measure voltage to make sure the correct voltage output is being fed to the actuators.

Each computer input and output passes through an individual metal terminal, or pin, which plugs into the vehicle wiring harness. ***Pin numbers*** identify the location and purpose (electrical value and internal connection) of each terminal in a computer wiring harness connector. You may have to probe computer terminal pins to find the source of complex problems. This will be discussed in a later chapter.

Again, always refer to the service manual for exact procedures when testing a computer system. One wrong electrical connection can destroy the computer.

Caution

Never use an ohmmeter to check a computer, as it will damage the computer's internal circuitry. If it is necessary to use an ohmmeter to check the continuity of a wire or circuit in the computer harness, disconnect all wiring harnesses from the computer before testing.

Saving Memory

Saving memory can be done by connecting a memory saver to the accessory port (lighter port) or the data link connector before disconnecting the vehicle's battery. The ***memory saver*** supplies enough power to keep the clock, stereo, and computer from losing the information stored in their memories. Some memory savers use a 9-volt battery and plug into the vehicle's accessory port. Other memory savers contain a rechargeable 12-volt battery and plug into the vehicle's accessory port or the data link connector. See **Figure 25-11**. In some cases, a battery jump start box can be used as a memory saver. A specially designed cable connects the jump start box to the vehicle's accessory port or data link connector.

Before using a memory saver, turn off all accessories (radio, blower, etc.). The current drain from these devices, combined with even the smallest voltage drop, could cause electronic devices (computer, clock, radio, etc.) to lose their preprogrammed data. You are still disconnecting the vehicle battery for safety. The memory saver cannot supply enough current to cause an electrical fire or operate the starting system.

Computer Replacement

Before disconnecting the battery and removing the computer from the vehicle, you should scan the computer and obtain the PROM identification number or the EEPROM calibration number. This information

OTC/SPX Corp.

Figure 25-11. This memory saver has cables for your vehicle's accessory port and for the data link connector.

Copyright Goodheart-Willcox Co., Inc.

is needed to check for updated PROMs that should be installed and calibration programs that should be downloaded to the new computer. External identification numbers are not always placed on the PROM.

When removing a computer, the ignition key should be off and the vehicle's negative battery cable disconnected. This will prevent voltage spikes from damaging the computer when the harness connectors are removed. Remove any shields or components necessary to access the computer. Unbolt the brackets holding the computer in place and unplug the computer connectors.

Identification information is usually stamped or printed on the computer. Use this data and the year, make, and model of vehicle to order the correct replacement computer. The VIN (vehicle identification number) may be helpful, as well.

Caution

When handling computers, keep one hand on chassis ground and use the other to remove the component. This will prevent a static electrical charge from entering and damaging the electronic circuitry. If available, wear an anti-static wrist strap when working on computer circuits. Static electricity may not instantly ruin an electronic part, but it can reduce the part's useful service life from years to days.

EEPROM Programming Using Computerized Equipment

Most newer computers use Electrically Erasable Programmable Read Only Memory (EEPROM) or Flash Erasable Programmable Read Only Memory (FEPROM) chips that are permanently soldered to the circuit board. These chips must be programmed using electronic equipment. They are often reprogrammed to correct driveability and performance problems.

EEPROMs are programmed using a method referred to as flash programming. Flash programming may be performed by downloading the vehicle's information through a computer, a computerized diagnostic analyzer, or a scan tool. Actual programming details vary between manufacturers, but the basic procedure begins by placing the computer in the programming mode. One of two methods is used to program the computer:

- Direct programming using a service computer or a laptop computer, **Figure 25-12**.
- Remote programming with the computer off the vehicle.

Direct Programming

Direct programming is the fastest and simplest method. The new information is downloaded by attaching a shop recalibration device (usually a laptop computer) directly to the data link connector. The erasure and programming is done by accessing the programming menu and following the instructions as prompted by the computer. Then, the vehicle's operating information and parameters are entered into the vehicle's computer through the connector.

Remote Programming

Remote programming is done with the vehicle's computer removed from the vehicle. This procedure is used when changes need to be made through a direct modem connection to a manufacturer's database computer. It can also be done in cases where direct programming is not practical or possible. Since special connectors and tools are required for this type of programming, this procedure is done only at new vehicle dealerships.

EEPROM Programming Procedure

To begin programming the EEPROM-equipped computer, make sure that the vehicle's battery is fully charged. Recharge the battery if necessary. Do not charge the battery during the programming procedure, as damage to the computer will result. Connect the programming computer or scan tool to the data link connector. Make any other vehicle connections as needed before proceeding with the programming sequence.

Caution

Do not disconnect the scan tool or programming computer from the data link connector during the programming sequence. Doing so will damage the vehicle's computer.

To start the programming sequence, the programming computer prompt may ask you to enter the engine type, vehicle type, and vehicle identification number (VIN) in a specific sequence. Once the vehicle information is entered, go to the programming software and follow the directions as prompted.

Figure 25-12. Most dealerships now have a dedicated laptop computer for EEPROM reprogramming. A—The laptop is plugged into the diagnostic link so it can download new information into the vehicle's computer. B—Icons on the laptop screen allow the technician to select the correct software for downloading.

Depending on the manufacturer, it may be necessary to turn the ignition switch on or off during the connection and programming procedure. Double-check any instructions on ignition switch position before making any connections or beginning the programming procedure. The next step is to determine the type of programming that is needed.

Programming a New Computer

If a new computer is being installed, program only that computer. In many cases, other on-board computers can be accessed and programmed using the data link connector. While most computers have internal circuitry that protects them from accidental programming, be careful not to program the wrong computer. Do not attempt to program a new computer with information from the old computer or a computer from another vehicle. Any attempt to do this will set a failed programming sequence code in the new computer's memory.

Tech Tip

In some cases, an erasure must be performed on a new computer before initial programming can take place.

Reprogramming a Computer

Computer reprogramming is often needed to solve specific performance or emission related problems. The auto manufacturer will put out a bulletin and provide the modified software to fix vehicle malfunctions. Before reprogramming a vehicle's computer, determine the date that the current programming was downloaded or check the program's calibration number. If the current program is the latest version, no further actions are required. If the latest program has not been downloaded, proceed with the reprogramming sequence.

Before reprogramming most computers, you must first erase the existing information. After this step is complete, select the updated calibration information from the programming computer or scan tool menu. Then download the new information into the computer. On some systems, the erasure step is not necessary since the programming computer or scan tool will erase or overwrite the old information as it loads the new program into the computer.

Tech Tip

If the computer does not accept the new program or cannot be programmed, check all connections first. Ensure that the correct computer is being reprogrammed with the proper information and that all procedures are being followed. If the computer still cannot be programmed, it may need to be replaced.

Allow sufficient time for the programming to take place. Monitor the computer or scan tool to determine when the programming sequence is complete. Do not touch any connections until you are sure the

Copyright Goodheart-Willcox Co., Inc.

programming sequence is complete. After programming is completed, turn the ignition switch to the position called for and disconnect the programming computer. Then, use a scan tool to check the computer and control system operation. While doing this, make sure you have installed the proper program into the computer by checking the program calibration number.

Computer Relearn Procedures

After being serviced, the computer system may have to go through a relearn procedure. A ***relearn procedure*** is a period of vehicle operation during which the computer system adapts to new components and programming information. The computer must receive inputs to formulate adaptive strategies to set some of its output parameters. The relearn procedure can often be done by simply driving the vehicle for several minutes. Some vehicles require a specific relearn procedure. Always check the manufacturer's service literature for exact relearn methods. In a few cases, sensors or actuators may have to be manually adjusted using a scan tool.

Diagnostic Case Study

Concern: Mr. Hayes brought his late model KIA into the shop, complaining of a hesitation, or stumble, when he accelerates the vehicle from a standing start.

Cause: Duff test drives the vehicle to double-check the symptoms and to observe engine performance. He immediately notices a hesitation during acceleration. The vehicle seems to operate normally at cruising speed.

Once back at the shop, Duff connects a diagnostic tablet to the vehicle and finds a trouble code for the throttle position sensor. Using the scope function on the tablet, he slowly opens the throttle and finds a spiking waveform as the throttle is opened. This indicates an internal resistance problem with the throttle position sensor.

Correction: Duff replaces the TPS and rechecks its scope pattern. The new TPS shows a gradual, smooth increase in voltage/resistance as the throttle is moved open. He then test drives the vehicle to make sure the repair fixed the hesitation problem before releasing the vehicle to the customer.

Summary

- Pinpoint tests are specific tests of individual components. They are completed after scanning for trouble codes.
- A preliminary inspection involves looking for signs of obvious trouble: loose wires, leaking vacuum hoses, part damage, etc.
- Semiconductors are very easy to damage. They can be damaged by static electricity, voltage spikes, heat, and impact shocks.
- Stress testing refers to the use of heat, cold, or moisture to simulate extreme operating conditions of components, like an electronic control unit.
- Poor electrical connections are the most common cause of electrical-related problems in a computer system.
- Vacuum leaks are frequently caused by deteriorated, broken, or loose vacuum hoses. Vacuum leaks often make a hissing sound.
- A reference voltage (typically 5 volts) is fed to switching and variable resistance type sensors.
- Sensor sockets have a deep pocket and a cutout for a sensor pigtail (wires).
- Since they contain movable contact points, relays are a common source of computer system problems.
- Computer service usually involves a few tests and computer replacement if needed.
- Some computers use the old PROM (memory chip) during computer replacement, since it stores data for the specific make and model vehicle.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

basic circuit problem
computer output

Activities

1. Describe and sketch the procedure you would use to test a temperature sensor for proper operation.
2. Demonstrate two methods of checking a knock sensor—with a multimeter and by manual tapping.
3. Look up vehicle software update on the Internet. Try to find which cars sometimes require computer reprogramming. Write a paragraph on your findings.

Review Questions

Answer the following questions using the information provided in this chapter.

l. What should you look for during a preliminary inspection of a computer system?
2. Explain five questions you should ask yourself when analyzing computer system problems.
3. How can a vacuum leak upset the operation of a computer system?
4. An engine runs poorly only when cold. Symptoms and a trouble code indicate a problem with the engine coolant temperature sensor. Technician A says to measure the engine coolant temperature sensor's resistance with a digital ohmmeter while measuring coolant temperature with a digital thermometer. Technician B says to measure the sensor's ac voltage output while measuring its temperature with a digital thermometer. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. How do you check sensor reference voltage?
6. Explain three ways to test an active sensor.
7. Describe three ways to test an actuator.
8. Relays are a common source of problems in a modern computer system. True or false?
9. How do you save computer memory?
10. The computer must be removed from a late-model vehicle. Technician A says to keep one hand on chassis ground when handling the computer. Technician B says to wear an anti-static wrist strap when handling the computer. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

ASE-Type Questions

1. Technician A says automotive computer system trouble codes are used to detect faulty components in the system. Technician B says automotive computer system trouble codes are used to indicate the general area of trouble in a computer system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. A trouble code is triggered in an automotive computer system. Technician A says fuel-contaminated engine oil could possibly trigger this trouble code. Technician B says fuel-contaminated engine oil has no effect on computer system operation. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says a basic circuit problem is caused by something in the circuit that increases or decreases current. Technician B says a basic circuit problem is caused by something in the circuit that increases or decreases resistance. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. A scan tool indicates a problem with the MAP sensor. Technician A says you should check the operating condition of the MAP sensor. Technician B says you should check for poor electrical connections in the system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

5. Technician A says a passive automotive sensor is capable of generating its own voltage. Technician B says a passive automotive sensor is not capable of generating its own voltage. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says that a variable resistance sensor can be tested with an ohmmeter. Technician B says that a variable resistance sensor can be tested with a voltmeter. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says a reference voltage of about 12 volts is normally required for an automotive variable resistance type sensor to operate properly. Technician B says a reference voltage of about 5 volts is normally required for an automotive variable resistance type sensor to operate properly. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. A trouble code shows a problem with an active sensor. Technician A says the voltage produced by an active sensor is very low, often under 1 volt. This makes sensor output and wiring harness continuity very critical. Technician B says that active sensor signals are just as strong as passive sensor signals. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. An automobile's oxygen sensor output needs to be checked. Technician A uses a digital voltmeter to check this sensor's output. Technician B uses an analog ohmmeter to check this sensor's output. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. An oxygen sensor tested faulty and must be replaced. Technician A says to use a sealant that is safe for oxygen sensors on the threads. Technician B says to use a sensor socket to prevent sensor damage. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Security and Navigation Systems

Almost every system in a modern vehicle uses some type of electric or electronic component. Electronic ignition, electronic fuel injection, computerized engine management systems, "smart" air bag systems, collision avoidance systems, anti-lock brakes, hybrid drive systems, and other advanced systems require technicians skilled in electricity and electronics. Even specialized technicians need a background in electricity and electronics to fix today's vehicles.

This section details the operation, diagnosis, and repair of the major electrical systems. It opens by explaining the operation and service of hybrid drive systems. It then presents detailed information on both 12-volt and HV batteries before progressing to starting, charging, ignition, and other systems.

Study the information in this section carefully. A technician who is well versed in electricity and electronics is in high demand. The information in this section will help you pass ASE Test A6, Electrical/Electronic Systems, and Test A8, Engine Performance.

Chapter 26
Hybrid Drive Technology

After studying this chapter, you will be able to:

- Identify the major parts common to hybrid gas/electric or all-electric vehicles.
- Compare hybrid design and construction variations.
- Explain the operation of a motor-generator, HV battery, and HV power control module.
- Correctly answer ASE certification test questions on hybrid drive systems.

A ***hybrid electric vehicle (HEV)*** uses two power sources for propulsion: a small gas or diesel engine is used in conjunction with a high-voltage battery and a motor-generator to produce torque for operating the vehicle's drive train and electrical systems.

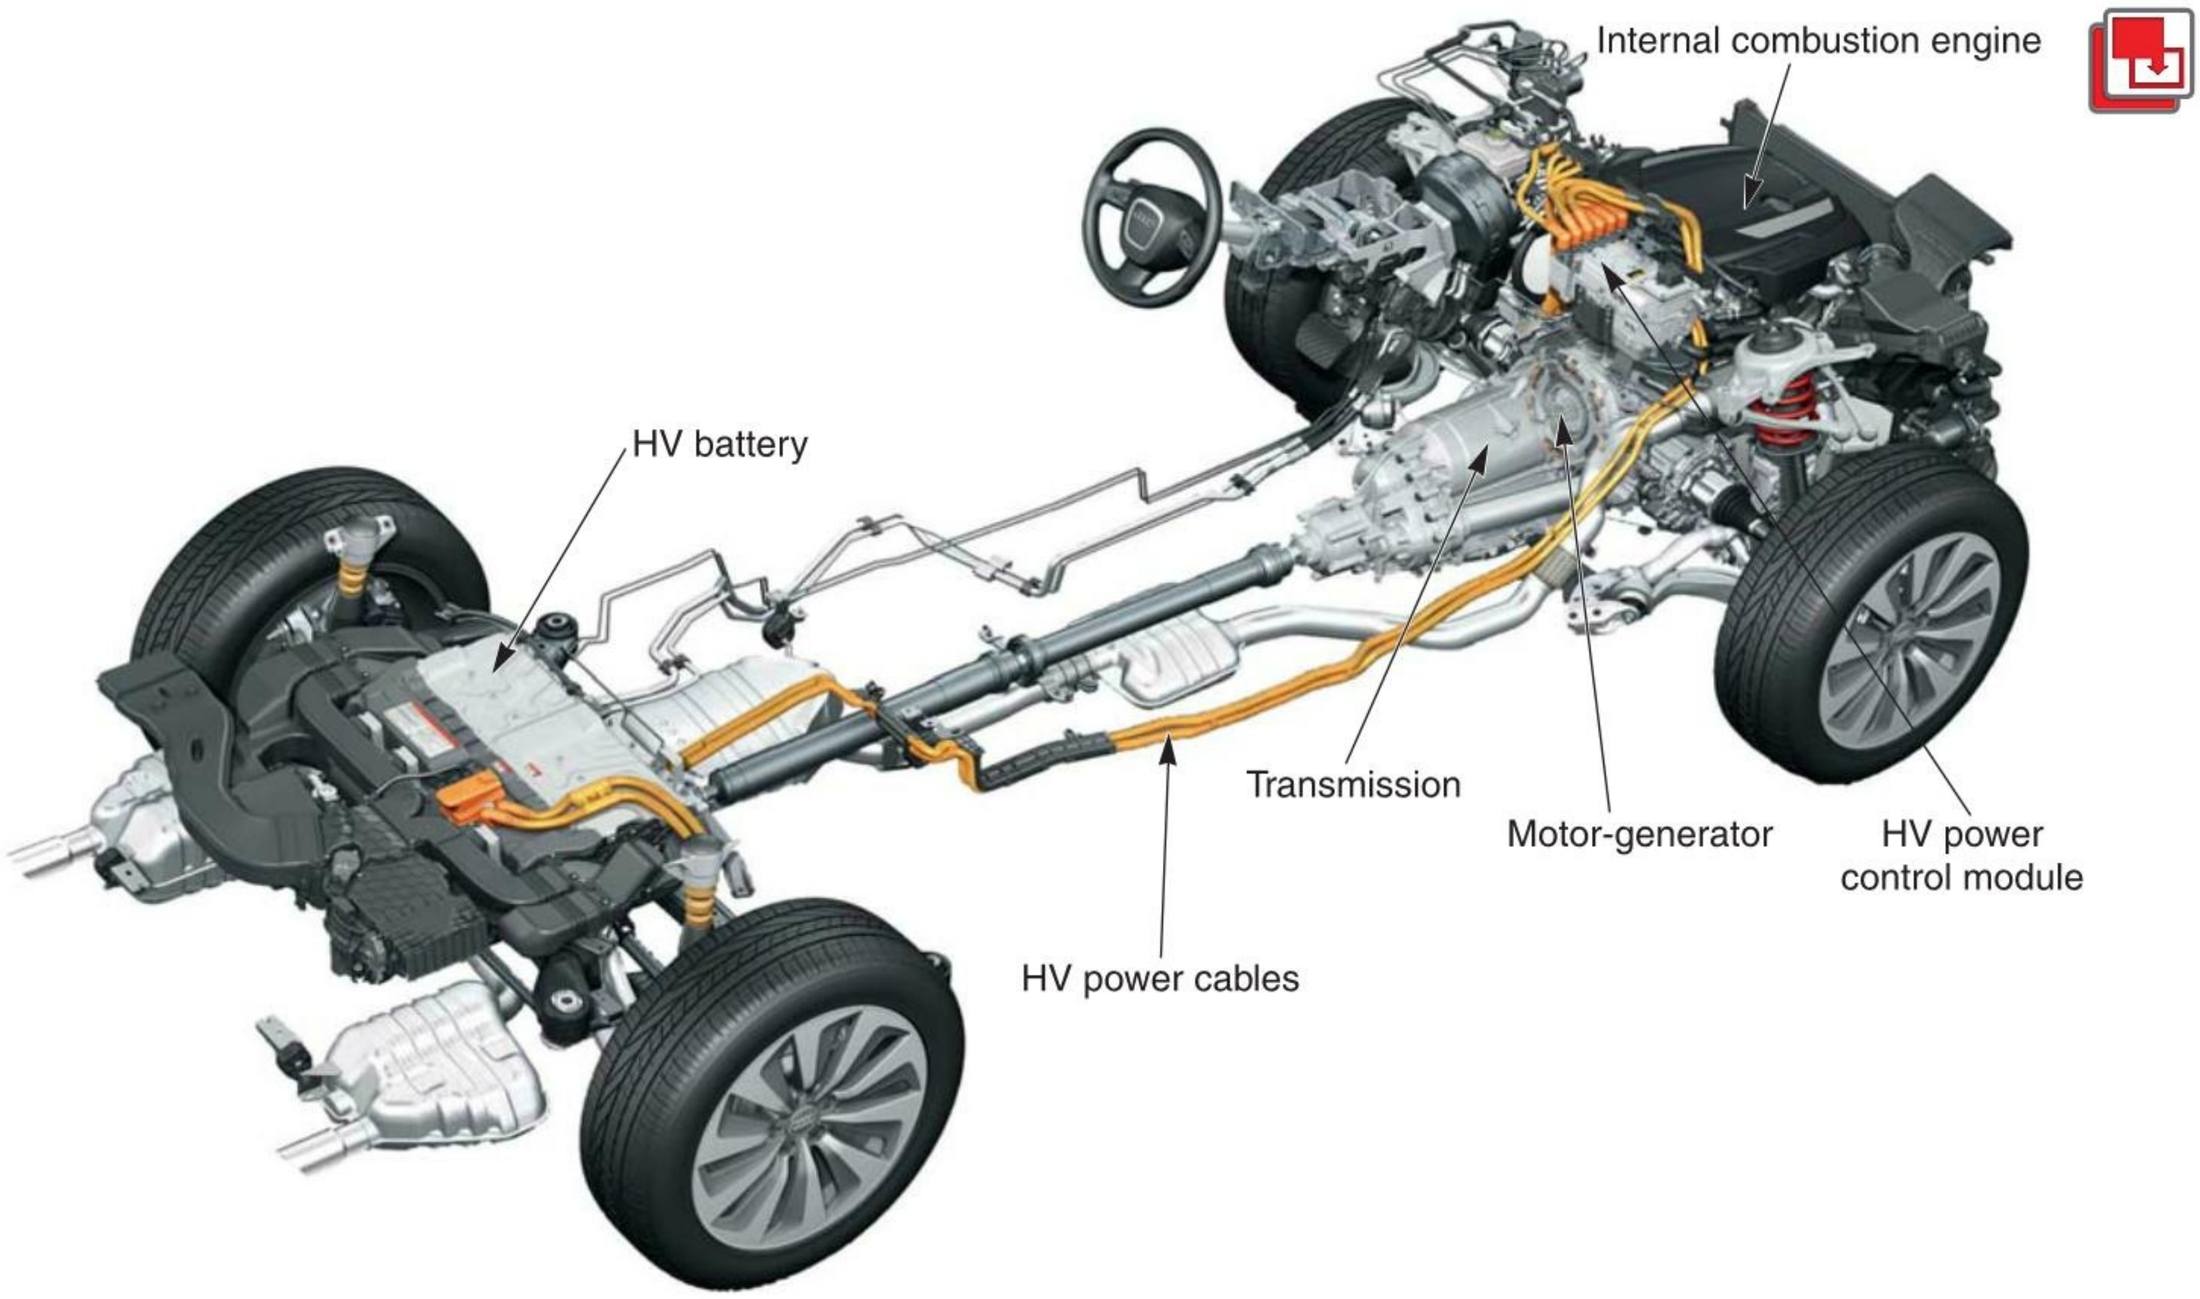
Hybrid electric vehicles are now produced and sold by all major auto manufacturers. Therefore, it is very important that you understand how various hybrid designs differ in their construction and operation. If you understand how any hybrid "is supposed to work," you will more clearly comprehend how to fix hybrid drive train problems.

Hybrid Vehicles

To electricians working on high-voltage transformers and power transmission lines, the abbreviation *HV* means "high voltage." All hybrid vehicles now operate on high voltage, so *HV* is used frequently when referring to the high voltage circuits and components found in hybrid vehicles. For example, the battery used in a hybrid vehicle is commonly called an "HV battery."

Discussed briefly, an HEV uses multiple individual power sources to provide useable energy for propulsion. In an HEV, an internal combustion engine and an electric drive system are combined to make up the vehicle's power train. The power train provides driving force to the wheels. Refer to **Figure 26-1**. Most HEVs on the road today use the electric drive system to assist the engine, especially during acceleration.

Copyright Goodheart-Willcox Co., Inc.



Audi

Figure 26-1. Study the major assemblies of a modern hybrid drive system. An internal combustion engine and a powerful electric drive train are used to propel this vehicle.

Tech Tip

To identify a hybrid vehicle, look for badges on the front fenders, engine cover, trunk, or hood, or open the hood and look for orange HV power cables. See **Figure 26-2**. You can also compare the vehicle's VIN (vehicle identification number) to factory reference information. The 5th, 6th, and 7th characters in the VIN identify hybrid vehicles.

Hybrid Vehicle History

In 1898, Ferdinand Porsche, the founder of Porsche Motor Car Company, designed and built a car that used a small internal combustion engine to spin a direct current (dc) electric generator. The electric generator powered electric drive motors at each drive wheel. No mechanical link, clutch, transmission, or mechanical drive train was used. Huge power cables were used between the electric generator and the electric drive motors. This basic engine electric-driveline principle is used today in locomotives.

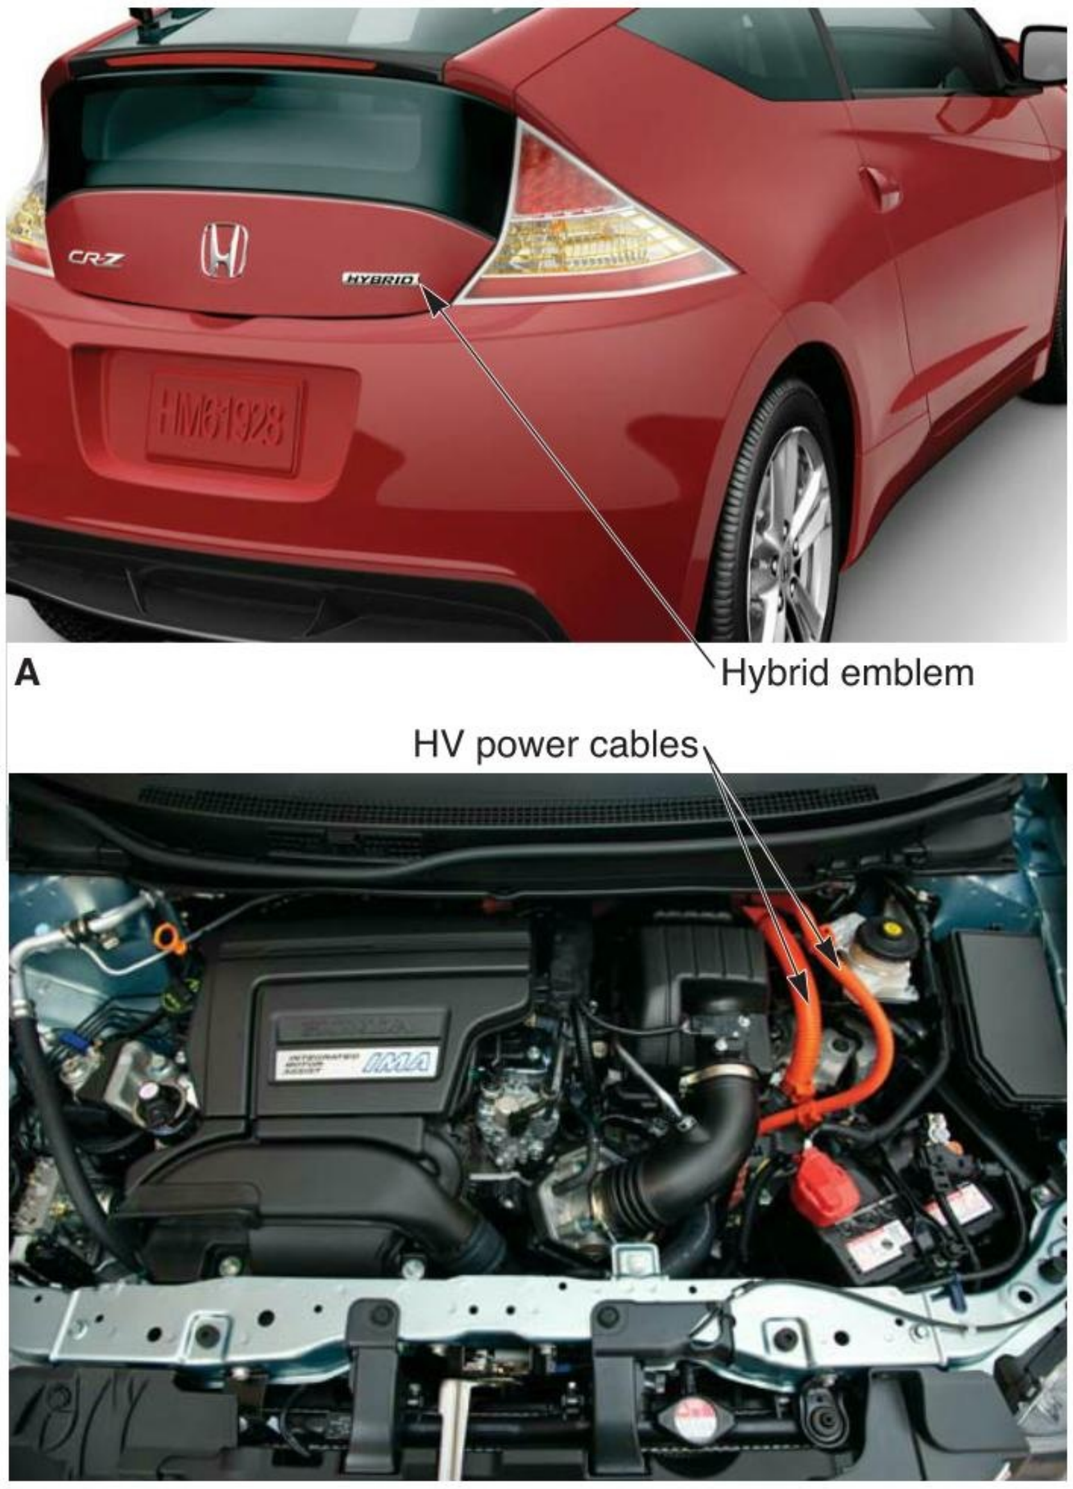
In 1966, the United States Congress passed a bill recommending the development of electric vehicles to reduce air pollution and our dependence on foreign oil. By the 1990s, automakers started perfecting hybrid drive systems to meet these demands.

Currently, all major automakers are building hybrid electric vehicles that are capable of operating on electricity only. When the HV battery is depleted, the gasoline or diesel engine "fires up" to provide propulsion energy and force. Full electric vehicles (no internal combustion engine) are only practical for short trips or city driving, since they require frequent recharging from a home wall outlet.

Tech Tip

In addition to hybrid electric vehicles, automakers are experimenting with fuel cell hybrids, hydraulic hybrids, and pneumatic hybrids.

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 26-2. Identifying a hybrid vehicle. A—Emblems or badges on the hood, trunk, fenders, or engine. B—The orange cables under the hood denote a high-voltage drive train.

Hybrid Drive Construction

Advances in electric motor, battery, and power transistor technology have allowed automakers to build hybrid vehicles that accelerate as well as, or even better than, conventional gasoline-powered vehicles. Hybrids also greatly reduce the amount of fuel burned in both city and highway driving.

In an HEV, the internal combustion engine and electric drive system work in unison under computer control to propel the vehicle and operate its electrical accessory systems.

When most hybrids come to a stop, both the internal combustion engine and the high-voltage charging system are shut off. This increases fuel economy over cars that keep the engine running when not moving. Since little energy is needed to operate the dash electronics, climate control, and other electrical accessories, a small conventional 12-volt battery is sometimes still used to operate the electrical systems of the vehicle. However, the design of some hybrids replaces the 12-volt battery, conventional starting motor, crankshaft ring gear, and alternator with the electric drive system.

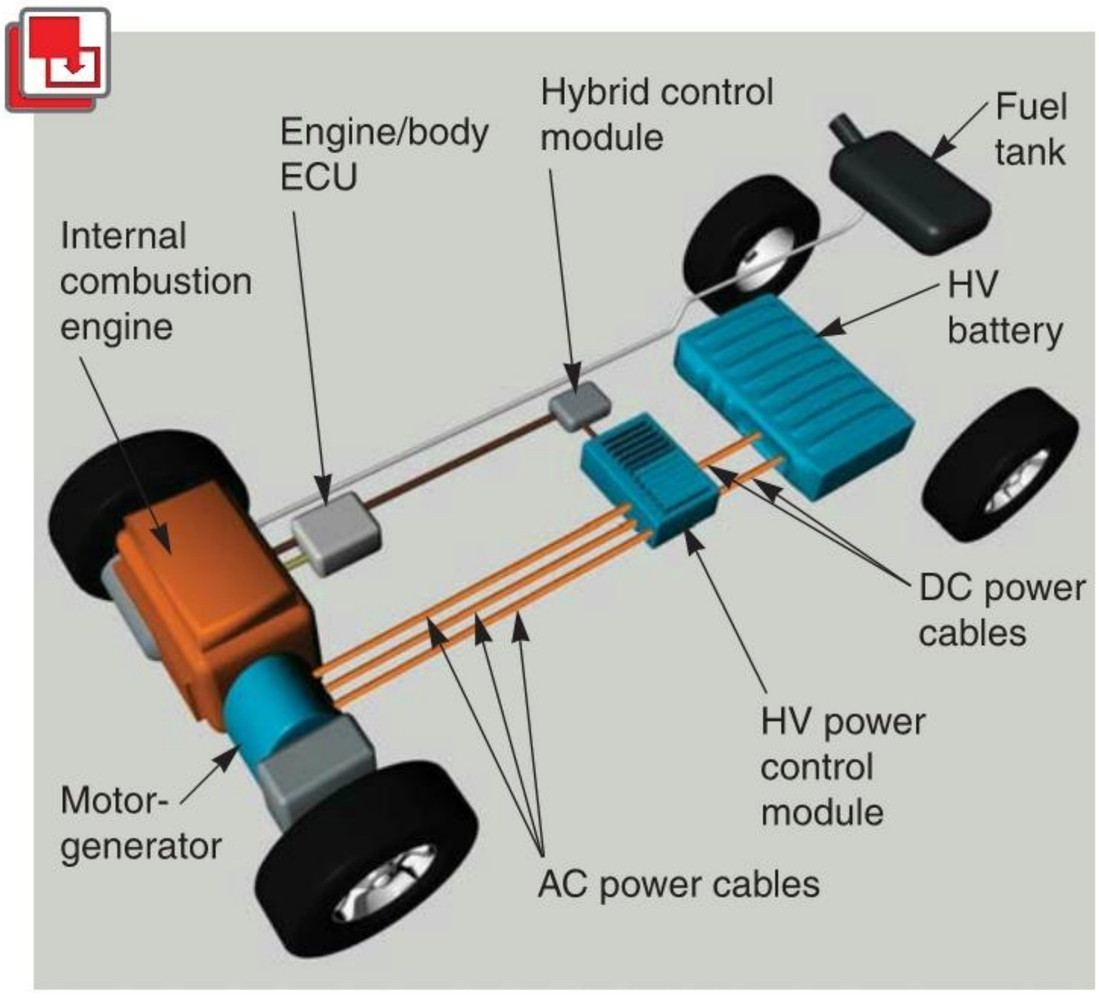
Today's hybrids also use their electric drive system to:

- Almost silently crank the engine over for starting. A conventional 12-volt starting motor and flywheel ring gear are not needed to rotate the engine crankshaft to force air and fuel into the combustion chambers.
- Step-down HV battery dc voltage to 12–15 volts dc to power the lights, instrumentation, and on-board computer circuits with the internal combustion engine running or not.
- Shut off the internal combustion engine when battery charging is not needed. When the vehicle is stopped, it is wasteful to keep an internal combustion engine running and idling. The power reserve of an HV battery is easily capable of powering the car's electrical accessories for hours without being depleted.
- A hybrid drive regenerative braking system helps prevent wear of conventional friction brake pads and brake rotors. The torque needed to spin the motor-generator during the generation of high voltage and current helps slow and stop the vehicle so there is less brake part wear.

There are six major assemblies (**Figure 26-3**) in a hybrid drive system:

- HV battery—An HV battery consists of a large number of voltaic cells wired in series to produce a high-voltage, high-power storage battery.
- Motor-generator—The motor-generator uses a brushless armature and multi-coil stator assembly to function as both an electric drive motor and a generator.
- HV power control module (HV PCM)—This high-voltage circuit controls current flow to the HV battery and motor-generator. It contains high-power transistors, rectifying diodes, large relays, and industrial contactors to change dc to ac or ac to dc while controlling output voltage, current, and frequency. The HV PCM can amplify voltage and current as needed for propulsion or lower voltage and current for HV battery recharging.
- Hybrid control module—This is a small electronic control circuit that monitors driving conditions, battery temperature, system voltages, and current

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 26-3. Review the major parts of a hybrid electric vehicle. Can you explain the purpose of each hybrid assembly?

loads to help control the operation of the HV PCM, battery pack, and motor-generator.

- HV power cables—HV power cables are large insulated conductors that electrically connect the battery pack, HV PCM, and motor-generator together. Two cables extend from the HV battery and three cables extend out of the motor-generator.
- Internal combustion engine—The gasoline or diesel engine propels the vehicle during heavy acceleration and at cruising speeds, and spins the generator to recharge the HV battery and/or power the electric drive train.

Tech Tip

The hybrid motor-generator is sometimes referred to as a "dynamotor." The term *dynamotor* comes from the words *dynamo* and *motor*. The first dynamotor (integral electric generator and motor assembly) was built in the early 1900s.

With most HEVs, a conventional fuel tank, fuel lines, and electronic fuel injection system feed gasoline to an internal combustion engine. Both the motor-generator and the engine work together to provide a dependable and fuel efficient means of transportation.

Warning

Hybrid electric circuits and HV power cables carry dangerous voltage levels (up to 300 volts dc and 600 volts ac). Because of the extremely high voltage and current levels inside a hybrid, you must know how to work safely with very deadly levels of electricity. If you were to accidently grab the metal terminals of any HV power cable with your body grounded, you could be killed.

Types of Hybrid Vehicles

There are several types and classifications of hybrid drive systems. For example, hybrids can be classified by the drive train configuration and by when the vehicle employs the internal combustion system. The following sections outline various hybrid classifications. You should understand their differences and similarities.

Full and Mild Hybrids

A ***full hybrid*** uses a motor-generator to initially accelerate and propel the vehicle. The internal combustion engine runs only when the battery pack becomes discharged, or during heavy acceleration. Full hybrids can accelerate normally (not full throttle) without consuming any fuel or emitting any exhaust emissions.

A full hybrid is propelled by the motor-generator until the HV battery has about a 30% charge remaining. Then, the hybrid control module "fires up" the internal combustion engine to simultaneously propel the vehicle and recharge the battery pack.

A ***mild hybrid***, or ***assist hybrid***, is propelled by its internal combustion engine only. This type of hybrid shuts down its internal combustion engine when the vehicle is coasting, braking, or stopped, and uses an HV starter-alternator to quickly restart the engine when the brake pedal is released. The HV starter-alternator functions as an electrical generator when the engine is running.

Most first-generation mild hybrids have a 36- or 42-volt electrical system that powers electric motors to drive accessory items, such as the power steering pump or the air conditioning compressor. In this way, these components continue to work even when the internal combustion engine is shut down.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

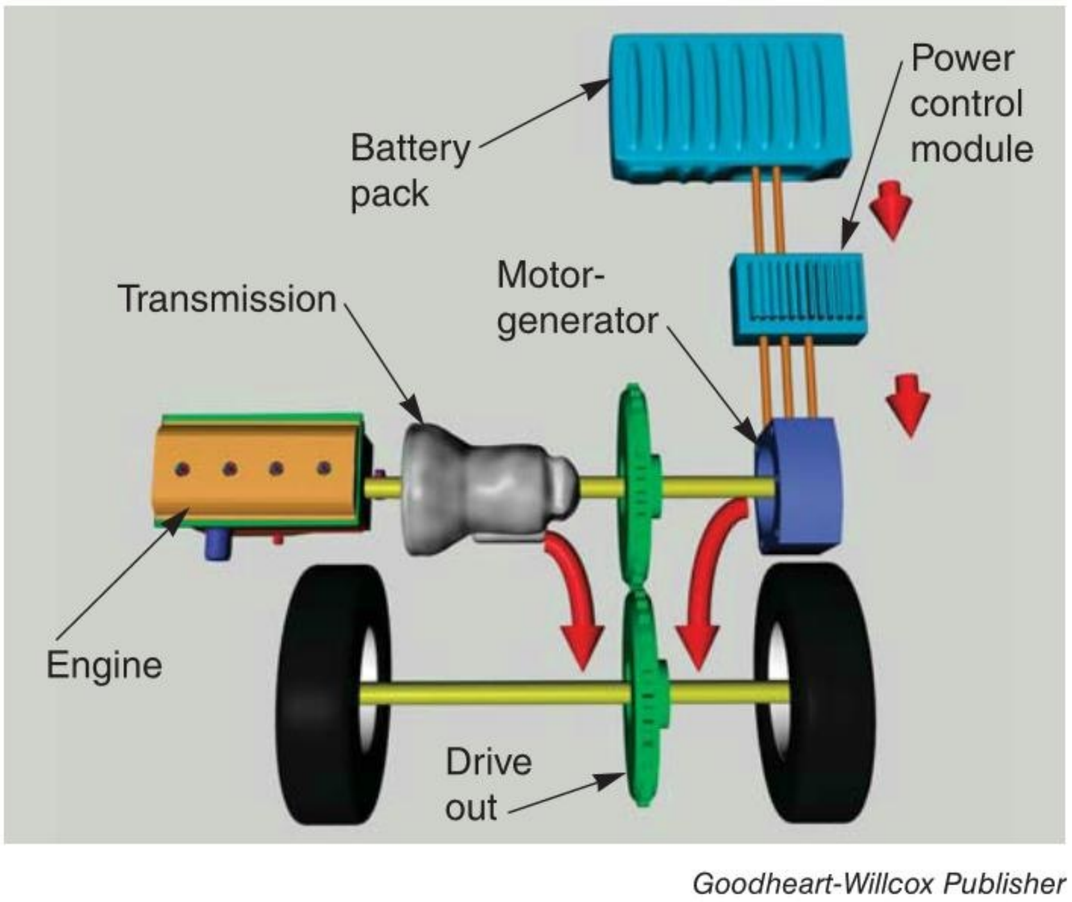
Some late-model mild hybrids use a 115-volt system, allowing the use of a larger starter-alternator that can assist the internal combustion engine in propelling the vehicle from a standstill. This improves fuel economy slightly, but not as much as a full hybrid drive train.

Series Hybrid

In a ***series hybrid*** configuration, an electric motor is the only method used to apply torque to the vehicle's drive train. See **Figure 26-4**. The internal combustion engine has no mechanical connection to the drive train. The series hybrid can operate in the all-electric mode when the battery pack charge is sufficient to propel the vehicle. When the battery pack becomes drained, the internal combustion engine starts and turns a generator to recharge the battery pack.

Parallel Hybrid

A ***parallel hybrid,*** **Figure 26-5**, uses both an internal engine and a motor-generator to apply mechanical torque to the drive train. The engine and motor-generator operate in parallel, or at the same time. During rapid acceleration, both the internal combustion engine and the motor-generator apply torque to the drive train. At low speeds, a parallel hybrid can operate in full-electric mode, with the engine completely shut down.



Goodheart-Willcox Publisher

Figure 26-5. Parallel hybrid drive configuration.

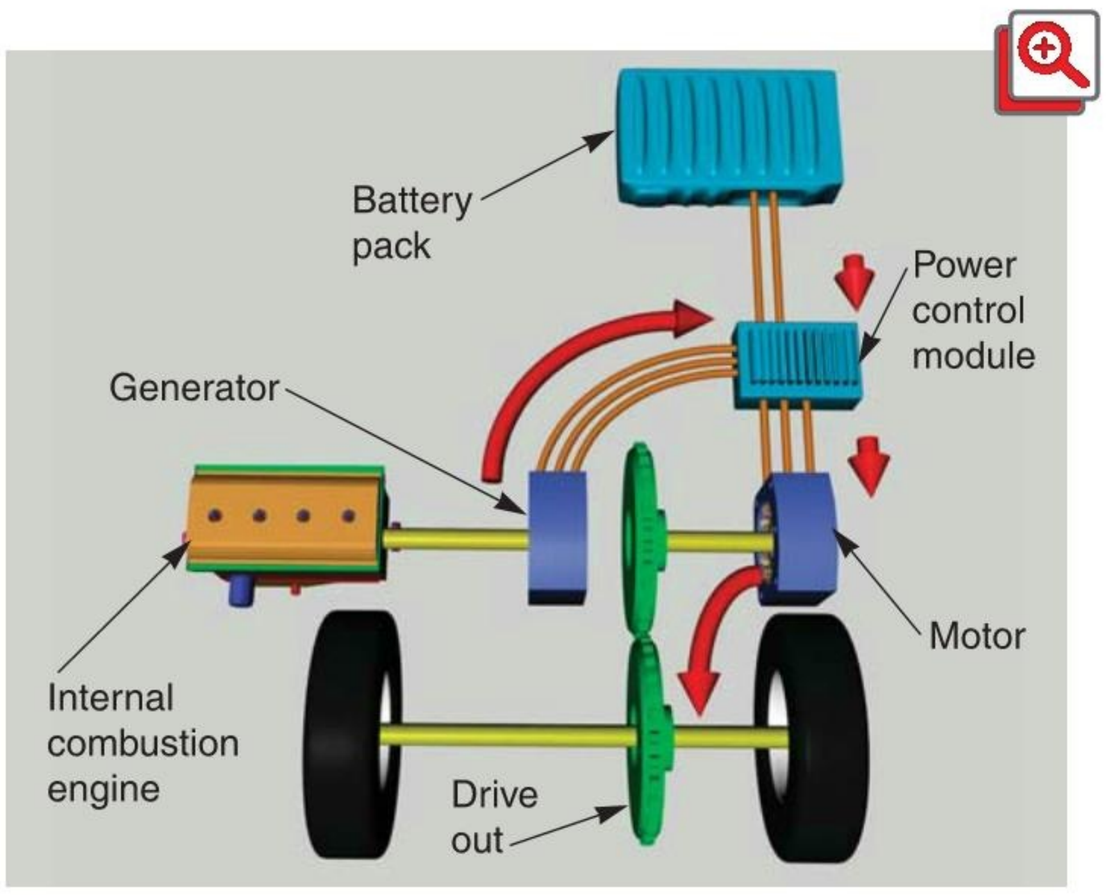
A parallel hybrid provides the advantages of a full-electric vehicle in city driving, but can perform like a conventional vehicle under full acceleration or at highway speeds. The drawback to the parallel hybrid is that the motor-generator cannot drive the vehicle and recharge the battery pack at the same time. This limits the amount of time the vehicle can be driven by the motor-generator.

Series-Parallel Hybrid

The ***series-parallel hybrid*** combines the advantages of a parallel hybrid with those of a series hybrid. Refer to **Figure 26-6**. A series-parallel hybrid can recharge the battery pack even when the electric motor is in use to drive the vehicle. The internal combustion engine can drive the wheels, but it can also be disconnected from the drive train so only the electric drive motor propels the vehicle. The engine can also power the motor-generator, which acts as a generator to recharge the HV battery.

Plug-In Hybrid Electric Vehicles (PHEVs)

A ***plug-in hybrid electric vehicle (PHEV)*** is designed so the battery pack can be fully recharged when the vehicle is not being driven. A charging station or high-voltage charger that plugs into a home



Goodheart-Willcox Publisher

Figure 26-4. Series hybrid drive configuration.

Goodheart-Willcox Publisher

Figure 26-6. Series-parallel hybrid drive configuration.

or garage wall outlet (120 volts ac or 240 volts ac) is used to re-energize the battery. See **Figure 26-7**. New PHEVs can travel 30–40 miles before the gas or diesel engine ever runs. When the engine is running, the electric drive system recharges the HV battery. This prevents the vehicle from ever being stranded without power.

Full-Electric Vehicles

A ***full-electric vehicle*** only has an electric propulsion system and no method of recharging the HV battery when driving. Full-electric vehicles are only practical for city driving. Their driving range, or distance between recharges, is limited to less than 100 miles (160.93 km).

General Motors Corp.

Figure 26-7. This PHEV is charging at a solar-powered charging station.

Flywheel Generator Hybrids

An ***HV flywheel generator***, or ***kinetic energy generator***, uses a large, heavy flywheel rotor spinning around a series of electromagnets to store large amounts of electrical energy. After years of development, the flywheel generator is being raced very successfully on international road race courses. A hybrid race car equipped with an HV flywheel generator is shown in **Figure 26-8**.

In this hybrid design, the rear wheels are powered by a gas-burning, six-cylinder, turbocharged engine with direct fuel injection. The front-drive wheels are powered only by the motor-generators. When braking, the motor-generators act as electric generators to help slow the car, and also send electrical energy to the flywheel motor. In a few seconds of ac current flow, the flywheel spins up to around 40,000 rpm, storing a huge amount of kinetic or spinning energy.

When coming out of a turn, the driver can press a small button on the steering wheel for electric boost power to the front wheels. The HV PCM then feeds high levels of electrical energy to the two motor-generators. With over 300 horsepower (223 kW) motor-generators, the car accelerates like a four-wheel drive vehicle, with almost 1000 total horsepower (746 kW). Flywheel generators for passenger vehicles are in development.

Hybrid Vehicle Operation

A typical series-parallel hybrid drive system has six basic modes of operation (**Figure 26-9**):

- All-electric drive mode.
- Motor-assist mode.
- Idle stop mode.
- Regenerative braking mode.
- Engine starting mode.
- HV battery recharging mode.

All-Electric Drive Mode

In all-electric drive mode, the hybrid vehicle operates just like an all-electric car. The battery pack provides all the energy needed for city driving, sometimes up to 50 miles. The internal combustion engine is shut off, but is ready to start up when the battery

pack becomes discharged or when more power is needed to help propel the vehicle.

Many hybrid vehicles stay in the all-electric mode when accelerating up to 20–40 mph. If the driver accelerates normally, the electric drive system will propel the vehicle up to city speed limits without starting the internal combustion engine. An internal combustion engine is least efficient when operating at very low rpm.

When backing up, most hybrids operate in all-electric mode—the internal combustion engine remains off. When a hybrid runs on electrical energy only, it does not burn fuel or emit hydrocarbons.

Motor-Assist Mode

In the hybrid motor-assist mode, both the motor-generator and the internal combustion engine apply torque to the drive train for propulsion. Some hybrid systems start out using only the motor-generator during acceleration and operate in the motor-assist mode at cruising speeds. Other systems use both the motor-generator and the internal combustion engine during acceleration and while cruising. Motor-assist allows an HEV to accelerate just as quickly as a conventional vehicle.

Idle Stop Mode

In idle stop mode, the system automatically shuts off the internal combustion engine when the vehicle comes to a full stop, and restarts the engine when the vehicle reaches a predetermined speed (about 20–40 mph) or when the HV battery is partially discharged. This conserves energy and reduces exhaust emissions during idle and at other times when the engine is not needed.

Regenerative Braking Mode

Regenerative braking is an electric braking system that works in conjunction with the conventional hydraulic brakes. During regenerative braking mode, the motor-generator serves as an electrical generator—sending high voltage and current through the HV power cables, to the HV PCM, and into the HV battery.

When the brakes are applied, a brake pedal sensor sends a signal to the hybrid control module, prompting the motor-generator to function as a high-current generator. With moderate brake pedal pressure, the conventional hydraulic brakes do not apply the friction pads into the spinning brake discs. Instead, the motor-generator's armature becomes more difficult to rotate. The large armature places a drag on the driveline, wheels, and tires, slowing the vehicle.

When the brake pedal sensor is depressed more for faster stops, the computer system applies the conventional hydraulic brakes and the "electric brakes" (motor-generator) to stop the vehicle. If the vehicle is slowed carefully, almost all the kinetic energy of the moving vehicle is recaptured as electrical energy and forced into the HV battery. The HV battery stores this energy and sends it to the motor during acceleration.

Light braking may feel different in a hybrid vehicle since the motor-generator drag slows the vehicle without applying hydraulic friction brakes.

Tech Tip

In some hybrid systems, the crankshaft of the internal combustion engine is disconnected from the driveline during regenerative braking. This prevents engine compression from slowing the vehicle without recapturing energy.

Engine Starting Mode

In the hybrid engine starting mode, the motor-generator spins the engine crankshaft to start the internal combustion engine. The engine then runs to propel the vehicle at cruising speeds, or to drive the motor-generator when the battery pack becomes partially discharged.

The hybrid ECU energizes transmission solenoids that apply and release clutches in the transmission so the engine crankshaft and motor-generator are locked and turn together. The power control module then sends just enough current to the motor-generator to spin the engine crankshaft at about 300 rpm.

The hybrid ECU also signals the engine ECU to provide "spark and fuel" to the engine. The engine ECU electrically energizes the engine's fuel pumps, electronic fuel injectors, and ignition coils while the motor-generator spins the crankshaft until the engine "fires" and runs on its own power.

Battery Charging Mode

After driving several miles in all-electric mode, the HV battery becomes partially discharged. When the hybrid control module detects the lower voltage (about 70% discharge), it starts the internal combustion engine to propel the vehicle and recharge the HV battery. The

Copyright Goodheart-Willcox Co., Inc.

engine crankshaft spins the motor-generator, which in turn sends electricity to the HV PCM and HV battery.

Hybrid Drive Assemblies

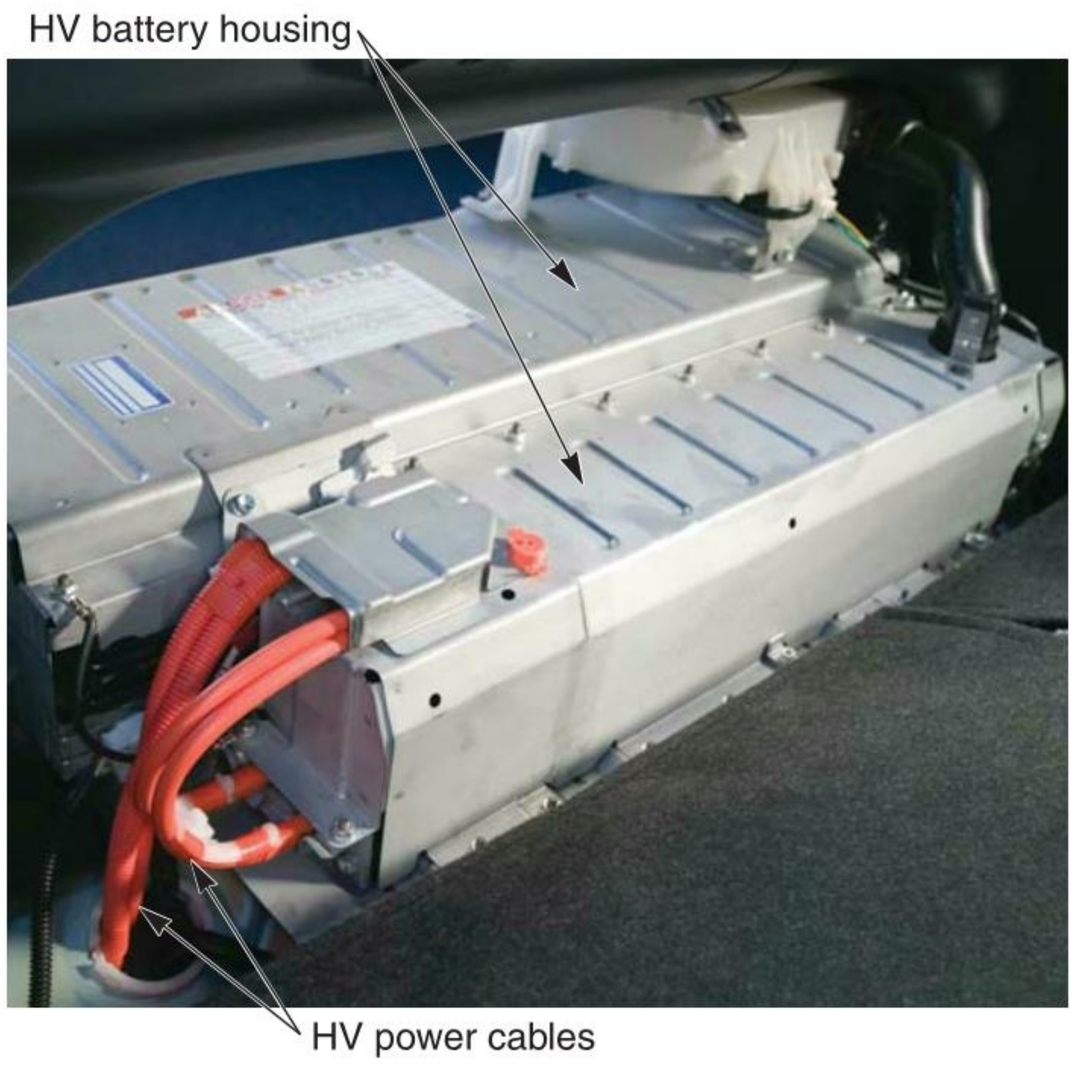
The following sections detail the construction and operation of various hybrid drive assemblies used in series, parallel, and series-parallel hybrid vehicles.

HV Battery

The ***HV battery*** sends high-voltage dc into the HV PCM through the HV power cables. The HV PCM converts this dc to ac, and usually steps the voltage up or down as needed by system circuits. HV battery dc can be converted into three-phase ac to operate the motor-generator. The HV battery and motor-generator can easily propel the vehicle or start the internal combustion engine, as needed.

An HV battery contains several high-efficiency lithium-ion battery modules stacked in a sealed enclosure. The lithium-ion modules are wired in series to produce a very high-voltage power source. Depending on the vehicle make and model, battery voltage can range from about 150 volts dc up to 400 volts dc for newer models.

The HV battery is normally mounted in the rear of the chassis, often behind or under the rear seat or in the trunk area. See **Figure 26-10**. An ***HV battery cover*** encloses the modules and protects them from damage. It also protects people from electric shock. HV battery covers are often held on with machine screws. A few hybrids have the HV PCM and HV battery housed together.



Toyota

Figure 26-10. The HV battery is in the lower trunk area of the vehicle. Note the large orange power cables that connect the HV battery to the HV PCM up near the engine.

Tech Tip

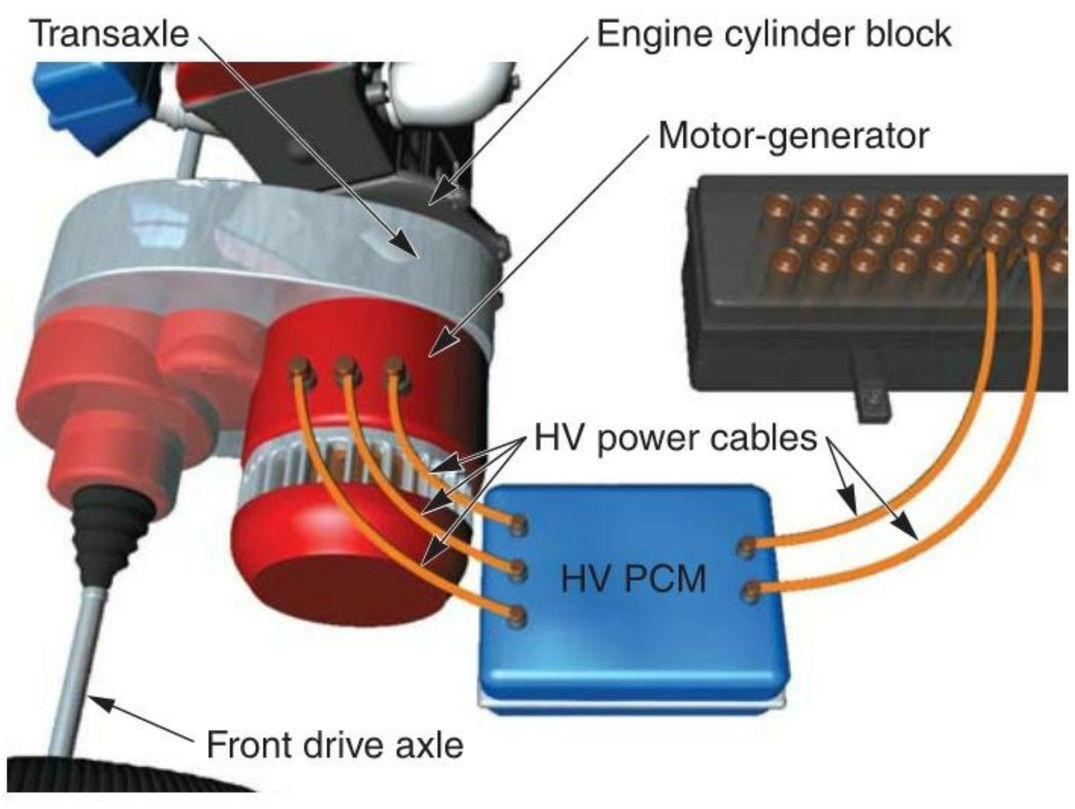
HV battery construction, operation, and service are covered in detail later in this textbook. Refer to the index for specific pages.

Motor-Generator

A motor-generator functions as both a traction motor and as an alternator (ac generator) in the vehicle's power train. The motor-generator has several functions:

- It helps power the drive train and propel the vehicle.
- It recharges the HV battery.
- It cranks the internal combustion engine.
- It helps slow and stop the vehicle.

The motor-generator can be attached directly to rear of the engine, on one side of the transaxle, inside the transmission, or inside the rear axle housing. Look at **Figure 26-11**.



Goodheart-Willcox Publisher

Figure 26-11. The figure shows the HV battery, the HV PCM, and the motor-generator, which is mounted on the side of the transaxle in this arrangement.

Copyright Goodheart-Willcox Co., Inc.

The basic parts of a motor-generator include the armature, stator, and housing. The basic components of a simplified motor-generator are illustrated in **Figure 26-12**.

The ***armature*** consists of a set of permanent magnets mounted inside a segmented steel or carbon fiber disc. Each magnet is spaced and positioned in the armature so its pole is near the outer edge of the armature. This allows the flux, or field, of each magnet to react with the flux produced by the stator's electromagnets.

Depending on hybrid design, the armature can be mounted on roller bearings or on the engine crankshaft flange, which keeps it from rubbing on the stator coils. In some designs, the motor-generator may also be splined to the transmission input shaft.

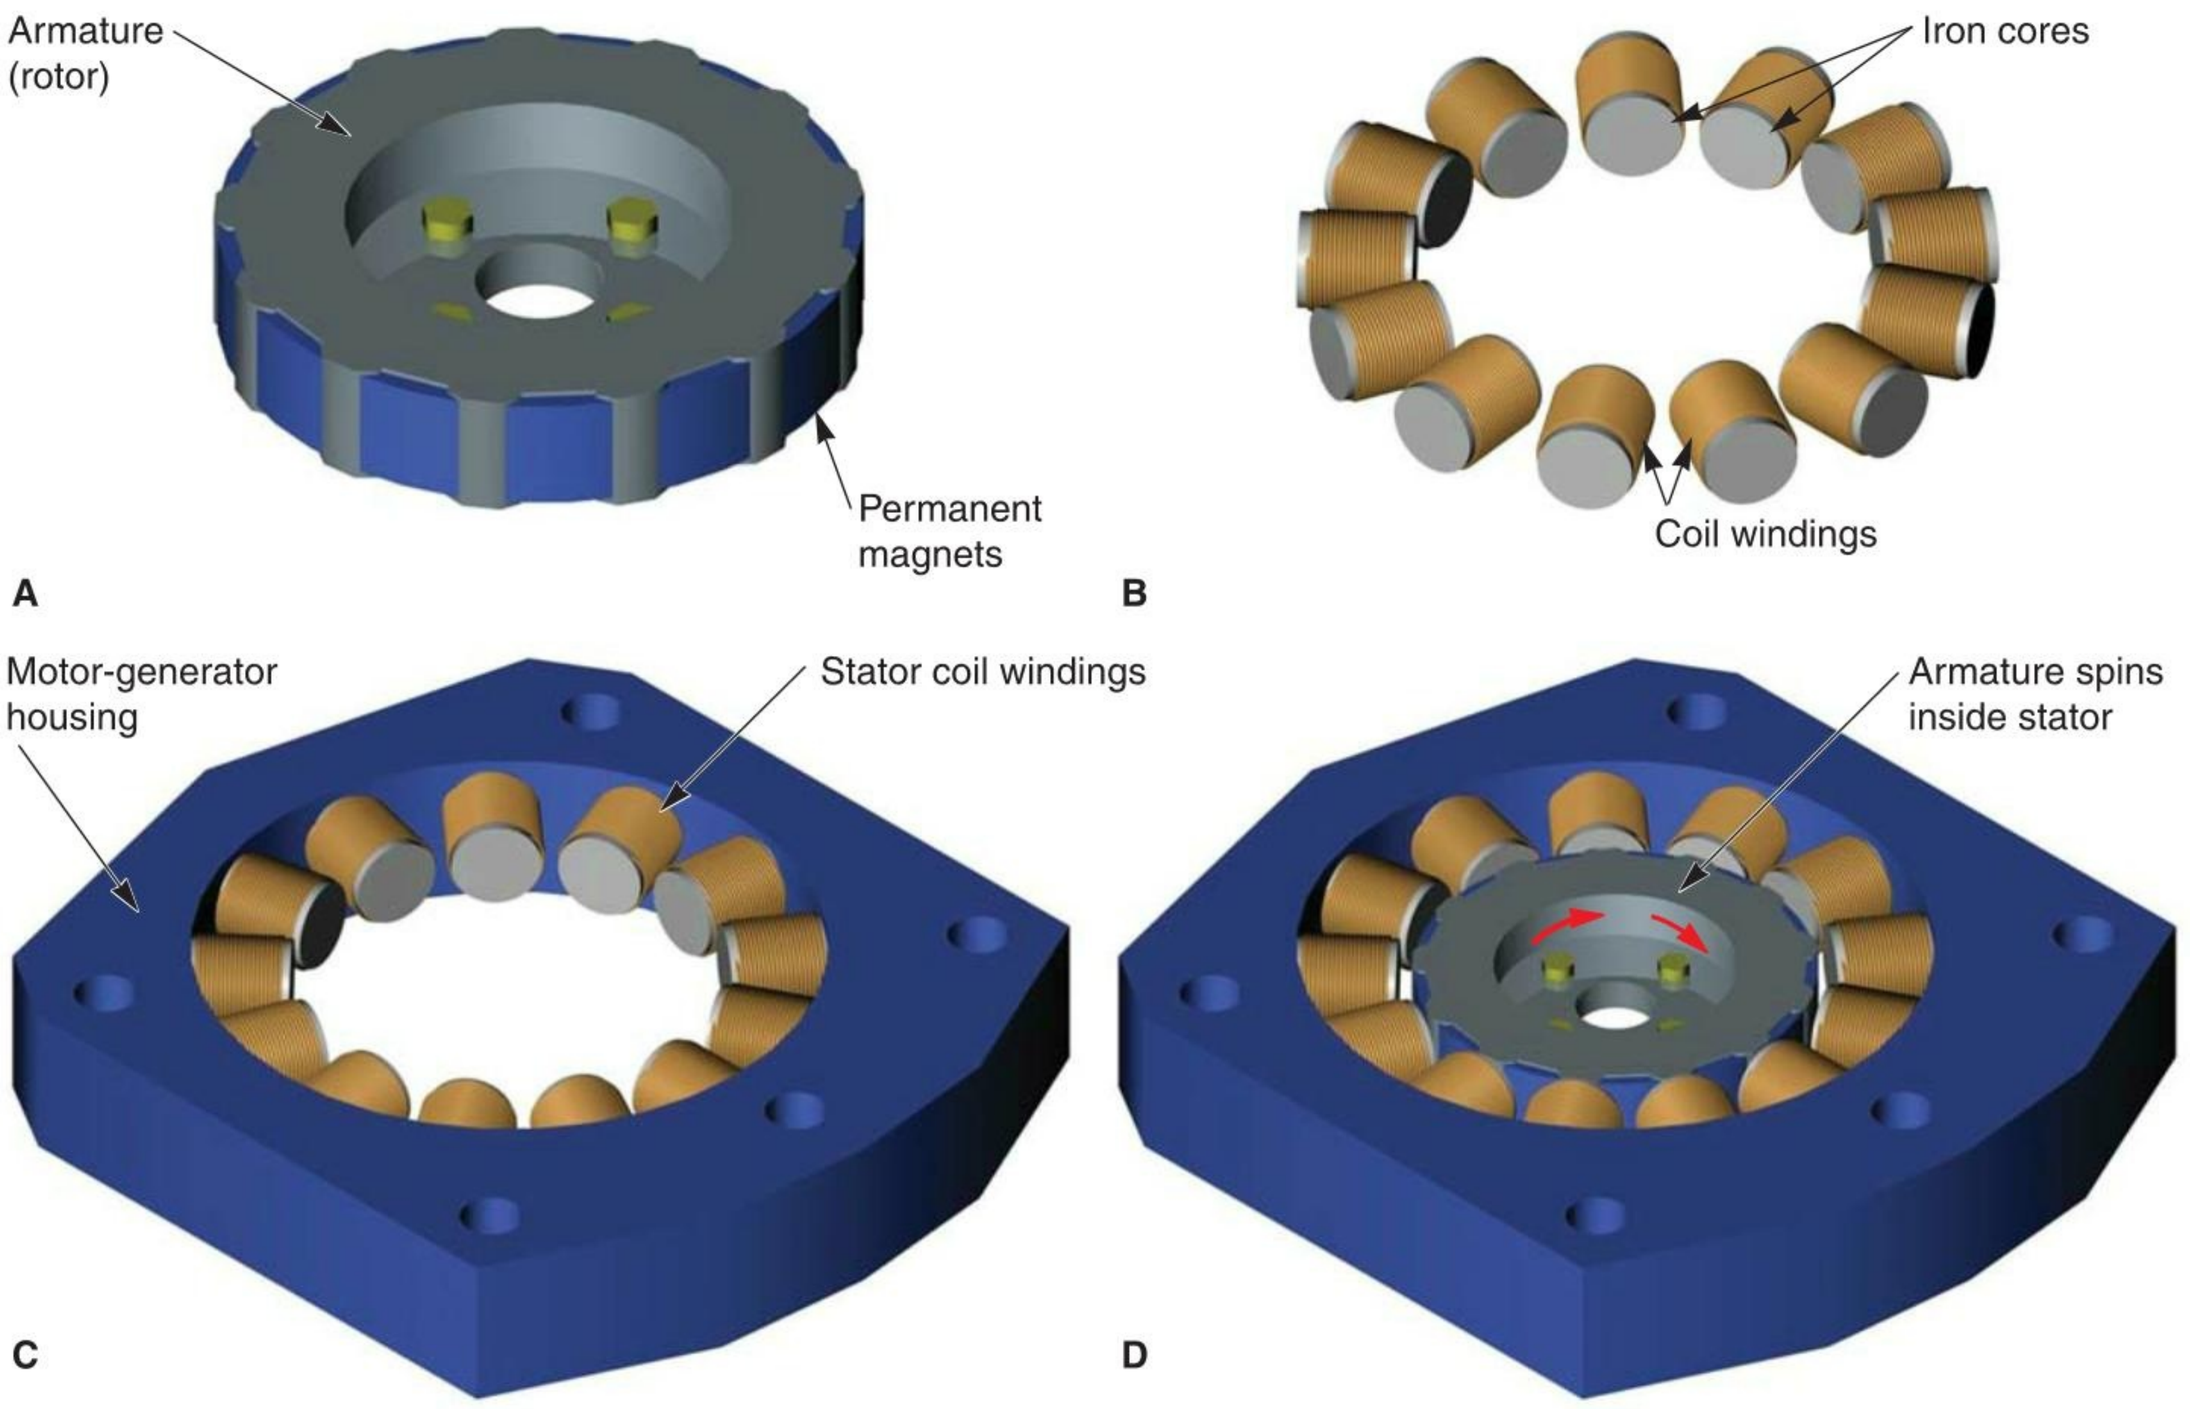
The ***stator*** is a set of stationary coil windings wrapped around iron cores and arranged around the armature. Each stator coil winding is positioned and spaced to match the placement of the armature's permanent magnets.

The housing holds the stator assembly and sometimes the armature in place. It also fastens the motor-generator to the rear of the engine, inside the transmission/transaxle, or in the rear drive axle assembly.

When the motor-generator is assembled, the armature magnets are very close to the stator coil windings. When the armature is rotated by engine power, the magnetic fields produced by the armature magnets cut across the stator winding coils. This induces current and voltage in all the stator coils, generating high-voltage electricity.

Motor-Generator as an HV Motor

When the motor-generator serves as an ***HV motor*** to propel the vehicle, three-phase voltage is applied to the stator windings by the HV PCM. Large amounts of direct current from the two HV power cables are converted into



Goodheart-Willcox Publisher

Figure 26-12. A simplified drawing of a hybrid motor-generator assembly. A—The armature is a steel or carbon fiber ring with permanent iron magnets imbedded in its outer diameter. B—The stator consists of several sets of coil windings wrapped around iron cores. C—The motor-generator housing holds the stator coils stationary and in perfect alignment. D—The assembly can function as a high-torque motor or a high-wattage ac generator.

Copyright Goodheart-Willcox Co., Inc.

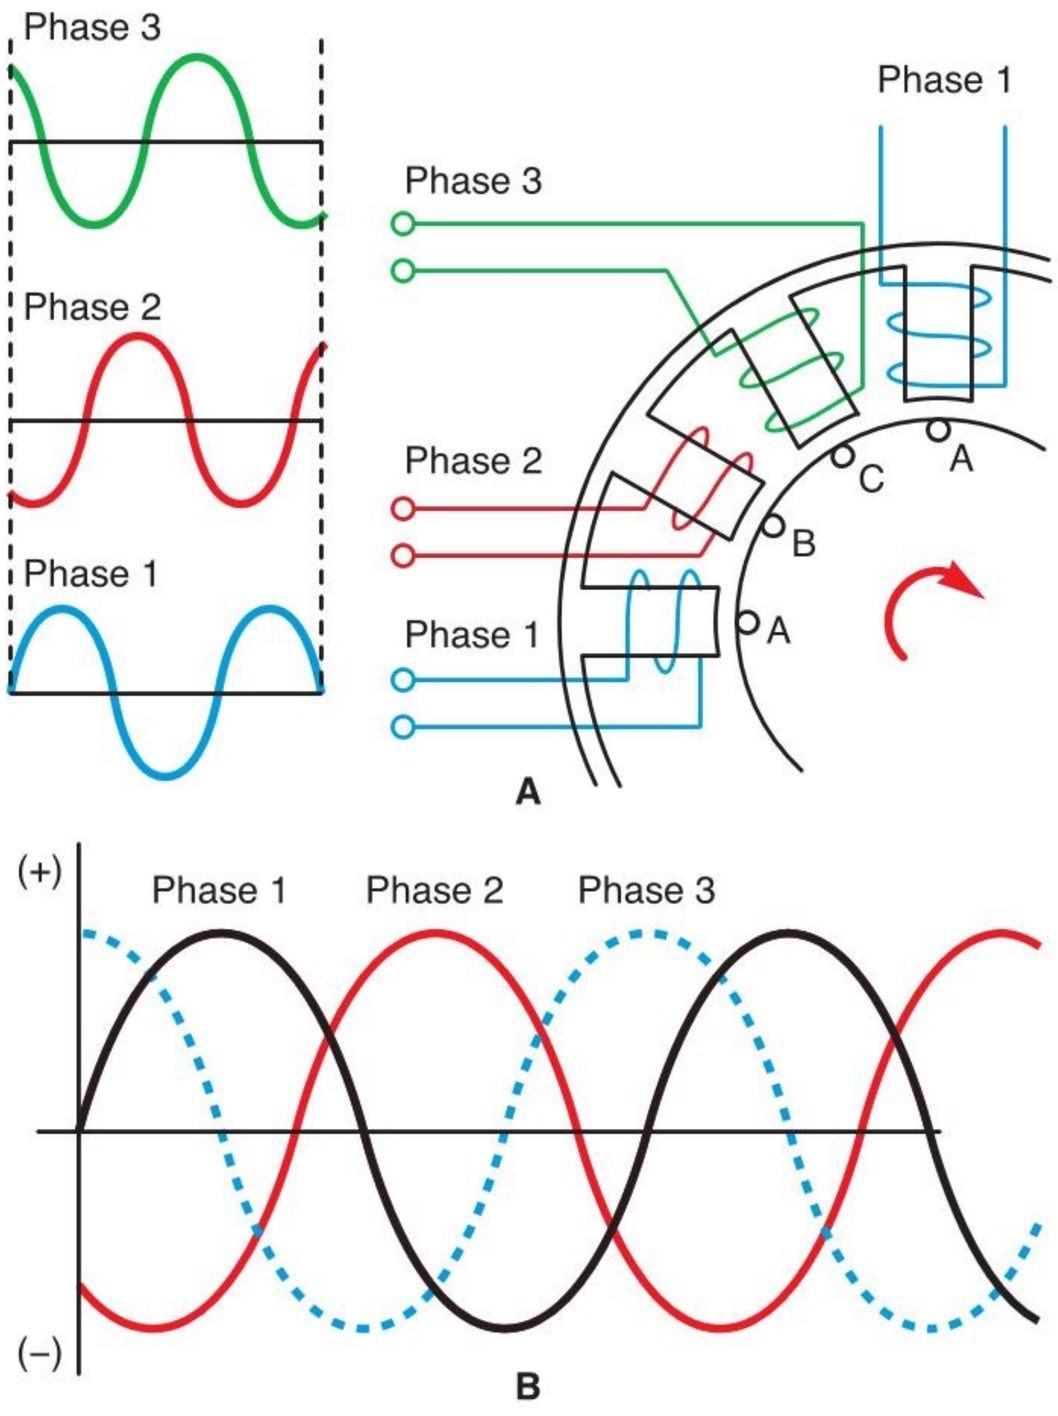
adjustable three-phase ac, flowing out through the three HV power cables going to the motor-generator.

Three-phase ac power consists of three single-phase alternating voltage waves flowing through three conductors at different intervals in time. The positive slope of the first ac sine wave leads the other two ac sine waves by 120° and 240° respectively. This provides 360° rotation of the permanent magnet motor armature as it follows the three voltage waves spaced into three phases of applied ac voltage.

Since the permanent magnets are spaced around the armature in three positions, each ac voltage wave acts on its set of magnets to push and pull the armature for shaft power output. See **Figure 26-13**. The permanent magnets are magnetically attracted and repulsed by the positive and negative voltage waves as they move around the stator coil windings. A north-facing magnet in the armature would be attracted by a south (or negative) wave moving past it. The south-facing waves would attract the armature magnets with their north end exposed to its corresponding stator electromagnet.

To efficiently control a motor-generator, the HV PCM can vary ac frequency, voltage, and resulting current to increase or decrease ***motor torque*** and ***motor speed***. Upon initial acceleration, the HV PCM would feed three-phase ac with a very low "motor start" frequency and moderate voltage to ramp up the motor armature quietly (less motor hum). As vehicle speed and armature speed increase, the HV PCM can increase output voltage, current, and frequency to strengthen the magnetic fields in the stator. The increased voltage and resulting current flow though the stator electromagnets form a stronger electromagnetic field to increase traction motor torque and speed. This progressively stronger stator field strength and increased frequency accelerates the armature and drive train up to an efficient operating rpm.

The HV PCM monitors motor load (current draw), resistance (inductance), and speed (rpm) to maintain an optimum frequency and voltage applied to the stator windings for maximum motor efficiency.



Toyota

Figure 26-13. Three-phase ac flows through the three power cables that run between the motor-generator and the HV power control module. A—Three-phase ac is used to spin the armature in this motor-generator. Phase 1 current attracts armature pole A. Phase 2 attracts armature pole B. Phase 3 attracts armature pole C. B—Three-phase alternating current is simply three single ac phases timed 120° apart. The voltage waves (shown as voltage waveforms) generate magnetic fields that circle inside the motor-generator to make the armature spin.

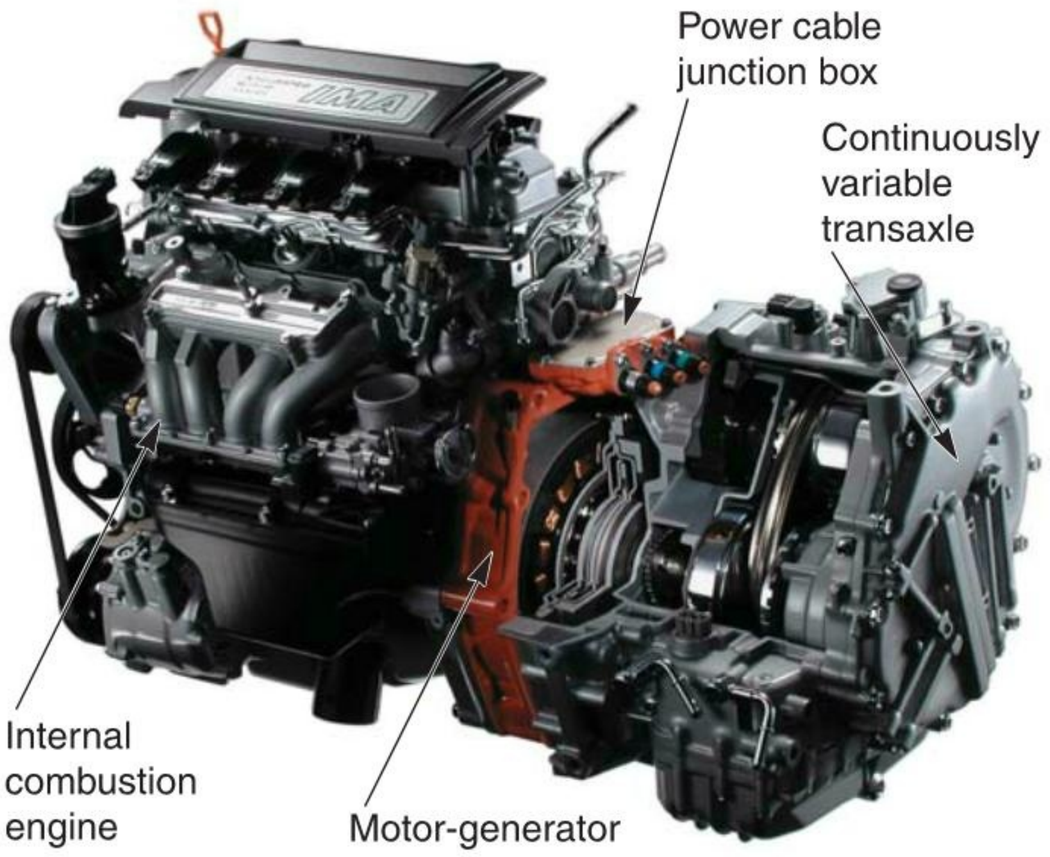
Motor-Generator as an HV Generator

The motor-generator acts as an ac generator (alternator) during regenerative braking and when being driven by the internal combustion engine or transmission. The internal combustion engine or drive train spins the motor-generator's armature to generate high-voltage electricity. The armature's magnetic fields cut through the coil windings in the stationary stator windings. This induces high alternating current in the stator windings, so high current levels are generated at the three power cables going to the HV PCM.

Single Motor-Generator Hybrids

A single motor-generator hybrid uses only one large motor-generator to assist the internal combustion engine. This is a compact design with the motor-generator assembly bolted to the rear of the engine block, in front of the transaxle or transmission. The motor-generator armature is connected to an engine crankshaft and to the transmission input shaft. As shown in **Figure 26-14**, the single motor-generator is the least complex type of hybrid drive train.

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 26-14. In this parallel hybrid arrangement, the single motor-generator is located between the engine block and transaxle. The motor-generator can assist the internal combustion engine to propel the vehicle or to crank and restart the engine. The motor-generator can also serve as a generator to recharge the HV battery.

Dual Motor-Generator Hybrids

A dual motor-generator hybrid uses two separate motor-generators to provide assist. The two motor-generators are usually located inside the transmission or transaxle. A cutaway view of a rear-wheel drive transmission with two motor-generators is shown in **Figure 26-15**.

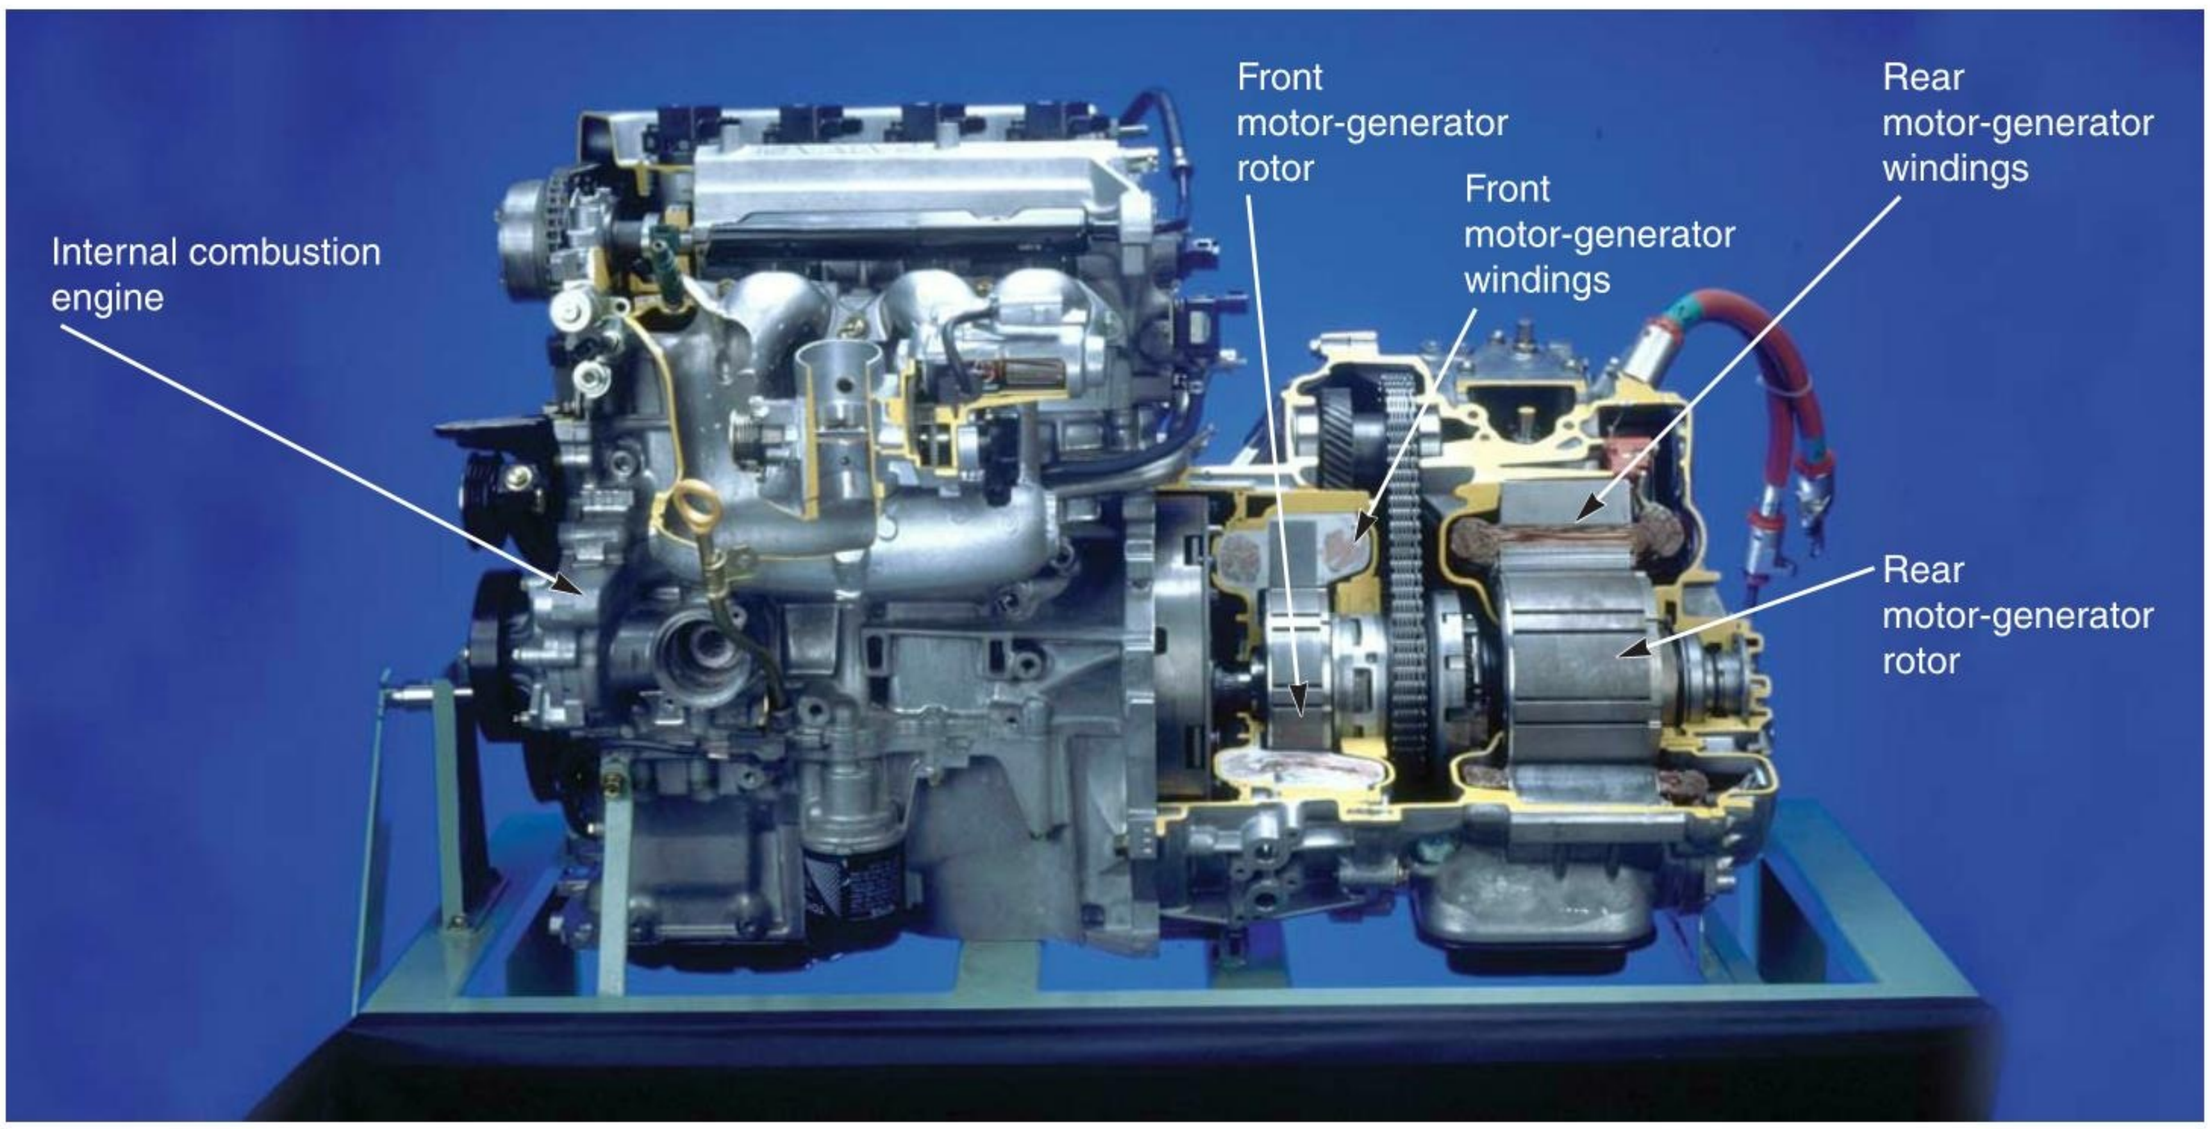
During regenerative braking, both motor-generators act as generators to recharge the battery pack and help drag the drive train to a stop. Both motor-generators act as motors to help propel the vehicle.

Triple Motor-Generator Hybrids

In some cases, three motor-generators are used in a hybrid vehicle, **Figure 26-16**. Two motor-generators are located in the transmission or transaxle, and one is located in the rear drive axle assembly. A triple, or even quad (four), motor-generator arrangement is often used in large four-wheel drive vehicles to help electrically drive all four wheels.

Power Splitter

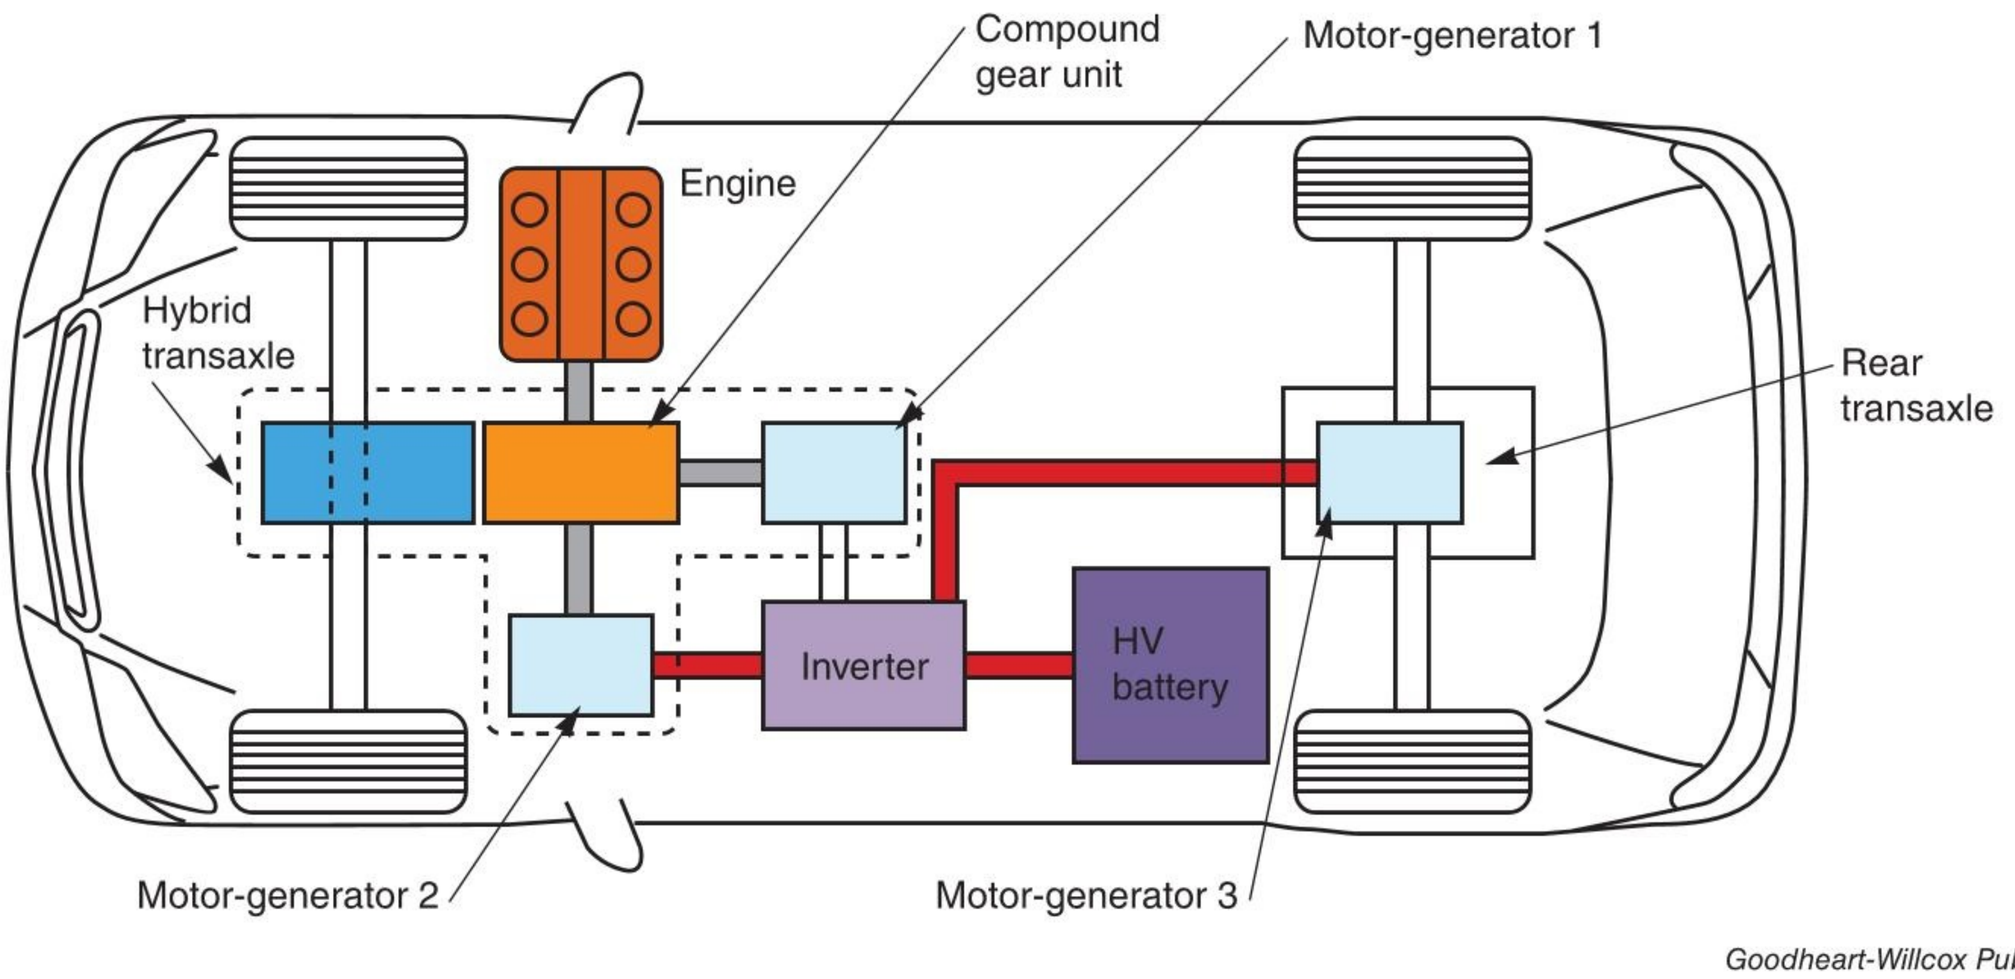
A hybrid ***power splitter*** is a planetary gearset used to control the transfer of power through the hybrid drive train. The hybrid power splitter and transaxle are under computer control.



Toyota

Figure 26-15. In this series/parallel hybrid configuration, the transaxle contains two motor-generators. To improve fuel economy, the internal combustion engine shuts off when braking, when stopped, and when initially accelerating.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 26-16. This all-wheel drive hybrid drive train uses two motor-generators in the transaxle and a third motor-generator in the rear drive axle assembly.

When the driver moves the gearshift selector in the passenger compartment, an electric signal is sent from the shift lever position sensor to the hybrid control module. The hybrid control module then energizes or shuts off specific solenoids in the transaxle. The solenoids can apply or release friction bands or clutches to hold or release members of the power splitter. By holding or releasing different parts of the power splitter, the solenoids control the planetary gearset(s) and the flow of torque from both the internal combustion engine and the electric drive system. When a motor-generator is operating as a generator, the splitter can transfer driveline torque into the motor-generator armature during braking or coasting.

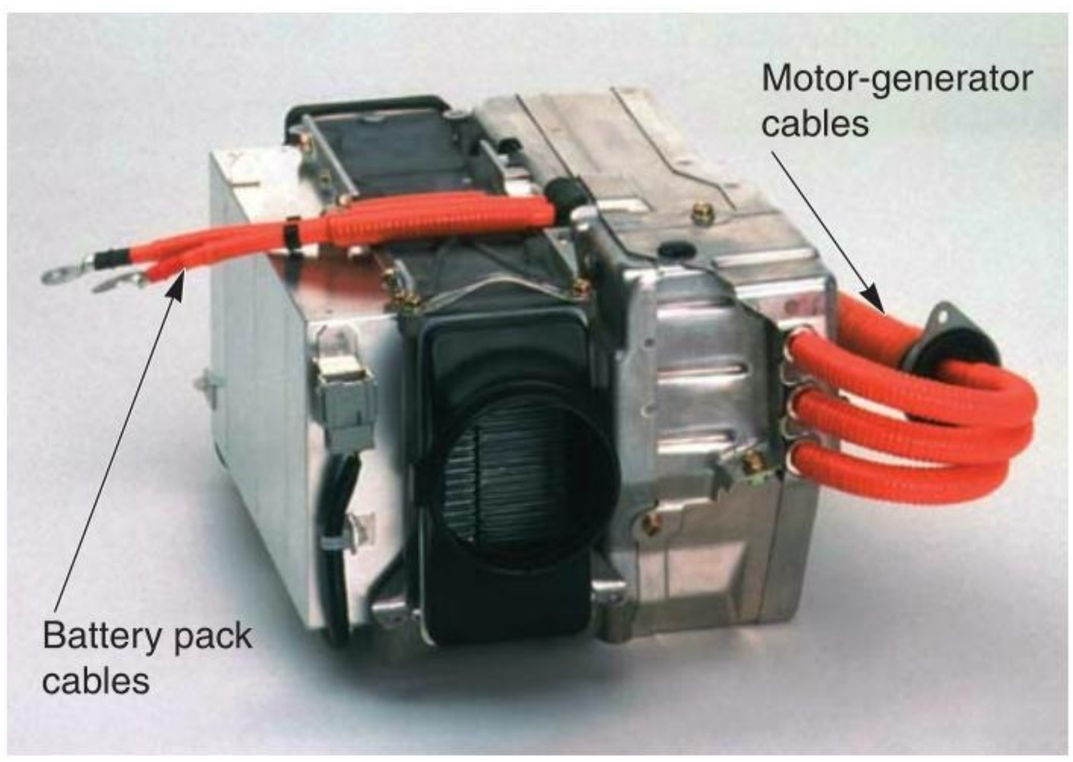
HV Power Control Module

The HV power control module (HV PCM) consists of a set of electronic/electric circuits that feeds voltage (ac and dc) between the HV battery and the motor-generator. See **Figure 26-17**. It controls the amount of ac or dc (0 to 200 amps) that flows through the high-voltage power cables. The HV PCM also controls the speed and torque of the motor-generator by varying ac frequency and ac phase shift.

The HV PCM may be located next to the HV battery, on the transaxle, or on top of the engine. The HV PCM normally contains a converter circuit and an inverter circuit.

The ***converter circuit*** in the HV PCM can step dc voltage up or down. It does not change ac to dc or dc to ac. Hybrid battery pack voltage must usually be stepped up to efficiently drive the inverter circuit and the motor-generator. Battery pack voltage must be stepped down to operate the vehicle's 12-volt or low-voltage circuits.

An ***inverter circuit*** in the HV PCM changes dc to ac and ac to dc. When high-voltage dc is fed into the inverter circuit from the HV battery for electric propulsion, the inverter circuit changes it to high-voltage three-phase ac to run the motor-generator. When



Honda

Figure 26-17. Most hybrid HV power control modules have two orange cables that connect to the HV battery and three large orange cables that connect to the motor-generator.

Copyright Goodheart-Willcox Co., Inc.

three-phase ac is fed into the inverter circuit from the motor-generator, the ac is changed back into high-voltage dc for recharging the battery pack.

Tech Tip

The HV battery, motor-generator, and HV PCM carry tremendous amounts of electrical energy and can become hot from the high current flowing through them. To prevent premature part failure, some provision must be made to carry this heat away from these components. Hybrid cooling system operation and service will be discussed in later chapters.

Hybrid Control Module

The ***hybrid control module*** controls the inverter and converter circuits to efficiently operate the motor-generator(s). The hybrid control module responds to control signals from other vehicle control modules.

The hybrid control module controls the HV PCM to keep the HV battery operating at the optimum temperature and state of charge. It helps utilize power efficiently and properly recharge the HV battery when partially drained by activating the regenerative braking system or generator function of the motor-generator. By keeping the HV battery at optimum charge and temperature, the hybrid control module increases battery service life and fuel economy.

When the accelerator of a hybrid is depressed, a pedal position sensor sends a signal to the hybrid control module. The hybrid control module determines whether to drive in the all-electric mode, start the engine (HV battery partially drained), or use a combination of an internal combustion engine and electric drive based on information in its memory and from sensors.

Hybrid Rotor Sensor

A hybrid ***rotor sensor*** measures armature speed and position to control ac phase shift, which controls motor torque and speed. A rotor on the motor-generator's armature spins inside three sensing coils. The motor-generator sensor produces ac signals that are processed by the HV PCM. Based on the frequency of the rotor sensor signals, the HV PCM can advance or retard the three-phase ac going to the motor-generator electromagnets for efficient traction motor operation and propulsion.

The center sleeve of the motor-generator sensor is splined to the rotor or armature shaft so they rotate together. A steel snap ring often holds the sensor on the motor-generator rotor shaft.

HV Power Cables

HV power cables transfer extremely high voltage and current levels to the components of the electric drive system. The power cables are heavily insulated to prevent these voltages from shorting to ground.

Two large HV power cables connect the battery pack to the HV PCM. Three more large power cables connect the HV PCM to the motor-generator. These three cables are normally routed under the floor pan on the inside of a rocker panel. All the HV power cables have orange insulation to warn technicians of their danger. Look at **Figure 26-1** and **Figure 26-2**.

When a hybrid uses several motor-generators, three HV power cables must be wired to each. For example, if the hybrid has two motor-generators, six HV power cables must be fed to the motors. Two dc power cables must carry current from the HV battery to the HV PCM for a total of eight high-voltage cables connected to the HV PCM.

Hybrid Ground Fault Interrupter

A hybrid ground fault interrupter constantly monitors the system for high-voltage leakage into the metal chassis of the vehicle. If high voltage from the HV battery or motor-generator is shorting to ground, the HV PCM will illuminate a warning light and de-energize the main power relays (contactors) to disconnect the HV battery from its drive circuit.

The main power relays will also open to disconnect the battery during air bag deployment. If the vehicle is in a collision serious enough to trigger an impact sensor, the vehicle control modules will cut power to the HV battery contactors so power cannot enter the HV PCM and other components in the high-voltage system. HV battery contactors are very large, electromagnetic relays with mechanical contact points to close or open the HV battery circuit to the HV PCM.

Impact Sensors

Impact sensors, or inertia switches, open during a severe impact to open the high-voltage circuits, disable the electric fuel pumps for the internal combustion engine, and deploy the air bags. If the air bags have deployed, you must follow manufacturer instructions to replace the air bags and re-energize the electric drive system.

Copyright Goodheart-Willcox Co., Inc.

Hybrid Dash Display

A ***combination meter*** in the dash of a hybrid displays many variables pertaining to the performance and condition of the internal combustion engine and electric drive system. The combination meter contains the speedometer, odometer, fuel gauge, engine gauges, hybrid power display, and the hybrid drive ready light, as well as several warning lights. One design is shown in **Figure 26-18**.

A ***hybrid drive ready light*** often blinks when you press the brake pedal and turn the ignition key to the *Start* position with the gear selector in *Park*. When the electric drive is engaged, the ready light glows continuously to let you know the vehicle is ready to be driven.

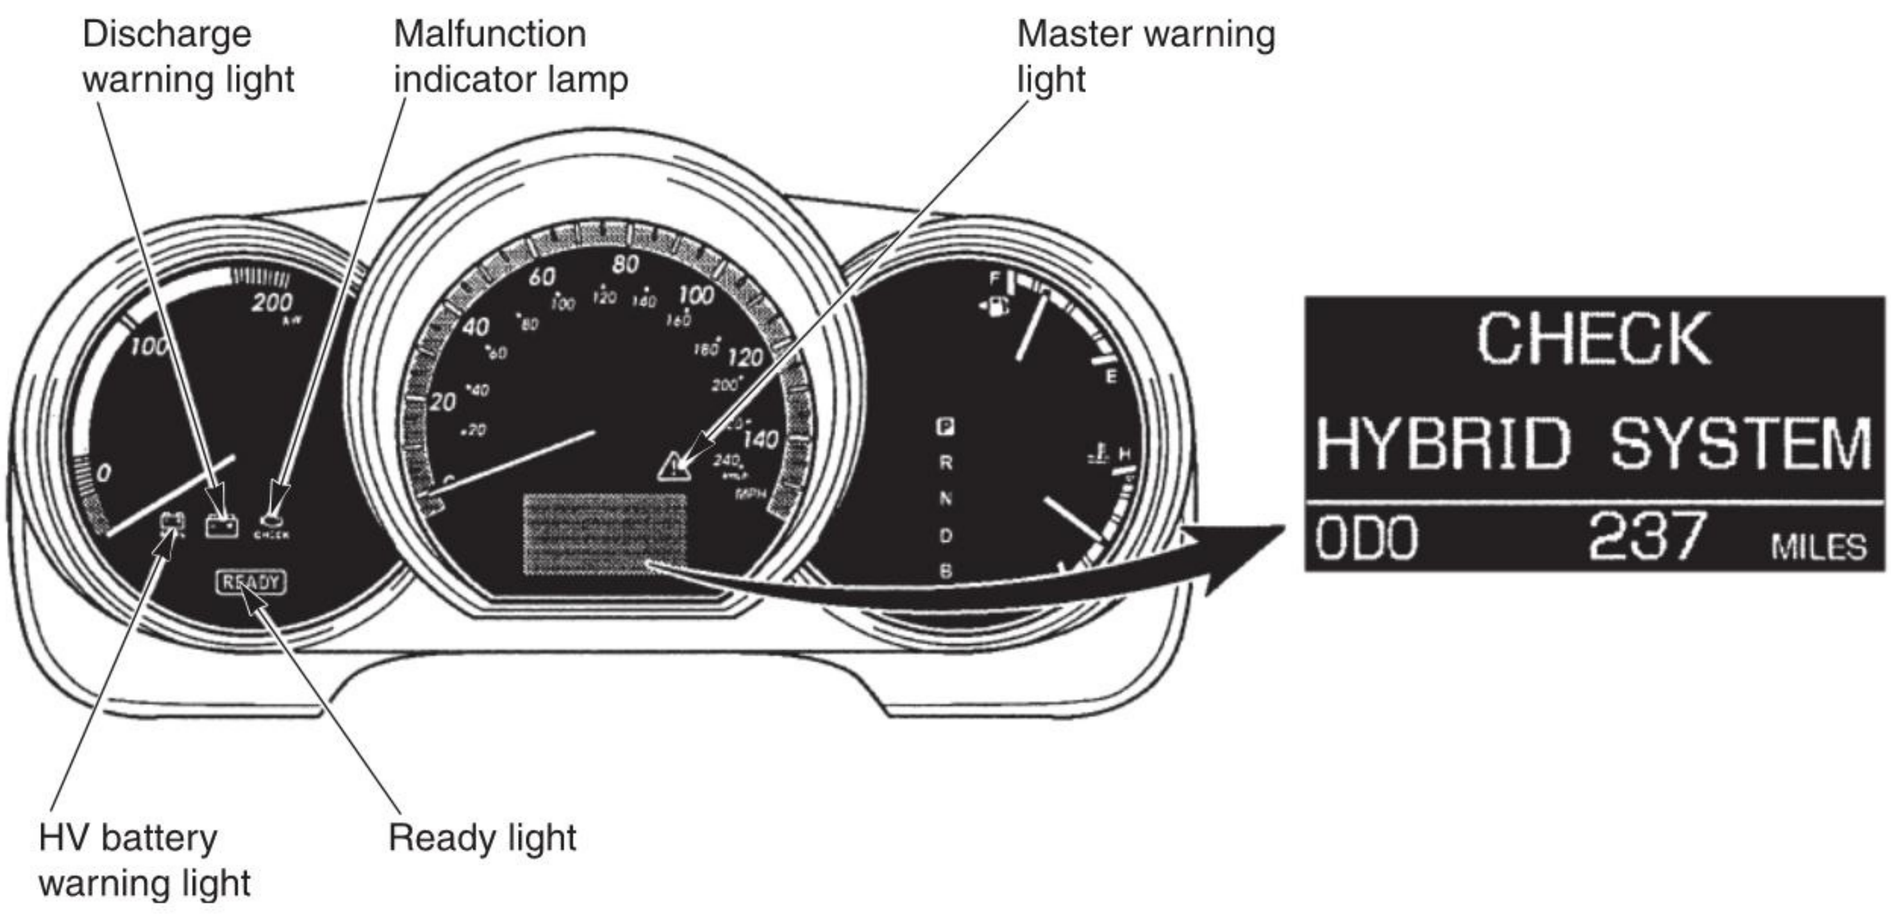
A ***hybrid master warning light*** in the combination meter warns if there is a problem in any part of the drive train. If the hybrid ECM detects any abnormal condition in the electric drive circuitry or related components, it will illuminate the master warning light to notify the driver that something is wrong.

A ***battery pack warning light*** in the instrument cluster illuminates to signal the driver about battery pack problems. This could be caused by running the air conditioning and other high-current draw circuits overnight, several shorted battery cells, or an HV PCM circuit problem preventing the HV battery from being recharged normally. A conventional ***malfunction indicator light (MIL)*** also turns on when any control module detects a vehicle malfunction.

A ***hybrid power display*** informs the driver of the hybrid drive operating conditions. See **Figure 26-19**. Many hybrid displays indicate when the electric "assist" is working, how electrical energy is being used, and how much energy remains in the HV battery. The power display often reads in kilowatts (kW) of power output from the HV battery. This display helps the driver monitor and gauge power usage while driving.

Toyota

Figure 26-19. Note how the hybrid energy monitor in the dash illustrates the flow of energy into or out of the system. Real-time fuel consumption is also indicated.



Toyota

Figure 26-18. The hybrid dash display provides information about the mode of operation and the condition of the electric portion of the drive train.

Hybrid Tip

A locomotive is considered a hybrid. It uses a diesel engine to spin an electric generator. The generator energizes one or more large, high-torque traction motors to turn the locomotive's steel drive wheels. The operator can adjust diesel engine's speed and the generator's electric current output to control the torque and speed of the traction motor.

Summary

- In an HEV, the internal combustion engine and electric drive system work in unison under computer control to propel the vehicle and operate its electrical accessory systems.
- A typical hybrid drive system has six major assemblies: an HV battery, a motor-generator, an HV power control module, a hybrid control module, HV power cables, and an internal combustion engine.
- A full hybrid is propelled by the motor-generator until the HV battery has about a 30% charge remaining.
- In a series hybrid configuration, an electric motor is the only method used to apply torque to the vehicle's drive train.
- A parallel hybrid uses both the internal engine and a motor-generator to apply torque to the drive train.
- The series-parallel hybrid can recharge the HV battery even when the electric motor is used to drive the vehicle.
- A typical series-parallel hybrid drive system has six basic modes of operation: all-electric drive mode, motor-assist mode, idle stop mode, regenerative braking mode, engine starting mode, and HV battery recharging mode.
- The HV battery sends high-voltage dc into the HV PCM through the HV power cables.
- A hybrid motor-generator functions as both a powerful traction motor and as a high-energy alternator in the vehicle's power train.
- The HV power control module is a set of electronic circuits that feeds voltage between the HV battery and motor-generator.
- The hybrid control module controls the HV PCM and motor-generator to keep the battery pack operating at the optimum temperature and state of charge.
- Hybrid power cables transfer extremely high voltage and current to the components of the electric drive system.
- The dash display of a hybrid presents many variables pertaining to the performance and condition of the internal combustion engine and electric drive system.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

armature
assist hybrid
battery pack warning light
combination meter
converter circuit
full-electric vehicle
full hybrid
HV battery

Activities

1. Inspect a hybrid vehicle. Locate the HV battery, HV PCM, power display, engine, power cables, and other parts. Make sure you wear insulated gloves and eye protection during your inspection.
2. Use the Internet to look up gas mileage figures for several cars, including conventional and hybrid electric vehicles. Write a report explaining which vehicles get the highest gas mileage and why.
3. Look up service data on a hybrid vehicle. Write a report summarizing what must be done to remove and replace the HV battery, HV PCM, or other parts of the hybrid drive.

Review Questions

Answer the following questions using the information provided in this chapter.

1. How many power sources does a hybrid vehicle use for propulsion?
2. When most hybrids come to a stop, both the internal combustion engine and the high-voltage charging system are shut off. True or False?
3. List the six major assemblies found in a hybrid drive system.
4. Explain the difference between a full hybrid and a mild hybrid.
5. In a(n) _____ hybrid, the internal combustion engine has no mechanical connection to the drive train.
6. What is the drawback to a parallel hybrid?
7. A full-electric vehicle has no method of recharging the HV battery when driving. True or False?
8. List the six modes of hybrid drive system operation.
9. In all-electric drive mode, the _____ provides all the energy to propel the vehicle.
10. During _____ mode, the motor-generator places a drag on the rotating tires, wheels, and drive train to help slow the vehicle.
11. HV battery voltage can range from about _____ to _____ volts dc.
12. The basic parts of a motor-generator include the _____, stator, and housing.
13. Explain the difference in operation when the motor-generator serves as an HV motor versus when the motor-generator acts as an ac generator.
14. A(n) _____ is a planetary gearset used to transfer power through the hybrid driveline.
15. The converter circuit in the HV PCM changes dc to ac and ac to dc. True or False?
16. How many HV power cables connect the HV power control module to the motor-generator?
17. A hybrid _____ monitors the system for high-voltage leaking into the metal chassis of the vehicle.
18. Explain the function of the combination meter.

ASE-Type Questions

1. Manufacturers are experimenting with each of the following hybrid types, *except*:
   (A) pneumatic hybrids.
   (B) hydraulic hybrids.
   (C) fuel-cell hybrids.
   (D) steam-powered hybrids.
2. Technician A says you can identify a hybrid vehicle by the badging on the engine cover. Technician B says you can identify a hybrid by comparing the vehicle's VIN to factory reference information. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says all mild hybrids use a small motor-generator to assist the gas engine during acceleration. Technician B says a mild hybrid shuts down its internal combustion engine when the vehicle comes to a stop. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

4. In all-electric drive mode, the energy needed to power the motor-generator is provided by the _____.
   (A) internal combustion engine
   (B) power splitter
   (C) battery pack
   (D) hybrid control module
5. A set of electronic/electric circuits that feeds voltage (ac and dc) between the HV battery and the motor-generator is the:
   (A) HV PCM.
   (B) HEV.
   (C) ECU.
   (D) None of the above.

Chapter 27
Hybrid Drive Systems Diagnosis and Repair

After studying this chapter, you will be able to:

- Use on-board diagnostics to find the source of problems in a hybrid drive system.
- Recall the safety measures that must be followed when working on high-voltage, high-current hybrid drive systems.
- Perform basic tests to verify hybrid drive trouble codes.
- Carry out proper procedures for safely removing and replacing a battery pack, an HV power control module, HV power cables, control modules, and motor-generator assembly.
- Correctly answer ASE certification test questions about hybrid drive systems diagnosis and repair.

Since hybrid electric vehicles (HEVs) are now produced and sold by many automakers, it is important that you understand how these vehicles operate, and the methods for safely servicing them. The electrical/electronic service methods you learned in previous chapters also apply to hybrid vehicles. The primary concern when working on an HEV drive train is the extremely high voltage and current stored and generated by the electric drive devices and circuits. You must learn how to work safely with up to 600 volts of alternating current (ac) and 300 volts of direct current (dc). It is recommended that you take specialized factory training before attempting to work on a hybrid. For example, if you are going to work on a Ford hybrid, you should attend a certified Ford training program.

Please remember that the information in this chapter is general and applies to all makes and models of hybrid vehicles. You must refer to factory service instructions to effectively and safely service hybrid vehicles. Even though hybrids can be serviced with conventional tools and equipment, the specifications, part locations, and repair methods vary slightly.

Hybrid Problem Diagnosis

Hybrid vehicles have extensive on-board diagnostic systems that will help you locate the source of system problems. The on-board diagnostic system monitors hundreds of operating conditions and turns on one or more warning lights if any monitored condition is not within specifications. **Figure 27-1** shows a few of the problems that can affect hybrid electric drive operation.

A ***hybrid ground fault interrupter*** constantly monitors the system for high-voltage leakage into the metal chassis of the vehicle. If high voltage from the HV battery pack or motor-generator is shorting to frame ground, the control module illuminates a

Goodheart-Willcox Publisher

Figure 27-1. Note some of the problems you may encounter when repairing an HEV drive train.

warning light and de-energizes the main power relays (contactors) to disconnect the battery pack from its electric drive circuit.

A glowing malfunction indicator light means that you should use a scan tool to retrieve stored trouble codes. An example of a hybrid drive trouble code index chart is shown in **Figure 27-2**. This chart explains what each code means and where to find instructions for further testing in the service manual.

Hybrid Service Safety

Modern HEV drive systems generate enough electrical energy to cause electrocution. It only takes a couple amps of current through your body to stop your heart and kill you. Most hybrid vehicles conduct almost 600 volts ac and 300 volts dc at hundreds of amps. By comparison, home wall outlet voltage is 120 volts. Therefore, it is important that you work safely when servicing a hybrid vehicle. To work safely, you should:

- Remove your jewelry.
- Wear eye protection.
- Wear insulating gloves.
- Wear rubber-soled shoes.
- Keep a fire extinguisher nearby.
- Follow towing safety procedures.
- Disable the hybrid drive when working.
- Set up a high-voltage buffer zone.
- Remove the high-voltage disconnect.

Remove Jewelry

Remove all jewelry when working on a hybrid's high-voltage circuits. It is easy for a metal watch to short between a high-voltage conductor and ground since high voltage can arc through the air and into the jewelry. The high voltage can instantly make the metal watch glow red hot, burning deep into your wrist or arm. Another potential danger is that the jewelry may come into contact with high-voltage conductors. If a metal necklace or bracelet touches high-voltage conductors in a hybrid, it will weld itself to the conductors. The increased current flow will instantly liquefy the highest resistance point in the jewelry. As a result, the metal in the jewelry will explode.

Wear Eye Protection

Make sure you wear safety glasses, goggles, or better yet, a full-face shield when working on high-voltage components. If an HV power cable shorts to ground, a violent electric arc will occur. The metal end of the shorted cable will melt and may shoot out molten metal. If the molten metal gets in your eyes, you can suffer permanent eye damage, even blindness.

Wear Insulating Gloves

Always wear ***insulating gloves*** rated for high voltage when working on high-voltage components and cables. High voltage and current can arc through cloth gloves, causing serious injury or death. Make sure you use OSHA-approved lineman gloves or approved insulating gloves with an insulation rating value of at least 1000 volts. See **Figure 27-3**.

Always inspect your insulating gloves, especially the fingertips, for tears or splits before using. To check the condition of insulating gloves, grasp a glove by the cusp and fold it over a couple times to seal air inside the glove. With the glove filled with air, check for air leakage and flaws. If the glove leaks air, it can also let voltage in. If your gloves are worn or damaged, discard them and purchase new ones.

Wear Rubber-Soled Shoes

You must wear shoes with rubber soles when working on hybrid vehicles because of the high voltages involved. Rubber soles help insulate your body from earth ground, preventing high voltage from arcing out and into your body while seeking earth ground.

Copyright Goodheart-Willcox Co., Inc.

Keep a Fire Extinguisher Nearby

Always keep a class A, B, C fire extinguisher near the work area when servicing hybrids. A high-voltage electrical short can cause a serious electrical fire. If fire starts, shut off the main contactor or switch for the HV battery, and then put out the fire with a fire extinguisher.

DTC Troubleshooting Index

* 1: These DTCs are indicated by a blinking IMA system indicator when the SCS line is jumped with the HDS.
* 2: To determine the correct troubleshooting procedure for these DTCs, jump the SCS line with the HDS, and read the flash code.

Toyota

Figure 27-2. This chart lists hybrid trouble codes from one automaker. If the scan tool reads code P0562 on this vehicle, go to pages 12–39 in the service manual for further instructions on testing and servicing the battery condition monitor.

Copyright Goodheart-Willcox Co., Inc.

Toyota

Figure 27-3. Wear thick rubber gloves to insulate your skin from the high voltages in a hybrid drive system.

Although you cannot turn off the power stored inside the HV battery, you can disconnect it from the rest of the electrical system.

To disable an HEV for repair, you must first turn the ignition key off. This will cause the hybrid control module to de-energize the relays that connect the high-voltage battery to the rest of the electric drive system. Some manufacturers also require that you disconnect the conventional 12-volt battery to help prevent the high-voltage circuits from accidentally being energized.

Disabling the system is important because a hybrid's drive train may be engaged and ready to accelerate even without the internal combustion engine running. If you leave the key "on" in a hybrid and the shift lever is in gear (*Drive* or *Reverse*), the vehicle can be propelled forward or backward by the motor-generator if you accidentally press the accelerator. This could cause the vehicle to lunge forward or backward and ram into a shop wall or run over coworkers.

Warning

If a collision-damaged lithium ion battery ever catches fire, do *not* spray water on the fire. When water comes in contact with the lithium electrolyte, it produces very explosive hydrogen gas. If a large volume of hydrogen gas ignites, it can explode with the power of several sticks of dynamite!

Tech Tip

If a hybrid is in a severe collision, the hybrid drive system will automatically disable the high-voltage battery pack. Most hybrids automatically disable the HV battery and generator when the air bags deploy in a collision. You will have to repair all damaged systems, check and erase trouble codes before powering up the high-voltage electric drive train.

Follow Towing Safety Procedures

With some hybrids, spinning the wheels and axles can cause the motor-generator to produce high voltage even with the electrical system disabled and the key off. This can be dangerous and may damage the drive system. When towing or moving a hybrid vehicle, the drive wheels engaged to the motor-generator should be raised off the ground so they do not spin when towed.

The front wheels of a front-wheel drive hybrid should be raised when towing. If towing an all-wheel drive hybrid with motor-generators at the front and rear, this type of four-wheel drive hybrid should be towed on a flatbed truck.

Disable the Hybrid Drive when Working

A "hot hybrid" system is one with high and low voltage still present in the electric drive system.

Set Up a High-Voltage Buffer Zone

When working on an HEV, set up a ***high-voltage buffer zone*** of about 3′ (1 m) around the perimeter of the vehicle. You do not want steel workbenches, large metal equipment, co-workers, or any other potential conductors of electricity in the buffer zone. Take the time to move objects or park the hybrid vehicle away from potential conductors.

If you accidentally move your body into a good conductor (such as a steel workbench) with your arm touching a source of high voltage, you could be electrocuted or severely injured as the voltage travels through your body to ground.

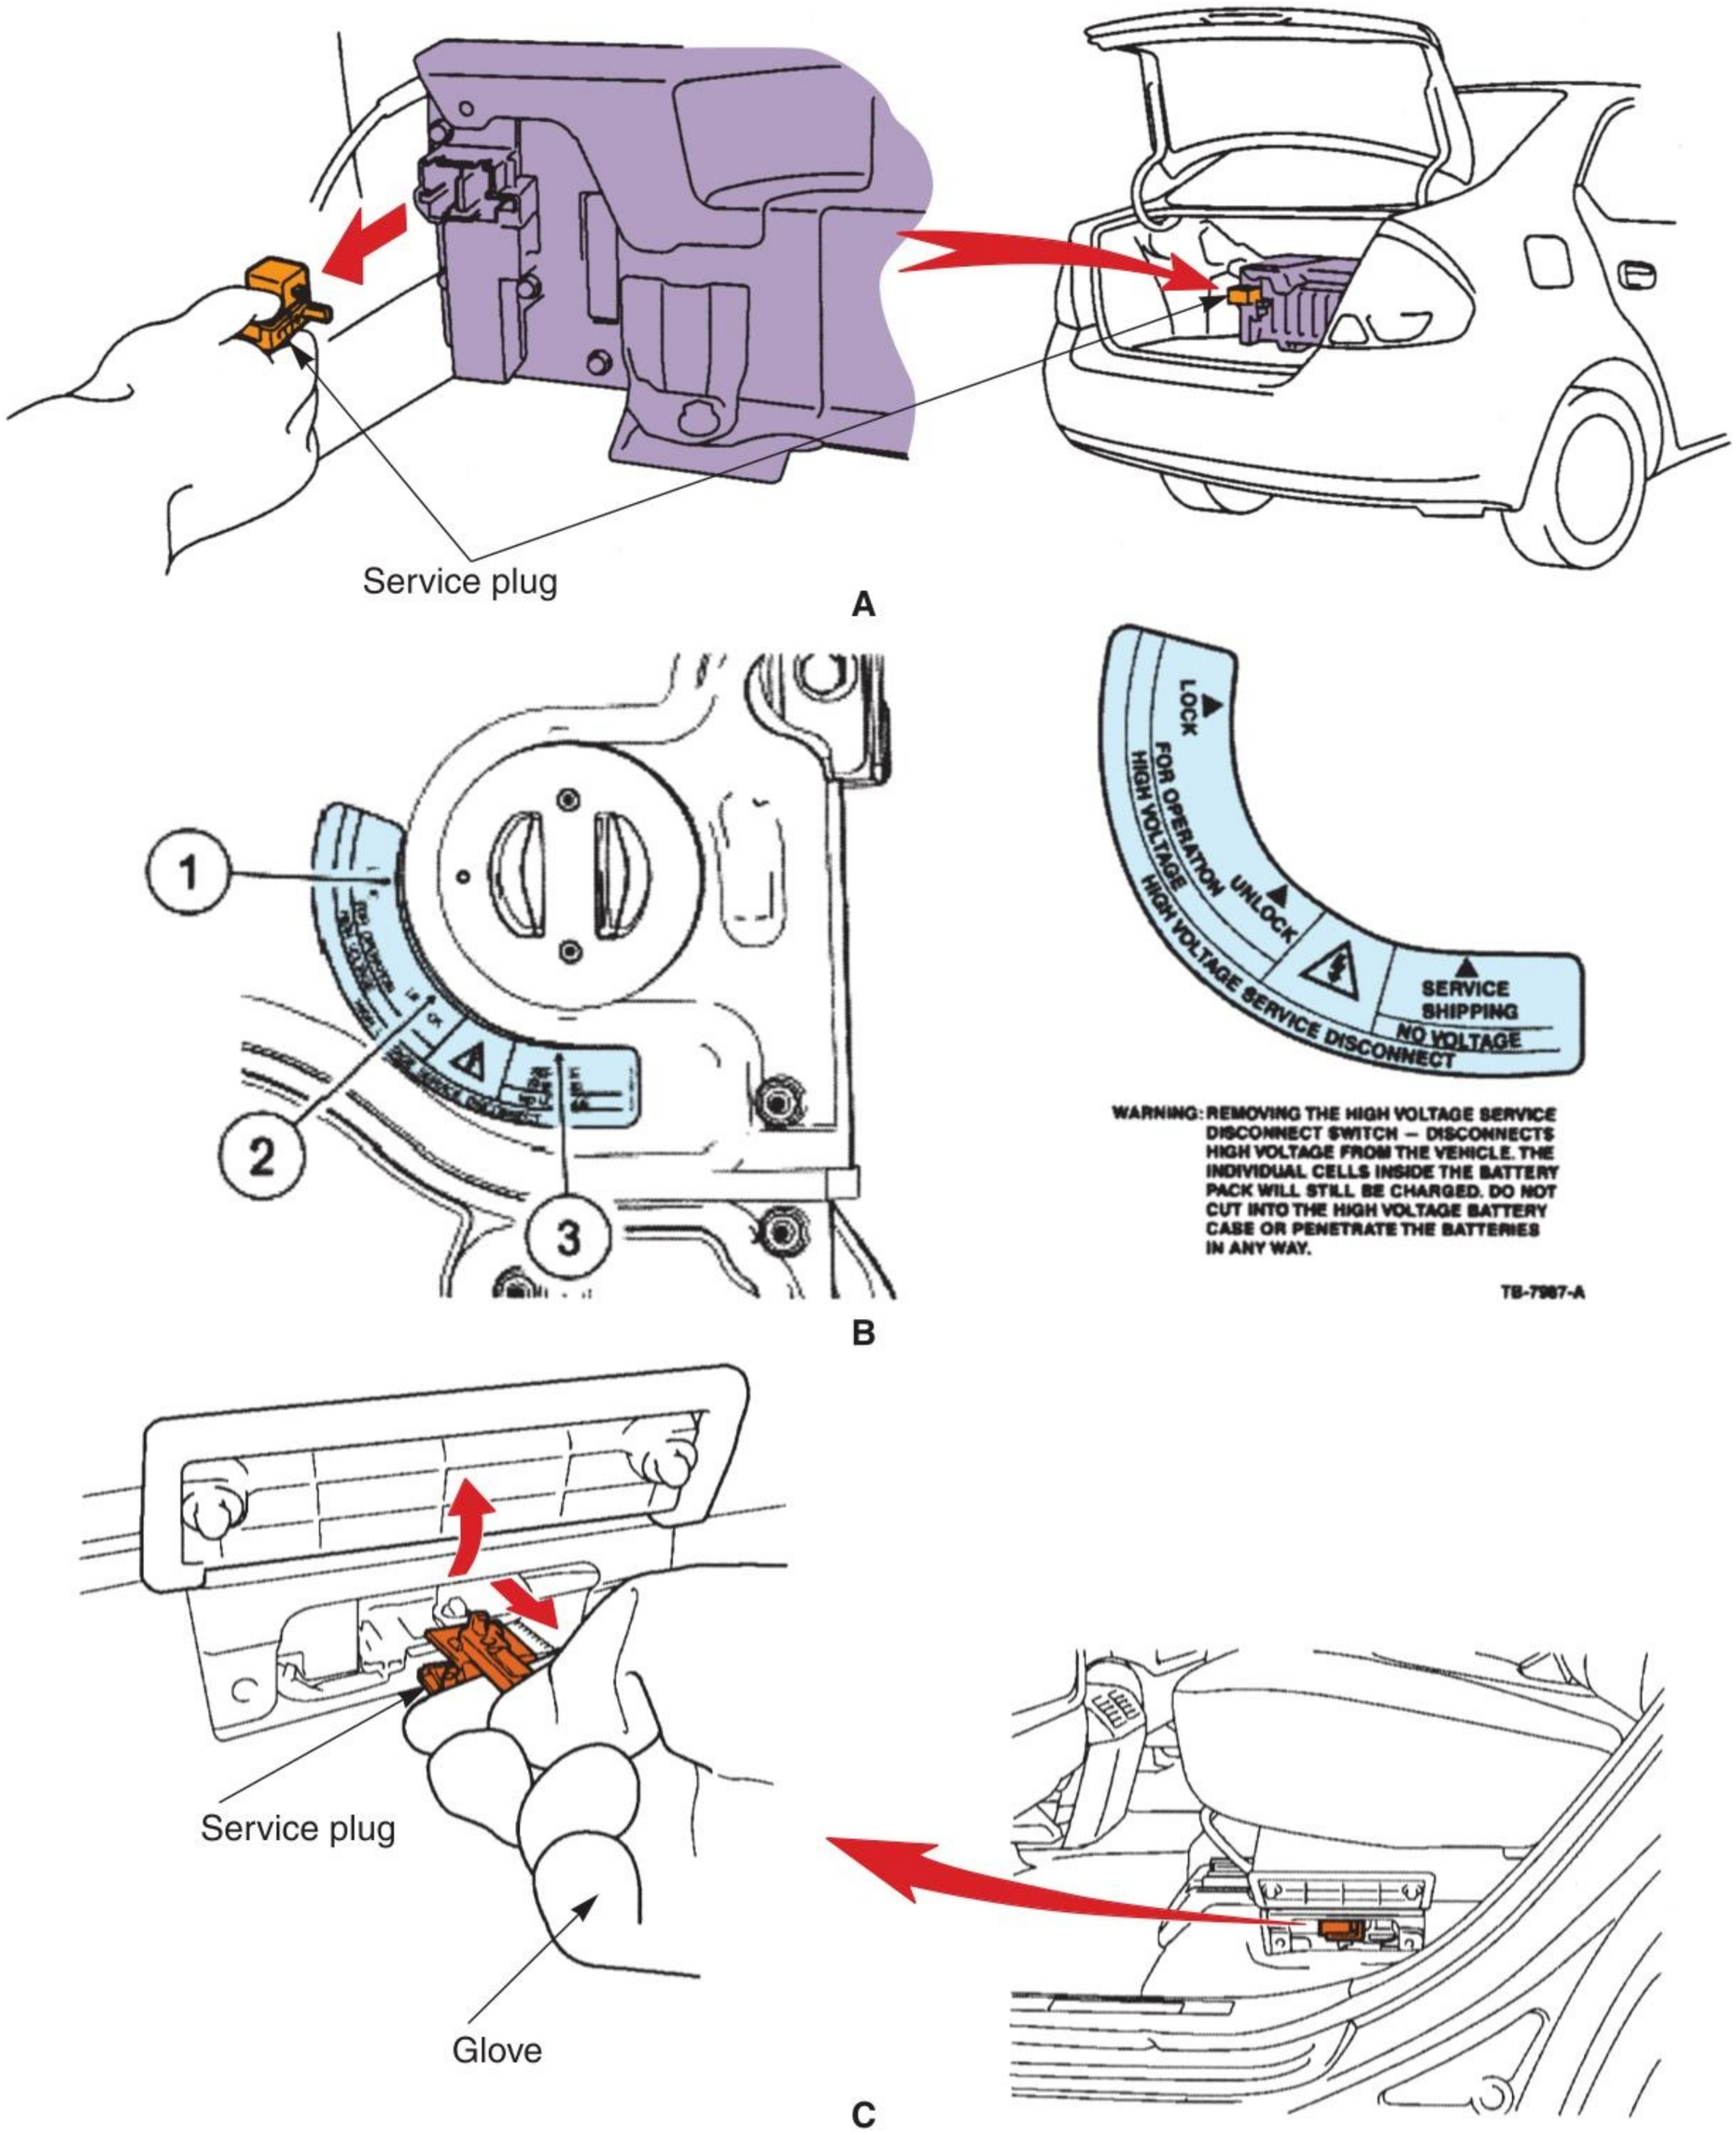
Remove the High-Voltage Disconnect

A ***high-voltage disconnect*** is provided on a hybrid to allow the HV battery to be physically

Copyright Goodheart-Willcox Co., Inc.

disconnected from all vehicle circuits. With many hybrids, you must pull out the disconnect to produce an open circuit between the HV battery cells and the power control module. Refer to **Figure 27-4**. With other designs, you must rotate a high-voltage disconnect switch to provide an open in the HV battery circuit.

Hybrid high-voltage disconnects are usually located near the battery pack in the trunk, under the



Ford and Toyota

Figure 27-4. The hybrid power disconnect can be difficult to find. A—This disconnect is located in the trunk of the vehicle. B—Here you must rotate a locking switch before you can remove the disconnect. C—This hybrid disconnect is located on the side of the rear seat, under a plastic trim piece.

Copyright Goodheart-Willcox Co., Inc.

seat, on the side of a seat under a trim panel, or in other similar locations. Refer to the factory service literature for details.

Warning

To prevent electric shock, wait at least five minutes after removing the high-voltage disconnect before working on the high-voltage circuits. It can take up to five minutes for any high-voltage capacitors in the inverter circuit to fully discharge.

Tech Tip

After you remove a high-voltage disconnect, remove the high-voltage fuse and keep it in your pocket. This will prevent anyone from accidentally reconnecting HV battery power when circuits are being serviced.

HV Battery Service

Hybrid battery packs have a warranty from the vehicle manufacturer. Some automakers offer a full HV battery replacement warranty for up to 8 years or 100,000 miles. HV batteries are very dependable and seldom fail. Nevertheless, they can lose efficiency after a period of extended service. The electrolyte and the metal plates in the HV battery can be depleted after years of operation.

Tech Tip

Remember that hybrid NiMH batteries should not be stored for long periods. When purchasing used HV batteries from recycling yards, find out how long the HV battery has been in storage. If left uncharged for over a year, the battery plates and electrolyte will deteriorate and the HV battery should not be purchased.

Diagnosing HV Battery Problems

Late-model hybrid vehicles have a very extensive on-board diagnostic system that monitors several operating parameters in the high-voltage electric drive system. The hybrid control module will check circuit conditions when the HV battery is discharging while powering the electric drive motor(s) and while it is being recharged by the motor-generator. Trouble codes will be stored in the control module's memory if any electrical value is not within specifications.

Most hybrids have a dash display that shows HV battery charge, temperature, and condition. The display will warn the driver when the on-board diagnostic system detects problems with the HV battery, HV power cables, HV power control module, or other components.

A scan tool will also quickly identify problems with the HV battery, motor-generator, high-voltage electrical connections, hybrid control module, and HV power control module. A scan tool can also be used to compare actual operating voltages to those on the dash display.

If an HV battery fails to accept and hold a charge, a trouble code will be set in memory. The hybrid control module will also trigger a malfunction indicator light in the dash display.

Tech Tip

On some hybrid models, the control module will disable the electric drive train when problems are detected in the battery circuit. When this occurs, the vehicle must be driven under engine power alone until the problem is repaired.

A failed HV battery must be replaced with a new or reconditioned unit. Most shops are not set up to replace individual battery packs. Batteries are sent to a specialty battery repair facility for recycling.

Tech Tip

Detailed information on testing and replacing HV batteries is presented in *Chapter 29, 12-Volt and HV Battery Service.*

Checking HV Battery Relays and Contactors

If the trouble codes and symptoms indicate battery power is okay, but battery power is not reaching the HV power control module (HV PCM), check the

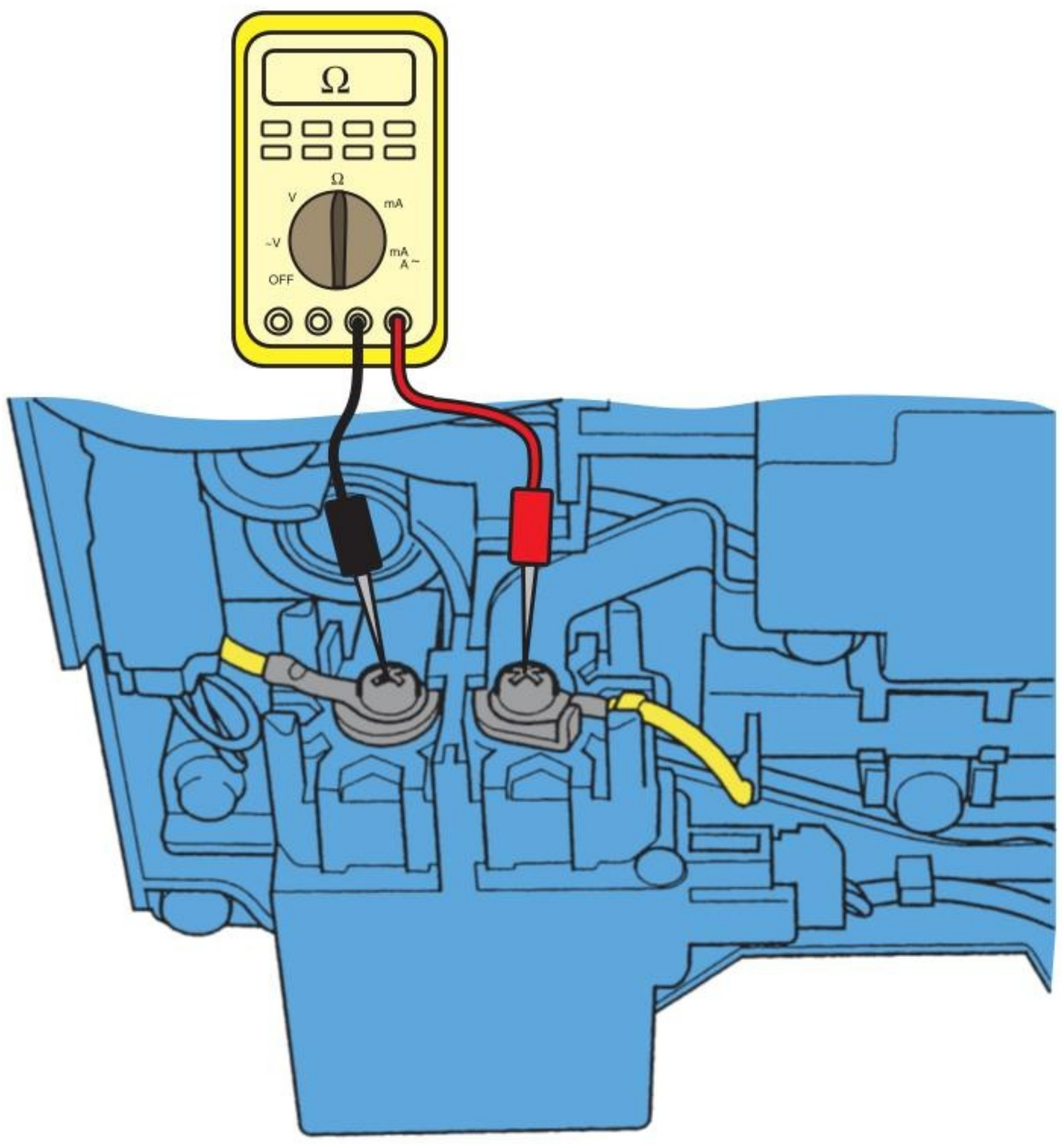
Copyright Goodheart-Willcox Co., Inc.

operation of the battery relays and contactors. Contactors are very large relays with contact points, or lugs. The contactors turn such a high electrical load on and off that their lugs can become burned and pitted. If burned enough, the lugs will develop high resistance and will not be able to carry enough current to the HV PCM and motor-generator. See **Figure 27-5**. Refer to factory service information for relay and contactor test points.

Service Procedure

To make a pinpoint test on a high-voltage contactor:

1. Remove or disconnect the HV battery.
2. Measure the resistance across the closed contactors with the ignition key *On* and then with the ignition key *Off*.
3. If the measurements are not within specifications, replace the contactors.



Goodheart-Willcox Publisher

Figure 27-5. Contactor lugs can become burned and pitted after shutting high voltage on and off thousands of times. If contactor terminals show high resistance when closed (HV battery disconnected from circuit), they should be replaced.

HV Power Cable Service

HV power cables are normally trouble free. However, they can become damaged during a collision, or their metal ends can become loose or corroded. Some HV cables have special watertight terminal ends, **Figure 27-6**. However, most hybrids use an eye-type connector that is secured to a threaded metal stud with a nut.

Service Procedure

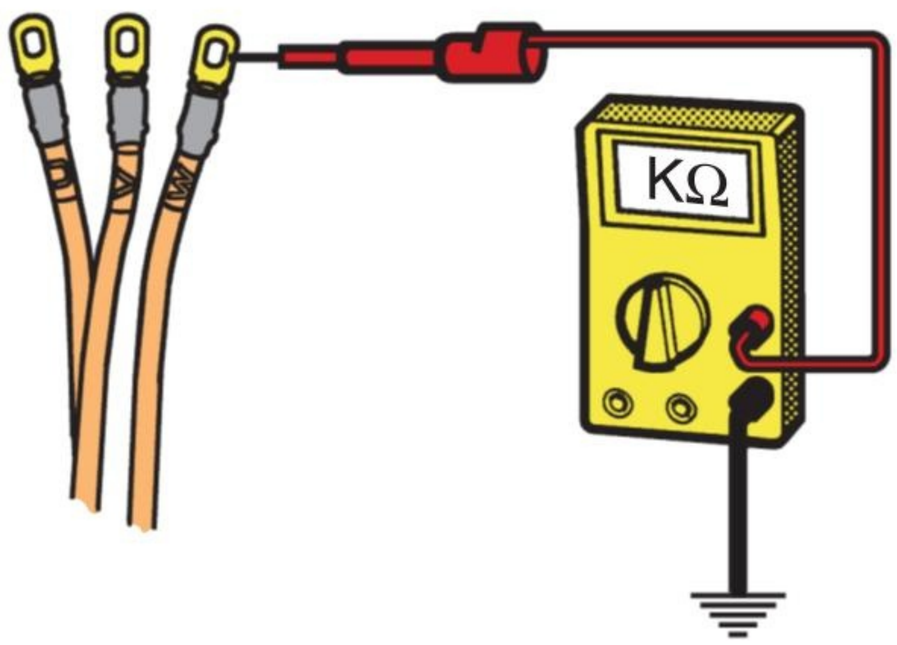
To check the HV power cables:

1. Note the conductor resistance values of the high-voltage circuit in the data list display of your scan tool.
2. If the conductor resistance values are not within specifications, tighten or repair the cable ends or replace the HV power cables, if needed.
3. If your scan tool reading shows a ground fault problem with the cables, they may be leaking current to frame or body ground. Touch your ohmmeter test lead on one end of the cable terminal and connect the other meter lead to frame or body ground. See **Figure 27-7**.
4. If the ohmmeter reading is lower than specifications (usually around 350 kΩ), the insulation may be leaking high voltage to ground and the cable should be replaced.

Goodheart-Willcox Publisher

Figure 27-6. This power cable has a waterproof terminal end. O-ring seals on the HV PCM or the motor-generator housing keep water out of the system.

Copyright Goodheart-Willcox Co., Inc.



Toyota

Figure 27-7. By connecting an ohmmeter between each cable end and ground, you can identify any cable that is leaking voltage. The cable's insulation may have broken down, allowing small amounts of current to leak out of the circuit.

Tech Tip

A high-voltage fuse will open and disconnect the HV battery power if current flow becomes too high due to a short. If this happens and no power is reaching the electric drive system, find out why the fuse burned open. Correct the problem. Then, install a new high-voltage fuse.

A loose cable end can overheat and burn the electrical connection. Always torque the hybrid cable fasteners to factory specifications using a torque wrench to ensure the connection is not too loose or too tight.

Service Procedure

To replace an HV power cable:

1. Disconnect both ends of the cable.
2. Remove the clips that secure the power cable to the vehicle.
3. Install the new power cable in reverse order of removal.

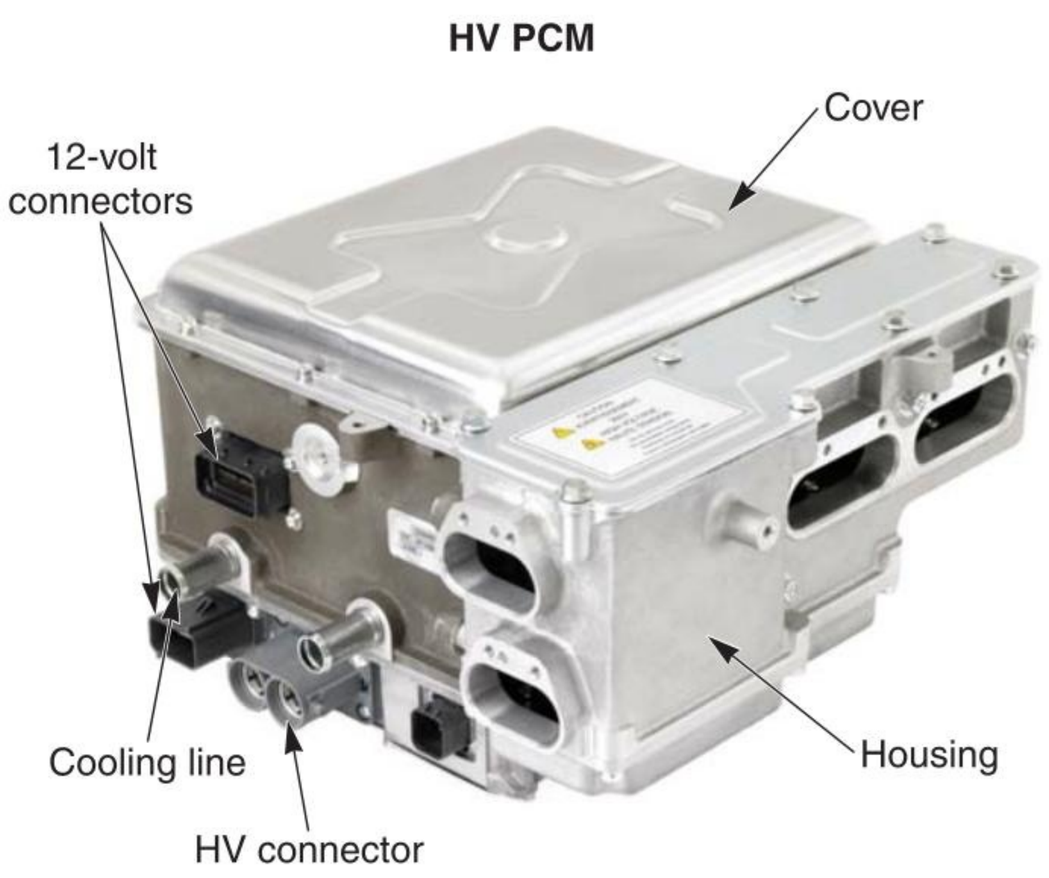
HV Power Control Module Service

The HV power control module (HV PCM) contains several circuits or modules that convert ac to dc and dc to ac. See **Figure 27-8**. The HV PCM also steps voltage up or down using transformers.

A faulty HV PCM can trip various trouble codes, indicating which circuit in the module might be faulty. Sometimes a specific circuit board in the power control module will fail and require replacement. Some hybrid vehicles use separate converter, rectifier, and three-phase circuits. If your scan tool indicates a problem with a specific circuit board, you may be able to order and install just the failed circuit board.

When the ignition key is turned to *Run*, the hybrid control module energizes the HV battery relays. The relays close and send current to large contactor coils, which pull the contactor lugs closed. High voltage and high current from the HV battery can then flow through the contactor lugs to the power control module.

Bad high-power contactor lugs (high-current relays) in the HV PCM can burn and develop high resistance after prolonged service. Bad contactor lugs can prevent normal current flow through the HV PCM and to the motor-generator. This will reduce motor-generator torque. Refer to factory service information for relay and contactor test points and service details.



Chrysler

Figure 27-8. The HV PCM can be located in the engine compartment, on the side of the transmission, or near the HV battery.

Copyright Goodheart-Willcox Co., Inc.

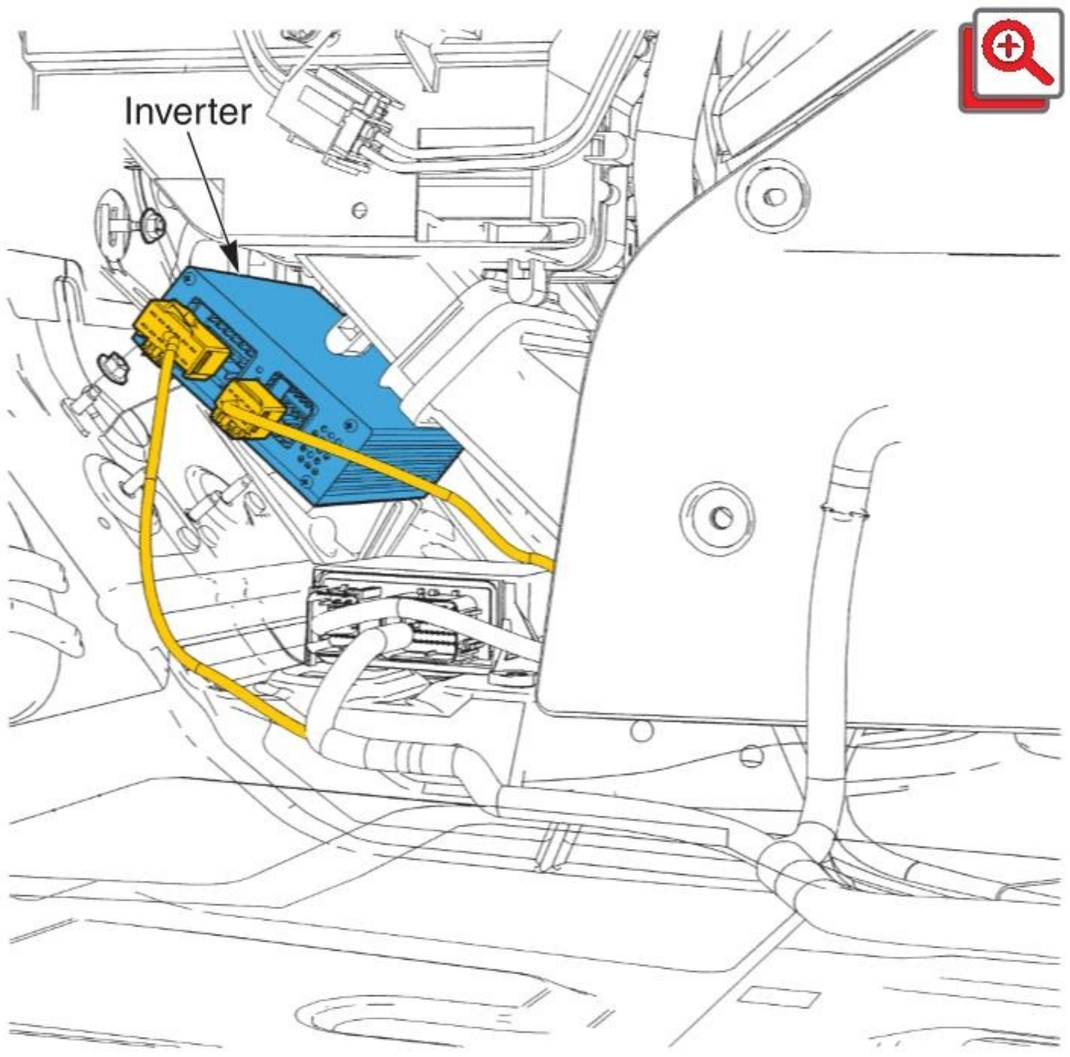
Some hybrid vehicles use discrete (separate) inverters. For example, **Figure 27-9** shows a dc-to-dc inverter that mounts in the engine compartment. If your scan tool indicates internal inverter problems, the defective inverter should be removed and replaced. You can measure actual voltages coming in and out of the unit, but your scan tool will usually pinpoint whether the inverter is bad.

A discrete dc-to-ac inverter is shown in **Figure 27-10**. This unit mounts under a trim panel in the console. Again, your scan tool will help you troubleshoot this converter to determine if it should be replaced.

Sometimes a circuit board in the HV PCM can fail and require replacement. A lack of normal air or coolant flow can cause HV PCM overheating, which will set trouble codes.

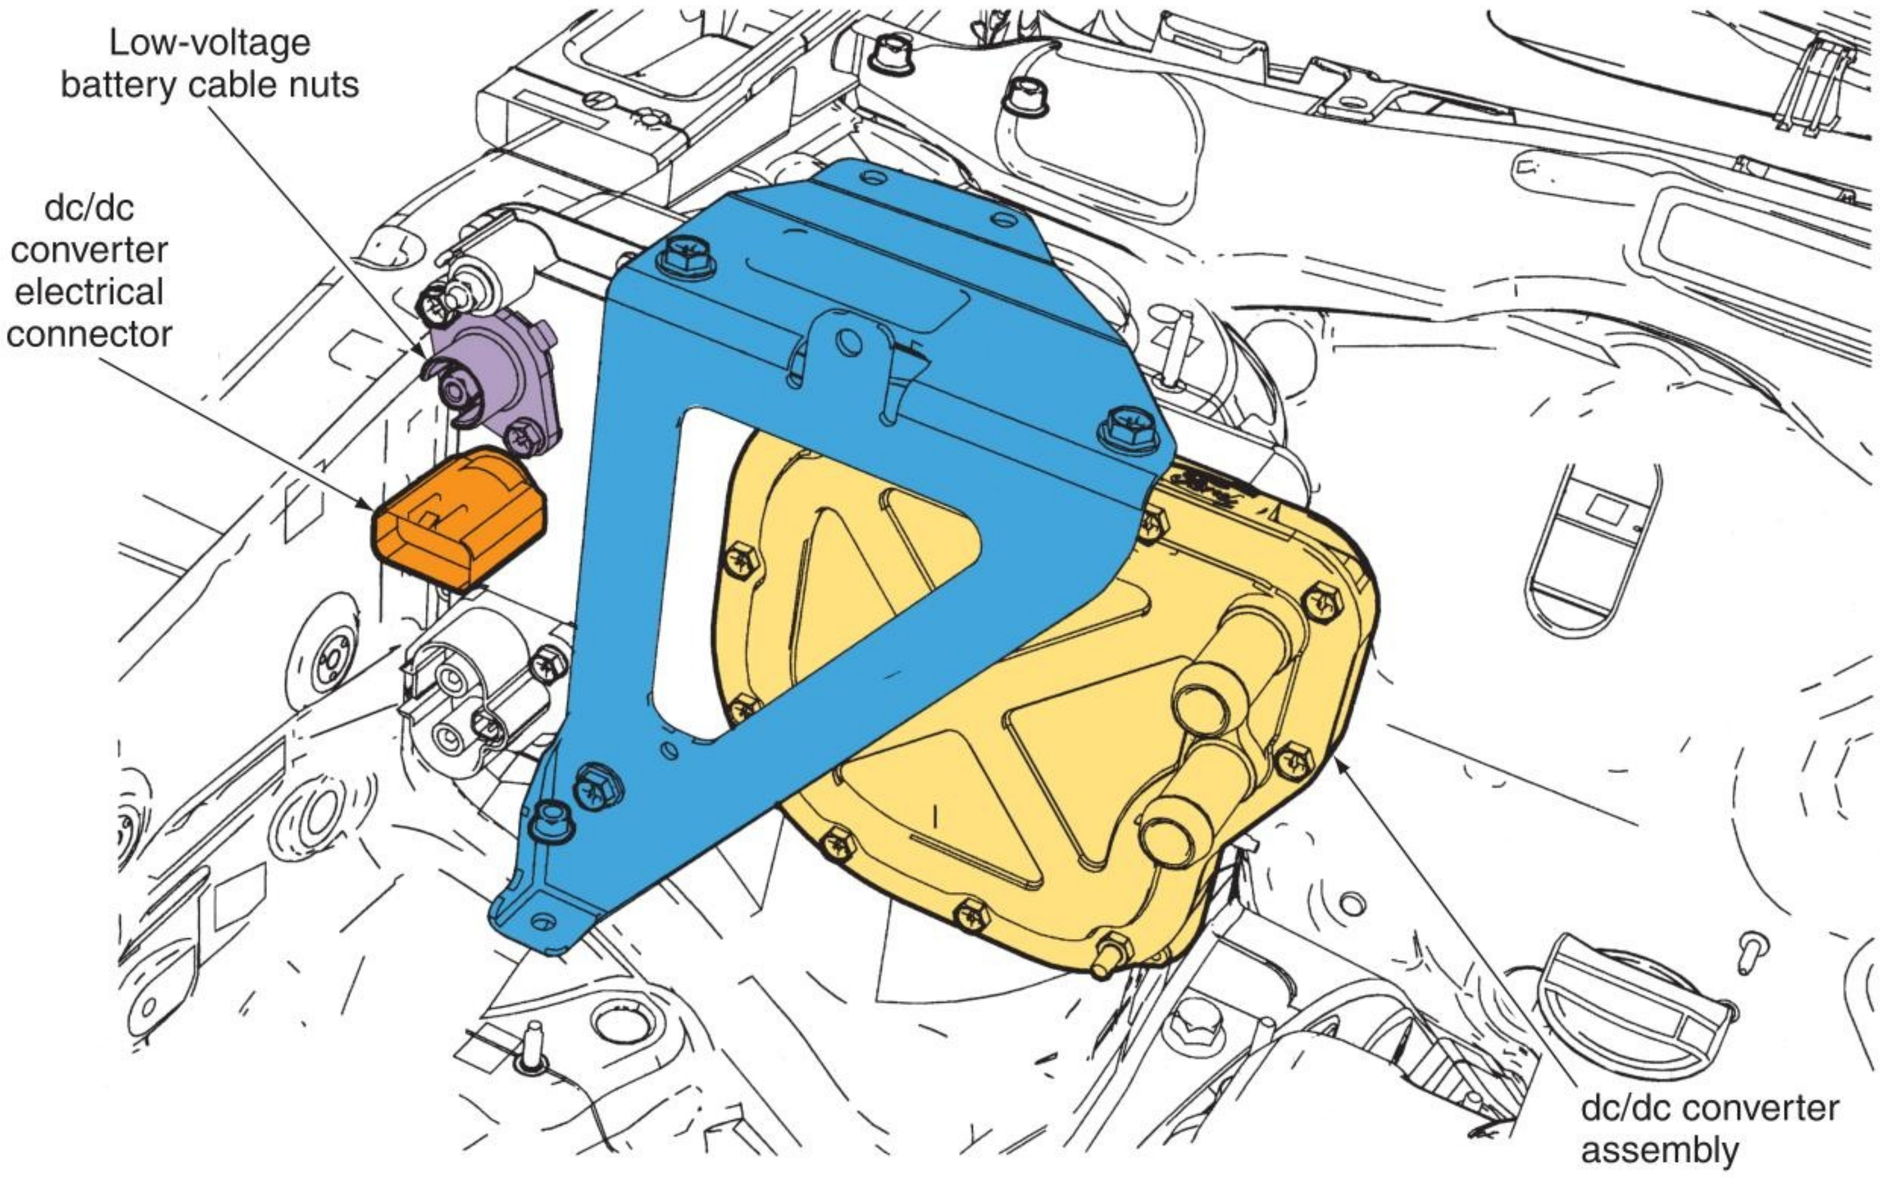
HV Power Control Module Replacement

If your scan tool and pinpoint test indicate a faulty HV PCM, either the affected circuit board or the entire unit must be replaced.



Ford

Figure 27-10. This dc-to-ac inverter mounts under the center console of the vehicle. By removing the trim panels, you can access the electrical connectors and fasteners for unit replacement.



Ford

Figure 27-9. This dc-to-dc inverter is a discrete unit. It mounts in the engine compartment on the firewall of the vehicle.

Copyright Goodheart-Willcox Co., Inc.

Service Procedure

To replace an HV PCM:

1. Make sure you use high-voltage safety gear and tools.
2. Disable the HV battery by pulling its service plug or lug, **Figure 27-4**.
3. Disconnect the low-voltage connections and wiring harness from the HV PCM.
4. Drain the HV cooling system of antifreeze and catch it in a plastic pan.
5. Remove the coolant lines from the side of the HV PCM.
6. Use an insulated socket set to disconnect the five or more high-power cables from the HV PCM. If the cables have special plastic connectors, remove them without damage. Normally, you must depress a small locking lever that secures this type of connection to free the cable end.
7. Wrap electrical tape around each exposed HV battery cable end to prevent a short to ground that can cause a major electrical explosion, injury, and part damage.
8. Remove the hold-down machine screws connecting the HV PCM to the body. They are located around the perimeter of the module.
9. Reinstall the new or reconditioned HV PCM in the reverse order of disassembly.
10. Reconnect the coolant hoses and wiring to the HV PCM.
11. If the high-voltage power cables have fastened or bolted electrical connections, tighten them to factory specs. Use a torque wrench and insulated extension with socket to ensure a good electrical connection.

Caution

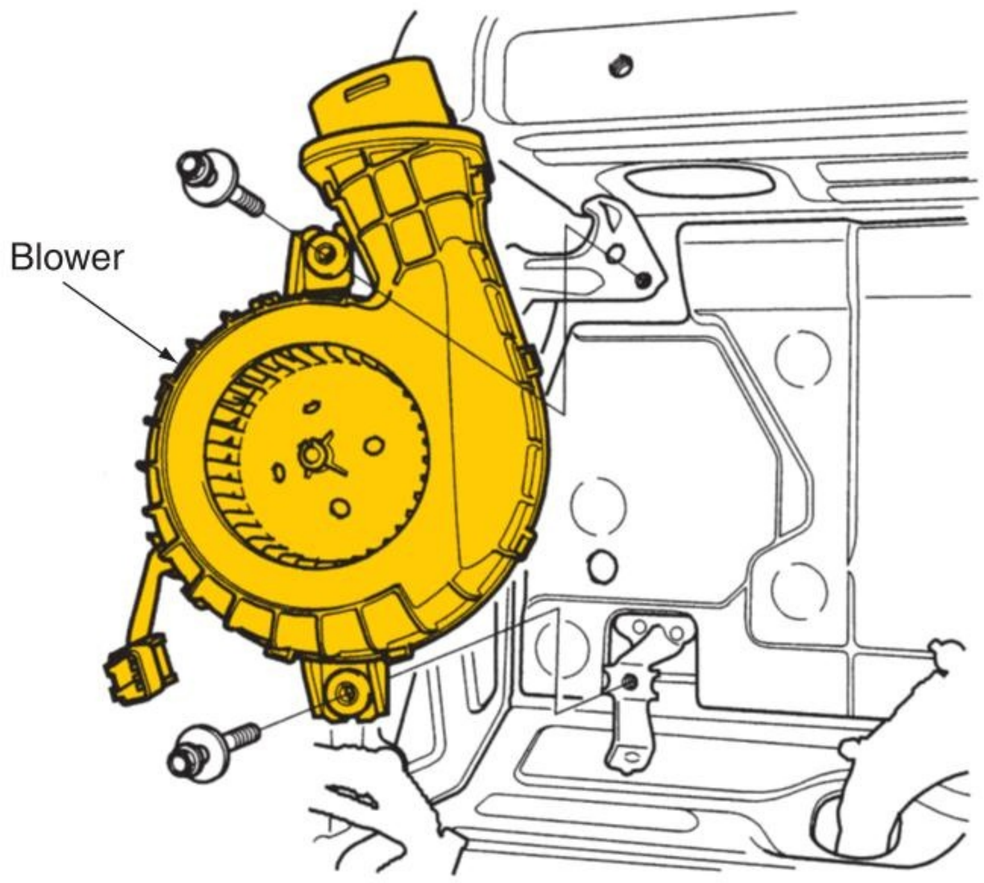
Undertightening the power cables can cause the high current to overheat and loosen the connection even more. Overtightening will strip the fastener threads. Vibration and heat will soon make an overtightened orange power cable connection trip a trouble code.

12. Erase any stored trouble codes and re-scan the hybrid drive system.
13. Double-check high- and low-voltage electrical levels with your scan tool. Check that all voltage and current levels viewed as data stream values are back to normal.
14. Test-drive the vehicle to verify your repairs.

Hybrid Cooling System Service

If the cooling system fails, components in the hybrid drive system can overheat. Trouble codes that indicate the components or circuits at fault will be set. If the system is air cooled, listen for normal operation of the cooling fan. If the system is water cooled, place a stethoscope on the electric pump to determine if it is running when the hybrid is under a high electrical load.

If you find an inoperative cooling fan blower motor, replace it as you would a climate control blower. Disconnect the wires and ducts before removing the fasteners that secure the blower motor to the vehicle. See **Figure 27-11**. With a liquid system, disconnect the hoses and wires going to the pump motor before replacement.



Toyota

Figure 27-11. The air cooling system for the HV battery and HV PCM is serviced the same way you service a climate control fan and wiring. After removing the cover, ducts, and fasteners, the blower motor assembly can be removed for replacement.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

More information on hybrid cooling system service is presented in *Chapter 48, Cooling System Diagnosis, Testing, and Repair.*

Motor-Generator Service

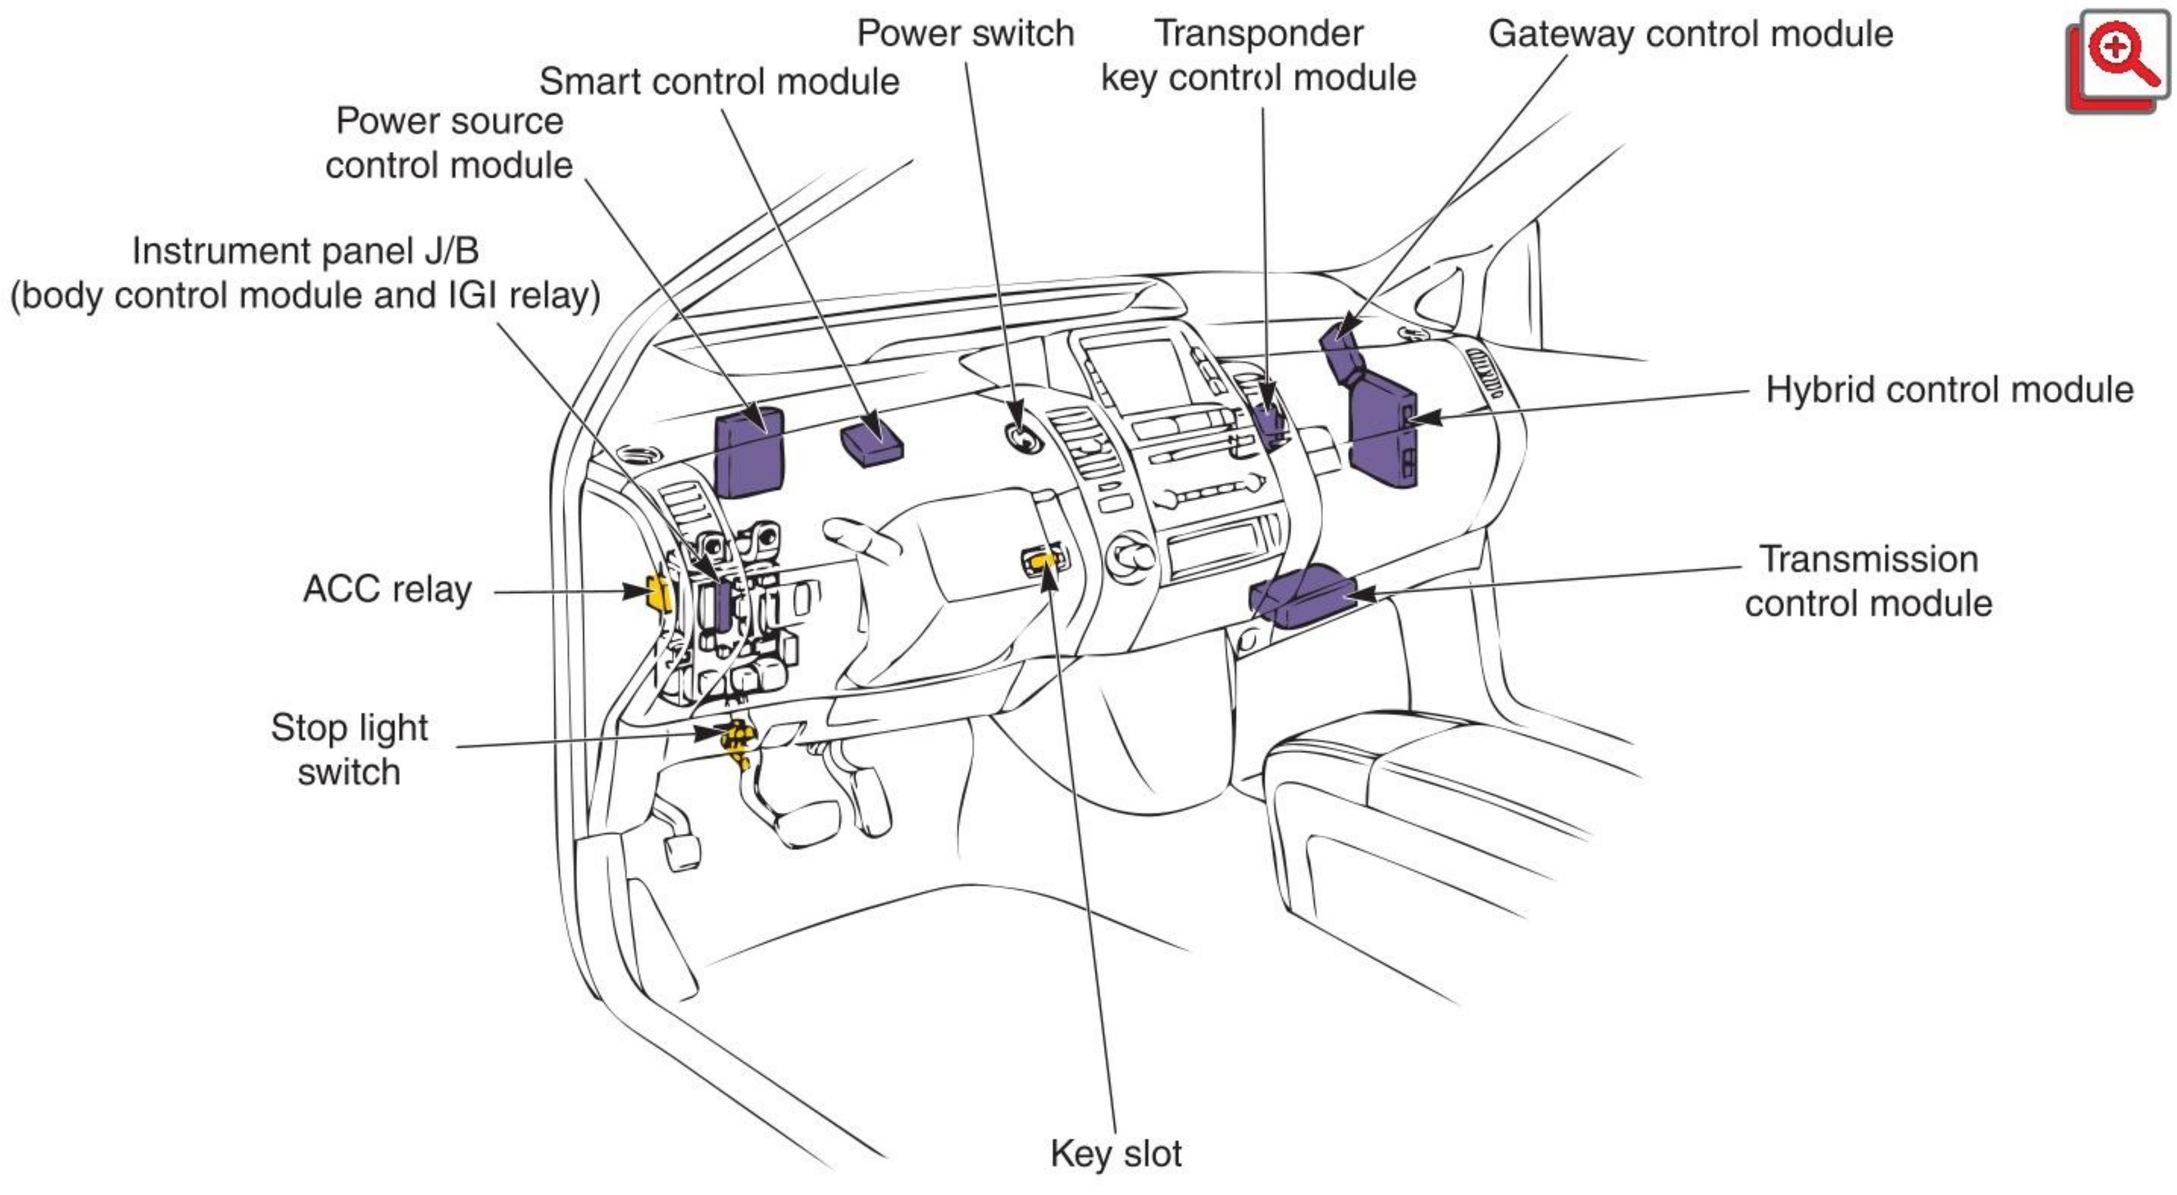
Normally, the motor-generator is trouble free. However, if the car is hit by lightning or used for an extended period, the motor-generator can fail. The stator coil windings in the unit can short or burn open, reducing motor-generator performance. A scan tool will retrieve trouble codes relating to the motor-generator. The instrument panel combination meter will also indicate poor electrical drive performance during all-electric (motor-generator driven) acceleration and regenerative braking.

Refer to the service manual for instructions when replacing a motor-generator, since part locations and procedures vary from one make to another. The most common motor-generator design requires you to remove the transaxle or transmission to access the motor-generator assembly.

A motor-generator trouble code indicates various problems: short coils, poor power cable connections, permanent magnet armature damage, and motor speed sensor failure, among other things. The hybrid control module, engine control module, and HV PCM monitor the condition of the motor-generator and store codes if any of these circuits are operating out of range. If a speed, torque, or temperature sensor signal is not within specs, the location and circuit in question will be tagged with a trouble code. See **Figure 27-12**.

Since transmission and motor-generator bearings can be splash oiled or pressure oiled, their useful service life can vary. In an engine-mounted motor-generator, the magnetic rotor is bolted directly to the rear of the crankshaft. The rear crankshaft main bearing centers the spinning rotor inside its stationary stator coils. This engine bearing seldom wears enough to affect motor-generator operation. The other end of the traction motor shaft is supported by another bearing in the end plate or the clutch of the motor-generator. This bearing can suffer more than the large crankshaft main bearing in the engine block.

With a transmission or transaxle-mounted motor-generator, various configurations are used to mount the motor armature (rotor shaft). Worn motor-generator bearings can cause excessive armature shaft runout.



Toyota

Figure 27-12. This service manual illustration shows locations of ECMs that can affect motor-generator operation.

Copyright Goodheart-Willcox Co., Inc.

With enough bearing wear, the rotating armature can hit and damage the stator windings.

Motor-generator stator problems will trip trouble codes when the circuit resistance, voltage, or current for any stator winding is not correct. If the vehicle has more than one motor-generator, the OBD code will indicate which traction motor or motor-generator is not working properly.

Loose high-voltage connections can trip trouble codes for the motor-generator and HV PCM. The computer only sees that something is preventing normal voltage or current flow in that section of the motor circuit. With a high mileage hybrid, this can be a common problem due to years of vibration, road salt, temperature changes, and such heavy cables. Always inspect, clean, and torque the three ac power cables if trouble codes point to the motor-generator or HV PCM. Refer to **Figure 27-13**.

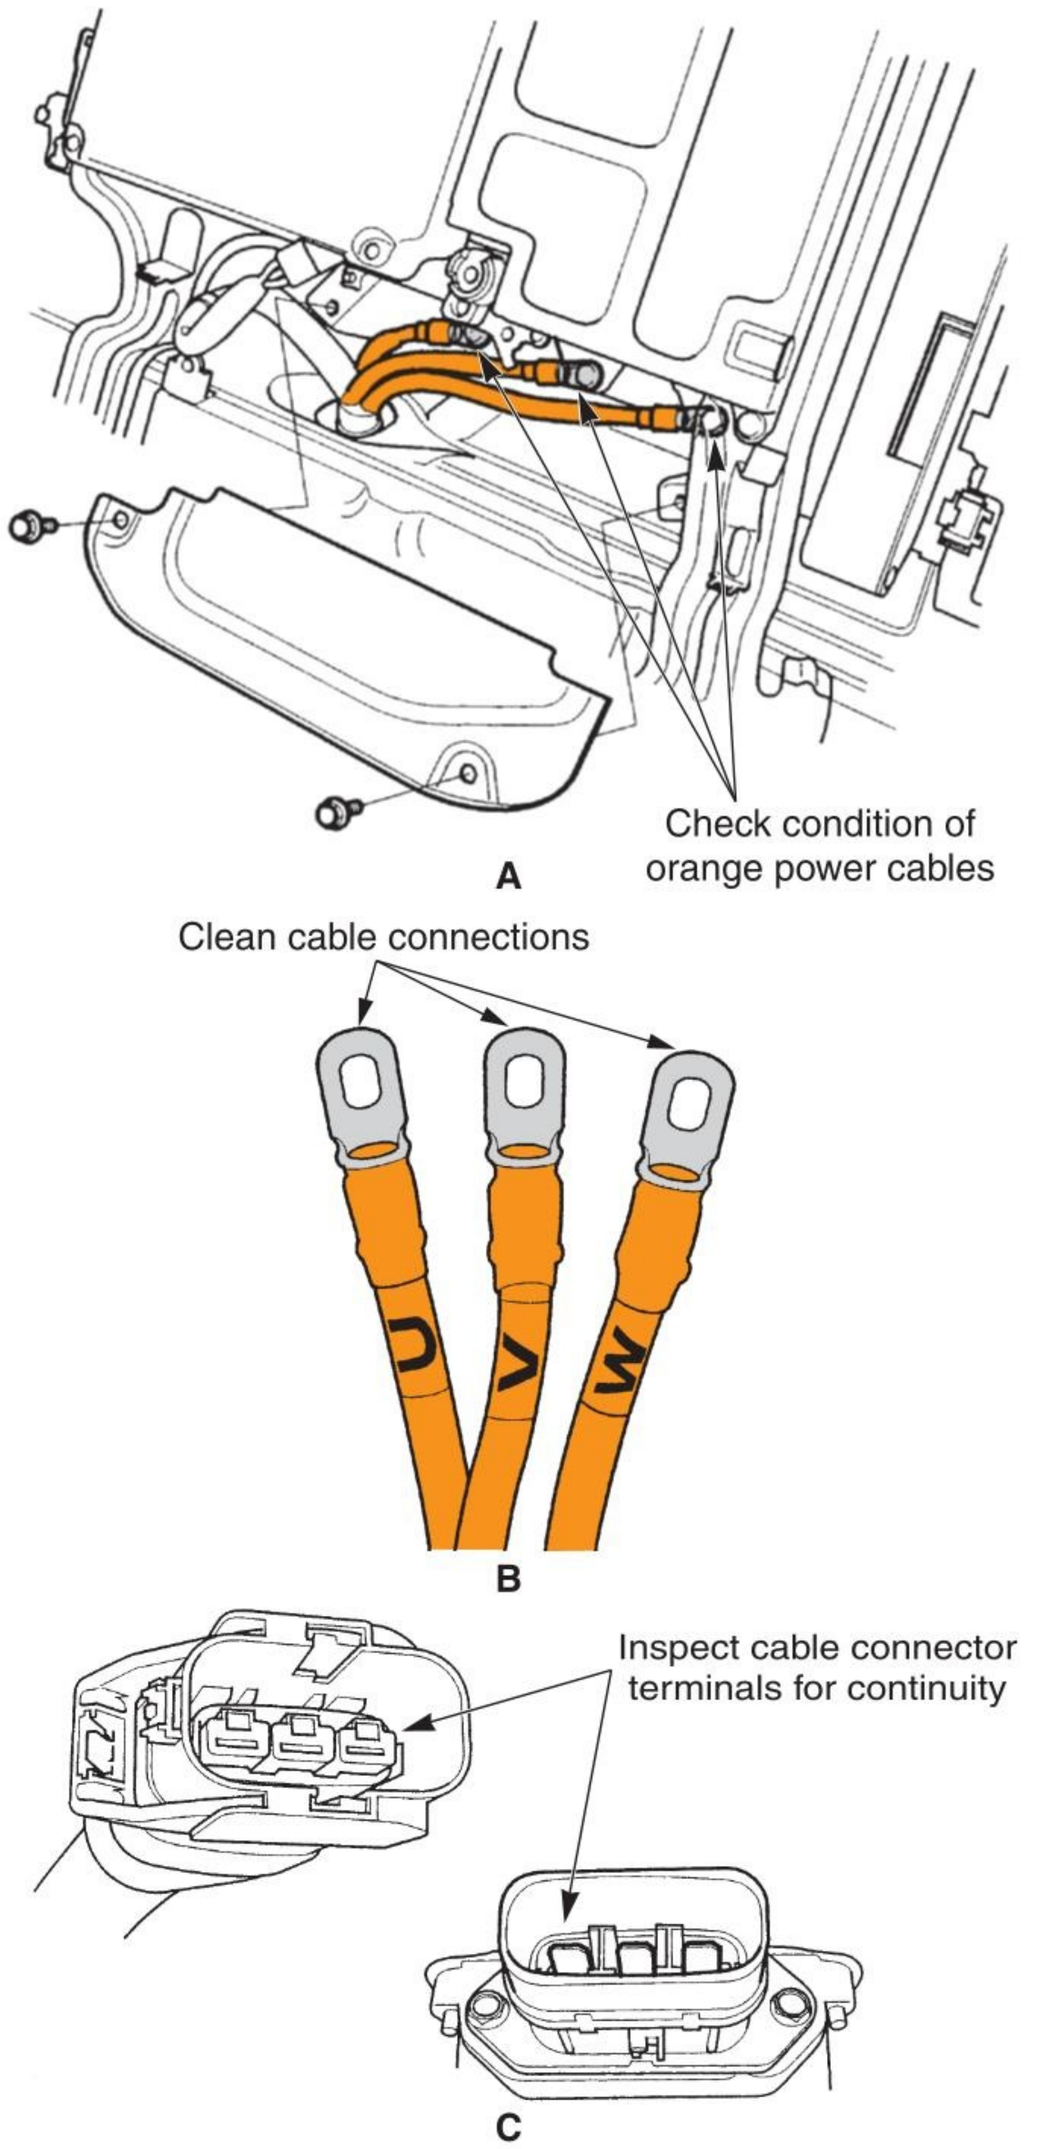
Testing a Motor-Generator

Use an advanced scan tool to perform any live tests of the HV system. Refer to factory service methods to safely perform any drive test or in-shop tests of the high-voltage starting and charging system. Each auto manufacturer has specialized tests that must be performed by following their specific instructions. Usually, the source of any hybrid starting problem can be found using your scan tool.

Service Procedure

To perform a motor-generator resistance test:

1. Wear insulated gloves and safety glasses, and use insulated tools.
2. Disable or disconnect the HV battery from its high-power circuit. Following manufacturer-specific instructions, pull out the high-voltage plug or fuse to disconnect the HV battery.
3. Disconnect the three power cables that connect to the motor-generator. Some plug together, and others are bolted together.
4. Inspect both sets of orange cable conductor terminals for damage from overheating and burning. A high-resistance connection can get very hot and tends to loosen with repeated heating and cooling. If a power cable has a poor electrical connection, the conductors can get hot enough to melt the orange insulation.
5. Connect an ohmmeter to each conductor going to the motor-generator stator windings and to ground.
6. Record and compare your ohmmeter reading for each of the three legs or circuits of the motor-generator. Normally, each leg of the stator windings should have the same reading.



Toyota

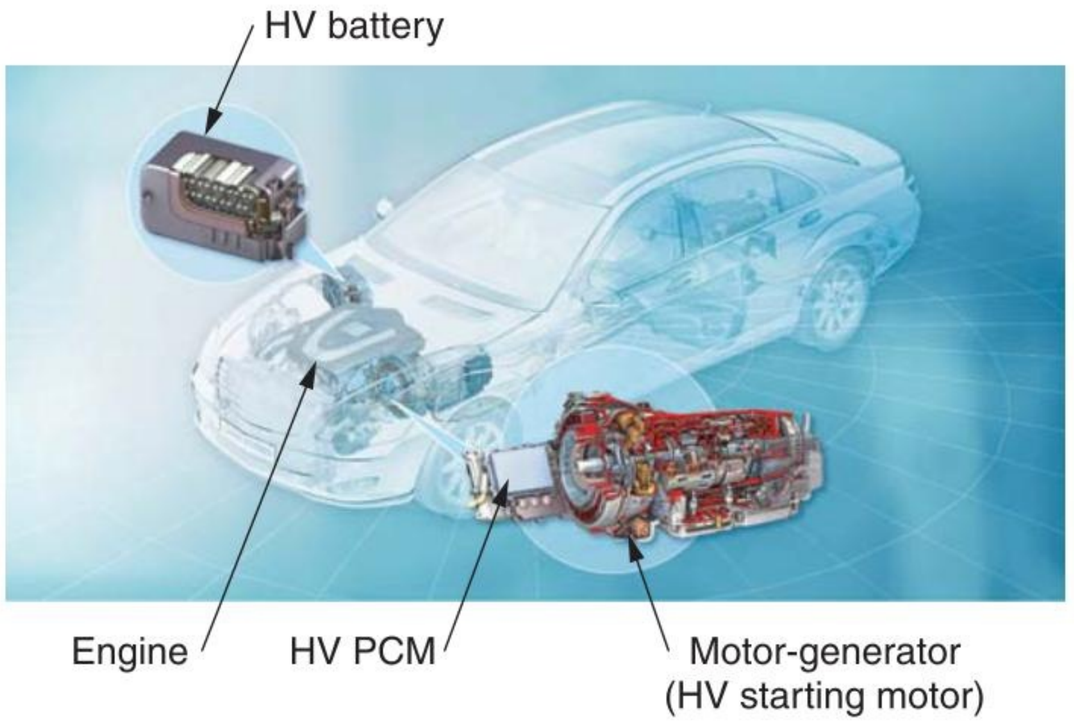
Figure 27-13. Three orange power cables going to the motor-generator must be in perfect condition for normal traction motor operation. Inspect and clean all high-power cable connections if needed or if a trouble code indicates a motor-generator circuit problem.

Copyright Goodheart-Willcox Co., Inc.

When reviewing the ohmmeter readings for each conductor, if one stator leg shows infinite or zero ohms, it is burned open or shorted to ground. Usually, only one phase or grouped set of windings in the motor-generator will fail. Any motor-generator stator winding that has infinite resistance has been burned or broken open, and does not generate its magnetic fields. In this case, motor-generator cranking speed would be slow or the ECM may disable the motor to prevent further damage. Any motor-generator stator winding that has zero resistance to ground might be physically damaged and shorted to ground.

Normal motor-generator stator resistance readings should be approximately 3–10 ohms. Refer to factory specifications if in doubt about normal stator resistance values.

You can also use a stethoscope to listen for motor-generator problems.



Mercedes Benz

Figure 27-14. Some hybrids mount the motor-generator between the transmission and the engine.

Service Procedure

To use a stethoscope to listen for motor-generator problems:

1. Raise the vehicle on a lift so its drive tires are off the ground.
2. Have another technician drive in all-electric mode until the HV battery drains enough for the system to attempt to start the engine.
3. Listen to the operation of the motor-generator during electric propulsion and engine starting.
4. Place a stethoscope against the side of the traction motor when it is running. This will let you hear any mechanical noises that might indicate dry, worn motor bearings, armature runout or wobble, or gear reduction failures.

Warning

The high voltages produced in a hybrid vehicle can cause electrocution. Always wear protective gear and use insulated tools when working around high-voltage hybrid circuits.

Removing and Installing a Motor-Generator

The process of removing a motor-generator varies with the vehicle make and model, and with the location of the motor-generator itself. Look at **Figure 27-14**.

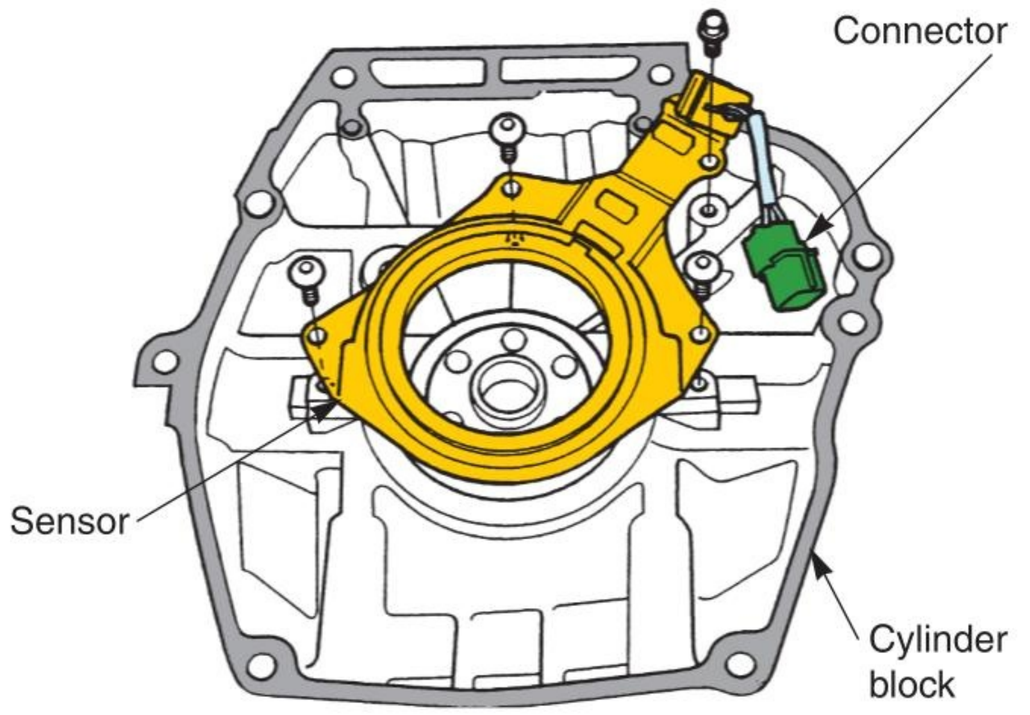
Service Procedure

To remove and install a crankshaft-mounted motor-generator rotor (**Figure 27-15**):

1. Disable the electric drive system and HV battery.
2. Remove the CV axles or drive shaft, wires, fluid lines, linkages, and body-to-transmission mounting fasteners.
3. Remove the transaxle or transmission, following service manual instructions.
4. Disconnect any cooling lines, wires, and flex or end plates from the motor-generator housing.
5. Install a plastic ring tool between the armature and stator. The plastic tool will protect the stator from damage when you unbolt the armature or stator housing. The plastic ring tool will keep the magnets from hitting and damaging the stator during removal.

Copyright Goodheart-Willcox Co., Inc.

6. Remove the armature bolts and pull the armature off the crankshaft flange with a wheel puller.
7. Unbolt and remove the stator housing from the rear of the engine block.
8. Check the resistance and condition of the armature sensor. Many are located under the crankshaft mounted motor-generator. See **Figure 27-16**.
9. Install the new motor-generator in reverse order.
10. Bolt and torque the armature to the crankshaft.
11. Install the plastic spacer ring tool over the armature. It will help protect and center the stator housing over the permanent magnet armature.
12. Torque the stator housing bolts to specs.

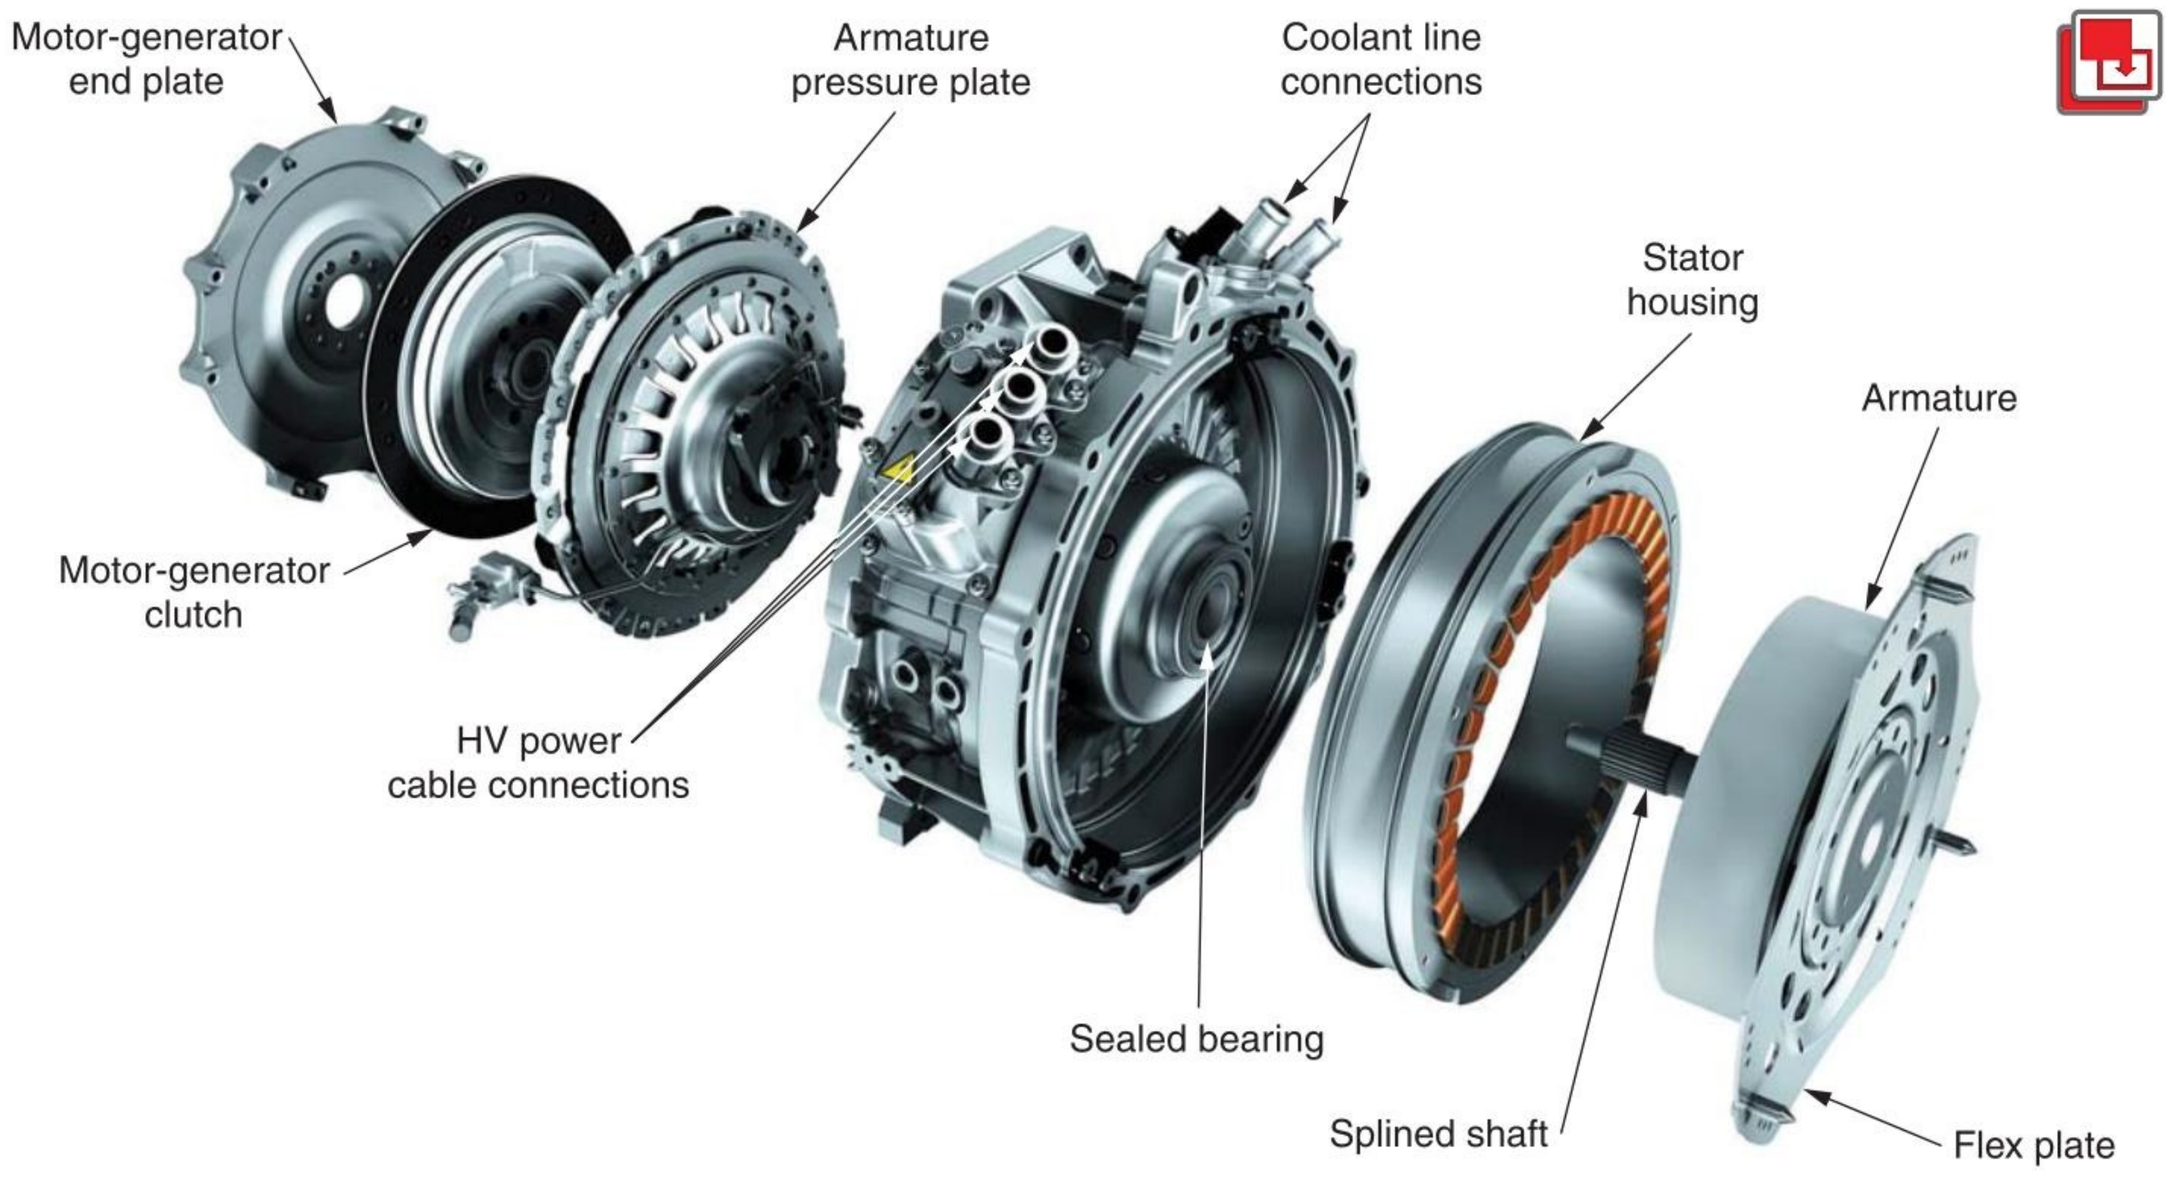


Toyota

Figure 27-16. This particular position sensor for the armature of a hybrid motor-generator is fastened to the back of the cylinder block. The transaxle and motor-generator must be removed to service it.

Figure 27-17 outlines the major steps for removing one motor-generator from one particular vehicle make. After removing the flex plate, a plastic sleeve is installed between the armature and stator to hold them apart during disassembly. This prevents the armature from contacting and damaging the magnets and coils in the stator. A puller is then used to remove the armature, which is press fit into the end of the engine crankshaft.

Some hybrids use two or three motor-generators to provide all-electric drive or electric assist. The motor-generators can be located inside the



Porsche

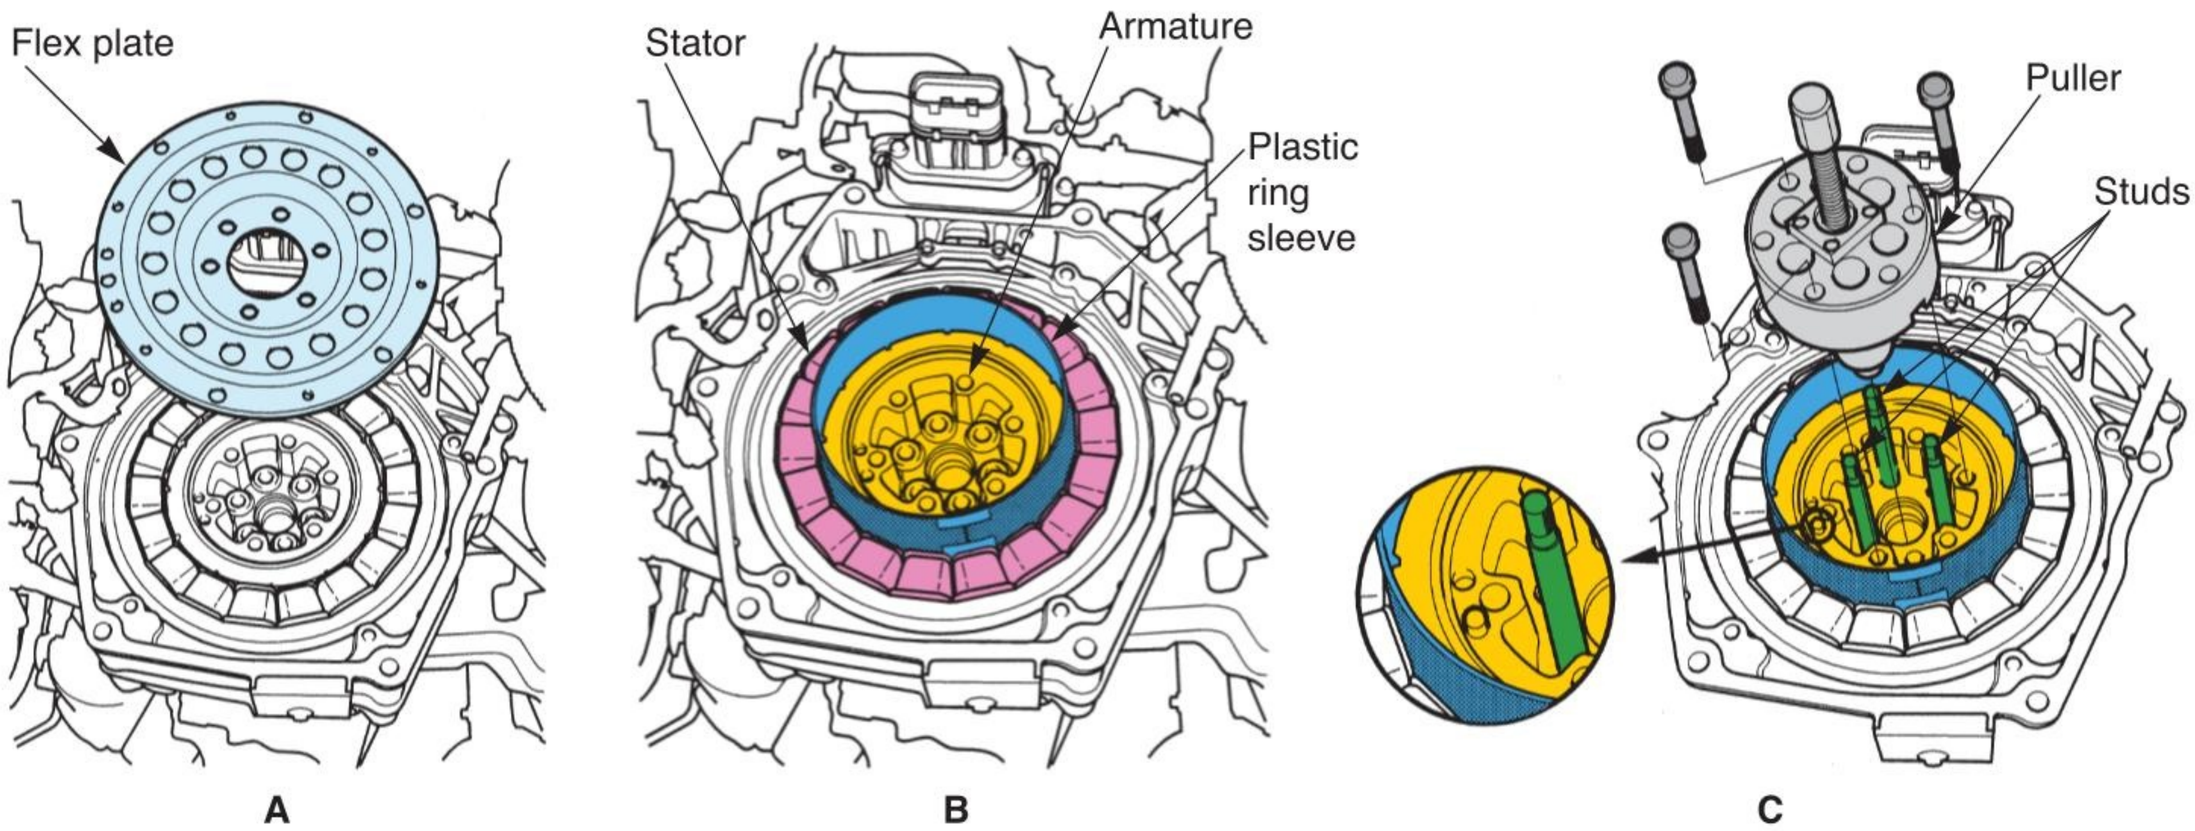
Copyright Goodheart-Willcox Co., Inc.



Toyota

Figure 27-17. Note the major steps for removing one type of motor-generator. This particular unit mounts on the rear of the engine and in front of the transaxle or transmission. A—The flex plate over the motor-generator can be removed after removing the cap screws that secure it to the crankshaft flange. B—A plastic sleeve should be installed between the rotor and stator of the motor-generator assembly. It will keep magnetism from pulling the two together when you are trying to remove the rotor. C—A wheel puller is used to force the rotor from the crankshaft. With the puller bolted to the rotor, tighten the puller screw to slowly force off the press fit rotor.

transmission or in the rear drive axle assembly with all-wheel drive vehicles. Refer to manufacturer service information to replace these units.

Tech Tip

Whenever you have to remove a vehicle's transmission, always check to see if you should replace the crankshaft's rear main oil seal. Find out how many miles are on the engine and inspect the seal to detect signs of leakage. If the old seal suddenly fails, you may have to perform the whole repair over to fix an oil leak.

Hybrid Wiring Problems

As with any electrical/electronic circuit, poor electrical connections, broken wire conductors, shorted wires, and similar problems can be difficult to diagnose and repair in a modern hybrid vehicle. When your scan tool shows a problem with a particular component but the component tests good, check for wiring problems in the corresponding circuit. Use factory diagrams, like the one shown in **Figure 27-18**, to locate any electric connector or other component that could be affecting the operation of that circuit.

Green Tech

Used Shop Rags

Used shop rags are a source of hazardous waste in automotive shops. If a rag has been contaminated with material considered to be hazardous waste, it must be handled properly. If thrown out, the contaminants on the used rag could do as much damage as the material itself. For example, if the rag has had used automotive fluid applied to it, that fluid could seep off into the soil or into the water and endanger ecosystems. The Environmental Protection Agency expects automotive shops to know how to deal with used shop rags. One option with used rags is to dispose of the rag in the same way as the hazardous waste. Another option is to have the rags taken to an industrial laundry so they can be used again.

Figure 27-18. Factory diagrams like this one will help you find loose electrical connectors and other problems in a hybrid drive system.

Summary

- Hybrid vehicles have extensive on-board diagnostic systems that help locate the source of system problems.
- Modern HEV drive systems generate enough electrical energy to cause electrocution. Work safely when servicing a hybrid vehicle.
- Evaluate HV battery condition using the combination meter in the dash battery and a scan tool connected to the diagnostic connector on the vehicle.
- The most common reason for HV battery replacement is physical damage. HV batteries are usually located in the trunk area or under the rear seat cushion or floor pan.
- Other factors to check when troubleshooting HV battery power problems include battery relays and contactors, condition of HV power cables, and an open fuse.
- A faulty HV PCM can trip various trouble codes, indicating which circuit in the module might be faulty. If your scan tool indicates a problem with a specific circuit board, you may be able to order and install just the failed circuit board.

Copyright Goodheart-Willcox Co., Inc.

- If the cooling system fails, components in the hybrid drive system can overheat. If the system is air cooled, listen for normal operation of the cooling fan. If the system is water cooled, place a stethoscope on the electric pump to determine if it is running when the hybrid is under a high electrical load.
- A motor-generator trouble code indicates various problems: short coils, poor power cable connections, permanent magnet armature damage, and motor speed sensor failure, among other things.
- Motor-generator stator problems will trip trouble codes when the circuit resistance, voltage, or current for any stator winding is not correct.
- The process of removing a motor-generator varies with the vehicle make and model, and with the location of the motor-generator itself.
- When a scan tool shows a problem with a particular component but the component tests good, check for wiring problems in the corresponding circuit.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

high-voltage buffer zone

high-voltage disconnect

hybrid ground fault interrupter

insulating gloves

Activities

1. Look up service information for two different make and model hybrid vehicles. For each vehicle, find service instructions for one of the step-by-step service procedures presented in this chapter. Compare all three sets of service instructions and note the differences in procedures, location of components, and general system operation.
2. While wearing insulated gloves and eye protection, inspect a hybrid vehicle. Locate the HV battery, motor-generator, and HV PCM. Trace how each of these components is connected to the others.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What will happen if high voltage from the HV battery or motor-generator is shorting to frame ground?
2. List nine safety rules you should follow when working on high-voltage, high-current hybrid drive systems.
3. To prevent electric shock, wait at least _____ minutes after removing the high-voltage disconnect before working on the high-voltage circuits.
4. What is the common cause of problems with contactors?
5. Describe the steps in a pinpoint test on a high-voltage contactor.
6. What common problems can occur with HV power cables?
7. What should you do if your scan tool shows that resistance values for a power cable are not within specification?
8. What will happen in a hybrid vehicle if current flow becomes too high due to a short?
9. Describe how to replace a high-voltage power cable.
10. What commonly causes a circuit board in the HV PCM to fail?
11. Which components monitor the condition of the motor-generator and store codes if any related circuits are operating out of range?
12. Normal motor-generator stator resistance readings should be approximately _____ ohms.

ASE-Type Questions

1. Technician A says that most hybrid vehicles conduct 300 volts dc. Technician B says hybrid vehicles only conduct the same voltage as a residential wall outlet. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says you should remove all jewelry before working on a hybrid's high-voltage circuits. Technician B says you should always wear rubber-soled shoes when working on a hybrid vehicle. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says that when working on HV power cables and other high-voltage components, you should wear gloves with an insulation value of 100 volts. Technician B says you should use OSHA-approved "lineman gloves." Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says that when towing a front-wheel drive hybrid, the front wheels should be raised off the ground. Technician B says that when towing an all-wheel drive hybrid with motor-generators at the front and rear, all four wheels must be raised off the ground. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Technician A says that you must wait at least three minutes after removing the high-voltage disconnect before working on the high-voltage capacitors in the inverter circuit. Technician B says that after you remove the high-voltage disconnect, you should remove the high-voltage fuse and keep it in your pocket. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Trouble codes and symptoms indicate battery power is okay, but battery power is not reaching the HV PCM. Technician A says to check the operation of the battery relays and contactors. Technician B says to check the condition of the HV power cables. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. A circuit board in the HV PCM has failed. Technician A says to check the cooling system. Technician B says the failed circuit board should be replaced. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Technician A says a motor-generator can fail if the car is hit by lightning or used for an extended period. Technician B says a failed motor-generator will not affect drive performance.
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Chapter 28
12-Volt and HV Battery Technology

After studying this chapter, you will be able to:

- Describe the operation of a basic battery cell.
- Summarize the functions of all types of automotive batteries.
- Explain the construction of a 12-volt battery and how it operates in a car engine.
- Compare battery terminals and connection types.
- Summarize typical 12-volt and HV battery types and ratings.
- Explain how temperature affects battery performance.
- Summarize the operation of both a fuel cell and a flywheel generator.
- Describe the role of capacitor banks in battery operation.
- Correctly answer ASE certification test questions that require a basic knowledge of chemical/electrical and mechanical/electrical storage devices.

Modern passenger vehicles use at least one of two types of automotive batteries: 12-volt or high-voltage. Conventional vehicles use a 12-volt lead-acid battery. Hybrid vehicles are equipped with a high-voltage nickel metal hydride or lithium-ion battery that can produce 100–300 volts of electricity. This type of battery is commonly referred to as an HV battery. Many hybrids use both a 12-volt battery and an HV battery.

Although the operating principles are similar for all automotive batteries, the HV battery found in hybrid vehicles is several times more powerful than the largest lead-acid battery. An HV battery contains as many as 50 kilowatts of potentially deadly energy.

To be a good technician, you must fully understand both 12-volt and HV batteries. Refer to **Figure 28-1**. Both battery types play an important role in the electrical and drive train systems of today's passenger vehicles.

This chapter will briefly explain the theory, construction, and operation of the batteries used in modern passenger vehicles. You will also learn about 12-volt and HV battery cables, terminals, connectors, and ratings. Experimental flywheel generators, ultracapacitors, and fuel cell battery designs will also be discussed. As a result of your study, you will be better qualified to service, troubleshoot, and test any kind of automotive battery.

Battery Principles

A ***12-volt battery***, such as an automotive battery, is an electrochemical device that produces and stores electricity. All batteries produce smooth, direct current (dc), where free electrons move in only one direction through their conductors.

When ***discharging*** (current and electrons flowing out of the cells), the battery changes chemical energy

Copyright Goodheart-Willcox Co., Inc.

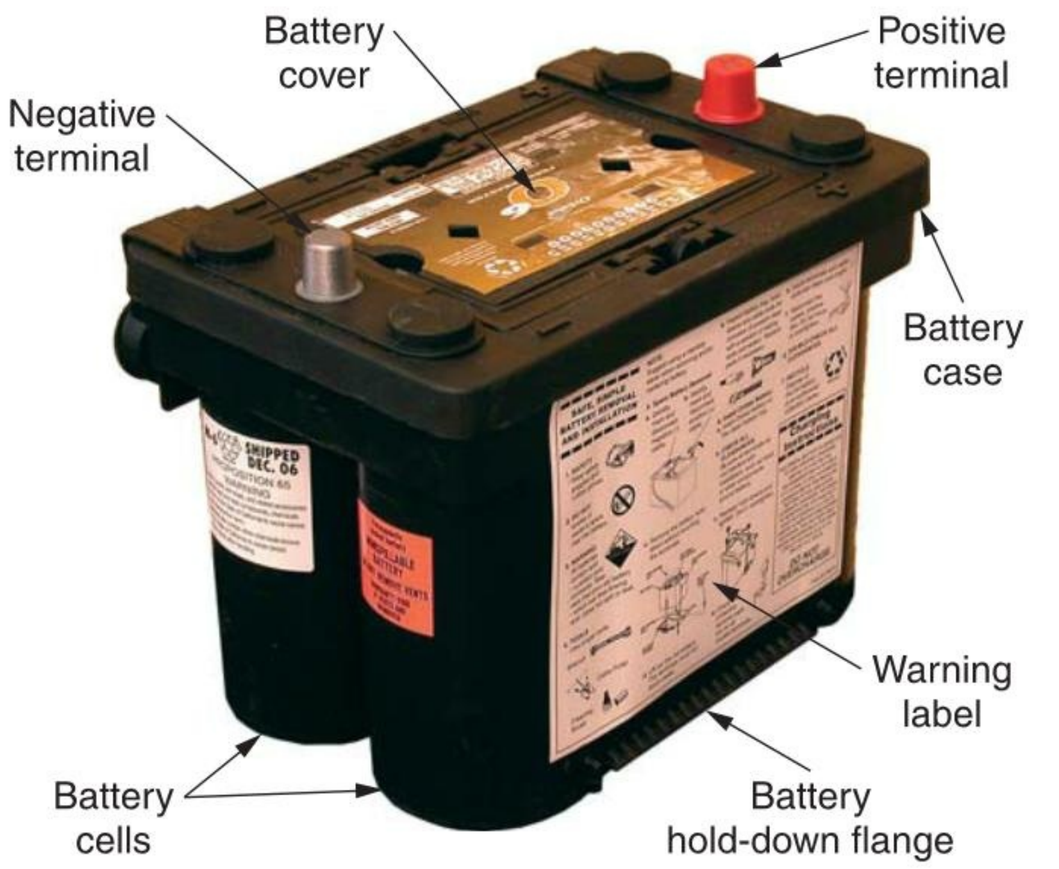

Figure 28-1. Compare a 12-volt battery and high-voltage battery. Note the large positive and negative terminals on the 12-volt battery that allow high current flow out of the battery. An HV battery encloses several individual battery packs wired in series.

into electrical energy. In this way, the battery releases stored energy.

During ***charging*** (current flowing back into the cells from the charging system), the battery converts electrical energy back into chemical energy. The battery can then store this energy for extended periods of time until needed.

Battery cycling refers to the amount of time between discharging and charging the battery cells. After not being charged for an extended period of time, a 12-volt battery can become almost fully discharged. If it still has enough stored energy to crank and start the engine, engine power will rotate the alternator or motor-generator to recharge the battery. Repeated ***deep cycling*** (going from a very low charge to a full charge) can shorten the service life of a 12-volt battery.

Basic Battery Cell

A simple metal-acid ***battery cell*** consists of a negative plate, positive plate, container, and electrolyte (battery acid). In an HV battery cell, the electrolyte is usually an acidic lithium paste or gel. A lead-acid battery uses liquid sulfuric acid as an electrolyte.

The battery plates are made of two different (dissimilar) metals. The plates are capable of storing a huge supply of free electrons. The battery cell container is usually plastic to resist corrosion.

If a ***load*** (current-using device) is connected to a simple battery cell, current will flow through the load. If the load is a lightbulb, for example, the bulb will glow because of electron movement.

When the battery cell is being charged, the alternator or hybrid motor-generator causes electron flow through the cell. Electron flow through the battery cell causes a positive (+) charge to be deposited on the positive plate and a negative (–) charge to be deposited on the negative plate. This causes the plates to have a difference in voltage potential (electrical pressure, or voltage).

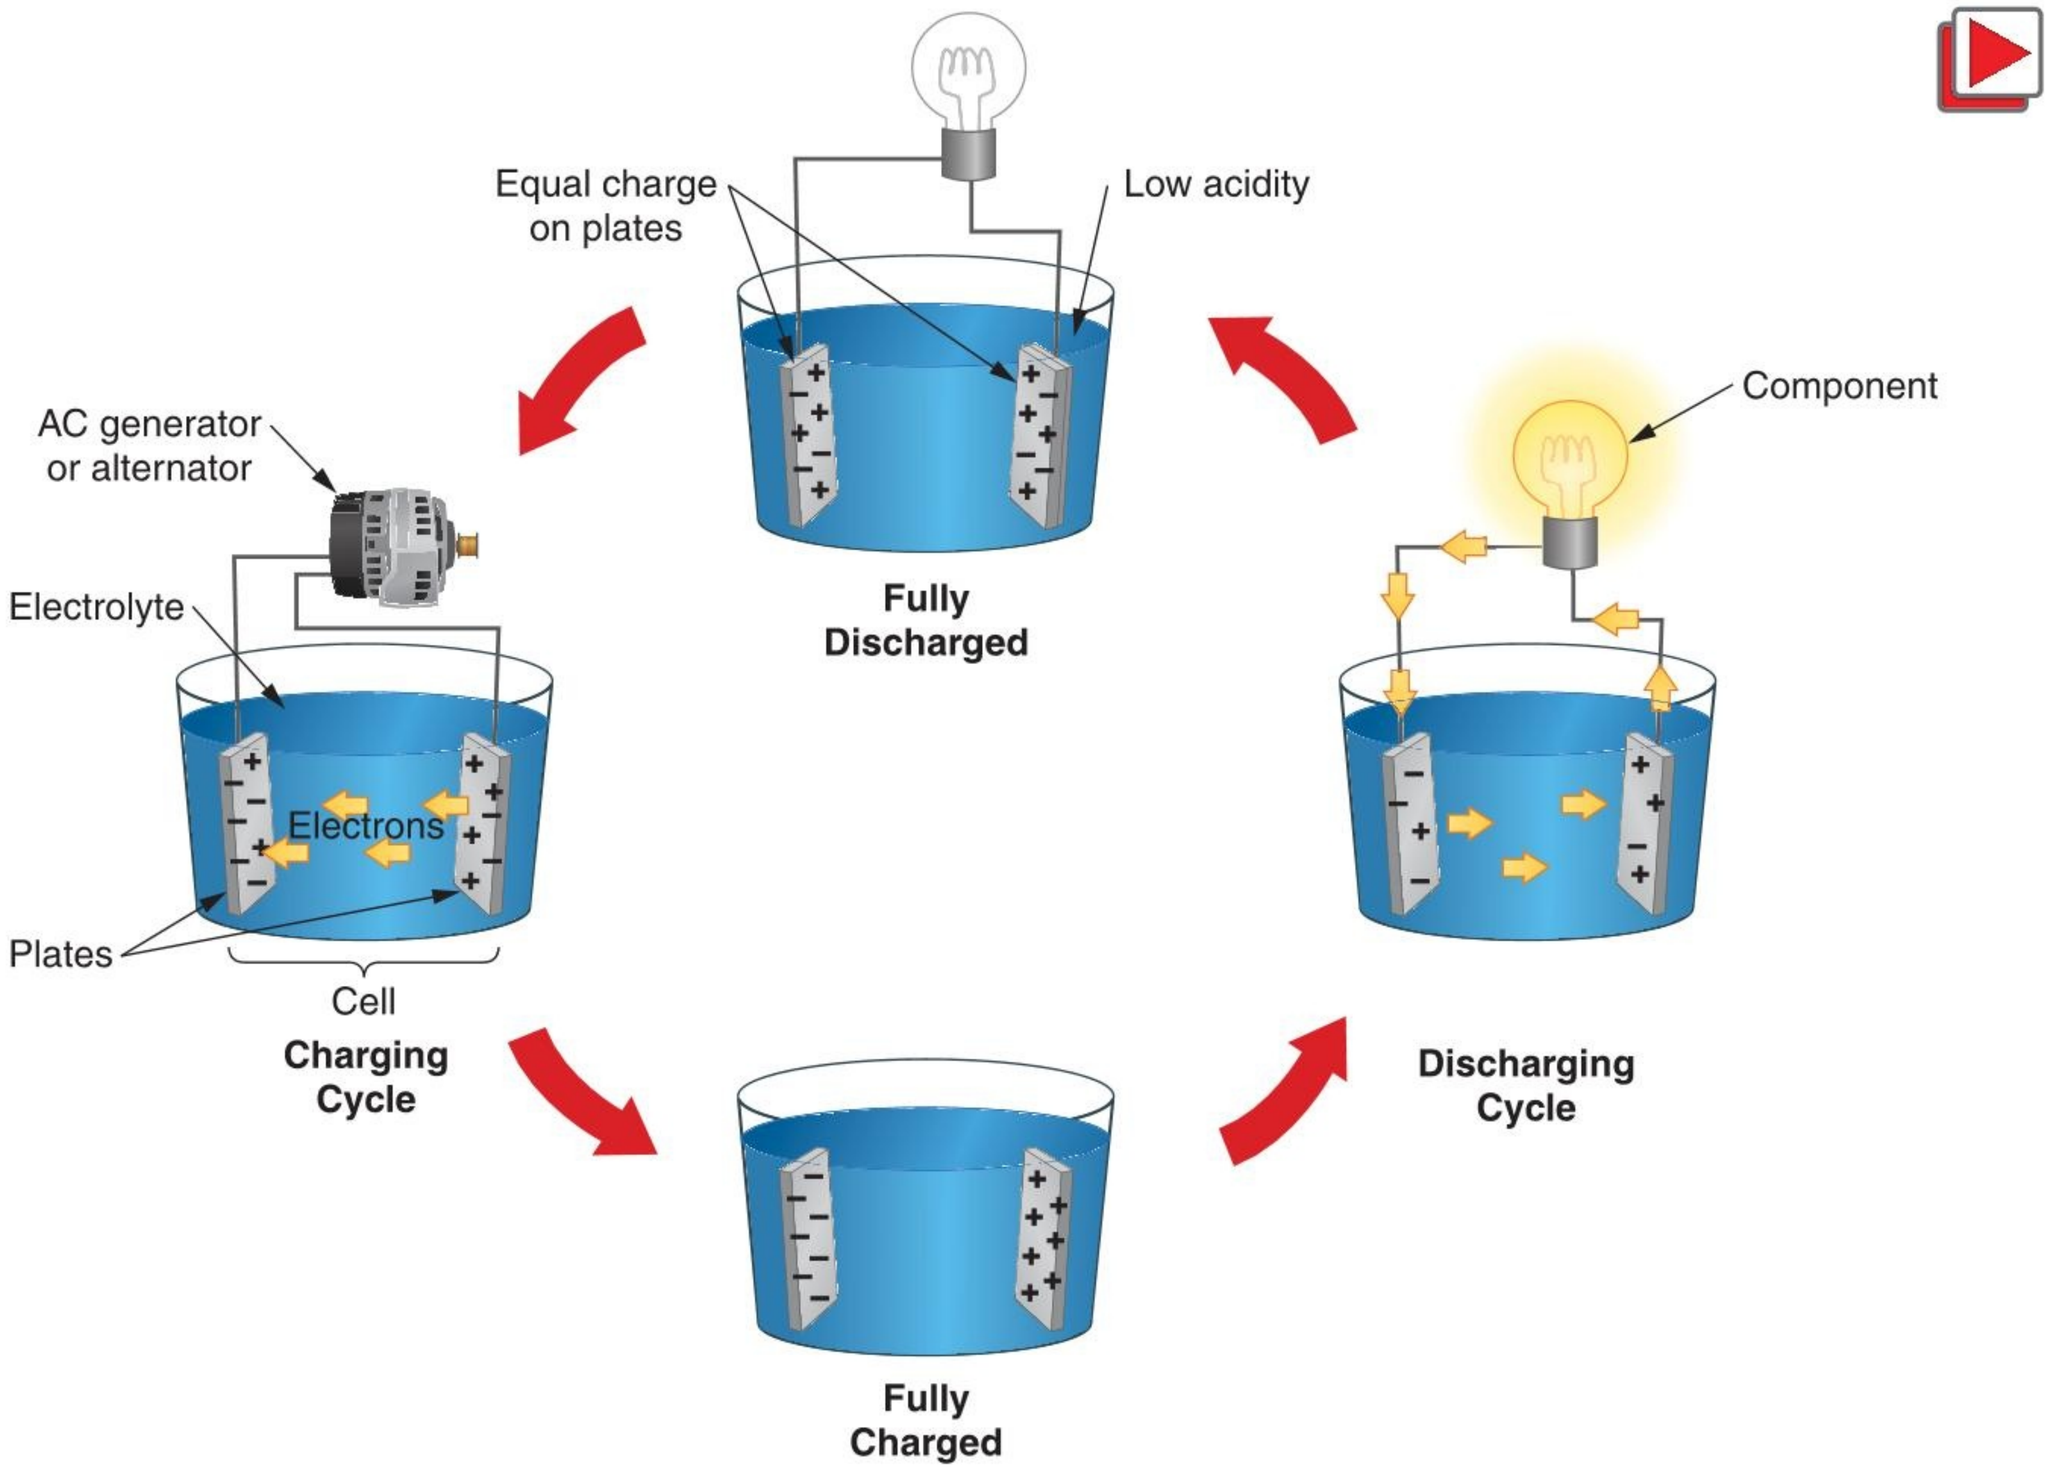
When a load is connected across the battery cell terminals, the resulting current attempts to equalize the difference in voltage potential on the two cell plates. Excess electrons move from the negative plate to the positive plate to cancel out the difference in potential. With enough current flow, the electrolyte will chemically change into water. Complete discharging of the plates results in a dead battery cell with no voltage potential. Refer to **Figure 28-2**.

Battery Functions

A vehicle battery has several important functions. It must:

- Operate the starting motor, ignition system, electronic fuel injection system, and other electrical devices during engine cranking and starting.
- Supply all the electrical power, even electric propulsion, for the vehicle whenever the engine is not running.
- Help provide electricity to the instrumentation and all electric circuits when the vehicle is stopped and the internal combustion engine is not running.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 28-2. Basic battery cycling.

- Act as a capacitor or filter (voltage stabilizer) that produces smoother dc than the alternator or motor-generator and send the filtered dc through the rest of the electrical system.
- Store huge amounts of potential electrical energy for extended periods.

To illustrate how a battery functions in a conventional vehicle, imagine the following scenario. You are sitting in your car, listening to the radio, but the engine is not running. The battery is supplying the current to operate the radio, any dash indicator lights, and the clock. You don't know it, but your battery is slowly discharging and draining. When you start the engine, the battery provides a tremendous amount of current (approximately 100 amps on a large V-8 engine). This current operates the starting motor and essential engine systems. This, too, drains more current out of the battery.

As soon as the engine starts, the charging system takes over. The alternator recharges the battery and feeds current to other electrical devices.

12-Volt Batteries

Most modern vehicles still use a conventional 12-volt battery and 12-volt main electrical system. A 12-volt battery has six cells, which produce an ***open circuit voltage*** of 12.6 volts.

Some large pickup trucks with diesel engines use two 12-volt batteries connected in parallel. When two batteries are in parallel, their output voltage stays the same, but their current output doubles. Dual batteries are needed to crank and start compression-ignition diesel engines with 12-volt electrical systems.

Caution

When two batteries are connected in series, their output voltage doubles. Keep this in mind when working with batteries. Two 12-volt batteries connected in series produce 24 volts, which could damage electrical devices.

Copyright Goodheart-Willcox Co., Inc.

12-Volt Battery Construction

Automobile batteries are built to withstand severe vibration, extreme temperatures, corrosive chemicals, high current discharge, and prolonged periods without use.

Battery Cell

A 12-volt battery cell is made up of positive plates, negative plates, straps, and separators. Look at **Figure 28-3**. These elements fit into a cell compartment in the battery case.

The ***battery plates*** are made of a grid (stiff mesh framework) coated with porous lead. Several plates are needed in each cell to provide enough battery power. The chemically active material in the negative plates is porous lead. The active material on the positive plates is lead peroxide. Since the lead on the plates is porous, like a metal sponge, the battery acid easily penetrates the material. This aids the chemical reaction and the production of electricity.

Calcium or antimony is normally added to the lead to increase battery performance and decrease ***gassing*** (acid fumes forming during chemical reaction).

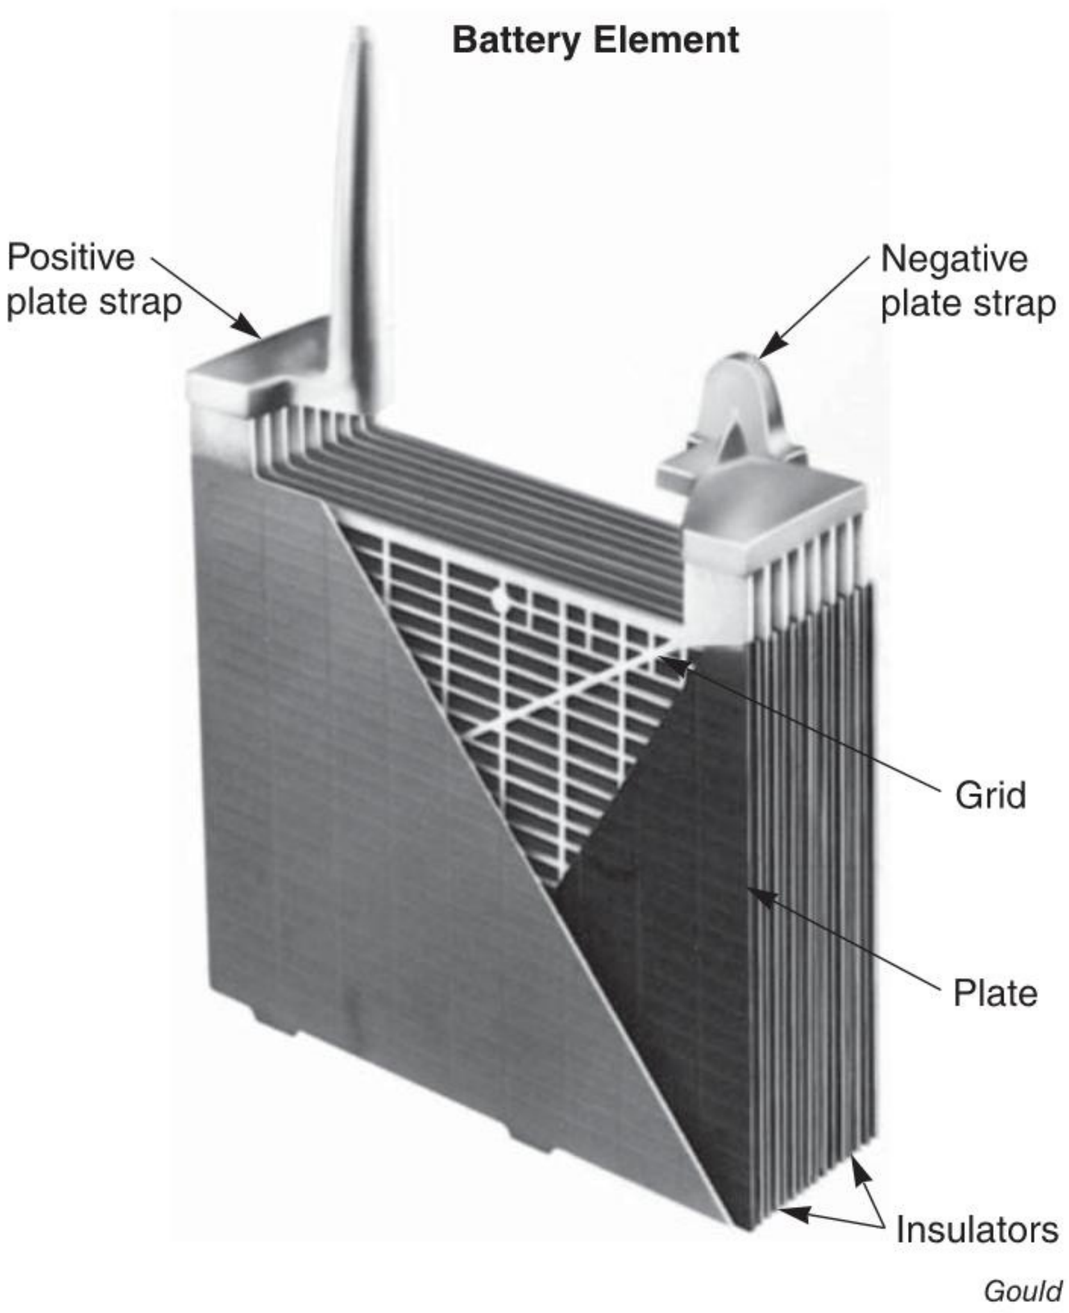


Figure 28-3. A battery element is made up of a positive plate group, negative plate group, separators, and straps. The elements fit into the battery case compartments that hold acid.

Gassing involves the conversion of water in the electrolyte into hydrogen and oxygen. These gases escape from the top of the battery. Gassing results in a loss of water.

Lead ***battery straps***, or ***connectors***, run along the upper part of the battery case to connect the plates. One strap connects the negative plates to form a negative plate group. Another lead strap connects the positive plates, forming the positive plate group. The battery terminals (top posts or side terminals) are constructed as part of one end of each strap.

Separators fit between the battery plates to keep them from touching each other and shorting. The separators are made of insulating material and have openings that allow free circulation of the electrolyte around the battery plates.

A 12-volt battery has six 2.1-volt cells wired in series to produce 12.6 volts dc. A voltmeter should read 12.4–12.6 with a fully-charged 12-volt battery.

Battery Case, Cover, and Caps

The 12-volt ***battery case***, usually made of high-quality plastic, holds the elements and electrolyte. The case must withstand extreme vibration, temperature change, and the corrosive action of the battery acid. Dividers in the case form individual compartments for each element. A compartment and its element make up one cell.

The ***battery cover*** is bonded to the top of the battery case and seals the top of the case. There is an opening above each battery cell for battery caps or a cell cover.

Battery caps snap into the holes in the battery cover. They keep electrolyte from splashing out of the battery. The caps also serve as spark arrestors (keep sparks or flames from igniting gases inside battery). Maintenance-free batteries have a large cap that is not removed during normal service.

Warning

Hydrogen gas can collect at the top of a battery. If exposed to a flame or spark, this gas can explode.

Electrolyte (Battery Acid)

Electrolyte, often called ***battery acid***, is a mixture of sulfuric acid and distilled water. Electrolyte is poured into each cell until the plates are covered. The acid should just touch the split ring in the top of the case.

Copyright Goodheart-Willcox Co., Inc.

Distilled water is used in 12-volt batteries because it does not contain many of the impurities found in tap water. These impurities can contaminate the battery plates and reduce efficiency.

Warning

Take precautions to prevent electrolyte from contacting your skin or eyes. The sulfuric acid in the electrolyte can cause serious burns or even blindness.

Battery Charge Indicator

A ***battery charge indicator***, also called a ***battery eye*** or ***test indicator***, shows the general charge condition of a 12-volt battery. See **Figure 28-4**.

Battery Terminals

Battery terminals provide a means of connecting the battery plates to the car's electrical system. Either two round posts or two side terminals are commonly used on 12-volt batteries. Refer to **Figure 28-5**.

Battery posts are round metal terminals that extend through the top of the battery cover. They serve as male connections for female battery cable ends. The ***positive post*** is larger than the negative post. It may be marked with red paint and has a positive (+) symbol on or near it. The ***negative post*** is smaller than the positive post and may be black or green in color. It normally has a negative (–) symbol on or near it.

Side terminals are electrical connections located on the side of the battery. They have female threads that accept a special bolt on the battery cable end. Side terminal polarity is identified by positive and negative symbols on the battery case.

12-Volt Battery Cables

Battery cables are large wires that connect the battery terminals to the vehicle's electrical system. They are usually made of a #10 gage to #1 gage copper conductor with plastic insulation and metal terminals—post clamping terminal, side bolt terminal, or eye terminal. See **Figure 28-6**.

The ***positive battery cable*** is normally red and fastens to the starter solenoid. The ***negative battery cable*** is usually black and connects to ground on the engine block or frame. Sometimes, the negative battery cable will have a body ground wire, which ensures that the vehicle body is grounded. See **Figure 28-7**. If this wire does not make a good

connection, components grounded to the car body may not operate properly. Note that ground cables do not always use insulation.

Battery Tray and Retainer

A ***battery tray*** and ***retainer*** hold the 12-volt battery securely in place. They keep the battery from bouncing around during vehicle movement. The retainer, or ***battery hold-down***, usually consists of a special bracket and fasteners that hold the battery to its tray. Look at **Figure 28-8**. It is important that the tray and retainer be tight and in good condition to prevent battery damage.

In many late-model vehicles, the battery tray houses a ***battery temperature sensor*** that monitors battery temperature. The engine control module uses data from this sensor to determine when to vary the battery charging rate.

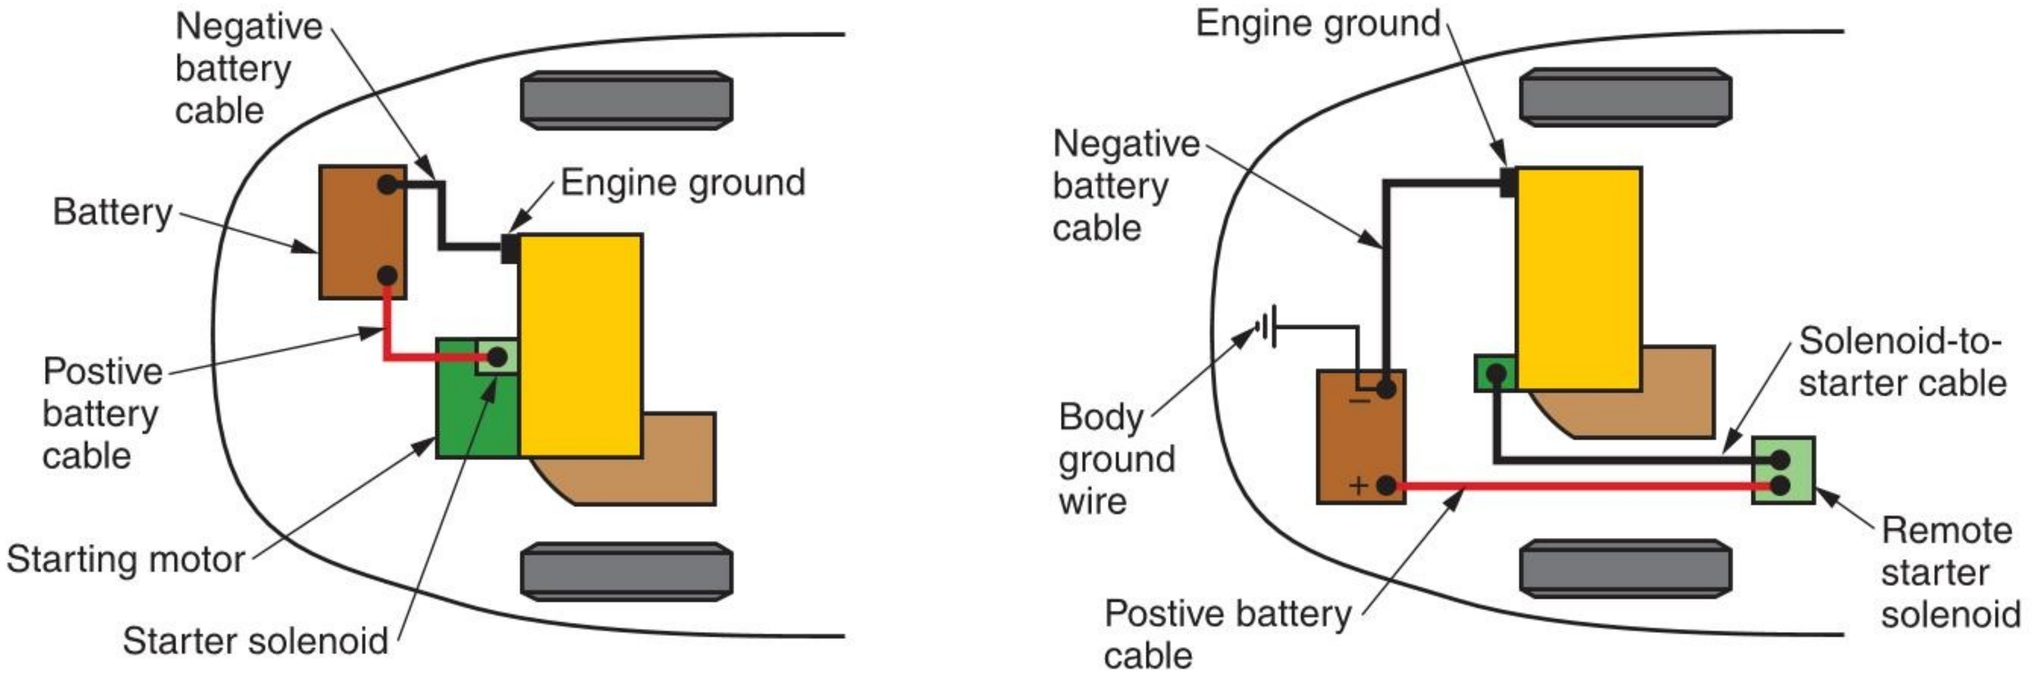
Battery heat shields are designed to keep excess engine heat from damaging the battery. They usually fit over the battery or between the engine and battery case. Always reinstall battery heat shields to ensure normal battery life.

12-Volt Battery Types

Several variations of 12-volt lead-acid batteries are available for today's vehicles. The differences are minor, but you should be aware of them.

A ***maintenance-free battery*** is easily identified because it does not use removable filler caps. The tops of the battery cells are covered with a large, snap-in cover. Calcium is used to make the battery plates, so water does not have to be periodically added to the electrolyte. The calcium in the plates reduces the production of battery gases. As a result, battery gas does not carry as much of the chemicals out of the battery. This increases battery service life and decreases service requirements.

A ***gel battery*** works just like a lead-acid battery, but it does not contain a liquid electrolyte. Instead, the electrolyte in a gel battery has a pastelike consistency.



Goodheart-Willcox Publisher

Figure 28-7. The battery cable may be connected to the vehicle's electrical system in slightly different ways, depending on the make and model.

Copyright Goodheart-Willcox Co., Inc.

Goodheart-Willcox Publisher

Figure 28-8. The battery retainer connects to the battery tray (under the battery) and holds the battery securely in place.

If the battery case is cracked or broken, the electrolyte will not leak out and the battery will continue to function. Additionally, this type of battery is completely sealed, eliminating gassing and minimizing the risk of explosion.

A disadvantage of a gel battery is that improper charging can burn a void in the electrolyte gel. This can permanently lower the power output of the battery. Therefore, gel batteries require a specific, low charging rate.

An ***absorbed glass mat battery***, or ***AGM battery***, contains fiber matting that absorbs the liquid electrolyte and holds it between the battery plates. Because AGM batteries are sealed, there is no gassing and the risk of explosion is minimized. AGM batteries are not as sensitive to improper charging as gel batteries.

12-Volt Battery Ratings

Battery ratings are set according to national test standards for battery performance. The ratings allow technicians and consumers to compare the cranking power of one battery to another.

The two most common methods of rating lead-acid storage batteries are by the cold cranking rating and by the reserve capacity rating. These ratings were developed by the Society of Automotive Engineers (SAE) and the Battery Council International (BCI).

The battery ***cold cranking rating*** is the amount of current (in amperes) the battery can deliver for 30 seconds at 0°F (–18°C), while maintaining terminal voltage of 7.2 volts (1.2 volts per cell). This rating indicates the battery's ability to crank a specific engine (based on starter current draw) at a specified temperature. For example, one auto manufacturer recommends a battery with 305 cold-cranking amps for a small 4-cylinder engine. A larger engine might require a more powerful battery with 450 cold-cranking amps. Engine size and its compression ratio generally determine the cold cranking rating for a replacement battery.

The ***reserve capacity rating*** is the time needed to lower 12-volt battery terminal voltage below 10.2 volts (1.7 volts per cell) at a discharge rate of 25 amps. Reserve capacity rating assumes that the test starts with a fully charged battery at 80°F (27°C). Reserve capacity is given as a time interval in minutes. For example, if a 12-volt battery is rated at 90 minutes and the charging system fails, the driver has approximately 90 minutes of driving time under minimum electrical load before the battery goes completely dead.

The ***amp-hour rating*** is a measurement of how much current the battery can produce for 20 hours at 80°F (27°C) with battery voltage staying above 10.5 volts. Amp-hour ratings are no longer used because manufacturers used different discharge rates to yield different amp-hour ratings.

Battery Temperature and Efficiency

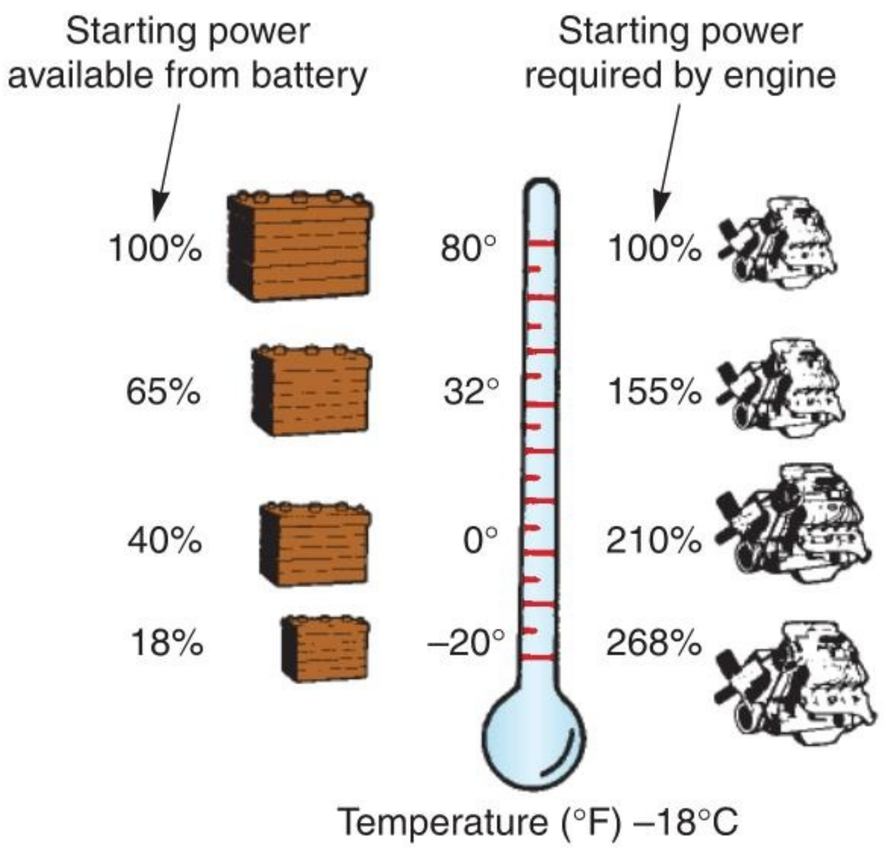
As battery temperature drops, battery power is reduced. At low temperatures, the chemical action inside the battery is slowed. When it is cold outside, a battery will not produce as much current as when the outside temperature is warm. This affects a battery's ability to start an engine in extremely cold weather. Also, when an engine is cold, the motor oil is very thick. This increases the amount of current and torque needed to rotate the crankshaft and slide the pistons in the cylinder block.

Figure 28-9 shows a chart comparing battery efficiency and required starting power. Note that at 0°F (–18°C), a battery has only 40% of its normal cranking power. In addition, starter current draw will be up approximately 200% of its normal value due to the increased viscosity of cold oil. The engine could be very difficult to start on a cold morning. The battery, starter, and electrical connections must be in almost perfect condition for an engine to crank on a cold morning.

HV Batteries

An HV battery, also called a ***battery stack*** or ***battery bank***, stores chemical-electrical energy for starting the internal combustion engine, for full-electric

Copyright Goodheart-Willcox Co., Inc.



Champion Spark Plugs

Figure 28-9. Temperature affects battery power and starter current draw. This is why engines crank slowly in very cold weather.

propulsion, and in some cases to provide 12–15 volts dc for the vehicle's electrical accessories and conventional electric circuits. HV battery technology has changed and improved considerably over the past few years. There have been three major stages of hybrid development: first generation hybrid electric drives, true high-voltage electric driveline, and lithium-ion (Li-ion) HV batteries.

First generation hybrid electric drives were not HV. These vehicles used a bank of 12-volt lead-acid batteries wired in series to produce a 24- or 48-volt battery stack. The electric drive voltage and current output from this setup was minimal. Lead-acid batteries provided minimum motor torque assist and minimum fuel economy gains.

Second generation hybrids connected a true high-voltage electric driveline to the conventional engine, transmission, and differential. These much-improved hybrids use NiMH battery cells to assist the engine with added drive torque.

Some second-generation hybrids use even more powerful lithium-ion (Li-ion) HV batteries, which provide an extended driving range and better fuel economy ratings. Lithium-ion HV batteries are designed to handle high current flow rates during charging and discharging. A lithium-ion battery has a superior weight-to-power ratio than lead-acid and nickel-acid battery designs. HV battery assemblies can weigh about 200 lbs. (91 kg) for electric-assist hybrids to over 600 lbs. (273 kg) for full-electric-drive hybrids.

Tech Tip

HV batteries are wet-charged with a semi-solid electrolyte. A special high-voltage battery charger is needed to recharge the large number of cells wired in series. Refer to the index for more information.

Many hybrids use a ***dual voltage system***: 12 volts for most of the vehicle's conventional electrical/electronic circuits, and high voltage (HV) for the double-ought (00) conductors and HV motor-generator of today's electric drive trains. Both electrical systems are wired separately, but interface through the ECMs and HV power control module. Refer to **Figure 28-10**. In other hybrid designs, the HV battery can be stepped down to provide lower voltages (13–15 volts) for conventional automotive circuits. This eliminates the need for a conventional 12-volt battery to reduce weight and complexity.

HV Battery Construction

The ***HV battery*** is normally mounted in the rear of the chassis, often behind or under the rear seat or in the trunk area. See **Figure 28-11**. Economy vehicles have only one large HV battery. Larger, full-size vehicles and full-electric-drive vehicles can be equipped with two or three HV batteries.

An HV battery is made of many small battery cells inside several battery packs wired in series to produce a high-voltage and current electrical power source. See **Figure 28-12**.

Battery Cells

A ***hybrid battery cell*** is often an individual rechargeable battery similar to those found in laptop computers and flashlights. Each NiMH or lithium-ion cell generates about 1.2–1.6 volts dc. Similar to the common rechargeable battery cells, each is individually sealed to hold its semi-solid electrolyte (acid paste or gel) around the positive and negative plates.

Wires from the positive and negative plate of each cell are soldered or mechanically fastened to adjacent cells in series. HV cells are designed to handle high current flow rates without heat damage during high power recharging and discharging cycles. Since like charges repel and unlike charges attract, a strong and sustained current leaves and re-enters the cell.

When being recharged, an external electrical power source (engine- or transmission-driven generator)

applies a regulated voltage to the HV battery pack, forcing the current into the cells in reverse direction.

The electrons (negative charge) or protons (positive charge) then migrate from the positive plate to the negative plate, where they become embedded in the porous electrode materials in a process known as ***intercalation***. Since current flow has caused the

Copyright Goodheart-Willcox Co., Inc.

protons and electrons to embed in the plate material, each has a potential difference trying to push it back out of the battery as stored energy, voltage, and current.

Warning

The electrolyte in lithium-ion HV batteries is very reactive and potentially dangerous. If you accidently pour water on an exposed or damaged lithium battery, a powerful chemical reaction will result. The water and lithium hydroxide acid will react with each other and emit large amounts of explosive hydrogen gas.

Never spray water on a shorted or smoking HV battery to put out a fire. Water will make the battery burn even more violently. If enough hydrogen gas collects in the work area, it could explode like a stick of dynamite.

Battery Packs

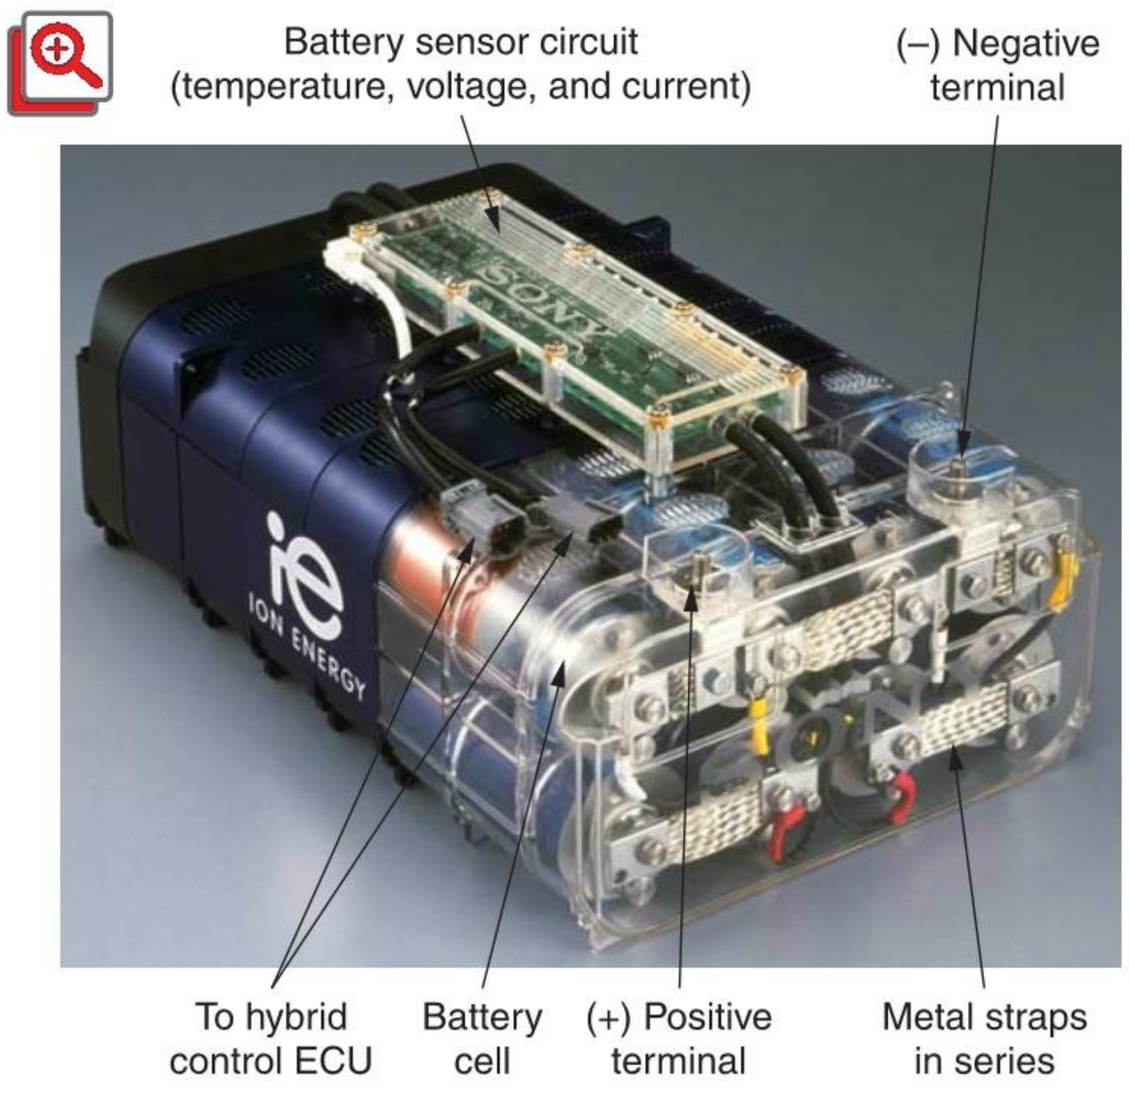
An ***HV battery pack*** is a set of low-voltage battery cells wired in series. Refer to **Figure 28-13**. A modern HV battery has approximately 30–40 individual battery packs. For all-electric vehicles, that number is even higher. Each battery pack has six or more battery cells enclosed in a small housing.

Battery pack voltage is 7.2–9.2 volts, depending on the number and types of cells. The battery packs are wired in series to produce a powerful, high-wattage means of storing chemical/electrical energy.

Banks of battery packs are wired in series to produce anywhere from 100–300 volts dc at HV battery cables. For example, an HV battery that has 38 battery packs with 7.2 volts each produces 274 volts dc. An HV battery with 28 7.2-volt battery packs would produce 201 volts dc. Another manufacturer's HV battery might have 30 battery packs of 9.6 volts for a nominal voltage output of 288 volts.

Auto manufacturers are steadily trying to increase HV battery voltages to improve all-electric driving distances without increasing engine operation and fuel consumption.

Battery pack fuses protect against shorts and excessive current draw from each group of cells. Each tiny fuse will overheat and burn open if current flow is too high. A blown fuse will open and isolate the failed battery pack from the rest of the battery. One failed battery pack will lower total HV battery power output slightly, but not significantly.



Nissan

Figure 28-13. Note how small battery cells are wired in series and connected to the sensor circuit on top of this HV battery pack.

Battery Cover and Frame

An ***HV battery cover*** is usually made of plastic. It encloses and protects the individual battery packs. The battery cover also protects against high-voltage dangers from the metal battery pack conductors.

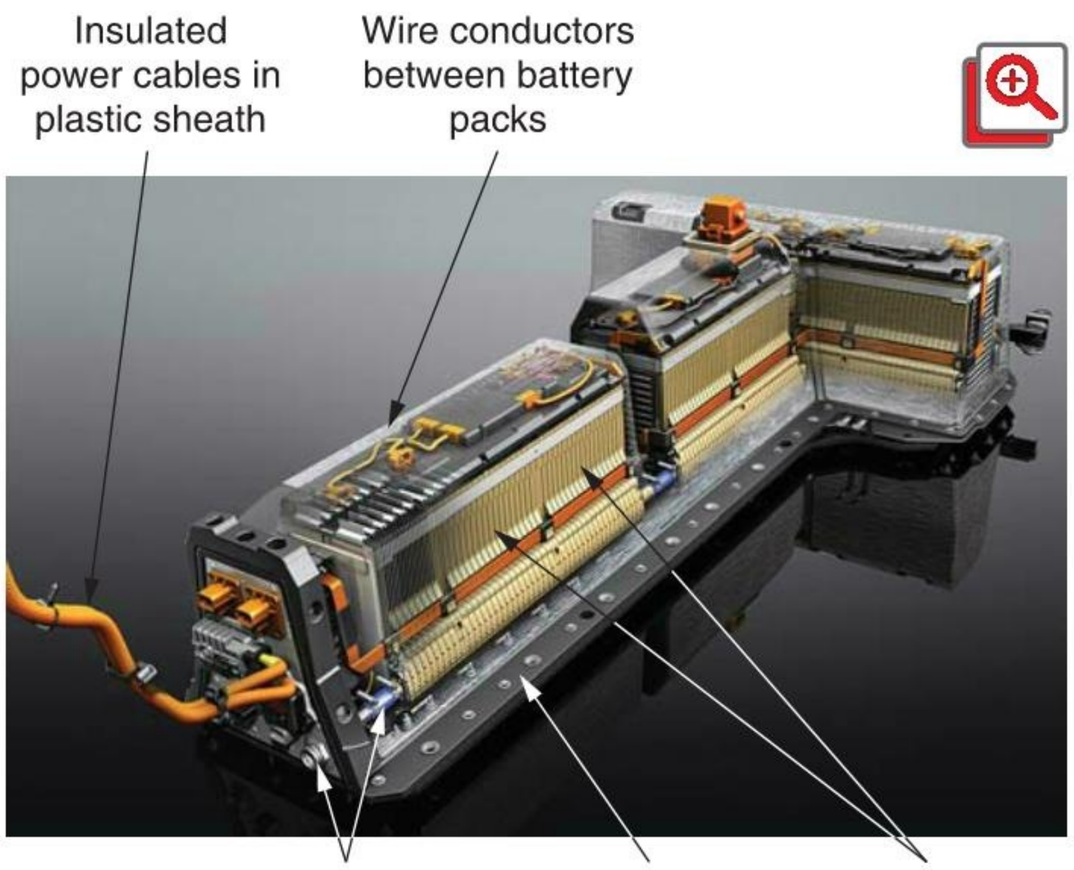
An ***HV battery frame***, usually made of metal, holds the battery packs together and allows the assembly to be bolted to the vehicle's frame. A flange on the HV battery frame provides for mounting the heavy battery assembly securely, protecting the battery in the event of an auto accident. See **Figure 28-14**. Bolting the HV battery to the vehicle frame also provides an excellent frame ground circuit.

Some hybrids do not have a 12-volt battery. Instead, these vehicles employ a step-down transformer and ac-to-dc diode rectifier circuit inside the HV power control module. The transformer-rectifier circuit sends clean 12 volts dc (no ripple in dc waveform) to the low-voltage electronics in the ECMs, electrical accessories, and instrumentation.

HV Battery ECM

An ***HV battery ECM*** is an electronic control circuit that reads signals from HV battery temperature and

Copyright Goodheart-Willcox Co., Inc.



General Motors

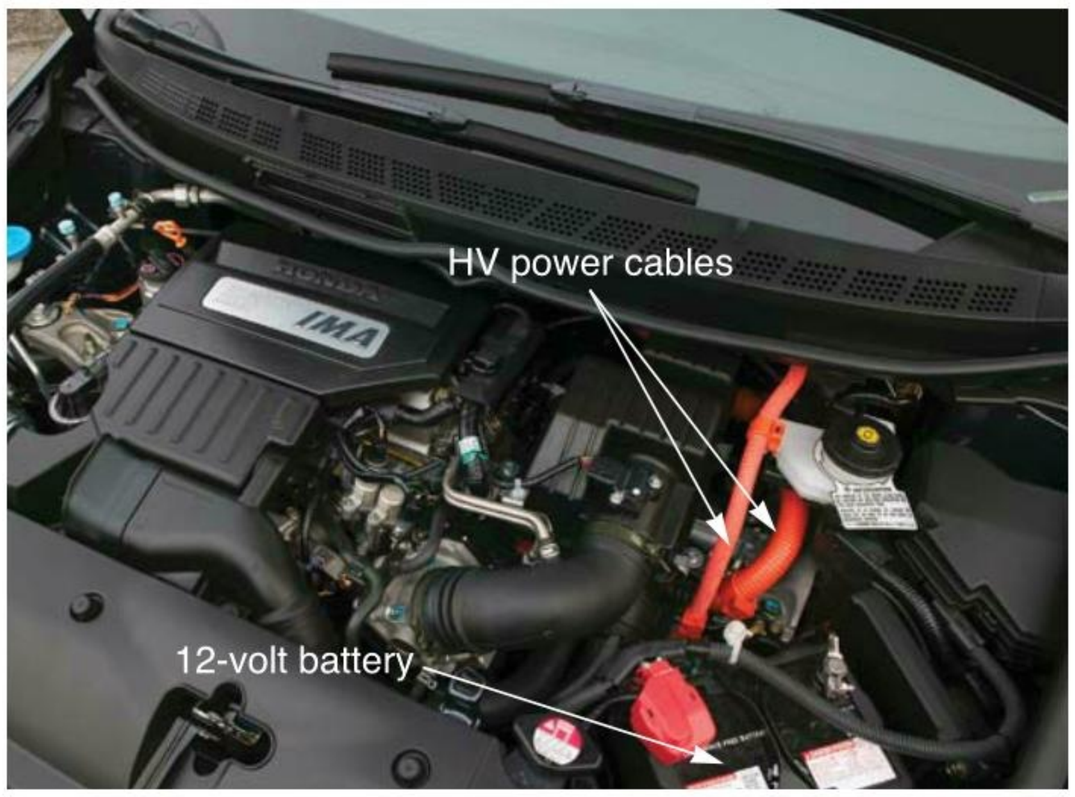
Figure 28-14. The hold-down flange on this battery stack runs the perimeter of the battery.

voltage sensors to prevent battery overheating. The HV battery ECM can activate an air, water, or refrigerant cooling system when the battery cells become hot. The HV battery ECM also maintains a preset state of charge on the HV battery by controlling current flow from the motor-generator. Sometimes the HV battery ECM is integrated into the HV battery assembly or the hybrid control module or power control module circuits.

HV battery temperature sensors are used to protect against battery thermal and overcharging damage. A tremendous amount of current flows in and out of the battery when it is being recharged by regenerative braking or when it is powering the electric driveline. If an HV battery temperature sensor detects cell overheating, it will signal the HV battery ECM to disconnect the HV power control module to prevent further overheating.

HV Power Cables

HV power cables include all large-diameter, high-voltage conductors that electrically connect the HV battery, HV power control module, and motor-generator. HV cables consist of large conductors (00 or 000 AWG) coated with bright-orange plastic insulation. The orange insulation serves as a warning of the deadly high voltage being carried by the conductors. Look at **Figure 28-15**. HV power cables



Honda

Figure 28-15. Orange high voltage and wattage cables are clearly visible in this engine compartment. Besides conventional wire insulation, power cables are also protected by thick, flexible plastic sheath.

can carry both high voltage dc and high voltage ac, depending on their location in the electric drive circuit.

HV battery cables are the two large orange conductors that connect dc to the HV power control module. The positive and negative battery cables sometimes extend out of the battery, or a high current/voltage connector is provided for the HV battery cables.

HV motor-generator cables electrically connect three-phase ac from the power control module to the motor-generator. Each motor-generator cable carries a single phase of ac, which is timed 120° from the next ac sine wave.

HV Battery Ratings

HV battery nominal operating voltage is the maximum dc voltage available from the HV battery. Actual HV battery voltage depends on the make and model of the vehicle and the number of cells and packs used in the battery. Nominal HV battery operating voltages can vary from about 150–300 volts dc. Higher nominal voltages increase the efficiency of the electric drive system.

An HV battery is so powerful that it is rated in kilowatts (thousands of watts) of electrical energy. An ***HV battery peak power rating*** might be 100–150 kilowatts (100,000 to 150,000 watts of power). Peak power rating basically determines how much current can be fed to the HV motor for a short period of time. This in turn determines how fast the vehicle can accelerate with full-electric propulsion.

Copyright Goodheart-Willcox Co., Inc.

An ***HV battery continuous power rating*** is the amount of voltage and current that can be safely generated before the battery is fully discharged. A typical value for a late-model HV battery might be 50 kWh (kilowatt hours). The continuous power rating determines how long the hybrid vehicle can be driven in electric mode. An HV battery rating of 50 kWh might allow the vehicle to operate for 40–50 miles per charge. On average, this means one kWh of battery power equals one mile of driving in the full-electric mode.

An ***HV battery amp-hour rating*** compares the electrical power available for one hour of continuous discharge—it is the equivalent of the cold cranking rating. Watt-hour rating basically determines how long the battery can hold its state of charge under full-electric propulsion. As a reminder, watts (power) = voltage × current.

Nickel and lithium HV batteries for hybrids commonly use the watt-hour rating. To convert amp-hour to watt-hour, simply multiply amp-hours by voltage. If an HV battery operates at 300 volts and outputs 50 amps for an hour, then it is producing 15,000 kWh, or 15 kWh of power. Large HV batteries normally produce 50–100 kWh for full-electric drive vehicles. This is a tremendous amount of electrical energy.

Warning

Never allow your skin to contact any conductor on or inside an HV battery. The high voltage and current produced by these batteries can cause severe burns or electrocution.

The charge indicator changes color as the level of battery charge changes. In cars with an electric or hybrid drive train, the battery charge indicator is in the dash display. It will indicate state-of-charge or percent power remaining, power use, gas or energy consumption, and other electrical values.

HV Capacitor Banks

HV capacitor banks are storage devices for electrical energy that do not require an electrolyte or battery acid. As you learned earlier, capacitors are basically made of aluminum foil wrapped around a thin strip of insulating material. Electrical energy flows into a capacitor until it is fully charged. The capacitor stores this energy until needed.

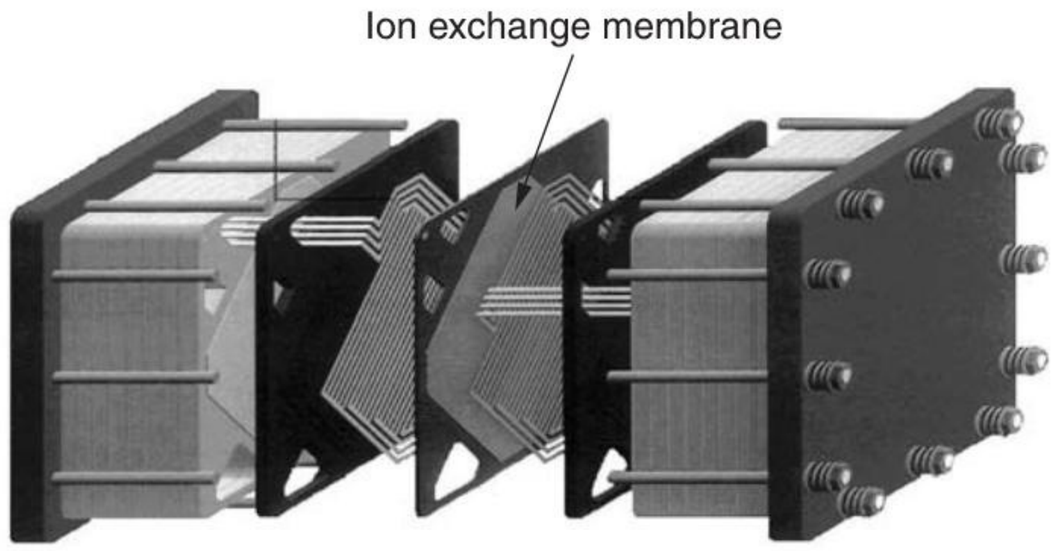
HV capacitor banks are wired in series to aid electric-drive vehicle acceleration. They are ideal for supplementing chemical batteries. Capacitor banks are very light, never wear out, and can accept or output short bursts of high-power electrical energy. Many hybrid buses and trucks now use capacitor banks to improve electric drive train efficiency and power for several seconds of rapid acceleration.

A capacitor will block the flow of alternating current (ac), but stores high voltage and a little current. Start capacitors help the motor start spinning when first turned on and are often used on industrial motors. When a low-resistance motor is connected across the capacitor, stored voltage and current shoot back into the motor windings to help initially spin and rotate the armature until ac current can keep the motor operating. Large capacitors are used in the HV power control module to help start the ac motor begin initial rotation from a standstill.

Fuel Cells

Fuel cells are similar to batteries, but they require an outside fuel source, usually hydrogen, to generate electricity. Like a battery, a fuel cell contains a positive plate (anode), a negative plate (cathode), and electrolyte. See **Figure 28-16**. Two chemical reactions occur in a fuel cell: a fuel is consumed and electrical energy is created.

The positive plate oxidizes the fuel (hydrogen) in the fuel cell. This converts the hydrogen fuel into positive-charged ions and electrons. Since the electrolyte in a fuel cell passes ions but blocks electrons, a voltage is generated. Look at **Figure 28-17**. Due to the potential difference in charges, free electrons pass



Honda

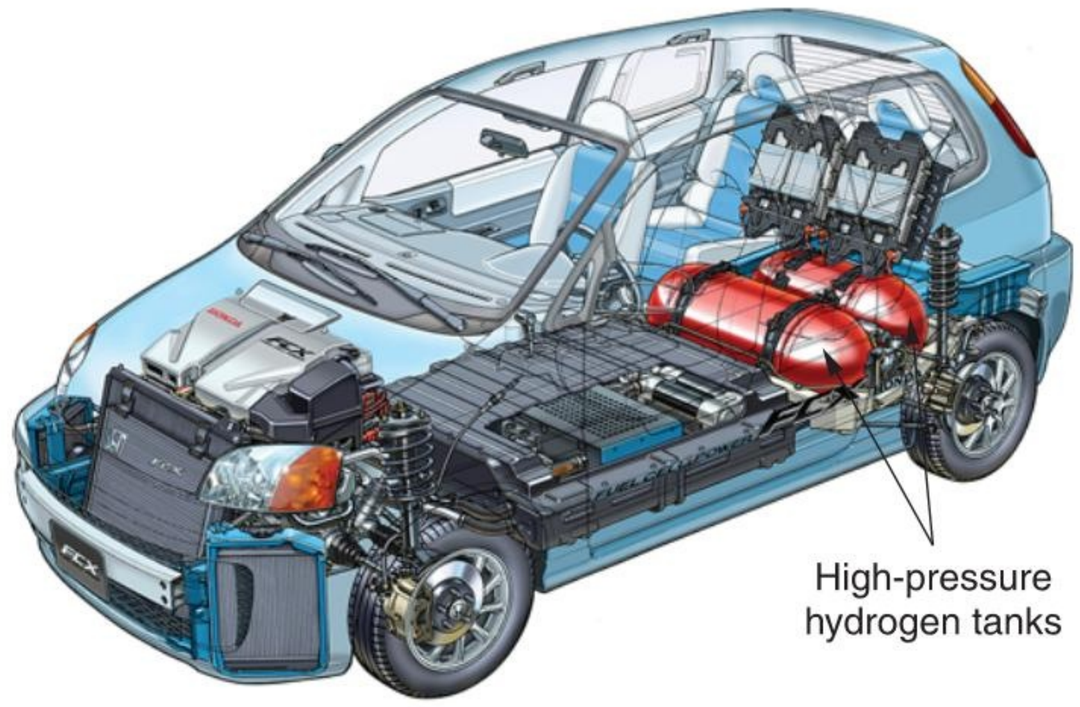
out of the fuel cell as direct current. Once the ions have passed through the electric circuit, they return to the negative plate. The ions then recombine with the electrons, where they react with oxygen to create water and carbon dioxide.

Fuel cell propulsion is very promising technology. However, hydrogen must be stored in high-pressure tanks, and refueling stations are not yet readily available. Refer to **Figure 28-18**.

Flywheel Generator

A ***flywheel generator***, also called a ***flywheel battery***, uses the kinetic energy of a high-speed ac armature (flywheel) to store huge amounts of electrical energy. Permanent magnets are mounted and spaced around the inside circumference of the armature to



Honda

Figure 28-18. This is an advanced fuel cell hybrid vehicle. The fuel cell, HV battery, conventional gasoline engine, and high pressure tanks for hydrogen provide propulsion.

form a stationary stator. The flywheel armature is enclosed in a vacuum chamber or housing, and levitates on a magnetic field to reduce friction.

During flywheel generator charging, three-phase ac is fed into the stator windings to produce reversing polarity magnetic fields at each coil winding. This causes the permanent magnets in the flywheel armature to be attracted or repelled by the stator's magnetic fields. As a result, the flywheel armature is spun up to 50,000–100,000 rpm. The three-phase current that spins the flywheel up to speed comes from the motor-generators during regenerative braking. The motor-generators serve as electric brakes to slow the car while producing large amounts of three-phase ac that is fed to the flywheel generator stator windings.

When spun up to full speed, a typical flywheel battery provides several hundred horsepower of electrical energy for rapid vehicle acceleration. Although still experimental, flywheel battery technology could see commercial use soon.

During flywheel battery discharging, the HV power control module connects the flywheel stator windings to the motor-generators. As the spinning magnets pass each stator coil, voltage and current are induced into the stator windings. Since all of the stator coils are wired together in a "Y" configuration, tremendous current levels flow out of the large power cables. The surge of electrical energy is conducted through the HV power control module and to the motor-generators.

Summary

- An automotive battery is an electrochemical device for producing and storing electricity.
- A simple metal-acid battery cell consists of a negative plate, positive plate, container, and electrolyte (battery acid, lithium paste or gel, or liquid sulfuric acid).
- A 12-volt battery has six cells, which produce an open circuit voltage of 12.6 volts.
- Battery cables are large wires that connect the 12-volt battery terminals to the vehicle's electrical system.
- Common types of 12-volt batteries include maintenance-free batteries, gel batteries, and AGM batteries.
- The two most common methods of rating lead-acid storage batteries are by the cold cranking rating and by the reserve capacity rating.
- As battery temperature drops, battery power is reduced.
- Many hybrids use a dual voltage system: 12 volts for most of the vehicle's conventional electrical/electronic circuits, and high voltage (HV) for the double-ought (00) conductors and HV motor-generator of today's electric drive trains.
- An HV battery is made of several battery cells wired in series to produce a high voltage electrical power source.
- An HV battery ECM is an electronic control circuit that reads signals from HV battery temperature and voltage sensors to prevent battery overheating.
- An HV battery is so powerful that it is rated in kilowatts (thousands of watts) of electrical energy.
- Capacitor banks can store electrical energy without an electrolyte, battery acid, or a fuel (hydrogen).
- Fuel cells are similar to batteries, but require an outside fuel source, usually hydrogen, to generate electricity.
- A flywheel generator uses the kinetic energy of a high-speed ac armature (flywheel) to store huge amounts of electrical energy.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

12-volt battery
absorbed glass mat battery
AGM battery
amp-hour rating
battery acid
battery bank
battery cables
battery caps
battery case
battery cell
battery charge indicator
battery cover
battery cycling
battery eye
battery heat shields
battery hold-down
battery pack fuses
battery pack voltage
battery plates
battery posts
battery stack
battery straps
battery temperature sensor
battery terminals

Activities

1. Survey the service managers of at least three businesses that sell and install vehicle batteries. Find out how they dispose of batteries they remove from vehicles.
2. Research the best battery value. Gather information from the Internet or visit stores that sell automotive batteries. Find the cold cranking ratings and prices of comparable-size batteries from different stores, and make a chart of your findings. Which battery will give you the most for your money?
3. Construct a model of a vehicle battery element (cell) for classroom display. Clearly label all components.
4. Ask a dealership to allow your class to visit their shop during HV battery replacement. Make sure you stand several feet away from the vehicle while observing.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What is the typical range of output voltage for HV batteries?
2. A(n) _____ is an electrochemical device for producing and storing electricity.
3. Define the terms “discharging” and “charging” as related to battery operation.
4. Which of the following is *not* part of a basic battery cell?
   (A) Positive plate.
   (B) Negative plate.
   (C) Electrolyte.
   (D) Spark arrestors.
5. List five functions of a car battery.
6. A 12-volt battery has _____ cells that produce an open circuit voltage of _____ volts.
7. Most modern vehicles use 6-volt batteries. True or False?
8. _____ gas can collect around the top of batteries. If this gas is exposed to a flame or spark, it can explode.
9. Electrolyte is a mixture of sulfuric acid and distilled water. True or False?
10. What is the purpose of a battery eye?
11. Describe the difference between battery posts and side terminals.
12. Which of the following is *not* a 12-volt battery rating?
    (A) Hot cranking rating.
    (B) Reserve capacity rating.
    (C) Amp-hour rating.
    (D) Cold cranking rating.
13. How is the power of large battery packs rated?
14. What is the standard color of HV battery cables?
    (A) Red.
    (B) Blue.
    (C) Orange.
    (D) Yellow.
15. HV _____ are storage devices for electrical energy that do not require an electrolyte or battery acid.
    (A) capacitor banks
    (B) fuel cells
    (C) motor-generators
    (D) side terminals
16. A flywheel generator uses the kinetic energy of a high-speed ac armature (flywheel) to store huge amounts of electrical energy. True or False?

ASE-Type Questions

1. An automotive battery produces:
   (A) hydrogen gas.
   (B) voltage.
   (C) direct current.
   (D) All of the above.
2. Battery charging converts:
   (A) atoms into electrolytes.
   (B) electrical energy into chemical energy.
   (C) chemical energy into electrical energy.
   (D) lead oxide into sulfuric acid and water.
3. Which of the following is *not* a battery cell component?
   (A) Eye.
   (B) Battery acid.
   (C) Positive plate.
   (D) Negative plate.

Copyright Goodheart-Willcox Co., Inc.

4. Battery plates are grids that are coated with:
   (A) plastic.
   (B) copper.
   (C) thin steel.
   (D) porous lead.
5. The active material on positive plates is:
   (A) antimony.
   (B) sponge lead.
   (C) lead peroxide.
   (D) None of the above.
6. Which of the following shows the general charge condition of a 12-volt battery?
   (A) Battery charge indicator.
   (B) Test indicator.
   (C) Battery eye.
   (D) All of the above.
7. When testing a battery's charge condition, the indicator shows a visible dark green dot. Technician A interprets this to mean the battery needs to be charged. Technician B feels the dot indicates the battery is fully charged. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Each of the following provides a means of connecting battery plates to a car's electrical system *except*:
   (A) battery caps.
   (B) battery posts.
   (C) side terminals.
   (D) battery terminals.
9. An HV battery stores chemical-electrical energy that is used to _____.
   (A) start the internal combustion engine
   (B) provide 12–15 volts dc for the vehicle's electrical accessories and conventional electric circuits
   (C) provide full-electric propulsion
   (D) All of the above.
10. Technician A says the HV battery ECM can activate a battery cooling system when the HV battery cells become hot. Technician B says that if the HV battery temperature sensor detects battery overheating, it can prompt the HV battery ECM to disconnect the HV power control module to prevent further overheating. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Chapter 29
12-Volt and HV Battery Service

After studying this chapter, you will be able to:

- Visually inspect a 12-volt battery for obvious problems.
- Perform common tests on 12-volt and HV batteries.
- Charge 12-volt and HV batteries.
- Replace a defective battery or battery pack.
- Describe safety practices to follow when testing and servicing 12-volt and HV batteries.
- Identify the major steps for safely removing and replacing an HV battery.
- Explain how to inspect, clean, and torque HV power cable connections.
- Correctly answer ASE certification test questions on battery service.

A ***dead battery*** (discharged battery) is a very common problem in vehicles with a 12-volt starting system. The engine will usually fail to crank and start. You will often hear a rapid clicking sound (or chatter) as the battery tries to repeatedly engage the solenoid. Even though the lights and horn may work, there is not enough "juice" (current) in the 12-volt battery to operate the starting motor.

Hybrid vehicles seldom suffer from a fully-discharged HV battery. If battery voltage is low, the on-board diagnostics warn the driver and technician of a battery problem. With a modern HV battery, the dreaded clicking noise (starter solenoid chatter) of a dead battery is a thing of the past.

It is important to know how to inspect, test, and service both 12-volt and HV batteries. This chapter covers the most common tasks relating to battery service and replacement. Study this information carefully since later chapters expand on this knowledge.

Warning

Working on high-voltage hybrid circuits is much more dangerous than working on conventional 12-volt circuits. The voltage in a 12-volt electrical system does not generate enough current flow to cause injury. An HV battery can output thousands of amps. Since only 1 amp of electrical current can be fatal, imagine what 1000 amps could do.

12-Volt Battery Maintenance

The average service life of a 12-volt battery is approximately 3–5 years. If a 12-volt battery is not maintained properly, its service life will be reduced.

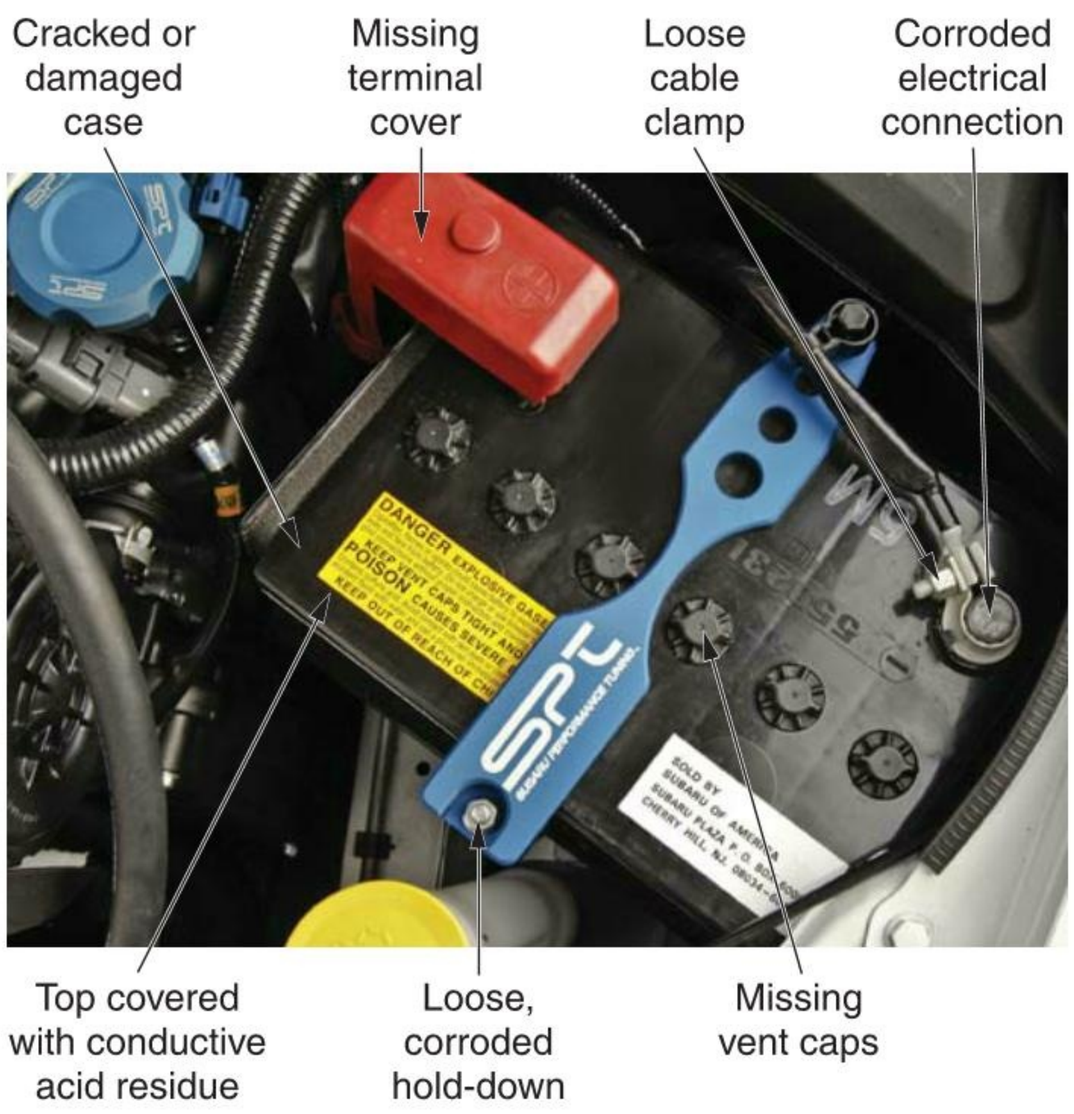
Copyright Goodheart-Willcox Co., Inc.

Battery maintenance should be done periodically—during tune-ups, grease jobs, or any time symptoms indicate battery problems.

12-volt battery maintenance typically includes:

- Inspecting the battery case, battery terminals, battery hold-down, and fasteners on the battery cable ends for corrosion and damage. Look for corrosion buildup on the battery top and electrical connections. Check the case for damage. See **Figure 29-1**. This should be done any time the hood is opened.
- Removing and cleaning the battery terminal connections.
- Washing off the top of the battery case with soap or baking soda and water to neutralize any acid or remove dirt buildup.
- Repairing the battery tray, if rusted or broken.
- Inspecting the electrolyte level. Most new low-current, 12-volt batteries for hybrids have removable vent caps for service. The battery case may also be semi-transparent so you can view electrolyte levels on the sides of the plastic housing.

Since battery connections suffer rapid corrosion from acid and hydrogen fumes, the 12-volt electrical connections can fail quickly, developing high electrical resistance.



Subaru

Figure 29-1. Visually inspect batteries for these kinds of problems. If any problems are found, correct them.

If you can wiggle and turn the cable connections by hand, they must be disassembled and serviced. If a problem is found, get the customer's permission to service the battery.

Warning

Wear eye protection when working around batteries. A 12-volt lead-acid battery contains sulfuric acid, which can cause severe eye burns, even blindness. The dirty film buildup on top of a battery contains acid residue that can attack the electrical connections, as well as your skin.

12-Volt Battery Service

If regular maintenance tasks reveal a problem or do not correct an existing problem with a 12-volt battery, further testing is required to identify the problem and determine the most appropriate and effective solution.

12-Volt Battery Leakage Test

A ***battery leakage test*** will find out if electrical energy is draining and discharging across the top of the battery case. A dirty battery can run down (discharge) when not in use. This can shorten battery life and cause starting problems.

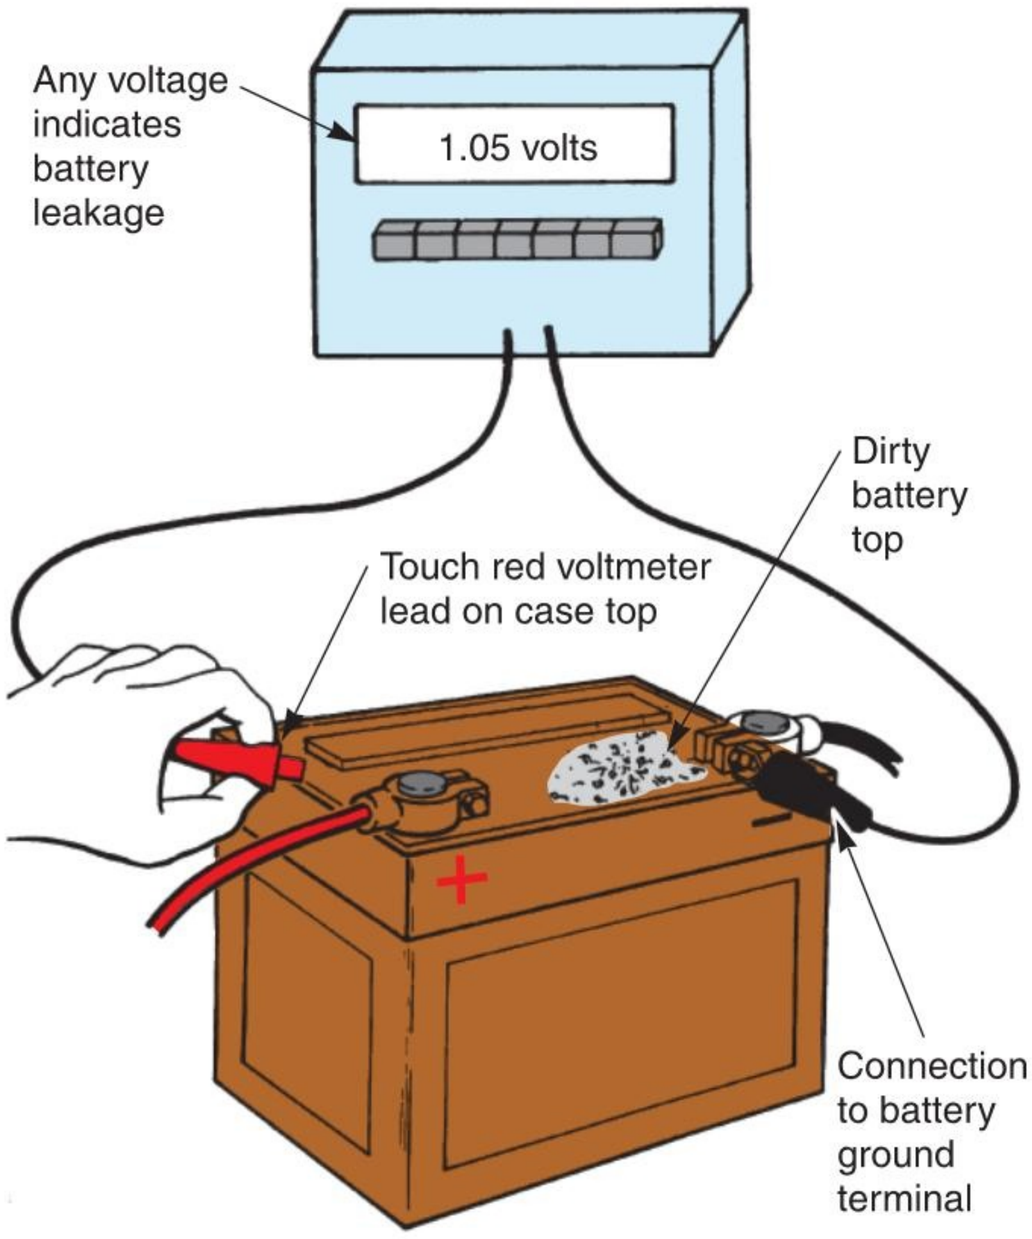
To do a battery leakage test, set a voltmeter to read 12–15 volts dc. Connect the black meter lead to the negative battery terminal and touch the red meter lead on the battery, as shown in **Figure 29-2**. If the meter registers any voltage, a proportional amount of current is leaking constantly out of the battery. You need to clean the battery top to correct this common problem.

If the top of the battery is dirty, wash it with baking soda and water. See **Figure 29-3**. This neutralizes and removes the acid and dirt from the battery case. If battery vent/fill caps are removed, be careful not to let debris enter the filler openings and contaminate the electrolyte.

12-Volt Battery Terminal Test

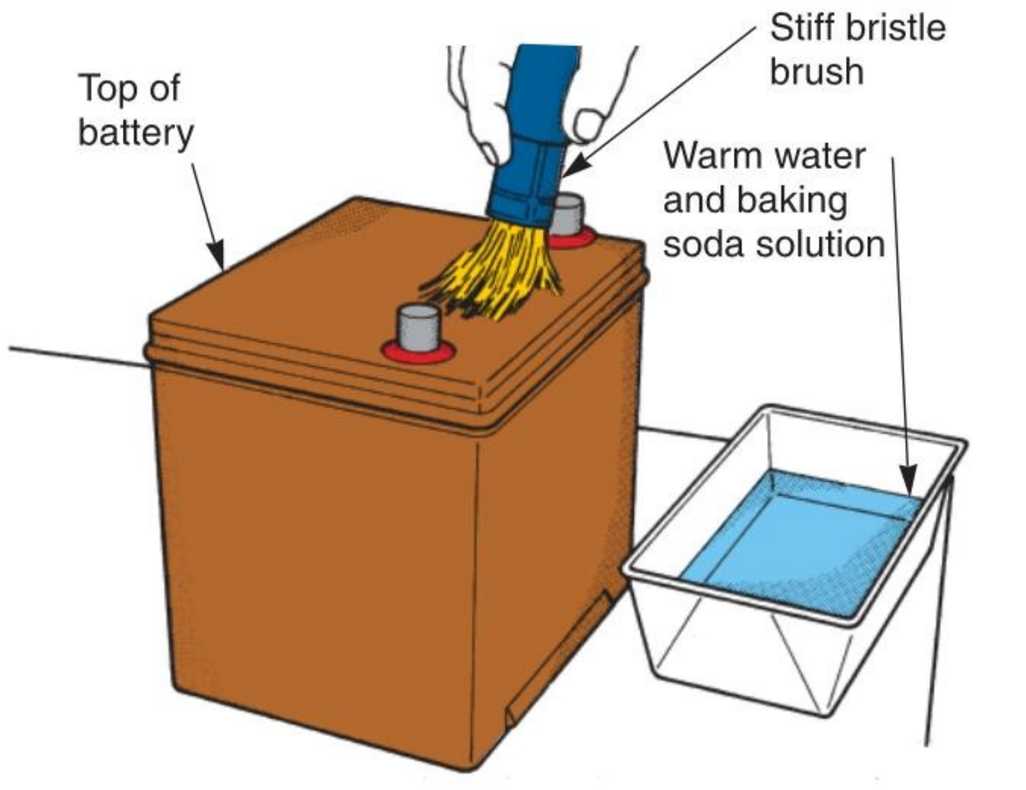
A ***battery terminal test*** quickly checks for a poor electrical connection (high voltage drop) between the battery cables and battery terminals on post-type batteries. A voltmeter is used to measure voltage drop across the cable ends and terminals. See **Figure 29-4**.

Copyright Goodheart-Willcox Co., Inc.



Sun Electric

Figure 29-2. A leak test will quickly show electrical leakage across the top of a battery. If the voltmeter registers any voltage, clean the battery.



Chrysler

Figure 29-3. Clean the battery with a solution of baking soda and water. Keep dirt out of filler openings.

Tech Tip

A battery terminal test cannot be performed on side-terminal batteries because the cable connector completely covers the battery terminal.

Service Procedure

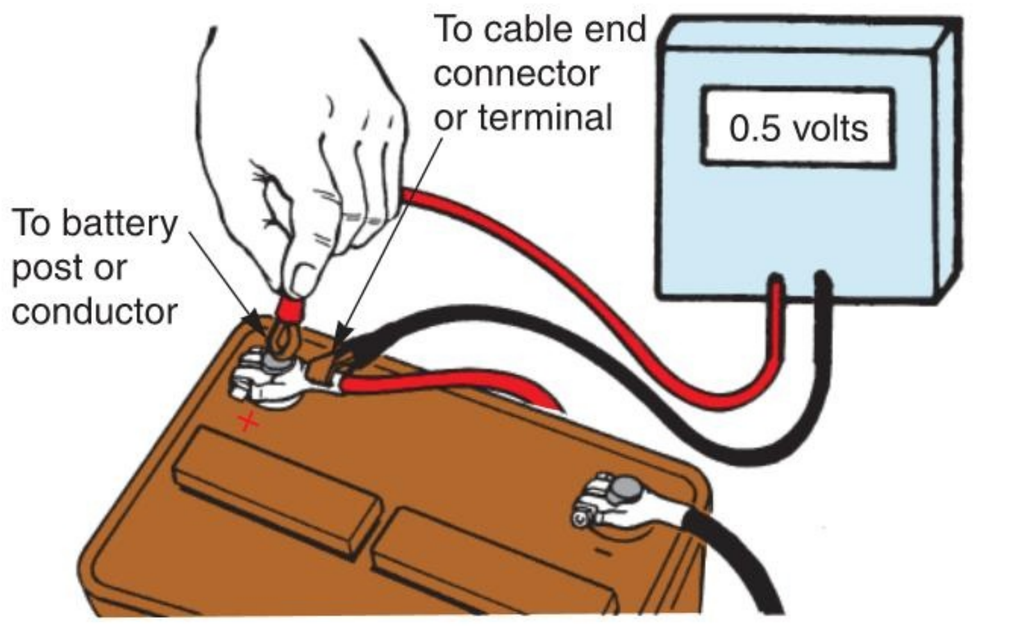
To perform a battery terminal test:

1. Connect the negative voltmeter lead to the cable end.
2. Touch the positive voltmeter lead on the battery terminal.
3. Remove the appropriate fuses to disable the ignition and fuel injection systems so the engine will not start.
4. Crank the engine while watching the voltmeter reading.

If the voltmeter shows 0.5 volts or more, there is a high resistance and poor electrical connection at the cable connection. Remove, clean, and retighten the battery connections. A good electrical connection has less than a 0.5 volt drop at 12 volts dc.

Cleaning 12-Volt Battery Terminals

To clean the terminals, remove the battery cable ends. See **Figure 29-5**. Use a six-point wrench if the bolt or nut is extremely tight. Use battery pliers only on



NAPA

Figure 29-4. To quickly find out if battery terminals need cleaning, measure the voltage drop across the cable-to-terminal connection. Crank the engine with the ignition disabled. A reading over 0.5 volt indicates that the terminal and cable end need cleaning.

B

C

Goodheart-Willcox Publisher

Figure 29-5. Note methods of removing a battery cable from a battery terminal. Be careful not to damage the post or side terminal. A—An open end wrench should rotate a battery terminal hex nut for cable removal. B—Battery pliers are needed if the hex nut is rusted or corroded so badly that a wrench will no longer fit. C—If the cable end is stuck to the battery post, use a terminal puller to remove the cable end without damaging the post. Most battery posts and straps are made of very soft lead.

spring-type clamps or when the fastener head is badly corroded and rounded off. Be careful not to damage the battery post or side terminal with excess side force.

To clean post-type electrical connections, use a battery cleaning tool to remove surface corrosion from the post and cable. Slide the female end of the battery tool around the post and twist the tool to abrade down to bare metal. See **Figure 29-6**. Slide the male end of the tool inside the cable end and twist the tool to clean the cable end's conductor mating surfaces. Rotate the battery tool until the contact surfaces are a shiny gray color. To clean side terminals, use a small, round wire brush. Twist the brush over the cable ends and the mating surfaces on the battery terminals.

Caution

Do not use a knife or scraper to clean battery terminals. Scraping the conductor surfaces can remove too much metal, roughen the smooth, parallel contact surfaces, and damage the soft metal. Scraping and gouging battery terminals can affect the durability and resistance at the electrical connections.

When reinstalling the 12-volt battery cables, coat the terminals with a conductive, dielectric compound or white grease. Look at **Figure 29-7**. This will keep acid fumes off connections and prevent the connections from corroding again. Tighten the fasteners just enough to secure the connection so it cannot be wiggled by hand. Overtightening can strip the cable bolt threads.

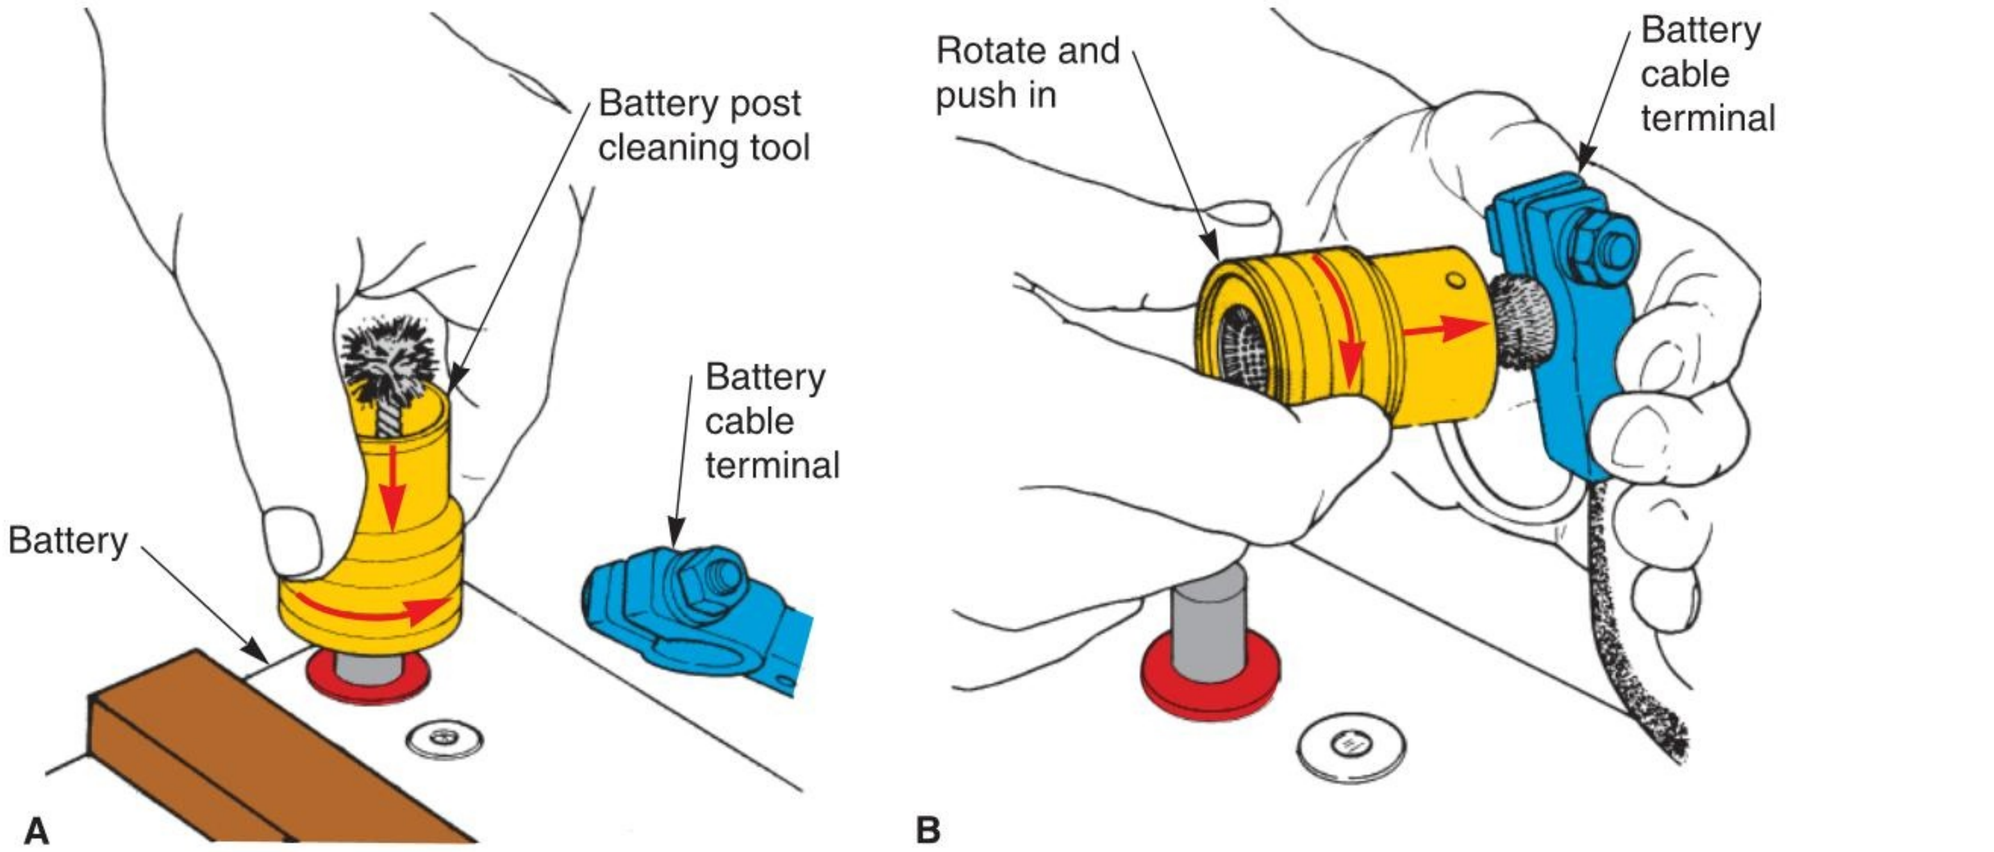
Tech Tip

When disconnecting a 12-volt car battery, consider using a memory saver to provide power to the computer. This will keep all driver-programmed information intact (clock, radio stations, ECM memory, etc.). A memory saver also prevents the computer from having to relearn information, which could temporarily upset drivability.

Checking 12-Volt Battery Electrolyte Level

Maintenance-free batteries do not need periodic electrolyte service. If they are overcharged and lose their electrolyte through gassing, maintenance-free

Copyright Goodheart-Willcox Co., Inc.



Chrysler

Figure 29-6. Note how to properly clean battery posts and cable ends. A—Rotate the female end of the cleaning brush on the post. B—Use the male end of the brush on the cable end. Turn it until all corrosion is abraded off and the metal surface is shiny.

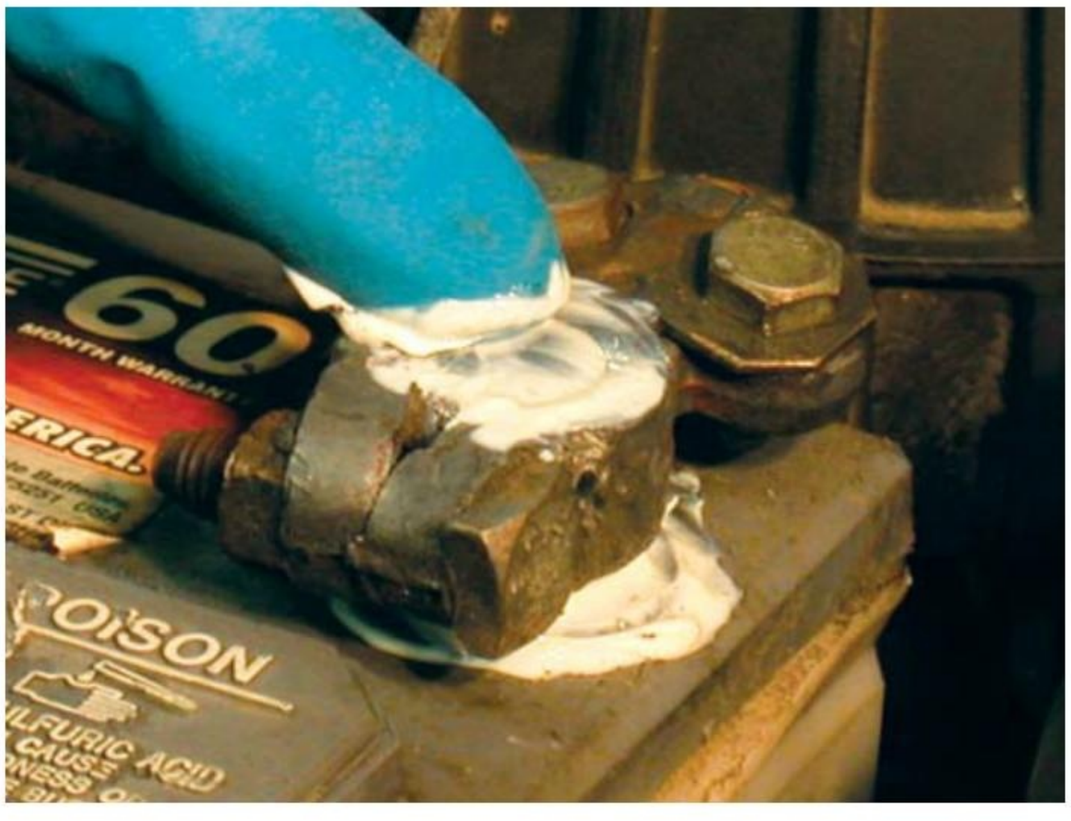
batteries must be replaced. Batteries with removable vent caps, however, should have their electrolyte level checked yearly.

The electrolyte should just cover the top of the battery plates and separators. Most batteries have a fill ring (electrolyte level indicator) inside the filler cap opening. The electrolyte should be even with the fill ring.

If the electrolyte is low, fill the cells to the correct level with ***distilled water*** (purified water). Distilled water should be used because it does not contain many of the impurities found in tap water. Water taken directly out of a water faucet can contain chemicals that reduce battery life. If enough contaminants collect in the battery, the cell plates can short out, ruining the battery.

Warning

The hydrogen gas produced by the chemical reaction in a battery is flammable. Keep all sparks and flames away from the top of the battery, especially during recharging. Batteries can explode if its hydrogen gas is ignited.



Goodheart-Willcox Publisher

Figure 29-7. Apply dielectric grease before and after the cable is installed to seal all moisture out of the electrical connection.

Checking 12-Volt Battery Charge

When measuring battery charge, you are checking the condition of the battery electrolyte and battery plates. For example, if a vehicle's lights are left on without the engine running, the battery will run down (discharge). Current flow out of the battery steadily reduces available battery energy, or power. There are several ways to measure battery charge.

Some batteries use a charge indicator eye that shows battery condition. This allows you to simply look at the eye in the battery cover to determine its general state of charge.

Copyright Goodheart-Willcox Co., Inc.

12-Volt Battery Voltage Test

A ***battery voltage test*** is done by measuring static battery voltage to determine the general state of charge. Look at **Figure 29-8**. This test provides a quick check of the battery condition. Connect the voltmeter across the battery terminals or posts and turn on the vehicle's headlights or blower motor to provide a small current load. For a fully charged battery under a light current load (less than 5 amps), the voltmeter should read 12.5 volts. The lower the voltage across the battery terminals, the less charge or energy in the battery.

When a battery fails a voltage test, other tests are needed to find or verify the actual problem.

Hydrometer Check

A ***hydrometer*** is used to measure the specific gravity (weight or density) of a liquid. A battery hydrometer measures the specific gravity of the battery electrolyte, which is an indication of the battery's state of charge. See **Figure 29-9**.

Water has a specific gravity standard of one (1.0). Fully-charged electrolyte has a specific gravity of between 1.265 and 1.279. Specific gravity greater than 1.0 indicates that electrolyte is denser (heavier) than water.

As a battery becomes discharged, its electrolyte has a larger percentage of water. Thus, the electrolyte of a discharged battery has a lower specific gravity than the electrolyte of a fully-charged battery.

Fluke

Figure 29-8. A digital voltmeter will check the general charge of a battery. Under a small load, voltage below 12.5 volts generally indicates battery discharge. This battery shows 12.49 volts, which is about 100% of a full charge with a 5-amp load.

Battery Voltage

Load on battery (Amps)	Specific Gravity (Percent charge)				
	1.265 (100%)	1.250 (95%)	1.230 (75%)	1.200 (50%)	1.175 (25%)
0	12.7	12.6	12.5	12.4	12.2
5	12.5	12.4	12.3	12.1	11.8
15	12.3	12.2	12.0	11.7	11.3
25	12.1	11.9	11.6	11.2	10.7

This is the range in which most vehicle batteries normally operate in customer service.

At 1.180 and below, starting will be unreliable and function of other circuits may be erratic.

Chrysler

Figure 29-9. This chart shows how battery voltage relates to specific gravity (hydrometer readings).

Tech Tip

Maintenance-free batteries do not have removable vent caps and therefore, cannot be tested with a hydrometer.

To use a float-type hydrometer, squeeze the hydrometer bulb and immerse the end of the hydrometer in the electrolyte. Then, release the bulb to draw in the liquid electrolyte. Look at **Figure 29-10**. Hold the hydrometer even with your line of sight. Compare the numbers on the hydrometer float with the top of the electrolyte.

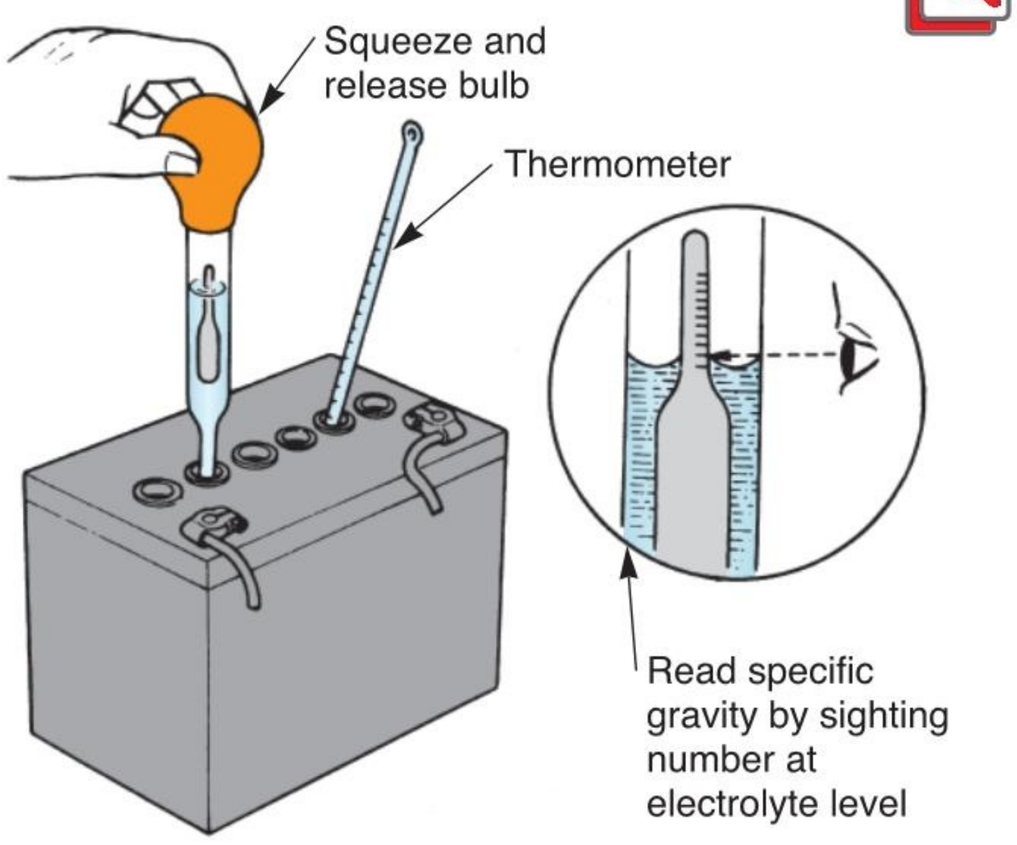
Warning

Wear safety glasses and do not drip electrolyte (sulfuric acid) on anything.

Specific gravity readings will vary somewhat with temperature and most float-type hydrometers are not temperature correcting. However, some models have a built-in thermometer and a conversion chart. This will let you compensate for temperature differences.

To use a ball-type hydrometer, draw electrolyte into the hydrometer with the rubber bulb. Note the number of balls floating in the electrolyte. Instructions on the hydrometer will tell you the battery's state of charge.

Copyright Goodheart-Willcox Co., Inc.



Mazda and Chrysler

Figure 29-10. To check battery charge, draw electrolyte into a hydrometer by squeezing and releasing the bulb.

A needle-type hydrometer uses the same principle as the ball-type. When the electrolyte is drawn into the hydrometer, it causes a plastic needle to register specific gravity.

A fully charged battery should have a ***hydrometer reading*** of at least 1.265. If the reading is below 1.265, the battery needs recharging or it may be defective.

A defective battery can be found with a hydrometer by checking the electrolyte in every cell. If the specific gravity in any cell varies excessively from other cells (more than 0.05), the battery should be replaced. Cells with low readings may have shorted or deteriorated plates. When all the cells have an equal specific gravity, the battery can usually be restored by recharging.

Cell Voltage Test

Just like a hydrometer cell test, a ***cell voltage test*** will indicate if the battery is defective or just discharged.

Service Procedure

To perform a cell voltage test:

1. Set your voltmeter to read low voltage.
2. Ground the black tester lead on the battery negative terminal.
3. Insert the other special cadmium (acid-resistant metal) tip into the cell.
4. Carefully test each cell starting at one end of the battery and working down to the other end.

If cell voltages are low but equal, recharging will usually restore the battery. If cell voltage readings vary more than 0.2 volts, the battery is faulty and should be replaced.

Warning

Make sure you do not drip electrolyte on the vehicle or your skin. The sulfuric acid in the electrolyte will eat through the vehicle's paint or burn your skin.

Discharged 12-Volt Battery

A discharged battery could have several causes:

- Defective battery.
- 1 Cell shorts, low electrolyte, or freezing damage.
- Charging system problem (loose alternator belt, for example).
- Poor cable connections causing high resistance and reduced current flow.
- Engine performance problem requiring excessive cranking time.
- Electrical problem drawing current out of the battery with the ignition key off.

Copyright Goodheart-Willcox Co., Inc.

Parasitic Loads

A ***parasitic load*** is any electric circuit current draw present when the engine and all electrical devices are shut off. This load would include any circuit that requires a small current when the vehicle is not running (clock, vehicle alarm, ECMs, etc.). This results in a continuous current draw on the battery.

If a vehicle sits unused for prolonged periods, the parasitic load can drain the 12-volt battery enough to prevent starting. A battery must be in good condition to withstand prolonged parasitic loads. Parasitic loads are not a problem with hybrids since the HV battery has a huge reserve of stored electrical energy.

Tech Tip

Remember that normal parasitic current load for the clock and computers can discharge a battery if the vehicle sits unused for an extended period (about a month).

Battery Drain Test

A ***battery drain test*** will check for an abnormal current draw (high parasitic load) with the ignition key off. When a battery repeatedly goes dead, you may need to check for an excessive parasitic load. It is possible that there is a short or other problem discharging the battery quickly.

A battery can be discharged if an electrical accessory (an interior light, for example) remains on when the ignition switch is shut off. For example, a short in a switch could cause a glove box light to stay on, even when the glove box door is closed. This could slowly drain the battery and cause a starting problem.

Service Procedure

To perform a battery current drain test:

1. Make the ammeter connections.
2. Close the doors and trunk, and turn off all electric components.
3. Unscrew the underhood lightbulb, if needed.
4. Read the ammeter and compare your reading to specifications.

Tech Tip

To prevent meter damage, do not operate starting motor or any high-current-draw device (blower motor) with the meter connected in series for measuring current drain. High-current draw will blow the meter fuse or damage the meter.

If everything is off (good condition), the ammeter should read almost zero or only a few milliamps—typically 10 mA. However, an ammeter reading above this would point to a drain and a problem. To help pinpoint a drain, pull fuses one at a time while observing the ammeter. Look at **Figure 29-11**. When the ammeter reads zero, the current drain problem is somewhere in the circuit that contained the fuse that was removed.

12-Volt Battery Chargers

When tests show that a battery is discharged, use a ***battery charger*** to re-energize it. The battery charger will force current back through the battery to restore the charge on the cell plates. A battery charger contains a step-down transformer and diode rectifier circuit that changes wall outlet voltage (around 120 volts ac) to a voltage slightly above battery voltage (14–15 volts dc). **Figure 29-12** shows a battery charger.

There are two basic types of battery chargers: slow chargers and fast chargers. Sometimes both are incorporated into one unit.

Slow Charger

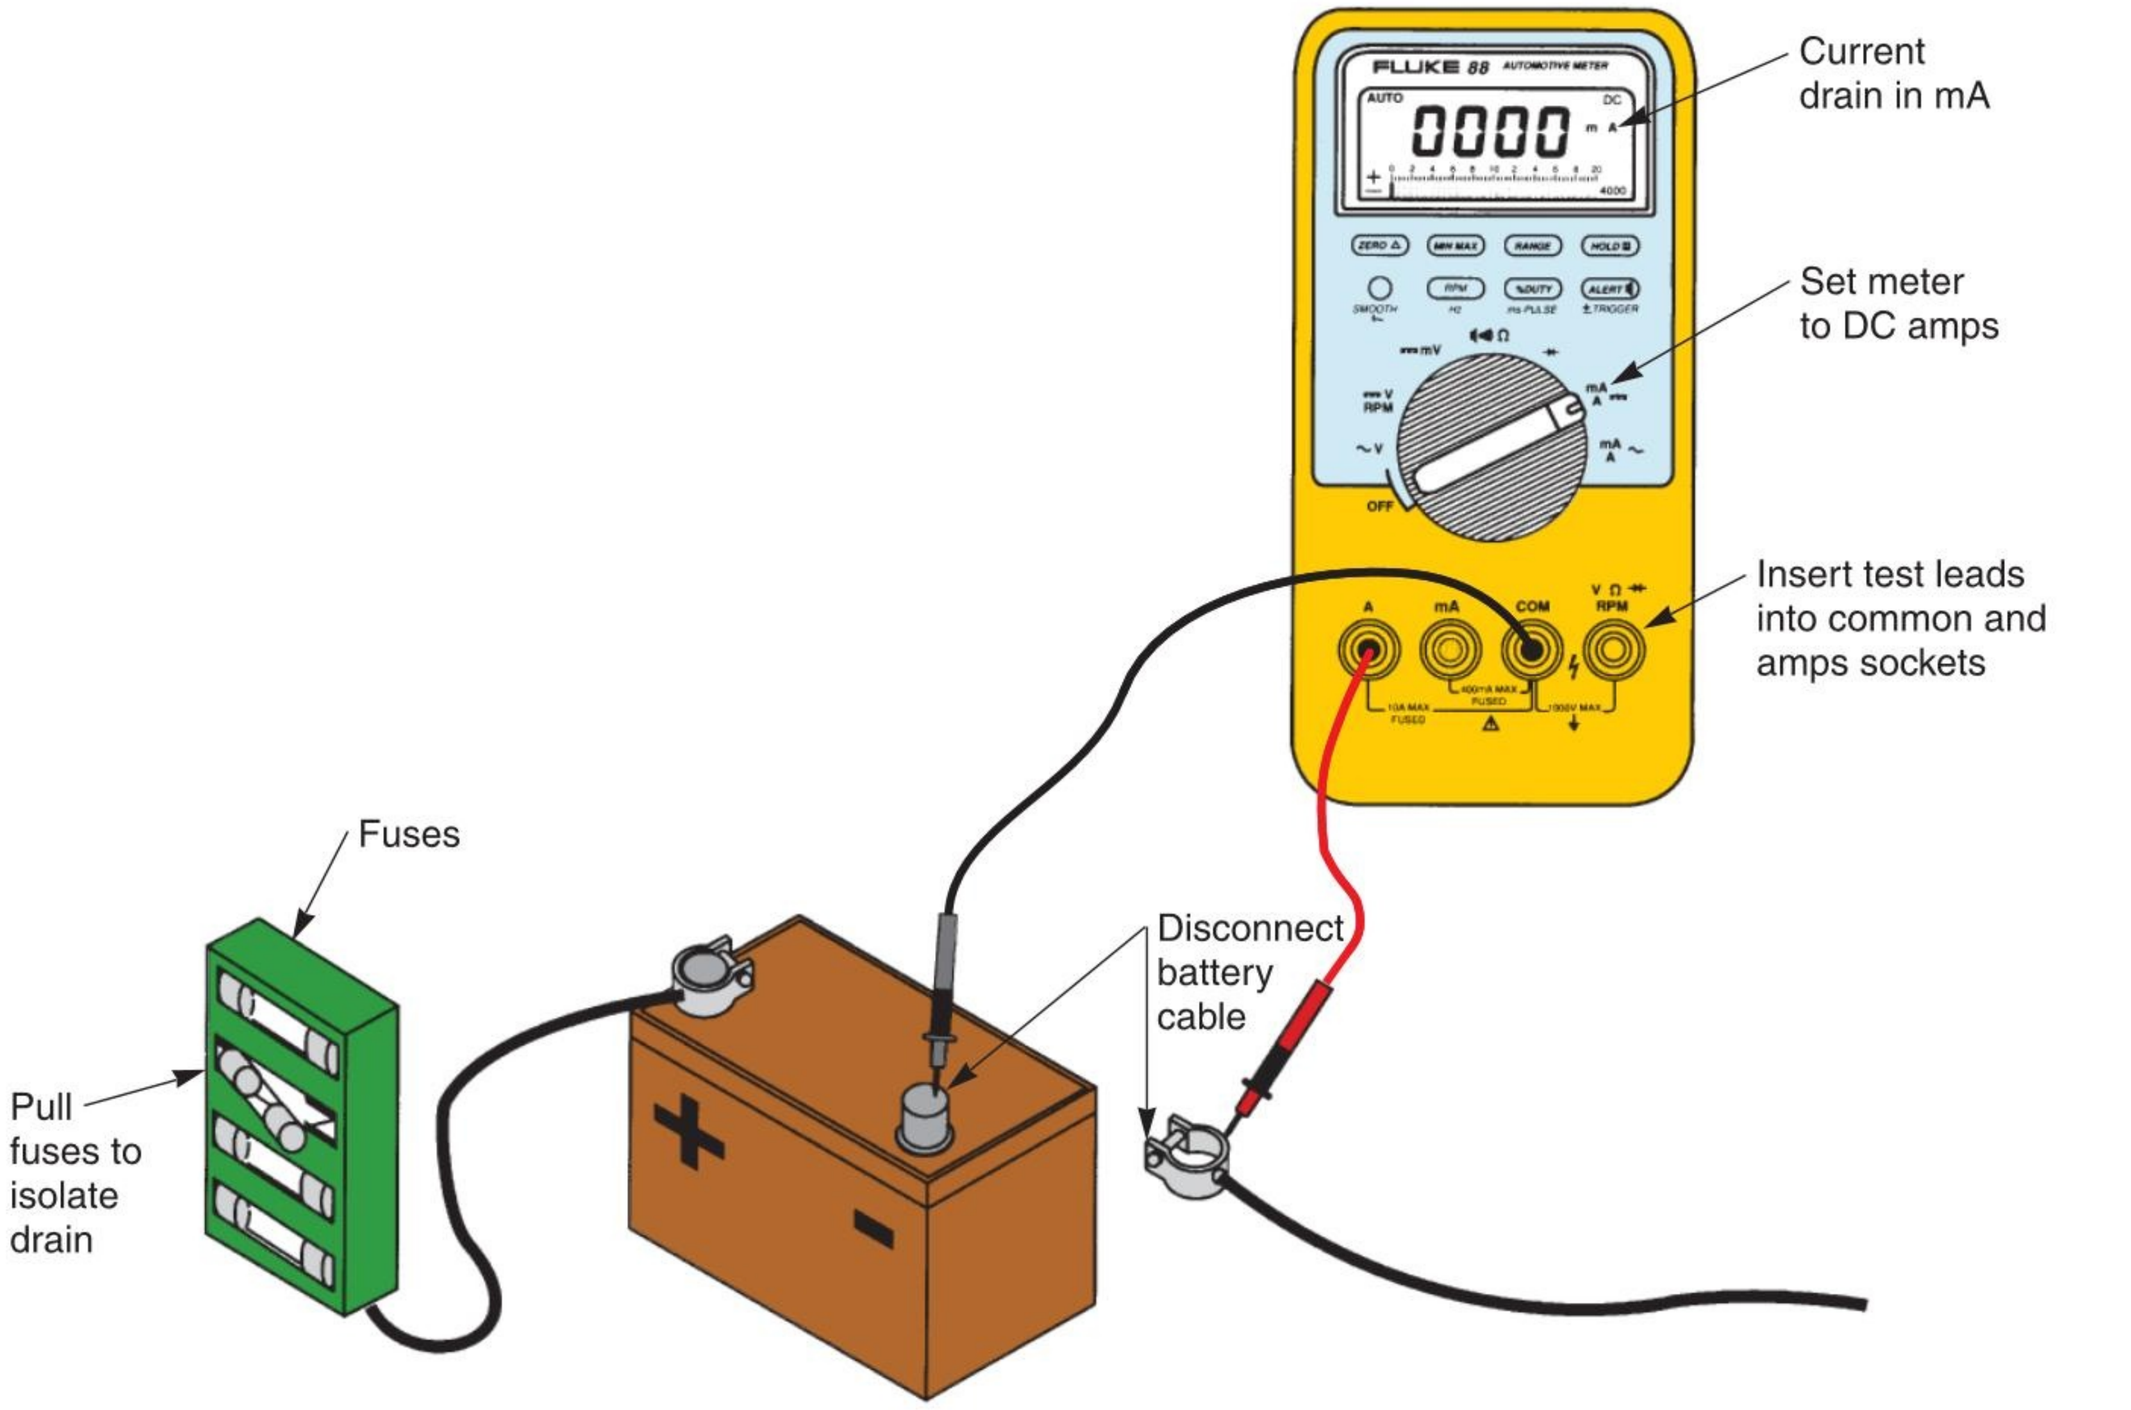
A ***slow charger***, also called a ***trickle charger***, feeds a small amount of current into the battery. When using a slow charger, charging time is relatively long (about 12 hours at 10 amps), but the chemical action inside the battery is improved. During slow charging, the atomic charges are forced back onto the battery plates and electrolyte better than they are with fast charging. When time allows, always use a slow charger for better recharging.

Fast (Quick) Charger

A ***fast charger***, also called a ***quick charger*** or ***boost charger***, forces a high current flow into the battery. When the customer needs the car, time may not allow the use of a slow charger.

Fast charging will usually allow engine starting in a matter of minutes. If possible, slow charging is recommended after fast charging.

Copyright Goodheart-Willcox Co., Inc.



Fluke

Figure 29-11. To perform a battery drain test, connect an ammeter in series with the negative cable. If current flowing out of the battery with everything turned off exceeds specifications, an electrical problem is discharging the battery. By pulling fuses, you can isolate the problem circuit.

Warning

Before connecting a battery charger to a battery, make sure the charger is turned off. Also, check that the work area is well ventilated. If a spark ignites any battery gas, the battery could explode. Wear eye or face protection when working on a car battery.

Caution

Make sure you do not accidentally reverse the cable connections when connecting a battery charger. Hooking a battery charger backward could burn diodes in the charging system and also destroy other delicate electronic circuits in the vehicle.

Charging a 12-Volt Battery

To use a battery charger, connect the red charger lead to the positive battery terminal. Connect the black charger lead to the negative terminal of the battery. With side terminal batteries, use adapters if needed to connect the large alligator clamps from the charger.

After correctly connecting the red and black cables to the battery, set the battery charger controls and turn on the power.

When fast charging, do not exceed a charge rate of 35 amps. Also, battery temperature must not exceed 125°F (52°C). Exceeding either charge rate or temperature could ruin the battery.

If you suspect a battery is frozen or has ice in it from extremely cold weather, do not charge it.

Copyright Goodheart-Willcox Co., Inc.

Schumacher Electric Corp.

Figure 29-12. A battery charger forces current through the battery to restore the charge on its plates. The charging voltage should be above battery voltage, usually 14–15 volts.

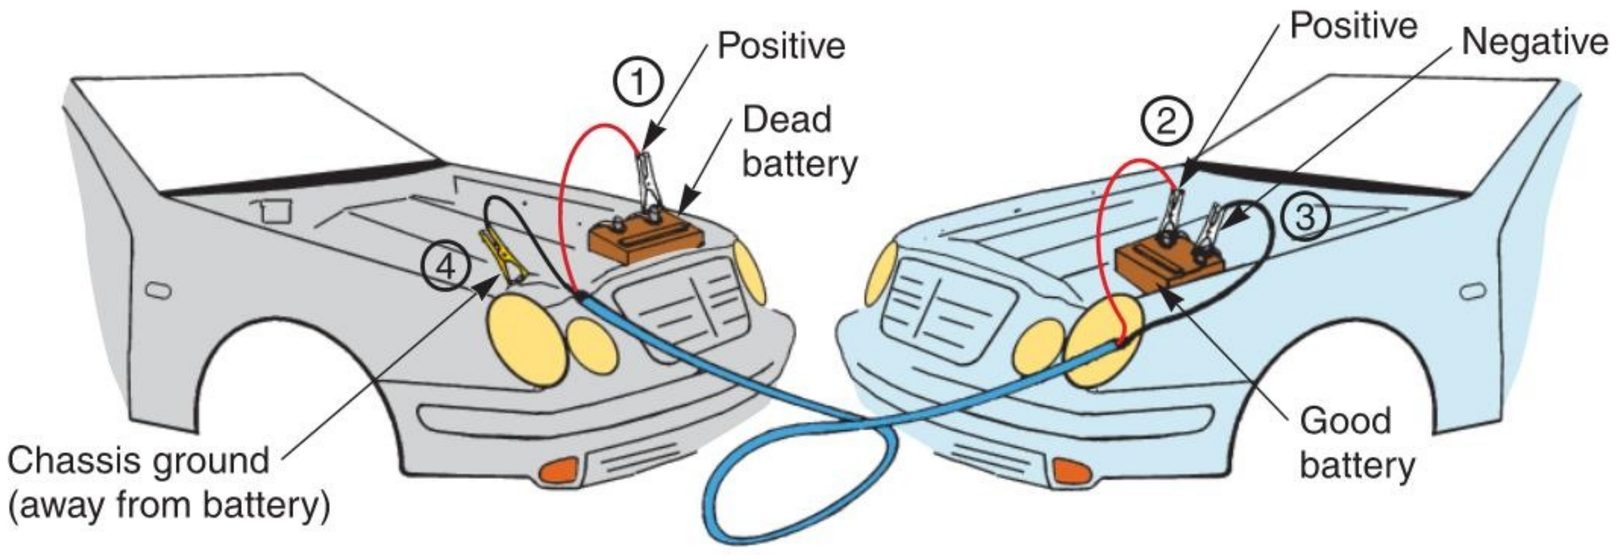
Charging a frozen battery can rupture the case and cause an explosion. A frozen battery will usually have plate and cell damage from ice expansion.

12-Volt Jump Starting

In emergency situations, it may be necessary to ***jump start*** an engine by connecting another battery to the discharged battery. Look at **Figure 29-13**. The two batteries are connected positive-to-positive and negative-to-negative. Connect the red jumper cable to the positive terminal of both batteries. Then, connect one end of the black jumper cable to the negative terminal of the good battery. Connect the other end of the black jumper cable to a good ground, away from the dead battery. See **Figure 29-14**. By connecting the last negative jumper cable to a ground away from the discharged battery, any spark that occurs when making the final connection will be far away from the explosive battery gas.

Caution

Do not short jumper cables together or connect them backward (positive to negative). This could cause serious damage to the vehicle's electronic systems. Diodes in the alternator and ac-to-dc rectifier circuits can be ruined by improper jumper cable connections.



Belden

Figure 29-13. Jumper cables can be used to start a vehicle with a dead battery. 1—Connect one end of the red jumper cable to the positive terminal of the dead battery. 2—Connect the other end of the red jumper to the positive terminal of the good battery. 3—Connect one end of the black jumper cable to the negative terminal of the good battery. 4—Connect the other end of the black jumper to a good ground on the disabled vehicle, away from the dead battery. Run the engine in the car with the good battery while starting the vehicle with the dead battery.

Chrysler

Figure 29-14. Close-up of jumper connections shows the connection of the negative (black) jumper to chassis ground. A spark near the dead battery could make battery gases explode.

12-Volt Battery Load Test

A ***battery load test***, also termed a battery capacity test, tests the battery under full-current load. A battery load test is one of the best methods of checking the condition of a 12-volt battery.

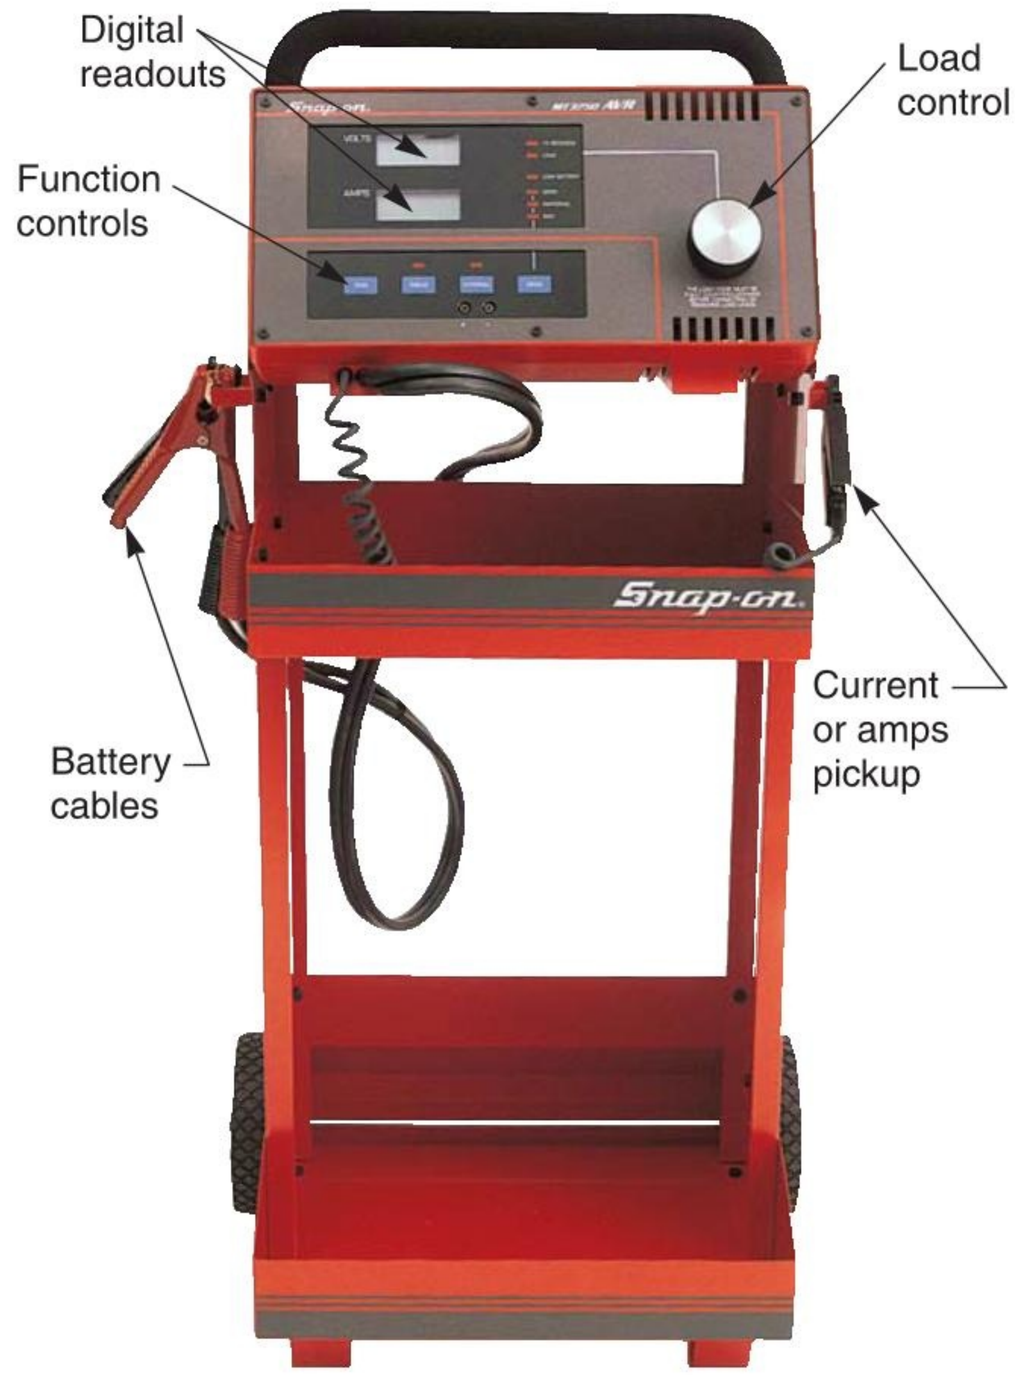
The hydrometer and voltage tests are general indicators of battery condition. The battery load test, however, actually measures the current and voltage output and overall performance of the cells. It is one of the most common and informative battery tests used in modern shops. Refer to **Figure 29-15**.

Connecting a Load Tester

Connect the load tester to the 12-volt battery terminals properly: positive-to-positive and negative-to-negative. Clamp the inductive amp pickup over the negative battery cable so it can measure magnetic field and current. Look at **Figure 29-16**. If the tester is not inductive, you must connect the ammeter in series with the load tester cables.

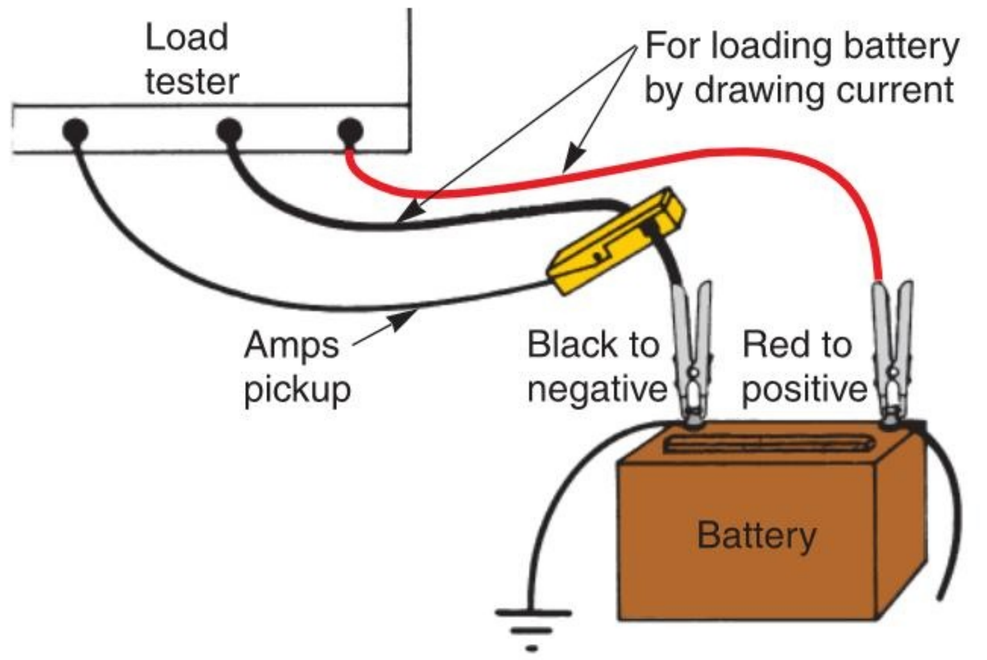
Tech Tip

Read and follow the operating instructions provided with the battery load tester.



Snap-on Tool Corp.

Figure 29-15. A load tester can be used to accurately determine battery condition. It is a commonly used testing device that measures actual battery performance.



Marquette

Figure 29-16. Load testers are connected as shown. Clamp the large cables to the battery. Clip the inductive amps pickup around the negative tester cable.

Copyright Goodheart-Willcox Co., Inc.

Before load testing a 12-volt battery, it is best to slow-charge the battery overnight. A partially charged battery will fail its load test. Adjust the load control on the testing machine to draw 50 amps for 10 seconds. This will remove any surface, or false static, charge from the battery. Then, check no-load battery voltage (also called open circuit voltage, or OCV), by reading the voltmeter.

A fully-charged battery should have a no-load voltage of 12.4 volts or higher. If battery voltage is below 12.4 volts, charge the battery before load testing. The battery is bad if it does not have almost 12.6 volts after a second charging and no-load voltage measurement.

Determine 12-Volt Battery Load

Before load testing a 12-volt battery, calculate the load test value (amp load) that should be applied to the battery. If the amp-hour rating is given, load the battery to three times its amp-hour rating. For example, if the battery is rated at 60 amp-hours, load test the battery at 180 amps ($60 \times 3 = 180$).

Many 12-volt batteries are now rated in SAE cold cranking amps (CCA), rather than amp-hours. To determine the load test values for these batteries, divide the cold cranking amps rating by two. For instance, a battery with a 400-cold cranking amps rating should be loaded to 200 amps ($400 \div 2 = 200$).

Figure 29-17 shows load test values for various battery ratings. A ***load conversion chart*** is normally provided with the load testing equipment. Refer to this material when in doubt.

Loading the 12-Volt Battery

After checking the battery charge and finding the amp load value, you are ready to test the battery output.

Service Procedure

To test the output of a 12-volt battery:

1. Double-check that the load tester cables and leads are connected properly (positive-to-positive and negative-to-negative).
2. Turn the load control knob until the ammeter reads the correct amp load for your battery.
3. Hold the load for 15 seconds to draw high current out of the battery.
4. Read the voltmeter while the load is applied.
5. Turn the load control completely off so the battery will not be discharged or drained fully.

If the voltmeter reads 9.5 volts or more at room temperature, the battery is good. This voltage value is based on a battery temperature above 70°F (21°C). A cold battery may show a lower voltage. You will need a temperature compensation chart, like the one in **Figure 29-18**, to determine the correct voltage value at temperatures below 70°F.

If the voltmeter reads below 9.5 volts at room temperature, battery performance is poor. This shows that the battery is not producing enough current to properly run the starting motor.

Activating Dry-Charged 12-Volt Batteries

There is no difference in the materials used in wet- and dry-charged lead-acid batteries. The difference is in how the batteries are prepared for service.

Battery ratings			Load test amps
Cold cranking current	Amp-hour (approx.)	Watts	
200	35–40	1800	100 amps
250	41–48	2100	125 amps
300	49–62	2500	150 amps
350	63–70	2900	175 amps
400	71–76	3250	200 amps
450	77–86	3600	225 amps
500	87–92	3900	250 amps
550	93–110	4200	275 amps

Marquette

Figure 29-17. This chart shows different battery ratings and calculated current values for load testing.

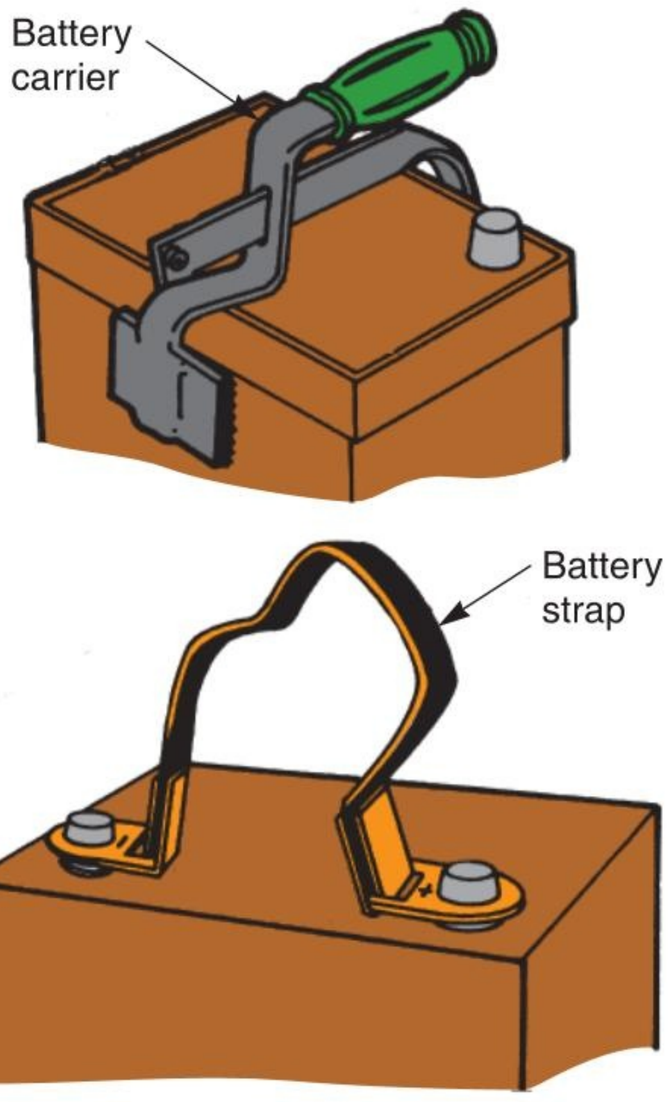
Approximate electrolyte temperature		Minimum acceptable voltage under load for good battery
60°F	(16°C)	9.5
50°F	(10°C)	9.4
40°F	(4°C)	9.3
30°F	(–1°C)	9.1
20°F	(–7°C)	8.9
10°F	(–12°C)	8.7
0°F	(–18°C)	8.5

Snap-on Tool Corp.

Figure 29-18. If the voltage reading is below the values presented in the chart for the specific battery temperature, the battery is probably bad.

Copyright Goodheart-Willcox Co., Inc.

A ***wet-charged battery*** is filled with electrolyte and charged at the factory. The battery is then tested and placed in stock, ready for service. A ***dry-charged battery*** contains fully-charged elements, but it does not contain electrolyte. It leaves the factory in a dry state. Before use, you must fill the battery with sulfuric acid. A dry-charged battery has a much longer shelf life than a wet-charged battery.



Florida Dept. of Voc. Ed.

Figure 29-19. If you lose your grip and drop a battery, acid could splash out and cause eye or skin injury. Always use a battery strap or carrier and wear eye protection for safety.

Service Procedure

To activate new dry-charged battery before installation:

1. Put on safety glasses and rubber gloves.
2. Remove the cell caps or covers.
3. Using a plastic funnel (acid will eat into a metal funnel), pour electrolyte into each cell. Pour in enough electrolyte to just cover the plates and separators.
4. Replace the caps.
5. Charge the battery as recommended by the manufacturer.
6. After charging, recheck the electrolyte level.

Removing and Installing a 12-Volt Battery

To remove a battery, disconnect its cable end clamps and loosen and remove the battery hold-down. Use a ***battery strap*** or ***battery carrier***, **Figure 29-19**, to carefully lift the battery out of the vehicle.

Tech Tip

A replacement battery should have a power rating at least equal to factory recommendations. If an ***undersized battery*** (lower watt or amp rating) is installed, starting motor performance and ***battery service life*** may be reduced.

Warning

Always wear safety glasses when carrying a battery. If you drop a lead-acid battery, electrolyte (sulfuric acid) can squirt out of the vent caps or a broken case and into your face and eyes.

To install a battery, gently place the battery into its clean tray or box. Check that the battery fits properly in the vehicle. The old and new batteries should be the same size (height, width, and depth). The tray edge must not cut through the plastic battery case, as this would allow electrolyte to leak out. Tighten the hold-down and install the cables. See **Figure 29-20**.

HV Battery Service

HV batteries for electric propulsion must be serviced differently from conventional 12-volt batteries. Since a large number of battery packs are wired together in series, the large cables leading out of the HV battery can carry 300 volts dc or more. You must learn many new techniques to safely service and replace an HV battery used in today's electric drive trains.

HV battery service life averages about 150,000 miles (240,000 km). Some HV batteries have failed in as few as 60,000 miles (100,000 km), but many last almost 10 years and/or 200,000 miles (320,000 km). An HV battery normally has a warranty from the

Copyright Goodheart-Willcox Co., Inc.

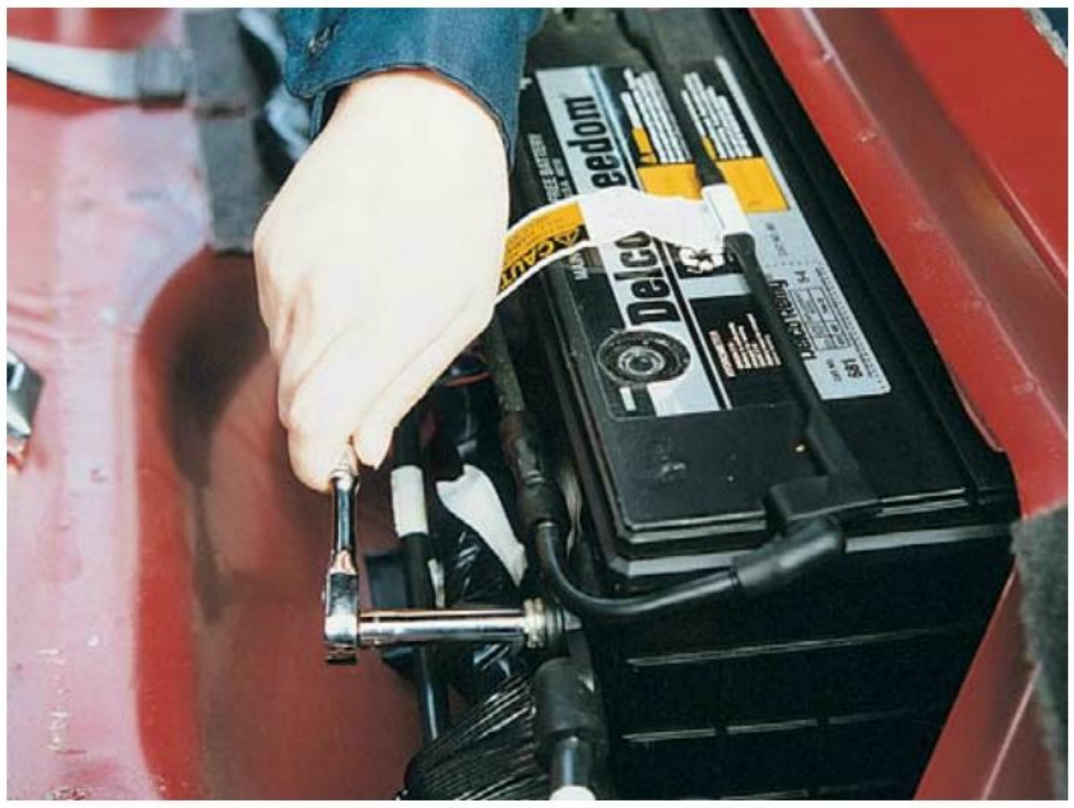


Figure 29-20. When installing a battery, do not overtighten cable terminals or you could strip the threads. Make sure the hold-down is secure.

vehicle manufacturer. One automaker, for example, offers an HV battery replacement warranty for up to 10 years or 100,000 miles (160,000 km).

HV batteries are very dependable and seldom fail. Nevertheless, even an HV battery can lose much of its electrical storage and output after years of extended service. The electrolyte and the plates can deteriorate and become depleted after years of recharging and discharging.

If the hybrid drive system is functioning normally, the motor-generator and HV power control module should keep the HV battery at a normal, or nominal, ***state-of-charge***. The hybrid dash display will inform you if the HV battery has a low state-of-charge or other problem.

Hybrid Jump-Starting

Avoid jump-starting a hybrid vehicle unless it has a 12-volt battery *and* a 12-volt starting motor. Some late-model full-electric drive trains cannot be jump-started. Full hybrids or full-electric vehicles must be towed to a service facility if they have a dead or discharged HV battery.

When a full hybrid fails to start, it is seldom because the battery is fully discharged. Another electrical problem is probably keeping the HV power control module from starting the engine or the electric drive system. A faulty HV power control module can sometimes cut power to every circuit, even low-voltage circuits.

Some vehicles use a starter/alternator instead of a 12-volt starting motor and 12-volt battery. The larger starter/alternator is actually a small motor-generator. It can be driven by the HV power control module to crank the engine over with its ribbed drive belt. When the engine is running, spinning the small motor-generator armature generates electricity for all electrical systems in the vehicle.

Connect your jumper cables from a good 12-volt battery to the dead battery. Connect the jumpers normally—positive-to-positive and negative-to-ground. Make the last jumper cable connection away from the dead battery.

Tech Tip

If a hybrid has a 12-volt battery, the cell plates might not be designed to handle the high current draw (100 amps or more) pulled by a conventional starting motor. Many hybrid gel and absorbed glass mat 12-volt batteries are designed to power only low-load circuits (instrumentation, lights, stereo, and ECMs) and are not powerful enough to operate the motor-generator as an engine starting motor.

Some hybrid designs have a rectifier and step-down transformer circuits built into the HV power control module. The two sets of windings of a large step-down transformer reduce HV battery voltage to a smooth 12–15 volts dc. A smaller gauge wire from the HV power control module feeds the low voltage to the vehicle's fuse panel. The fuses and circuit breakers then feed 12–15 volts dc to all conventional electrical circuits in the vehicle.

Warning

Never connect two HV batteries together with battery jumper cables. If one HV battery is totally discharged, a powerful electric arc can jump between the cable ends when connected. Thousands of amps can try to flow into the dead HV battery, making a loud pop. The resulting electric arc can instantly burn and destroy the metal ends of the HV power cables. You could be temporarily blinded by the bright light and burned by the molten metal shooting from the cable ends. If an HV battery is fully discharged, it must be recharged with an automatic HV battery charging machine or a recharging station.

Copyright Goodheart-Willcox Co., Inc.

Checking HV Battery Condition

Use the vehicle's dash display and/or a scan tool to observe the vehicle's HV battery readings. See **Figure 29-21**.Hybrid drive trains have an HV battery control module with extensive, built-in, high- and low-voltage monitoring capabilities. Some hybrids have a separate HV battery control module, while others have it built into the HV power control module.

To check general HV battery performance, connect a scan tool to the diagnostic connector on the vehicle and test drive the hybrid. Watch the combination meter in the dash display as you accelerate and brake. Also, use regenerative braking to try to recharge the HV battery. The live readings on your scan tool should be the same as those shown in the dash display.

The ***HV battery control module*** will usually monitor battery pack temperatures, current input and output levels, recharge and discharge voltages, and battery state-of-charge. The vehicle's hybrid control module will convert these values into a percent of charge for the driver, technician, and scan tool data readings. Either the hybrid dash display or an advanced scan tool and the HV battery control module will let you determine the condition of the HV battery.

HV battery state-of-charge should be at least 80% of maximum voltage rating after a full recharge (300-volt batteries would show about 240 volts dc). The hybrid control module or the HV battery control module uses the HV power control module to make the engine and motor-generator recharge the HV battery whenever its state-of-charge goes below 20–30%.

Chrysler

Figure 29-21. Most hybrids will provide an in-dash display of the vehicle's electric drive conditions. This display shows battery level, or state-of-charge, in a graph form. Note the HV battery has 75% of its full charge.

You must refer to the vehicle specifications to determine HV battery voltage and state-of-charge after the vehicle has been driven in all-electric mode.

A bad HV battery will have a state-of-charge that is lower than specifications. If the HV battery state-of-charge drops below a preset level, the hybrid control module will start the internal combustion engine and motor-generator until the battery is almost fully charged.

Testing HV Battery Voltage

To properly test HV battery voltage, fully recharge the battery using a plug-in charger station or HV battery charger, **Figure 29-22**. Preferably, charge the HV on slow charge (or low amps) setting for at least eight hours.

Honda

Figure 29-22. Proper charging will take from 8 to 12 hours, and will allow the vehicle to operate in all-electric mode for up to 50 miles before the gas engine has to take over.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

Never use a conventional digital or analog test instrument to measure the voltages and current levels in a high-voltage electric power train. The high voltage will instantly "arc and spark" inside the instrument, shorting out and badly burning internal meter circuits. Use only a high-voltage VOM with an insulation rating of 1000 volts or more when testing hybrid drive circuits.

To measure HV battery voltage, connect a high-voltage voltmeter across the two HV battery cables. Look at **Figure 29-23**. Compare your meter reading to the known acceptable voltages of a fully-charged HV battery and to the dash display.

A fully-charged HV battery should show voltage levels to within 60–75% of specifications. For instance, if your meter reads 150 volts dc across the terminals of a fully charged battery rated at 288 volts dc, the battery has lost some of its power. The low voltage reading would indicate that some of the battery packs in the HV battery have failed or that there is a problem in the charging system.

If a plug-in hybrid originally had an all-electric driving range of 50 miles, a weak HV battery might only be able to propel the car for 25 miles before the gas engine starts to assist the HV battery.

Charging an HV Battery

A hybrid battery charger uses a step-up transformer to force high voltage back into the HV battery to re-energize all of its cells. Follow the battery charger's and vehicle manufacturer's instructions for safely connecting the charger cables to the HV battery. Procedures vary by hybrid vehicle make and model.

Service Procedure

To charge a hybrid HV battery:

1. Set up a buffer zone around the vehicle by moving all carts, tools, and equipment away from the car body.
2. Plug in the hybrid battery charger. The charger will require either 120 volts ac or 240 volts ac. Refer to the charger's manual for the correct voltage.
3. Connect the hybrid charger leads to the hybrid vehicle. See **Figure 29-24**. A charging connector is usually provided on late-model hybrids so you can easily plug in the hybrid battery charger.
4. Set the battery charging rate and turn the charger on. Charge the HV battery overnight, if possible.

If voltage has not increased to within minimum levels, the battery has failed and should be replaced.

HV Battery Load Test Drive

An HV battery load test drive measures current and voltage levels into and out of the large battery pack while driving or during simulated driving. An HV battery can be load-tested during a vehicle test drive or by placing the car on jack stands with the drive wheels and tires off the ground.

Warning

Never attempt to use a conventional battery load tester to check an HV battery. The load-carrying capability of a conventional 12-volt load tester is insufficient. The kilowatts of power of an HV battery will burn the carbon pile in the tester.

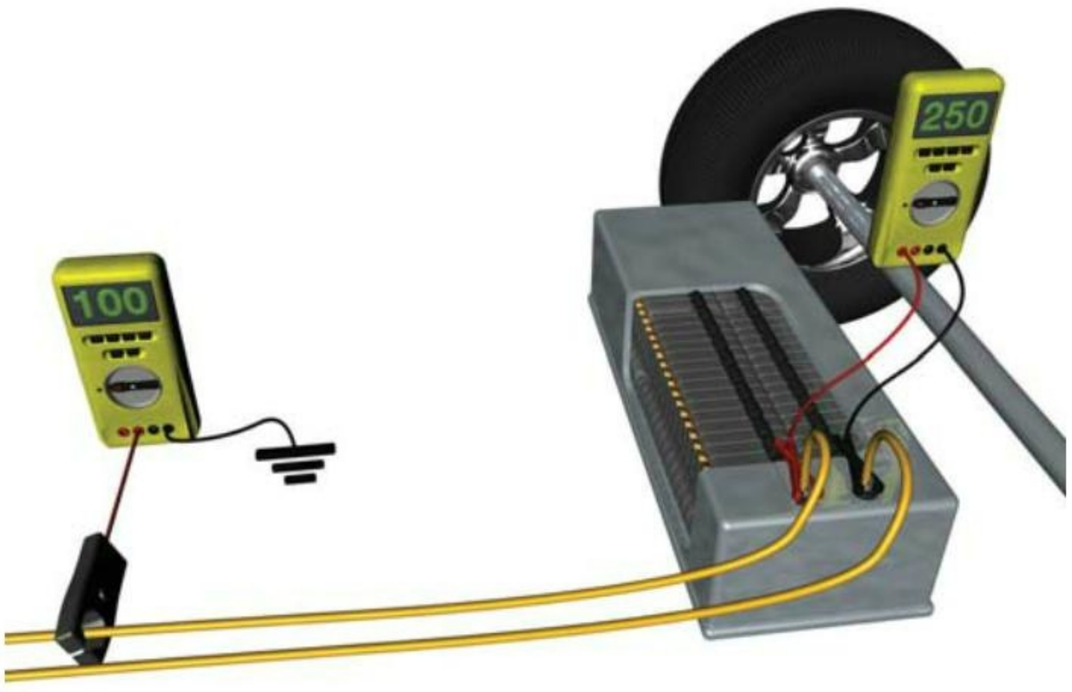

Figure 29-23. If the dash OBD system indicates an improperly charged HV battery, measure battery voltage with a high-voltage meter. If the battery is supposed to have 288 volts and it shows only 250 volts, you can calculate its percent of charge (87%).

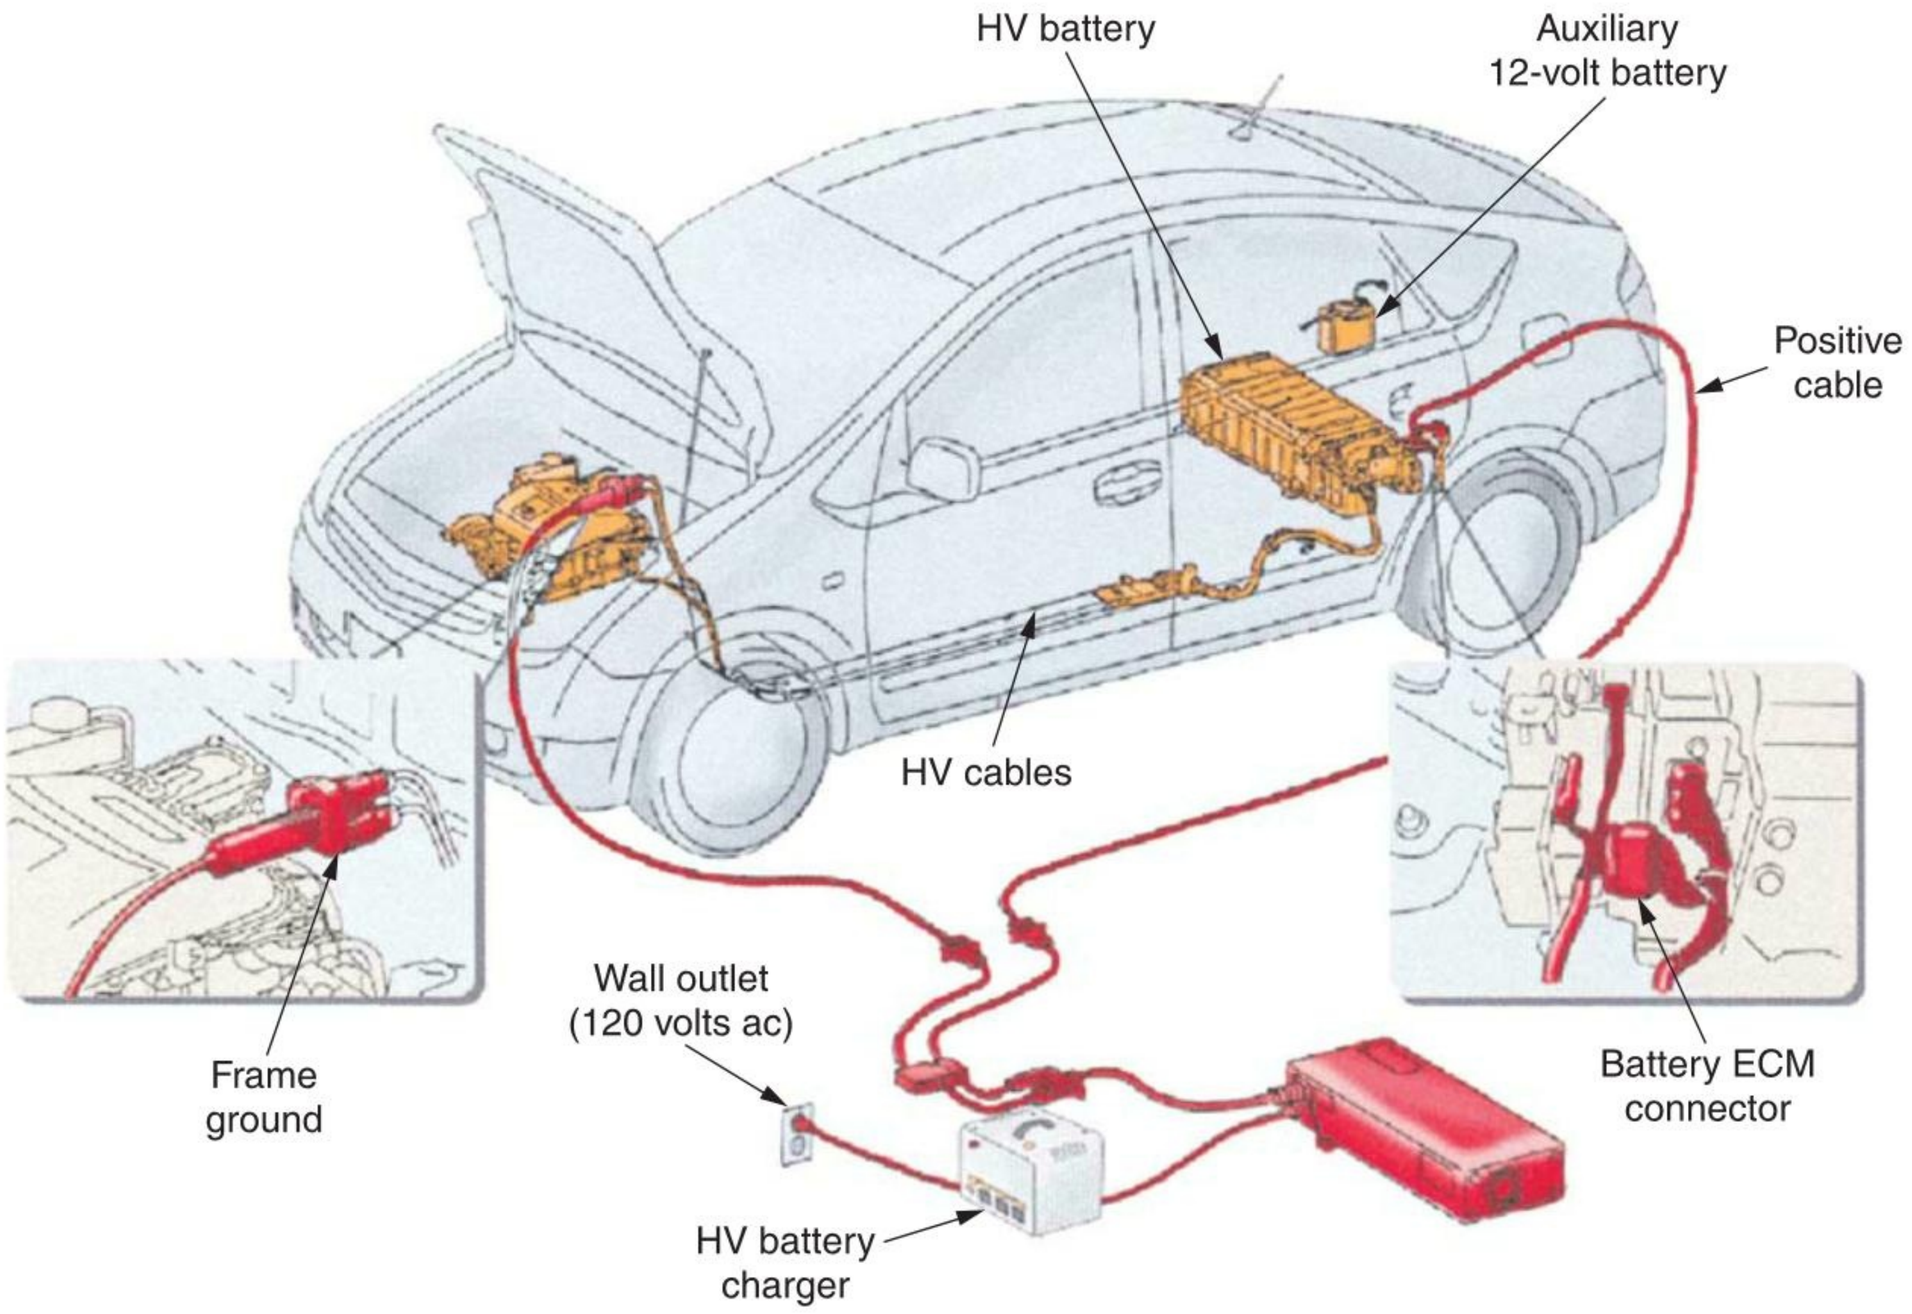
Copyright Goodheart-Willcox Co., Inc.



Toyota

Figure 29-24. A high-voltage battery charger is connected to ground and to the battery pack positive at special service connectors.

Service Procedure

To perform a battery load test drive:

1. Fully recharge the HV battery with an external battery charger, or plug the battery into an HV charging station.
2. Connect your laptop or scan tool to the vehicle's diagnostic connector.
3. Adjust your diagnostic tool to take live readings of the HV battery.
4. Test drive the vehicle while recording live data on the laptop or advanced scan tool.

If the battery load test drive indicates poor battery capacity, the entire HV battery must generally be replaced. HV batteries are usually sent to a specialty shop for refurbishing.

In-Shop HV Battery Load Test

If you need to load test the HV battery in the shop, secure the vehicle on jack stands so the drive tires are several inches off the ground. Place your jack stands under the control arms to prevent drive axle damage. This positioning will let the HV battery and traction motor spin the CV axles and wheels without binding and resulting in CV joint noise. Place blocks or chocks under the nondriving tires that are still on the ground so the vehicle cannot move.

Service Procedure

To perform an in-shop HV battery load test:

1. Make sure the HV battery is fully recharged.
2. Connect an inductive ammeter around the positive battery cable.
3. Attach the voltmeter leads to the HV battery as shown in **Figure 29-25**.
4. Press the electric drive train *Start* button and put the transmission in *Drive*.
5. Press the accelerator pedal gently to slowly spin the drive wheels. This normally makes the HV battery send high current to the motor-generator for full-electric propulsion.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

You may need to have a co-worker activate the electric drive train while you observe meter readings.

6. If possible, keep the vehicle in full-electric mode to increase current draw on the motor-generator and pull more current from the HV battery.
7. Compare the battery performance (live scan tool or voltmeter and ammeter readings) to that of a known good battery or to specifications.

Normal battery voltage but low current might point to HV control module or a motor-generator problem. Low voltage and low current may indicate a bad HV battery.

HV Battery Removal and Replacement

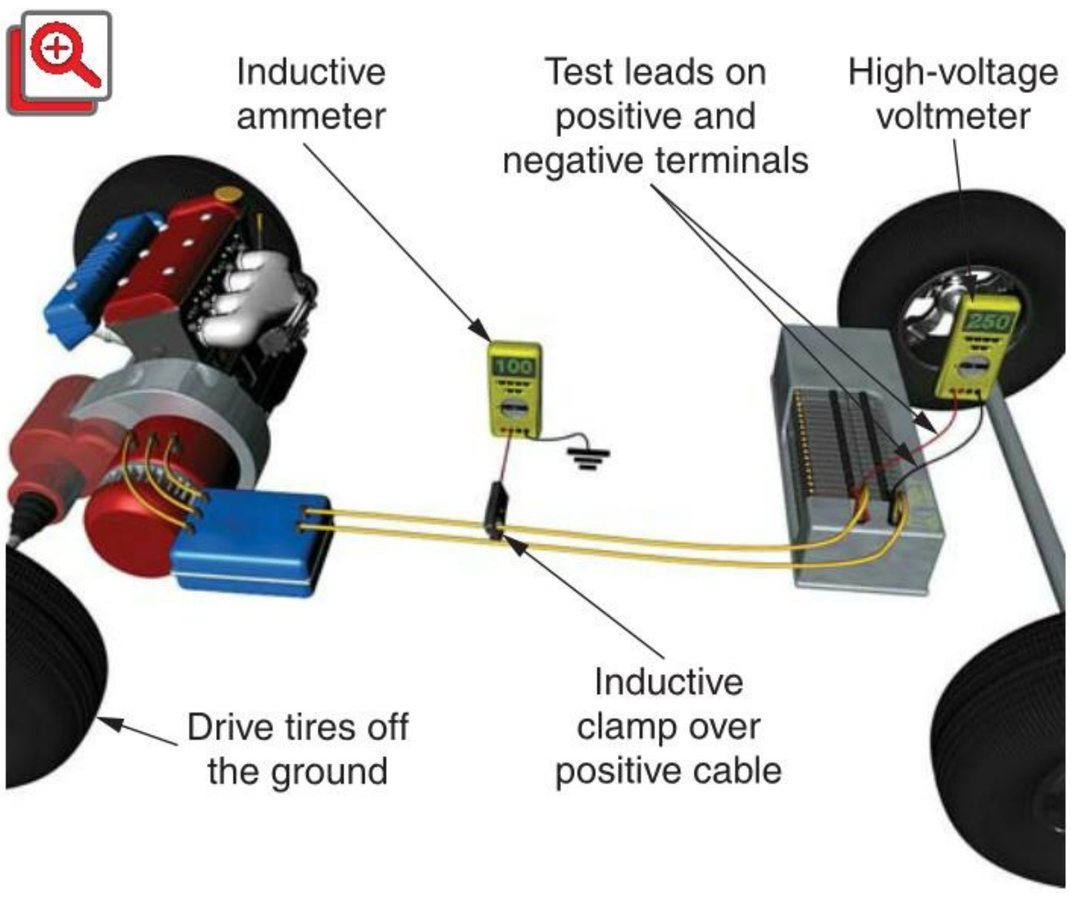
The most common reasons for HV battery replacement are age and physical damage. A severe collision can rupture the battery pack elements. This can penetrate the cell insulation, allowing cell plates to short out.

Before removing the battery, depower the electrical system according to the vehicle manufacturer's instructions. Normally, you must pull a safety disconnect plug or move a battery disconnect switch to disconnect the HV battery from its electrical system, **Figure 29-26**.

Refer to factory service information showing battery location, electrical connections, and mounting. HV batteries may be located in the trunk area, under a rear seat cushion, under the hood, or under the vehicle body. If the HV battery is mounted under the rear seat, remove the interior trim, seats, and carpeting over the top of the battery. If the battery is in the trunk, remove any carpet, spare tire, or cover over the HV battery. Look at **Figure 29-27**. If the battery is water cooled, remove a lower hose on the reservoir to drain the coolant out of the system.

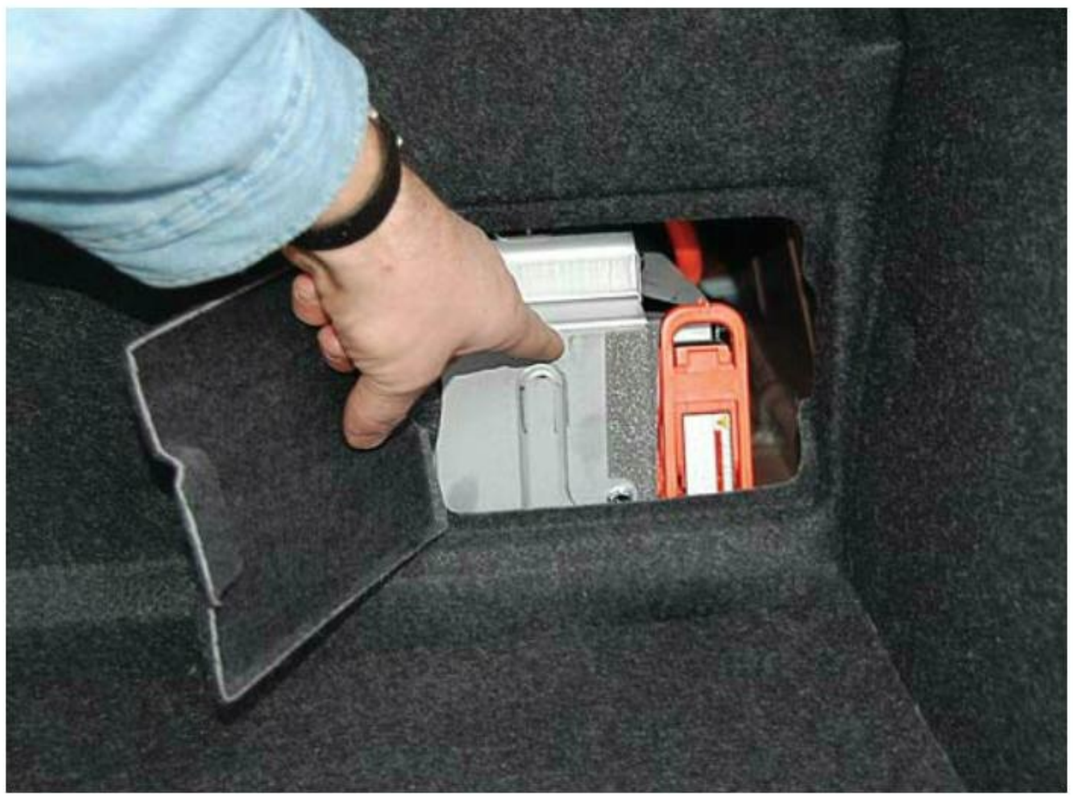
While wearing insulated rubber gloves and appropriate eye protection, remove the large fasteners or connectors that secure the HV power cables to the HV battery. To prevent a high-voltage short, wrap electrical tape around the metal terminals on the ends of the HV power cables. You do not want them to accidentally contact anything and conduct high-voltage electricity into anyone or anything.

Unbolt the HV battery hold-down flange from the vehicle frame. A mild hybrid battery assembly can weigh 100–300 lbs. (45–136 kg). An HV battery for a full-electric drive vehicle can weigh over 1000 lbs. (454 kg). If the battery is very heavy, use an engine crane and nylon straps to raise the large assembly up and out the vehicle. The battery should be handled carefully since it contains a tremendous amount of stored chemical-electrical energy.



Goodheart-Willcox Publisher

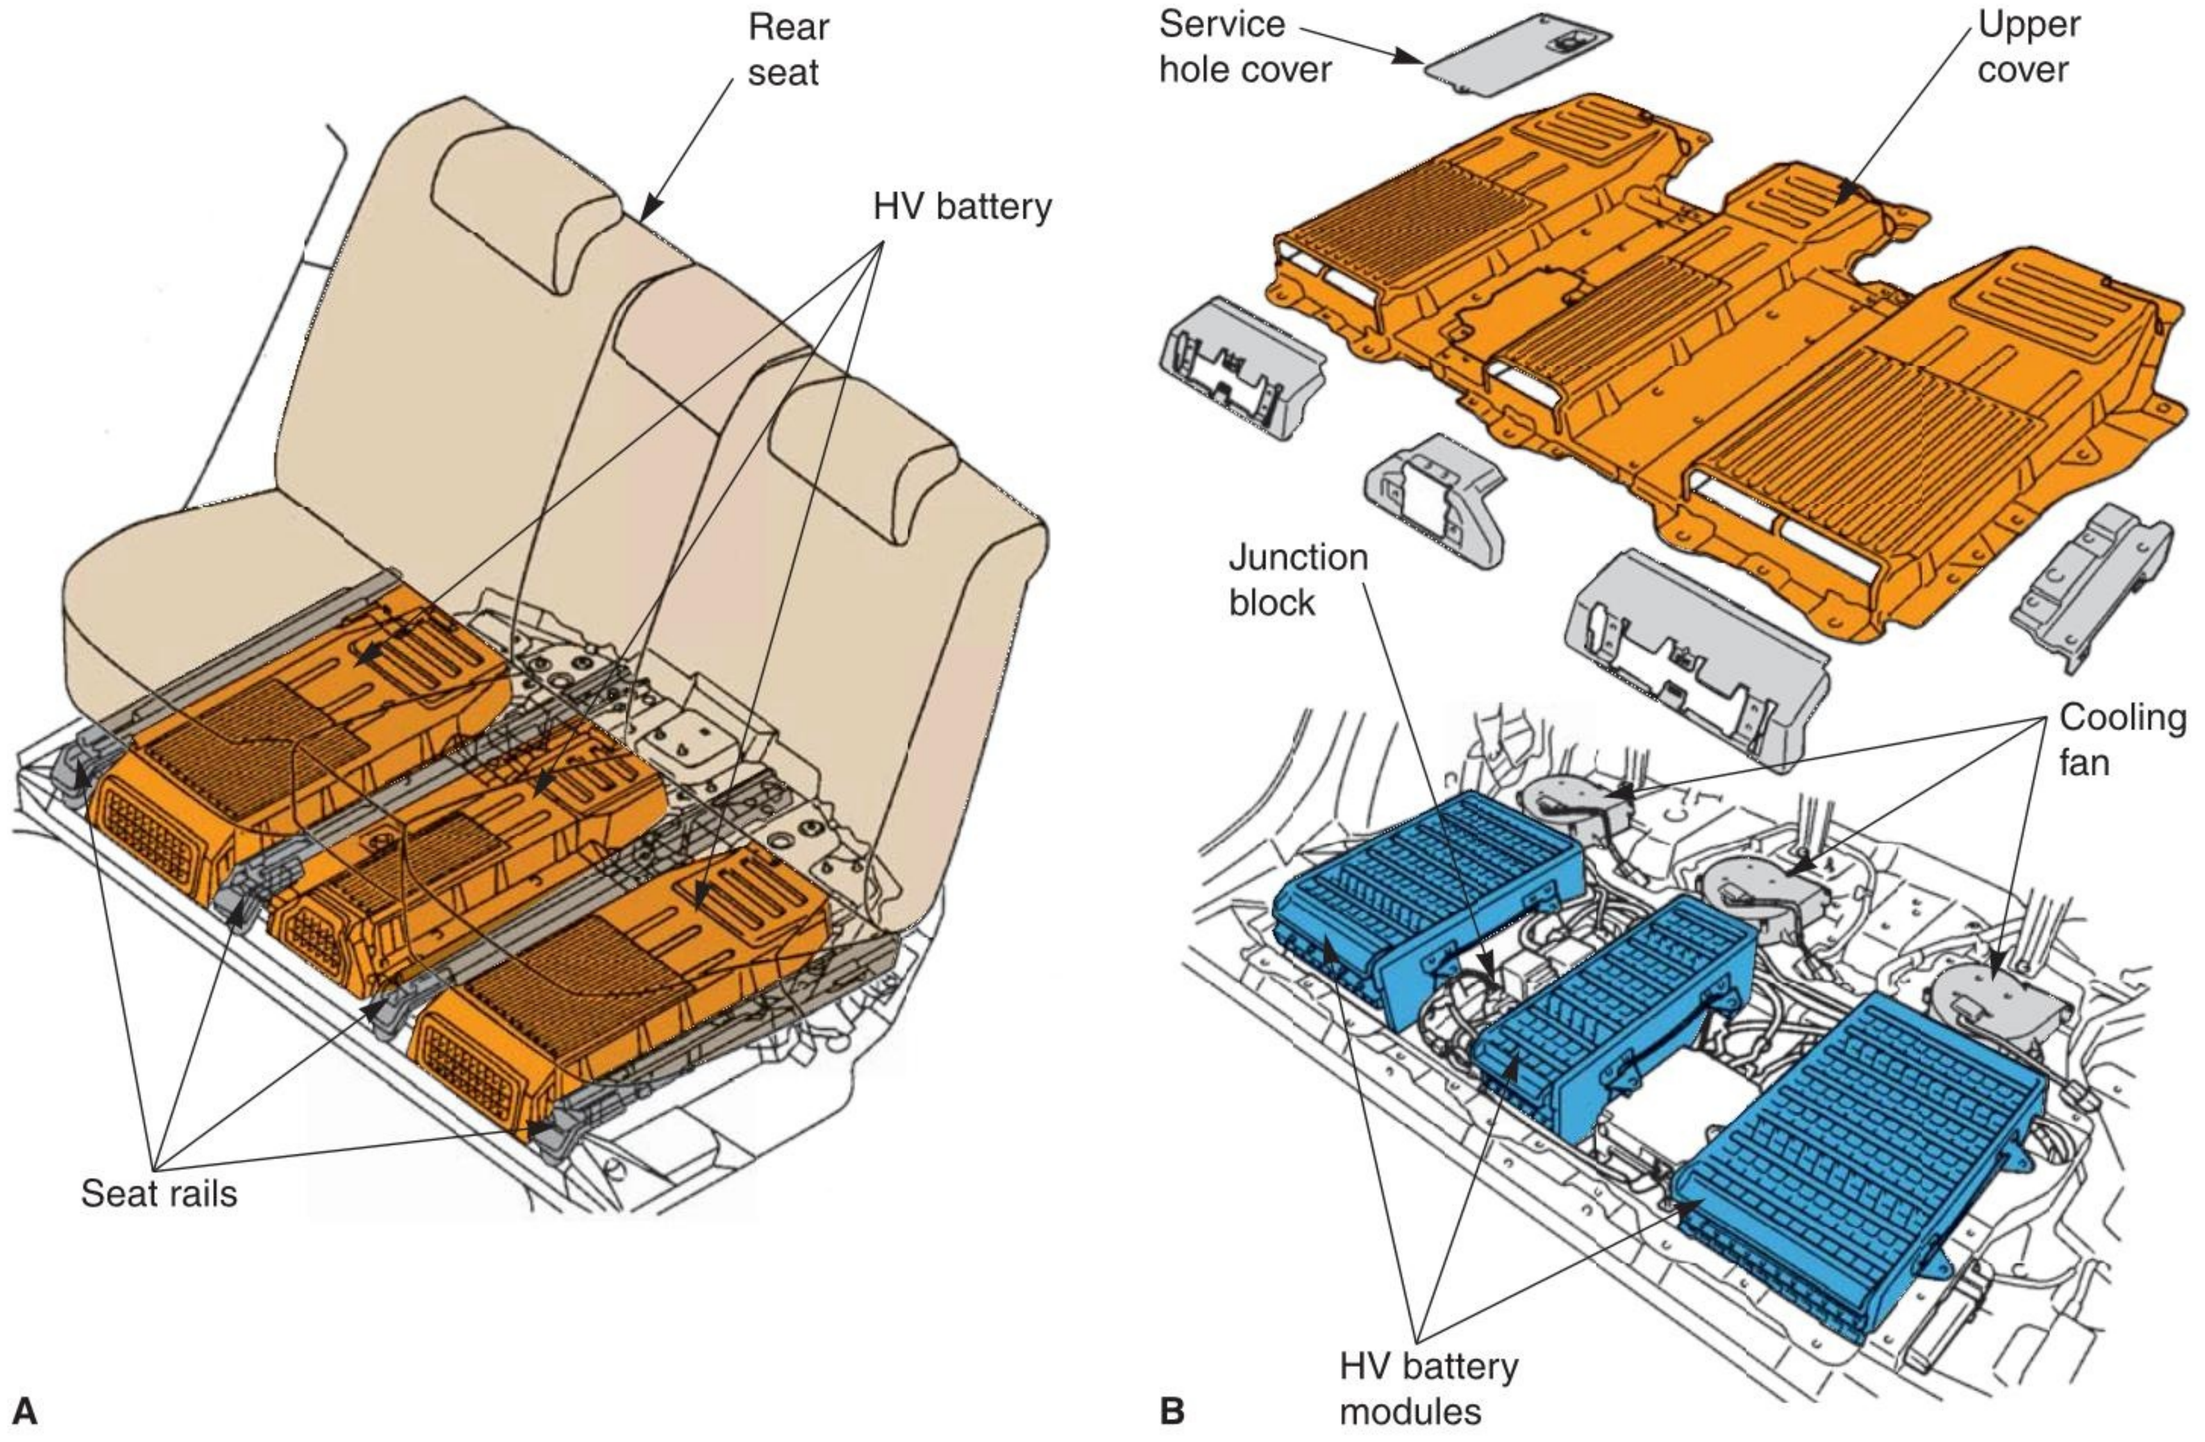
Figure 29-25. For an in-shop load test of an HV battery, connect an inductive ammeter around the positive battery cable and attach the voltmeter leads to the HV battery, as shown.



Goodheart-Willcox Publisher

Figure 29-26. The main battery disconnect can be under the seat, on the side of the HV battery, or in the trunk of the vehicle.

Copyright Goodheart-Willcox Co., Inc.



Toyota

Figure 29-27. These HV batteries are located under rear seat cushion. A—Remove the rear seat and trim panels to gain access to the batteries. B—Remove the cover over the batteries to access the batteries, HV battery control module, cooling fans, and other units that affect battery performance.

Warning

When removing the HV battery cover, never lay tools or test equipment on top of the battery packs. These items could easily touch a metal conductor and cause a small electrical explosion and total destruction of the tool or test instrument.

Some electric and gas-electric power trains have the HV battery located under the center console of the vehicle. The battery fits into the center hump under the floor pan and bolts to the metal frame. Locating the heavy battery in this position lowers the vehicle's center of gravity. It also isolates battery heat and any hydrogen gas outside the passenger compartment for driver and occupant safety.

Service Procedure

To remove an HV battery that is mounted under the floor pan:

1. Raise the vehicle on a two- or four-post lift. A single-post lift will not let you access the battery.
2. Unfasten and disconnect any wires, hoses, or ducts that prevent battery removal.
3. Place a transmission jack or an HV battery jack under the HV battery.
4. Position the lifting arms on the jack so they balance and support the weight of the unit.
5. Remove the bolts or nuts that secure the heavy battery to the unibody structure.
6. Two workers are needed to slowly lower the HV battery to the ground.

Copyright Goodheart-Willcox Co., Inc.

If you accidentally drop an HV battery, especially a lithium-ion battery, it can rupture several of the lithium cells and short them out. The damaged HV battery cells can start to smoke and hiss, as if catching fire. The smoke is acidic and should not be inhaled or make contact with your skin. Open the shop overhead doors and stay clear of the damaged HV battery for a few minutes until it stops smoking.

Warning

Never spray or pour water on a smoking modern lithium-ion battery pack. The exposed lithium acid and plates will pull hydrogen atoms out of the water in large quantities, resulting in the emission of pure hydrogen in a gas form. If enough hydrogen gas is ignited at once, a powerful explosion could result.

Place the HV battery assembly on a wooden pallet for shipment to an authorized recycler. Wrap electrical tape over the battery cables or connectors. Cover the battery with a thick plastic box and place it in a shipping container. Place warning labels on the outside of the battery module or shipping container to warn others of the high voltage and chemical dangers inside.

To replace an HV battery, use the same procedures used during removal. Make sure the battery is secured to the lift and will not fall. Only raise the HV battery high enough to clear the car body. Also, make sure the battery terminals are covered and insulated so you cannot be shocked and killed.

Use a torque wrench to tighten any HV power cable fasteners to specifications, and make sure all electrical connectors are fully engaged and reconnected. Reinstall any air ducts that connect to the HV battery housing. If water cooled, refill the HV battery cooling system with antifreeze or a factory recommended coolant liquid.

Use your scan tool to erase any battery trouble codes, and recharge the battery by connecting an HV battery charger or connect the battery to a charging station. Test-drive the car to check for proper electric assist or full-electric propulsion, if available.

HV Cable Connections Service

Since HV power cables in the electric drive train system carry tremendous amounts of current, it is critical that all cables and their connections are in good condition. See **Figure 29-28**. A poor power cable connection with just a few extra ohms of resistance will greatly affect electric drive train performance. A bad connection can cause cable overheating, reduced current flow, lowered motor-generator torque, and overall reduced electrical efficiency.

Goodheart-Willcox Publisher

Figure 29-28. Inspect HV power cables for looseness, signs of overheating, rust, and corrosion.

To check for a poor HV battery connection, inspect all fasteners and terminals closely. If the power cable end bolts to the HV battery or motor-generator, try to wiggle each connection by hand (while wearing insulating gloves). All orange cable connections must be tight enough that you cannot move them by hand.

Check HV power cable ends closely for signs of overheating and corroding. A poor current connection will become extremely hot and tends to loosen cable ends even more during heating/cooling cycles.

If a power cable end is loose, rusted, or damaged, remove the cable. Clean off the cable end with a wire brush or stiff scuff pad. Coat the cable ends with dielectric grease to protect them from moisture and corrosion.

Use a torque wrench to tighten each HV cable fastener to specifications. If a power cable connection is loose, the cable can overheat. If you overtighten the cable connection, you can damage the threads on the HV battery, HV power control module, and motor-generator.

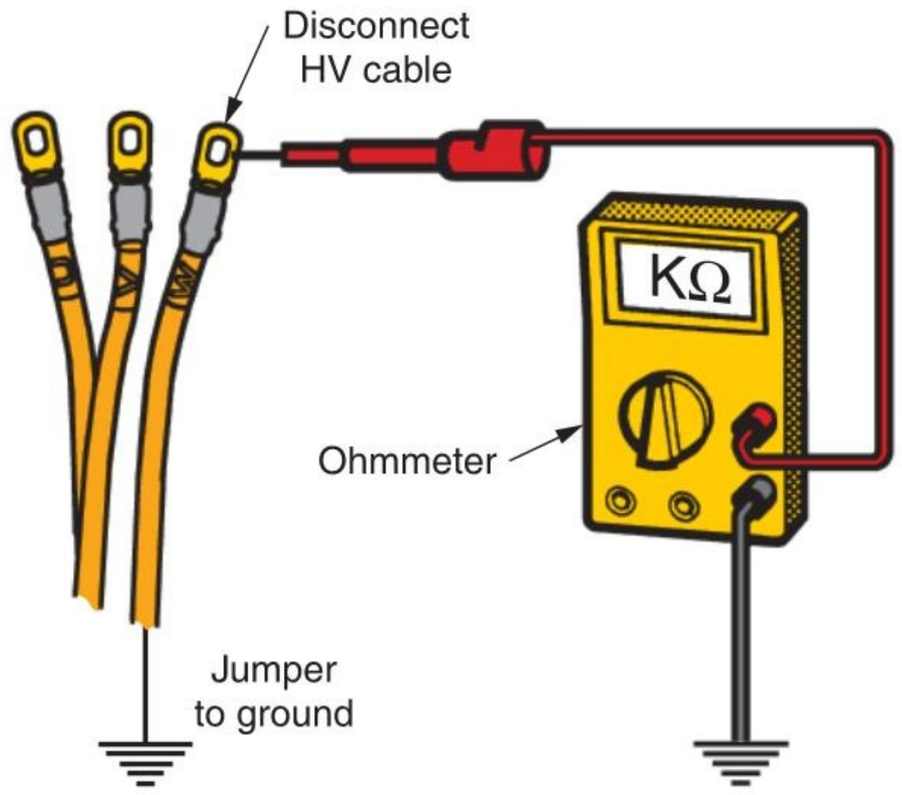
If the HV power cables use factory plastic connectors, use a small wire brush (known as a rifle brush) to clean inside the large round terminals. Remove any rust or corrosion that could affect the cable's electrical conduction. Coat both the male and female high-voltage terminals with dielectric grease to protect them and prevent corrosion.

If you suspect that an HV power cable is restricting current flow, measure its resistance with an ohmmeter. Connect one end of the power cable to ground and the other end of the power cable to your

Copyright Goodheart-Willcox Co., Inc.

grounded ohmmeter. Refer to **Figure 29-29**. ***HV power cable resistance*** should be less than 0.001 ohm (1 milliohm) per 10 feet of cable. If the cable is only 5 feet long, the maximum resistance specification should be half, or 0.0005 ohm (0.5 milliohm). When measuring HV power cable resistance, add approximately 0.025 ohm per electrical connection.

To check for ***HV power cable leakage*** or bad orange insulation, disconnect the cable at both ends and measure its resistance to ground. With the ohmmeter grounded, touch the test lead on the metal end of the cable. If the HV power cable insulation is good, your meter should read infinite resistance. Any resistance reading indicates deteriorated cable insulation allowing unwanted current leakage to ground. If the HV power cable shows any electrical leakage, replace it and any others with poor insulation.

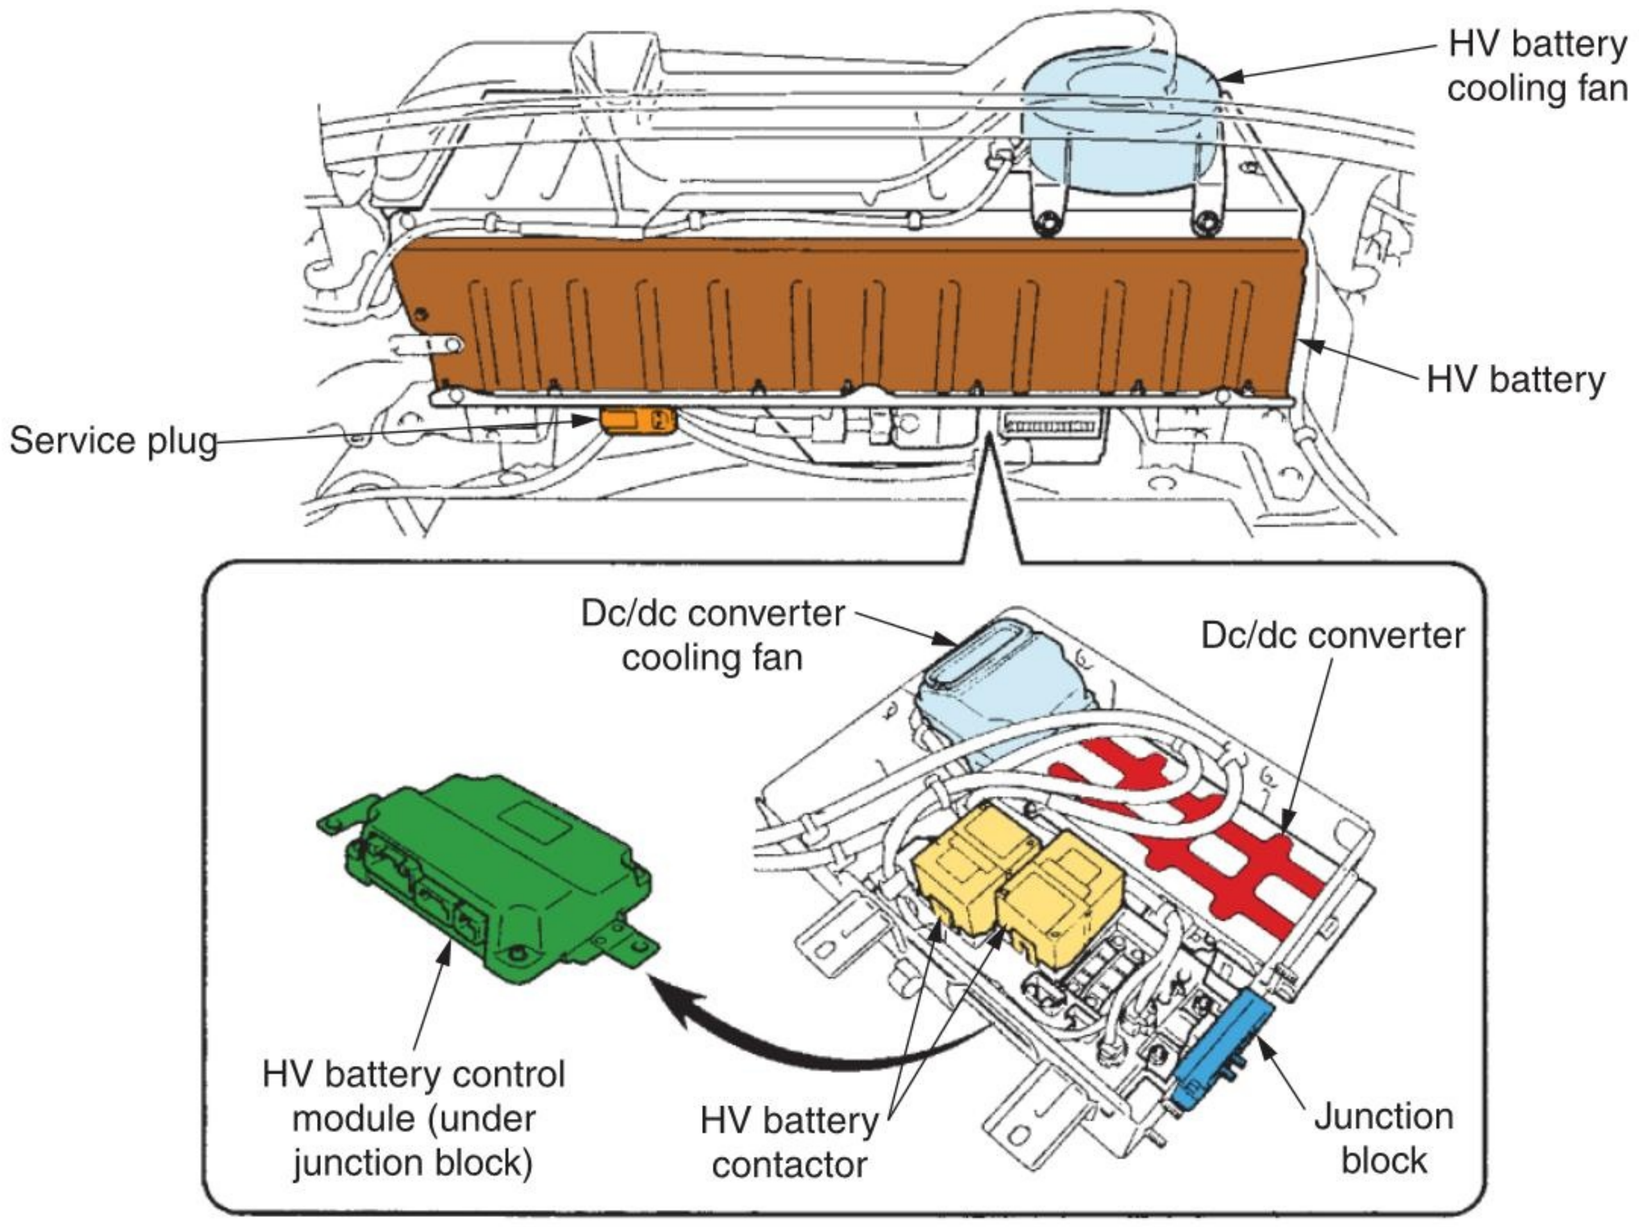


Goodheart-Willcox Publisher

Figure 29-29. Use an ohmmeter to check HV power cable resistance. Generally, a power cable should not have over about 0.001 ohm, or one milliohm, per ten feet of length.

HV Battery Control Module Service

A bad HV battery control module usually trips a trouble code. Your scan tool will flag any problem with this component and its wiring. Sometimes the HV battery control module is located inside the HV battery. It can also be mounted next to or away from the HV battery, depending on the vehicle make and model. See **Figure 29-30**.



Toyota

Figure 29-30. A bad HV battery control module can prevent normal charging. It is often mounted under, near, or inside the HV battery enclosure.

Diagnostic Case Study

Concern: Mr. Nagdamoor drives his 2011 Toyota Camry to the shop, complaining that his new battery keeps going dead and that he has to jump start the car every morning.

Mr. Nagdamoor explains to Duff that the vehicle's battery is less than three months old and that it seemed fine for several weeks. For the last few days, however, he had to jump start the vehicle after it sat overnight. The car generally starts fine after the initial jump start.

Cause: Since the battery is new and the problem occurs after the vehicle sits overnight, the symptoms seem to point to a battery drain, or parasitic loss, problem rather than a charging or starting system problem. Duff thinks an electrical component might be staying on after the vehicle is turned off, draining the battery.

Duff relays the information he gathered to the shop's electrical technician. The technician first turns off all the vehicle's electrical accessories and removes the lightbulb under the hood. He then connects an ammeter in series with one of the battery cables. The ammeter shows a 2-amp draw, confirming Duff's suspicion that something is draining the vehicle's battery. The technician pulls fuses to see which circuit is causing the current drain—the ammeter stops registering when the fuse to the circuit containing the drain is removed. The problem is narrowed down to the accessory lighting system. The technician begins removing bulbs from the accessory lighting circuit while watching the ammeter. He discovers that the current draw stops when the trunk bulb is removed and the trunk is closed. Further tests show that the switch in the trunk lighting circuit is shorted closed, supplying power to the trunk light even when the trunk is closed. This slowly drains the battery whenever the vehicle sits unused for an extended period.

Correction: After changing the trunk light switch, the technician again connects the ammeter to check for excessive current draw. Not finding any other problems, the technician charges the battery and performs a charging system output test. The charging system shows an output of 13.8 volts with all electrical accessories turned off. The technician returns the vehicle to Mr. Nagdamoor, assuring him that the problem has been corrected.

Summary

- 12-volt battery maintenance tasks should be performed regularly to ensure optimal service life.
- A battery leakage test will find out if current is discharging across the top of the battery case.
- A battery terminal test quickly checks for a poor electrical connection between the battery cables and terminals.
- Clean battery terminals and coat with a conductive, dielectric compound or white grease before reinstalling the battery cables.
- When measuring battery charge, you are checking the condition of the battery electrolyte and battery plates.
- A parasitic load is any electric circuit current draw present when the engine and all electrical devices are shut off.
- A battery charger forces current back through the battery to restore the charge on the cell plates.
- A battery load test actually measures the current and voltage output and overall performance of the battery cells.
- A fully charged battery should have an OCV (no-load, open circuit voltage) of 12.4 volts or higher.
- HV battery service life averages about 150,000 miles.
- Full hybrids or full-electric vehicles cannot be jumped and must be towed to a service facility if they have a dead or discharged HV battery.
- Use a scan tool and the combination meter in the dash display to evaluate HV battery condition.
- HV battery state-of-charge should be at least 80% of maximum voltage rating after a full recharge.
- An HV battery load test drive measures current and voltage levels into and out of the large battery pack while driving or during simulated driving.
- The most common reasons for HV battery replacement are age and physical damage.
- When removing an HV battery, refer to factory service information showing battery location, electrical connections, and mounting.
- A poor HV power cable connection can cause cable overheating, reduced current flow, lowered motor-generator torque, and overall reduced electrical efficiency.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

battery carrier
battery charger
battery drain test
battery leakage test
battery load test
battery service life
battery strap
battery terminal test
battery voltage test
boost charger
cell voltage test
dead battery
distilled water
dry-charged battery
fast charger
HV battery control module
HV power cable leakage
HV power cable resistance
hydrometer
hydrometer reading
jump start
load conversion chart
parasitic load
quick charger
slow charger
state-of-charge
trickle charger
undersize battery
wet-charged battery

Activities

1. Get permission from several classmates to conduct a 12-volt battery maintenance inspection on their vehicles. Check for the points listed in the *12-Volt Battery Maintenance* section of this chapter. Create and complete a simple checklist or write a short report for each vehicle inspected. Give the form or report to the vehicle owner.
2. Select any make and model hybrid vehicle. Look up the operating specifications in the service literature for the vehicle. While wearing insulated gloves, but without touching the power cables, trace the path of the two dc orange cables from the battery pack to the power control module. Then, trace the three ac cables from the power module to the motor-generator. Make a top view sketch of component placement and hybrid power cable routing.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List the five tasks typically involved in 12-volt battery maintenance.
2. A(n) _____ test will determine whether current is discharging across the top of the 12-volt battery case.
3. If a voltmeter shows a 0.8 volt drop across the 12-volt battery post-to-cable connection during a battery terminal test, what should be done?
4. A knife or scraper is a good tool for cleaning corroded 12-volt battery terminals. True or False?
5. When measuring _____, you are checking the condition of the 12-volt battery electrolyte and plates.
6. The voltmeter reading for a 12-volt battery under a light current load should be _____ volts.
7. List six possible causes for a discharged 12-volt battery.
8. A customer complains that her battery goes dead when the car is not driven for an extended period. A new battery has been installed and tested by another shop. Technician A says that starting motor current draw should be measured. A shorted starting motor could be draining the battery. Technician B says that a battery drain test should be done. An electrical short could be discharging the battery, even with the ignition key off. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. When using a 12-volt battery charger, connect the red lead to positive and the black lead to negative. True or False?
10. When fast charging a 12-volt battery, you should never exceed a charge rate of _____.
11. Explain how to safely connect jumper cables.
12. A(n) _____ test is one of the best methods of checking the condition of a 12-volt battery.
13. Explain how to load test a 12-volt battery.
14. If a 12-volt battery shows less than _____ volts during a load test at 70°F (21°C), the battery is bad.
    (A) 9.9 volts.
    (B) 9.5 volts.
    (C) 9.7 volts.
    (D) 10.0 volts.

Copyright Goodheart-Willcox Co., Inc.

15. HV battery service life averages about _____ miles.
16. Explain how to check the condition of an HV battery.
17. A mild hybrid battery assembly can weigh over 1000 lbs. True or False?
18. Identify three problems that can be caused by a bad HV power cable connection.

ASE-Type Questions

1. 12-volt battery maintenance and inspection should be conducted:
   (A) during tune-ups.
   (B) during grease jobs.
   (C) any time symptoms point to battery problems.
   (D) All of the above.
2. Which of the following will neutralize and remove an acid-dirt mixture from a 12-volt battery case?
   (A) Sulfur and water.
   (B) Baking soda and water.
   (C) White grease and a solvent.
   (D) Distilled water and gasoline.
3. Each of the following can be performed using a voltmeter *except:*
   (A) battery plate test.
   (B) battery voltage test.
   (C) battery leakage test.
   (D) battery terminal test.
4. A discharged 12-volt battery can be caused by a(n):
   (A) defective battery.
   (B) starting system problem.
   (C) engine performance problem.
   (D) All of the above.
5. Charging time for this device with a 12-volt battery is about 12 hours.
   (A) Fast charger.
   (B) Slow charger.
   (C) Quick charger.
   (D) Boost charger.
6. Technician A feels the best test to determine 12-volt battery current output and performance is the battery load test. Technician B feels hydrometer testing is the best choice. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. A fully charged 12-volt battery should have an open circuit voltage of:
   (A) 5.5 volts.
   (B) 12.4 volts or higher.
   (C) 25.0 volts or higher.
   (D) None of the above.
8. Technician A says that a good hybrid HV battery should show a voltage reading of almost 100% of maximum charge. Technician B says that most hybrids only charge their battery packs to about 80% of maximum charge. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says that you should never put any kind of grease on HV power cable connections. Technician B says that dielectric grease prevents electrical corrosion and the resulting bad connections that can burn up cables and components. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says to use live readings from a scan tool or laptop computer to read HV battery voltage, current output while driving, battery temperature, and other readings to evaluate battery condition. Technician B says to use a conventional 12-volt battery load tester by connecting it to the HV power cables. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. Which of the following should *not* be done when servicing an HV battery?
    (A) Use a crane to lift the heavy battery.
    (B) Wrap electrical tape over the battery cables or connectors.
    (C) Pour water on smoldering lithium-ion electrolyte.
    (D) Wear rubber gloves and use insulated tools.

Chapter 30
Engine Starting Systems

After studying this chapter, you will be able to:

- Explain the principles of 12-volt dc and high-voltage ac electric motors.
- Describe the construction and operation of conventional 12-volt and high-voltage starting motors and circuits.
- Sketch a simple computer-controlled starting system circuit.
- Explain the operation and location of starting motor solenoids and HV contactors.
- List and describe the purpose of major starting circuit components.
- Compare different types of starting motor drive mechanisms.
- Describe starting system safety features, especially with high-voltage hybrid starting systems.
- Compare 12-volt engine starting circuits with HV starting circuits.
- Correctly answer ASE certification test questions that require a knowledge of both 12-volt and HV starting system fundamentals.

An ***engine starting system*** must crank or spin the engine until fuel combustion forces the pistons down and the engine begins to operate on its own power. When the driver turns the ignition key or presses the start button, electrical energy is sent to the starting circuit to energize the 12-volt starting motor mounted on the engine block. A small gear on the starting motor engages and rotates a large gear on the engine flywheel. This spins the engine crankshaft, pulls air into the cylinders, and operates the spark plugs to fire up the engine.

The starting system in today's hybrids and ECM-controlled starting circuits can also shut the engine off when it is not needed. This feature saves a tremendous amount of gasoline that is normally wasted when a car is sitting idle at stoplights or intersections.

The starting system has helped make the modern automobile a reliable and convenient means of transportation. It provides an effortless method of cranking and starting multi-cylinder engines. Few car owners would be physically capable of starting a multi-cylinder engine using a hand crank. The electric starting motor is designed to crank the engine with the simple turn of a key or press of a button.

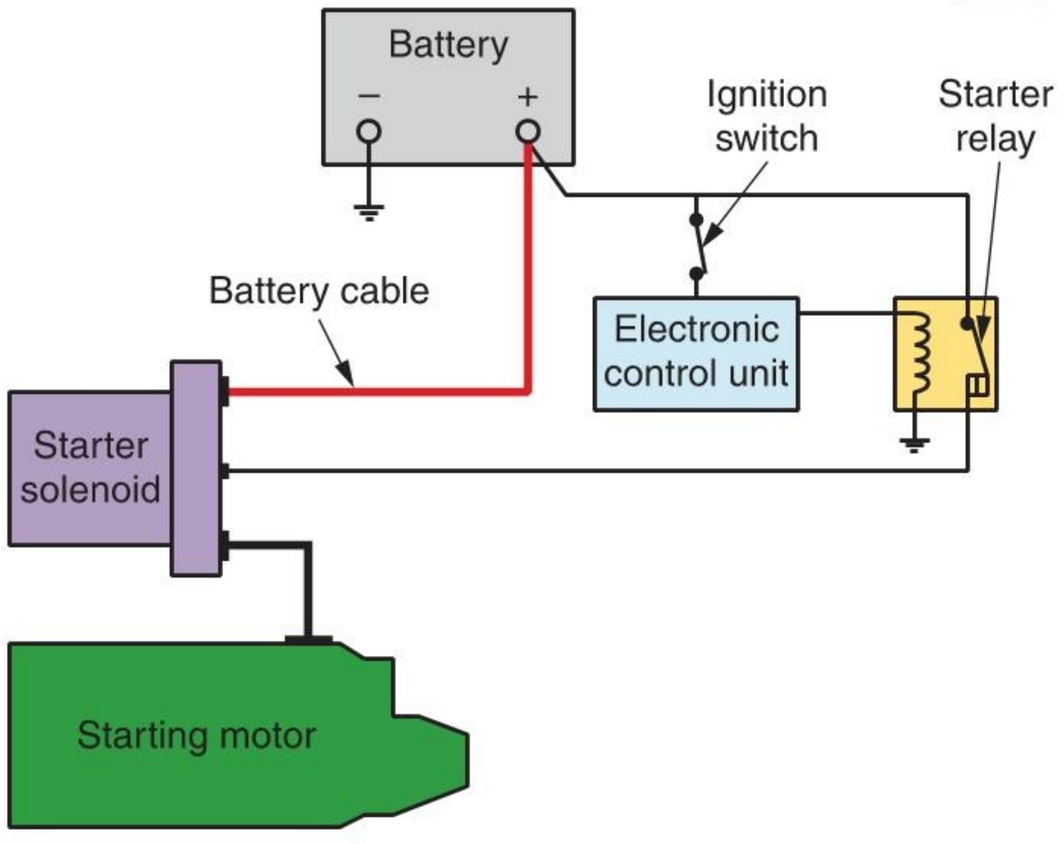
This chapter provides the information needed to understand how any starting system is supposed to function. You will learn about the operation of conventional 12-volt starting circuits before studying more complex hybrid high-voltage starting systems. You will also learn about electronic starter disengagement systems.

Copyright Goodheart-Willcox Co., Inc.

12-Volt Starting System Principles

The ***12-volt starting system*** uses battery power and an electric motor to turn the engine crankshaft for engine operation. The main parts of a starting system include:

- Battery—The ***battery*** is a source of electrical energy for the starting circuit.
- Ignition switch—The ***ignition switch***, or ***start switch***, allows the driver to control starting system operation.
- Starter solenoid—The ***starter solenoid*** is a high-current contactor for connecting the battery to the starting motor.
- Starter relay—The ***starter relay*** is a low-current relay that operates the starter solenoid.
- Starting motor—The ***starting motor*** is a high-torque electric motor for turning the gears at the engine flywheel.
- Engine control module—The ***engine control module (ECM)*** reacts to the voltage of the starter button or ignition key to energize the starter relay. See **Figure 30-1**.



Goodheart-Willcox Publisher

Figure 30-1. Note the basic starting system operation. The start switch energizes the engine ECM. If conditions are correct for sensors and switches, the ECM will energize the starter relay and solenoid. The solenoid then energizes the starting motor. The motor turns the flywheel gear for engine starting.

Starting System Action

When you turn the ignition key or press the start button, current flows through the ECM and starter relay. This closes the relay and solenoid contacts, connecting the positive battery cable directly to the starting motor windings. The starter pinion gear is pushed into and meshes with the flywheel ring gear. The motor-driven pinion gear turns the flywheel and crankshaft until the engine starts, or fires, and runs on its own power.

On many cars, when the engine starts, you have to release the ignition key to disengage the 12-volt starting motor. The ignition switch then cuts power to the solenoid and starting motor. The starting motor stops spinning, and the pinion gear is pulled away from the flywheel gear.

Starting Motor Fundamentals

The starting motor converts electrical energy from the battery into mechanical energy to crank the engine. It is similar to other electric motors. All electric motors (wiper motors, fan motors, fuel pump motors, etc.) produce a turning force through the interaction of magnetic fields inside the motor assembly.

Simple Electric Motor

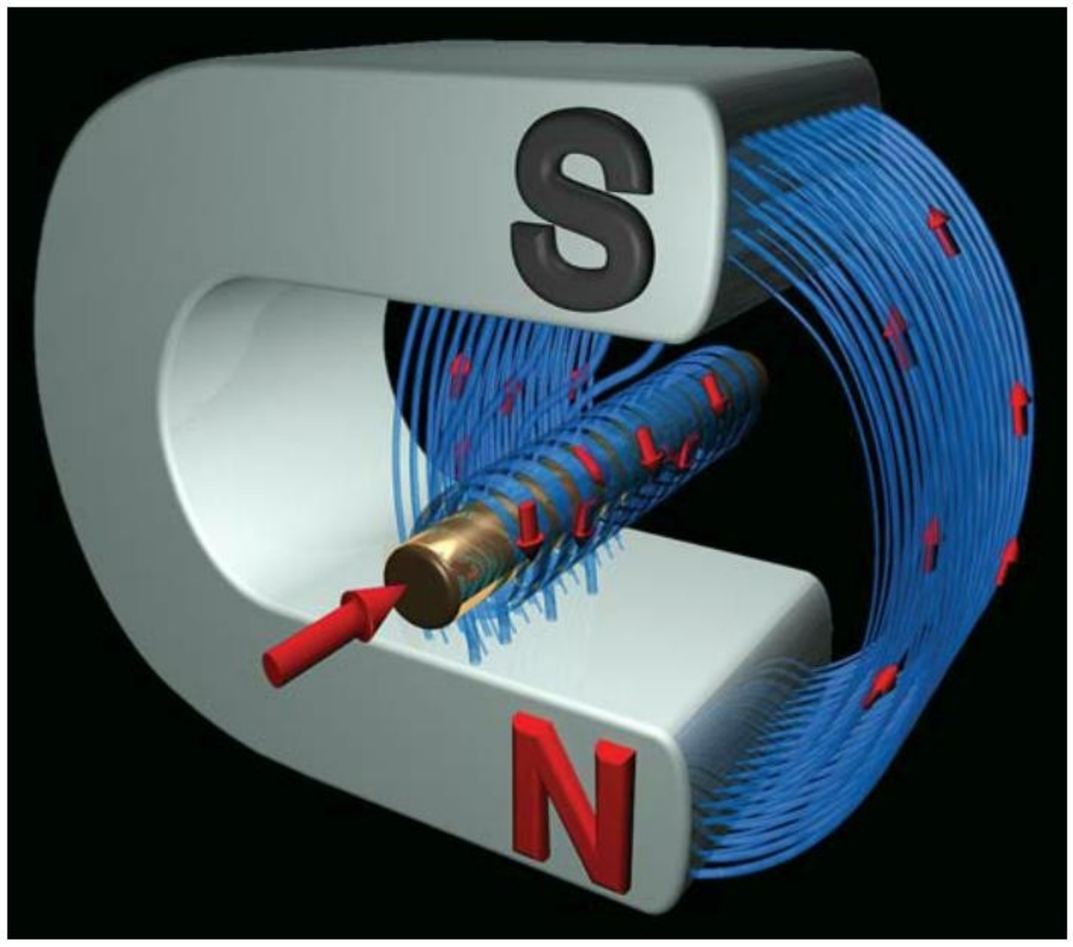
As explained in earlier text chapters, a ***magnetic field*** is made up of invisible magnetic lines of force. The lines of force flow between the poles of a permanent magnet. They also flow around the outside of a wire that is carrying current.

Since ***like charges*** (fields) repel each other and ***unlike charges*** attract each other, magnetic fields can be used to produce motion. Look at **Figure 30-2**. Note how the lines of force in the magnet and the lines of force around the conductor act upon each other. This principle is used in electric motors.

To build a simple electric motor, you would start by bending a piece of wire into a loop. When current is passed through the wire loop (winding), a magnetic field forms around the wire.

Pole shoes, or pole pieces, are needed to make the loop of wire move. A magnetic field is set up between the pole shoes.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 30-2. Magnetic fields from magnets and the fields around a current-carrying conductor can be used to produce motion. Note how the fields interact.

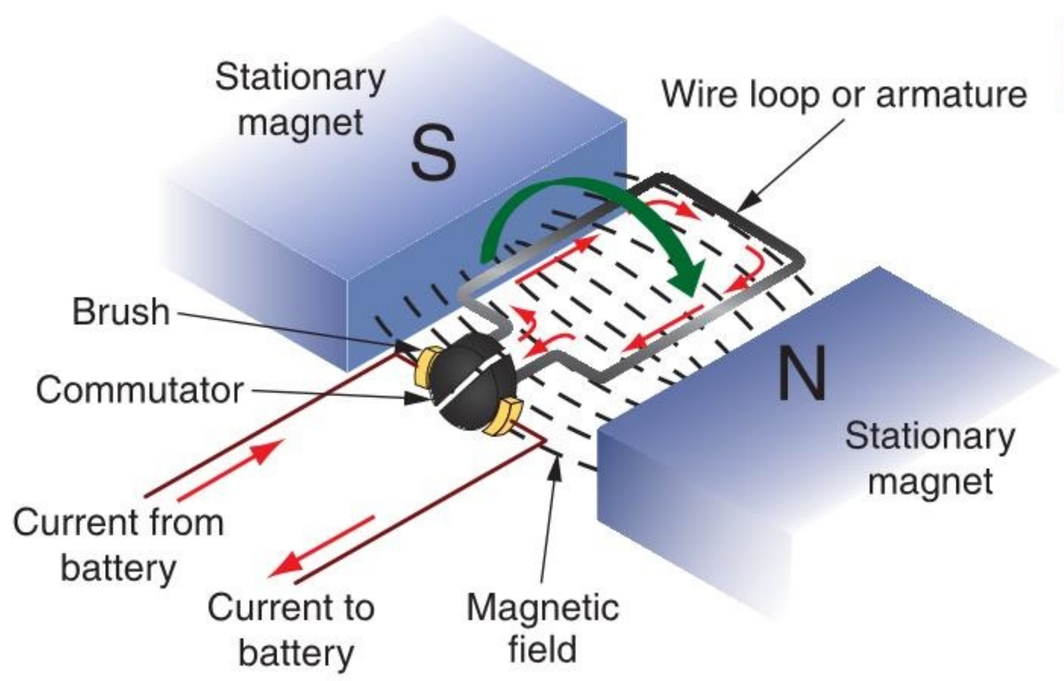
Changing Electricity into Motion

Electric current can be changed into a strong rotating motion by placing the winding between the pole shoes. When current passes through the winding, the magnetic field around the winding and the field between the pole shoes act on each other. This causes the winding to move toward a vertical position. A commutator and brushes are used to keep the electric motor spinning. The ***commutator*** serves as a sliding electrical connection between the armature winding and the brushes. It is divided into segments, which are insulated from each other. The ***brushes*** slide on the commutator to carry battery current to the spinning winding.

As the winding rotates away from the pole shoes, the commutator reverses the electrical connection between the brushes and the winding. This reverses the magnetic field around the winding. Then the winding is pulled around and passes the other pole shoe. The constantly changing electrical connection keeps the motor spinning. A push-pull action is set up as the winding moves around inside the pole shoes. See **Figure 30-3**.

Increasing Motor Power

Several windings (loops of wire) and a commutator with many segments are used to increase motor power and smoothness. Each winding is connected to its own segment on the commutator. This provides current flow through each winding as the brushes contact each segment. As the motor spins, many windings contribute to the motion. This produces a constant and smooth turning force. See **Figure 30-4**.

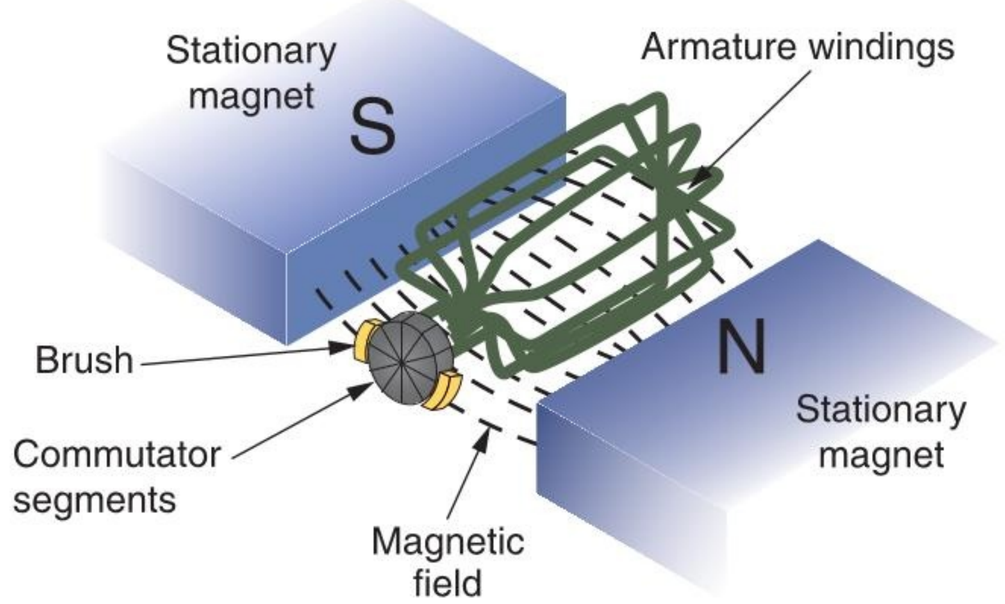


Goodheart-Willcox Publisher

Figure 30-3. A simple electric motor consists of a winding (loop of wire), located inside stationary pole shoes. The magnetic field around the winding and the magnetic field between the pole shoes act upon each other to make the winding rotate.

12-Volt Starting Motor Construction

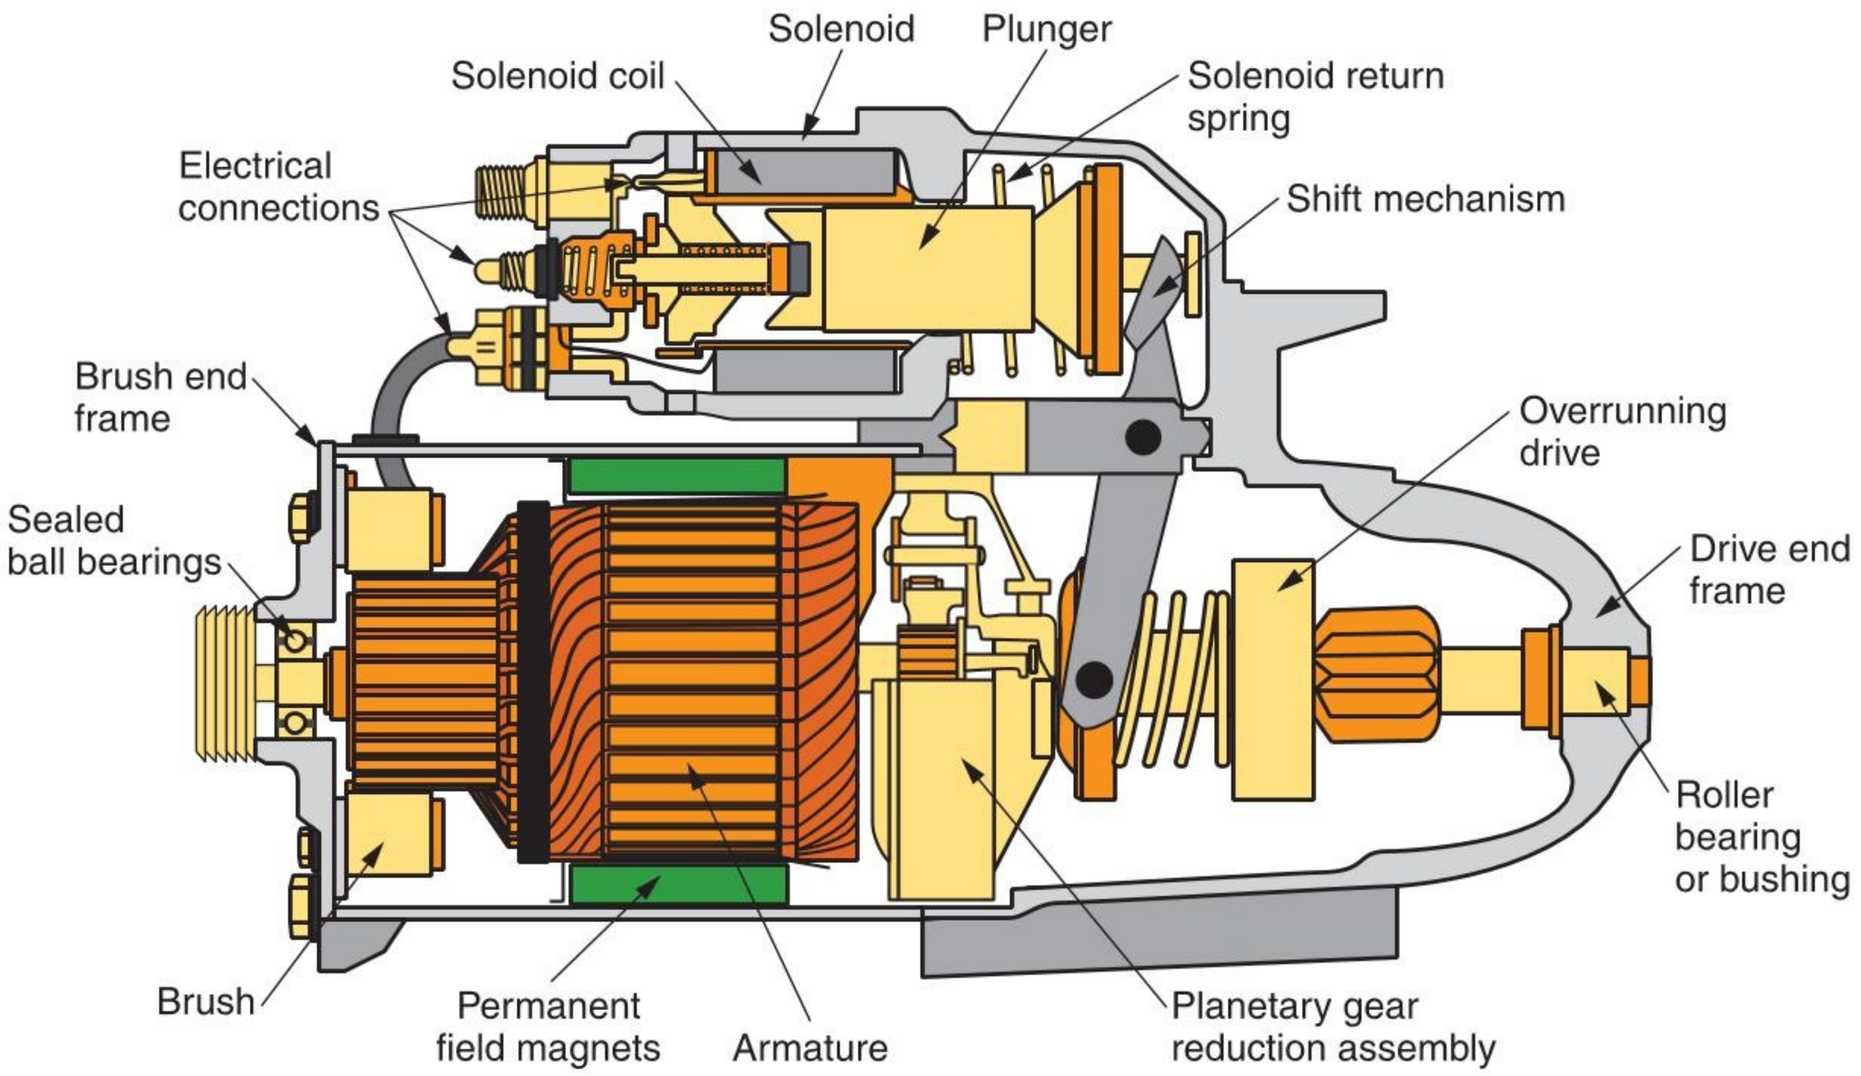
The construction of all 12-volt starting motors is very similar. There are slight variations in design, however. A typical starting motor is shown in **Figure 30-5**.



Goodheart-Willcox Publisher

Figure 30-4. A starting motor would not have enough power with only a single winding. Instead, many windings are used to increase power and smoothness. Note that each winding is connected to a separate commutator segment.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 30-5. Observe a cutaway of a typical starting motor. Note that this motor uses permanent magnets instead of field windings.

Refer to this figure as you study the main parts of a starting motor covered in the following sections.

Armature

A starting motor must produce very high torque (turning force) and relatively high speed. Therefore, a system to support the windings and increase the strength of each winding's magnetic field is needed.

A ***starter armature*** consists of the armature shaft, armature core, commutator, and armature windings. The ***armature motor shaft*** supports the armature as it spins inside the starter housing. The commutator is mounted on one end of the armature shaft. The ***armature core*** holds the windings in place. The armature core is made of iron to increase the strength of the magnetic field produced by the windings.

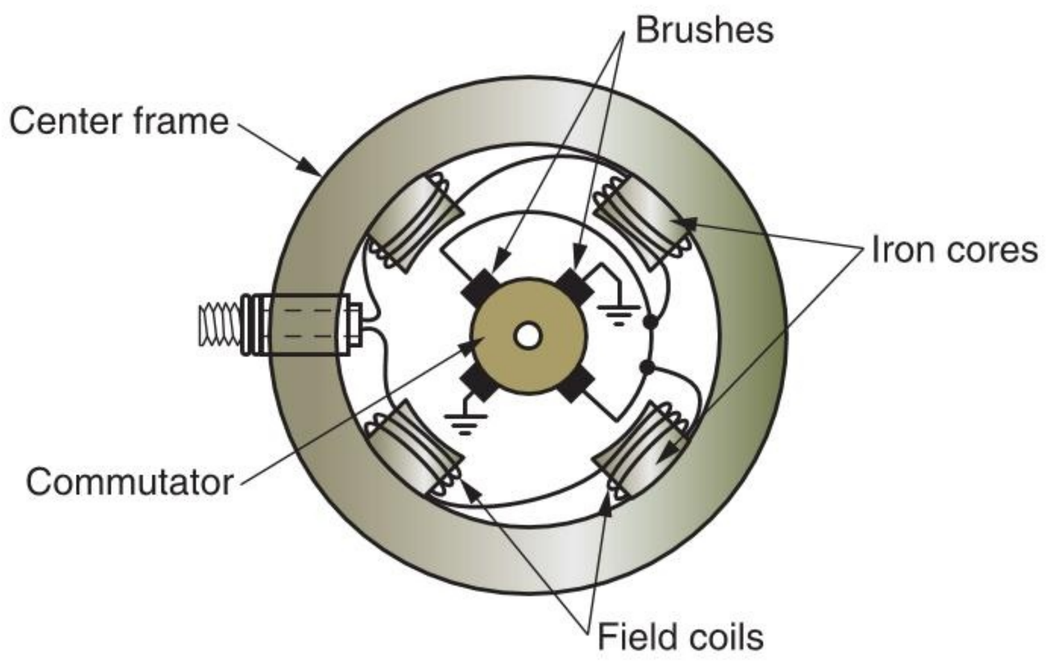
Field Windings

Field windings are stationary insulated wires wrapped in a circular shape around iron pole shoes located inside the starting motor housing, **Figure 30-6**.

When current flows through the field windings, the magnetic field between the pole shoes becomes very large. It can be 5–10 times that of a permanent magnet. As the magnetic field between the pole shoes acts against the field developed by the armature, the motor spins with extra power and torque.

Field Magnets

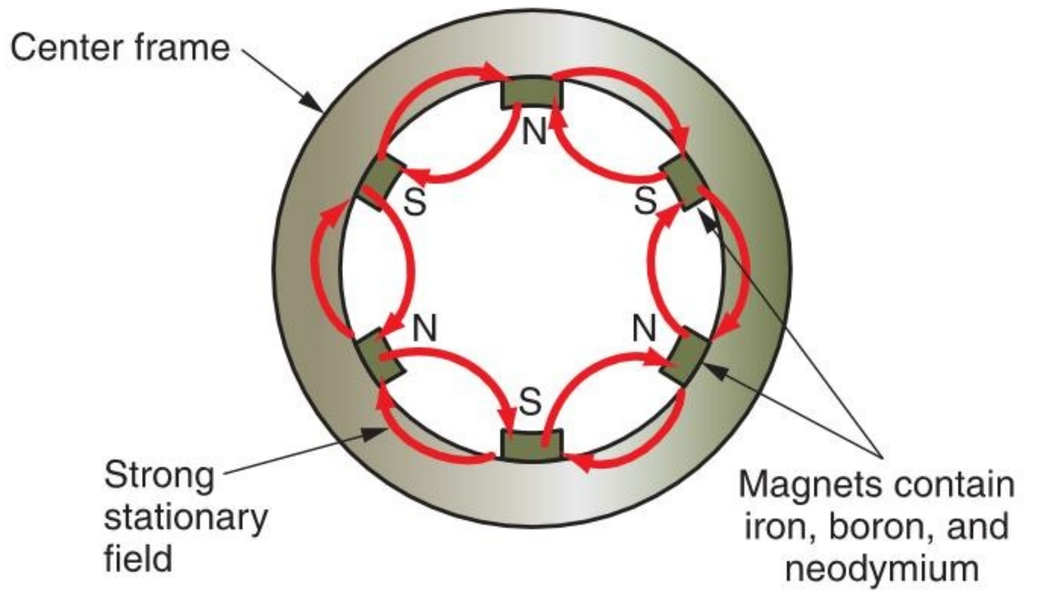
Some starting motors use special high-strength magnets instead of conventional field windings. The magnets produce a strong magnetic field capable of rotating the armature with enough torque to crank the engine. See **Figure 30-7**. Starting motors that use field magnets are referred to as ***permanent-magnet starters***.



Goodheart-Willcox Publisher

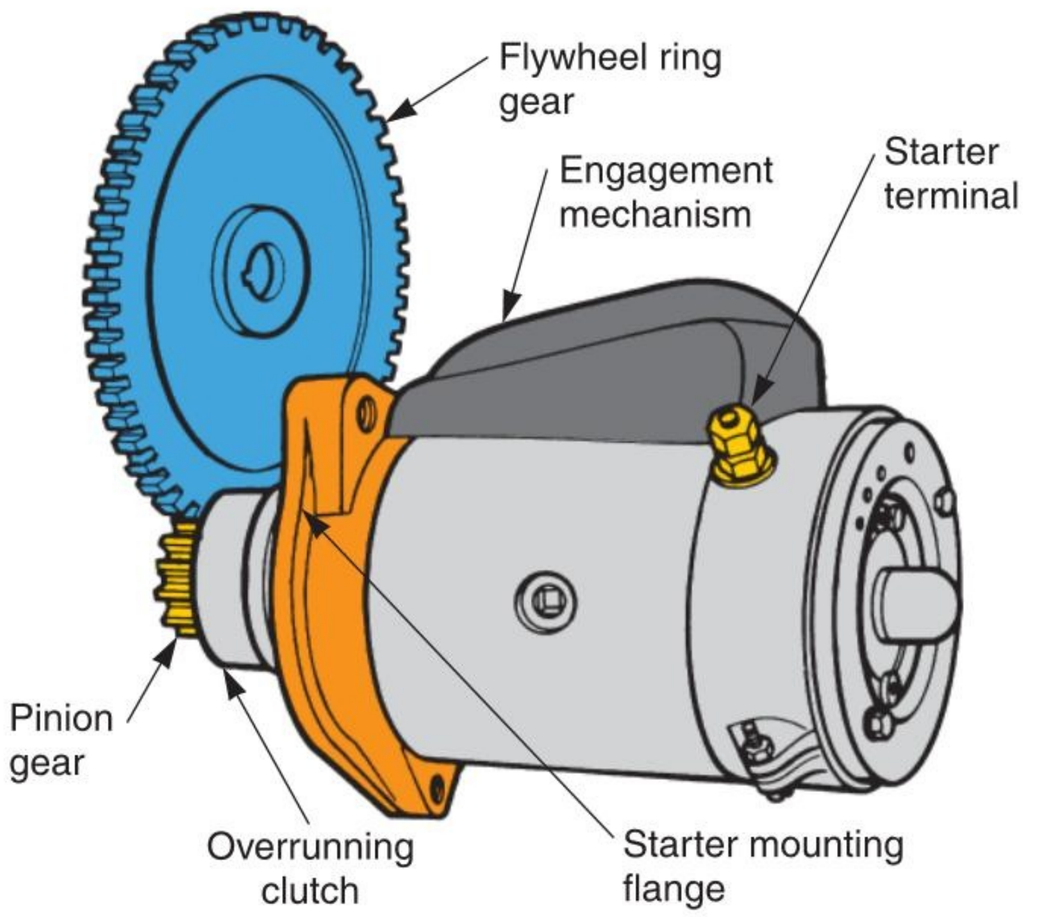
Figure 30-6. This starter uses field windings wrapped around iron pole shoes. Current through the coils produces a powerful magnetic field that acts on the armature.

Copyright Goodheart-Willcox Co., Inc.



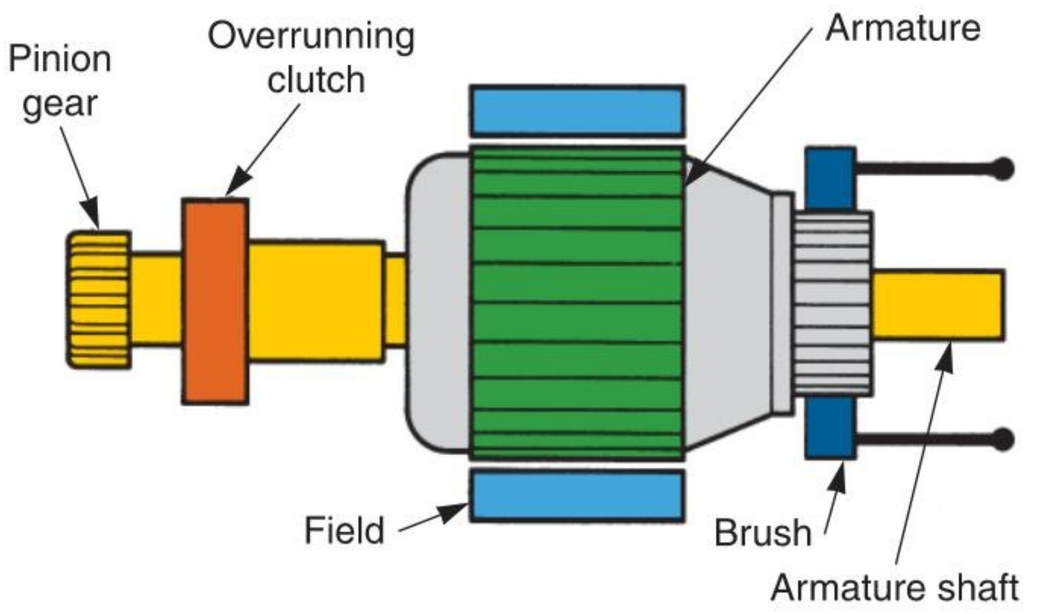
Goodheart-Willcox Publisher

Figure 30-7. This starter does not need field windings. It uses permanent magnets that are strong enough to rotate the armature.



Goodheart-Willcox Publisher

Figure 30-8. The starter pinion gear meshes with the large ring gear on the engine flywheel.



Robert Bosch

Figure 30-9. The pinion gear clutch assembly slides onto one end of the armature shaft. Note the other parts.

Frames

The frames, or housings, are the three main sections of the starting motor. The frames hold the other components. The center frame, or field frame, is the large steel cylinder that holds the field windings or field magnets. The two end frames fasten to each end of the center frame.

The drive end frame is the housing around the starting motor pinion gear. The drive end frame contains a bushing for the armature shaft. The shaft spins inside this bushing. The drive end bushing helps keep the pinion gear properly meshed with the flywheel ring gear.

The brush end frame usually holds the brushes and brush springs around the armature commutator. It bolts to the end opposite the drive gear. Two long bolts commonly fit through the brush end frame and thread into holes in the drive end frame. This holds both end frames securely onto the center frame.

Pinion Gear

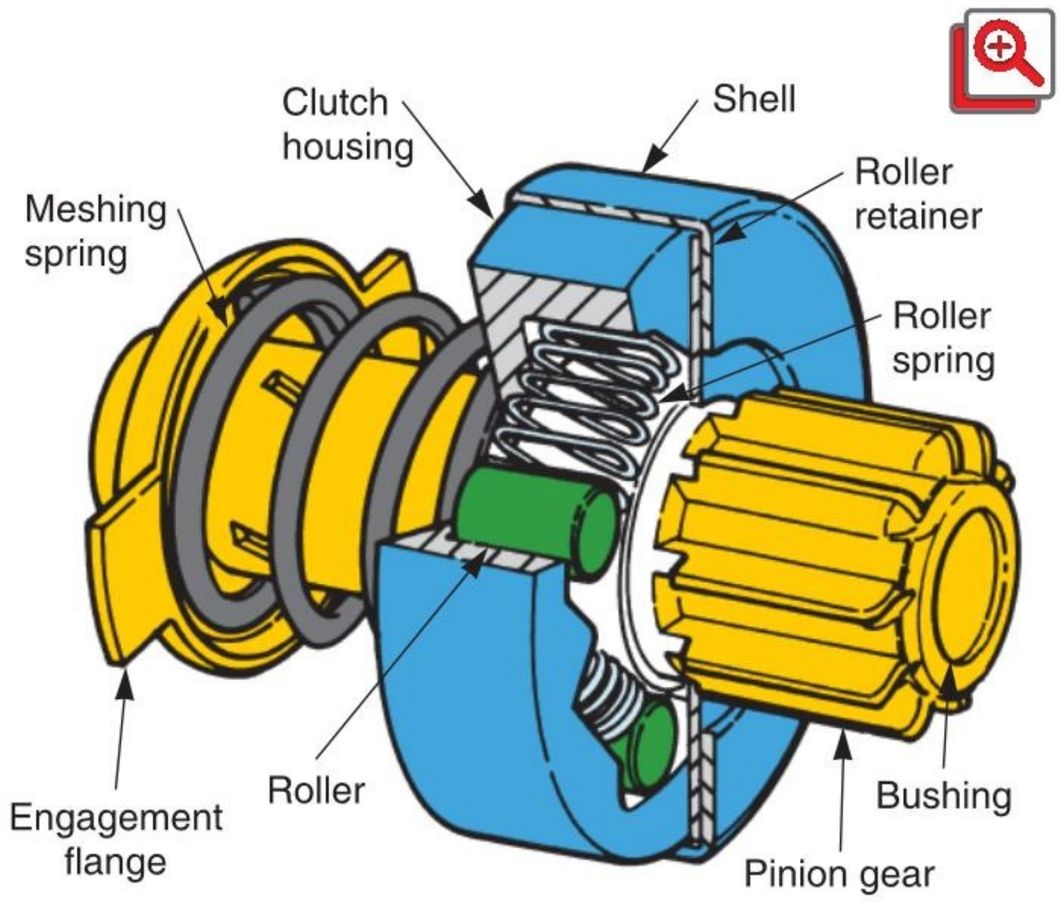
A ***pinion gear*** is a small gear mounted on the armature shaft that engages a large ring gear on the engine flywheel. It moves into and meshes with the flywheel ring gear any time the starter is energized. Most pinion gears are made as part of a pinion drive assembly (pinion gear, overrunning clutch, and housing). The pinion drive assembly slides over one end of the armature shaft, **Figures 30-8** and **30-9**.

A starting motor must produce high torque to start an engine. The pinion gear is much smaller than the flywheel ring gear. Therefore, the starting motor armature turns at a relatively high speed. This helps prevent stalling of the motor. The difference in gear size also increases turning force applied to the crankshaft.

The ***overrunning clutch*** locks the pinion gear in one direction and releases it in the other. This allows the pinion gear to turn the flywheel ring gear for starting. It also lets the pinion gear freewheel when the engine begins to run. Refer to **Figure 30-10**.

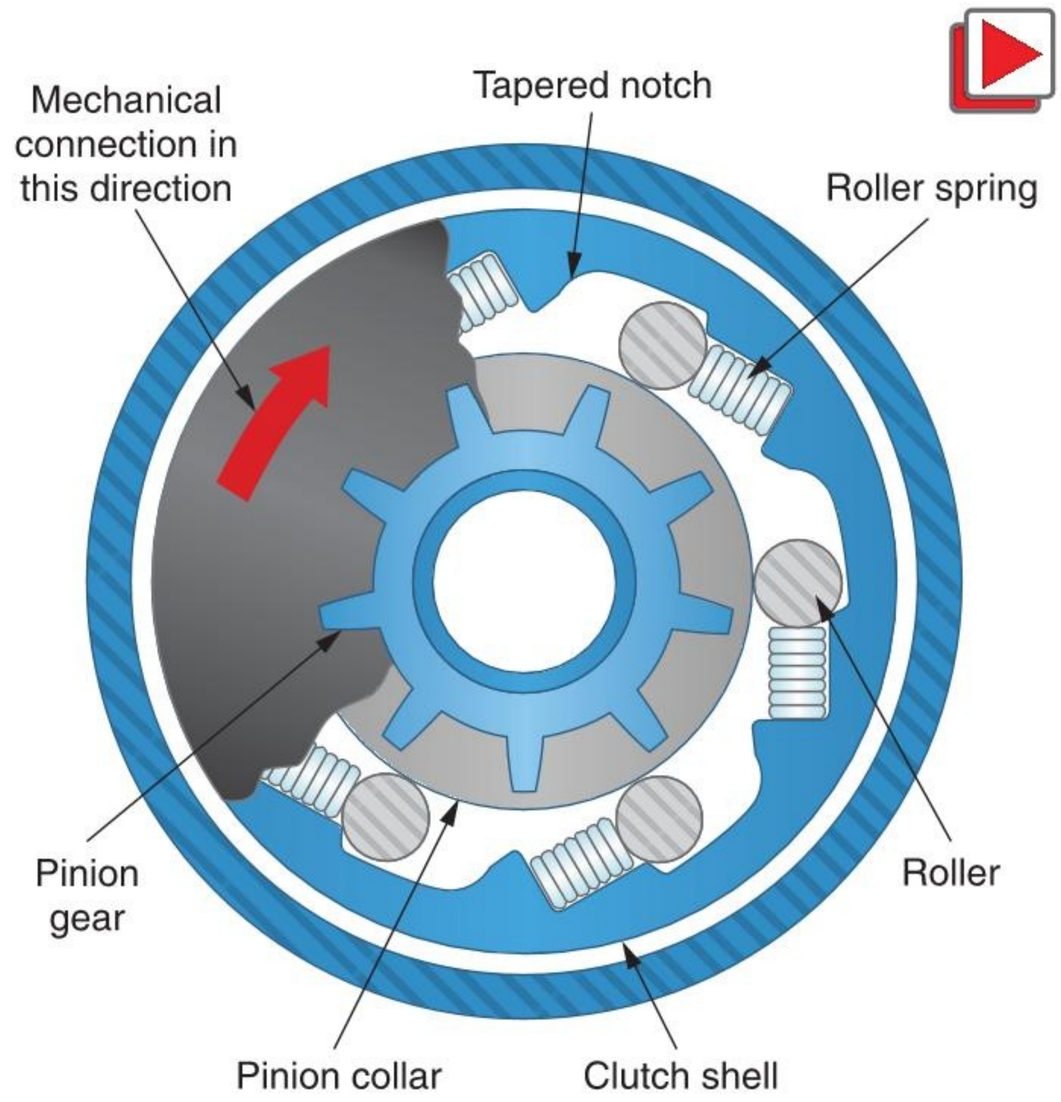
Small spring-loaded rollers are located between the pinion gear collar and the clutch shell, **Figure 30-11**. These rollers wedge into the notches in the shell in the driving direction. They slide back and release when driven in the other direction (freewheeling direction).

Copyright Goodheart-Willcox Co., Inc.



Ford

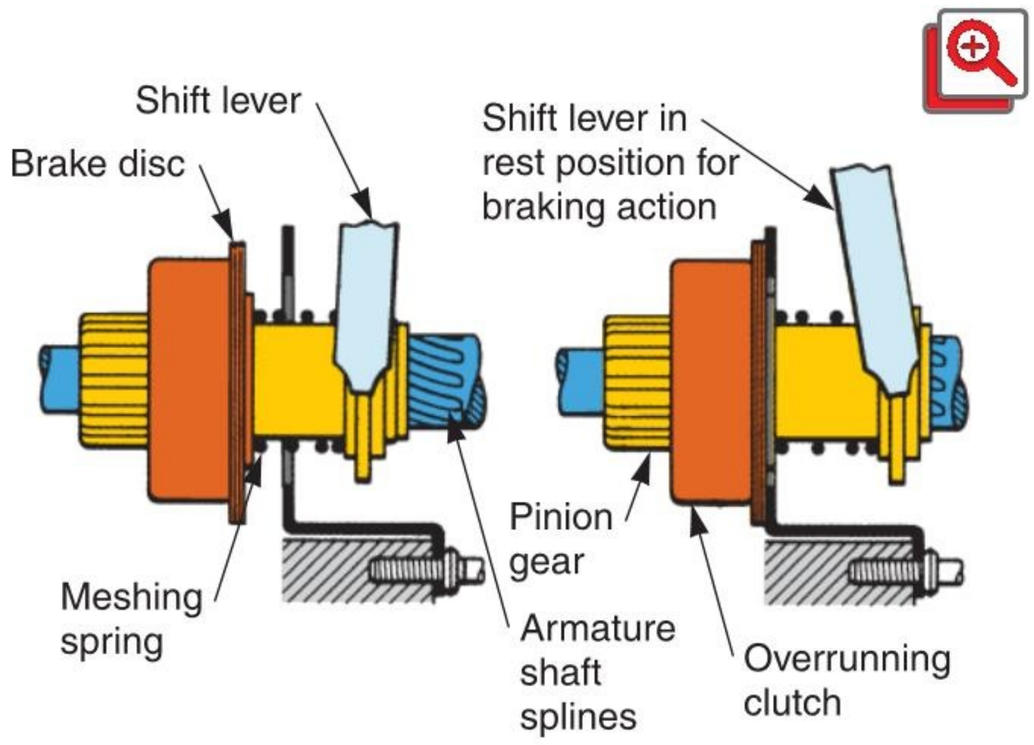
Figure 30-10. Study the construction of the starter overrunning clutch. It is simply a one-way clutch. It locks the flange to the pinion gear in one direction and releases in the other direction.



Robert Bosch

Figure 30-11. This cutaway shows how rollers fit in the clutch. Rollers jam and lock units together one way. Going the other way, they release, allowing the pinion to freewheel.

Spiral grooves on the armature shaft and the inside diameter of the clutch force the shaft and pinion drive assembly to turn together. They also allow the pinion drive assembly to slide on the armature shaft. Refer to **Figure 30-12**.



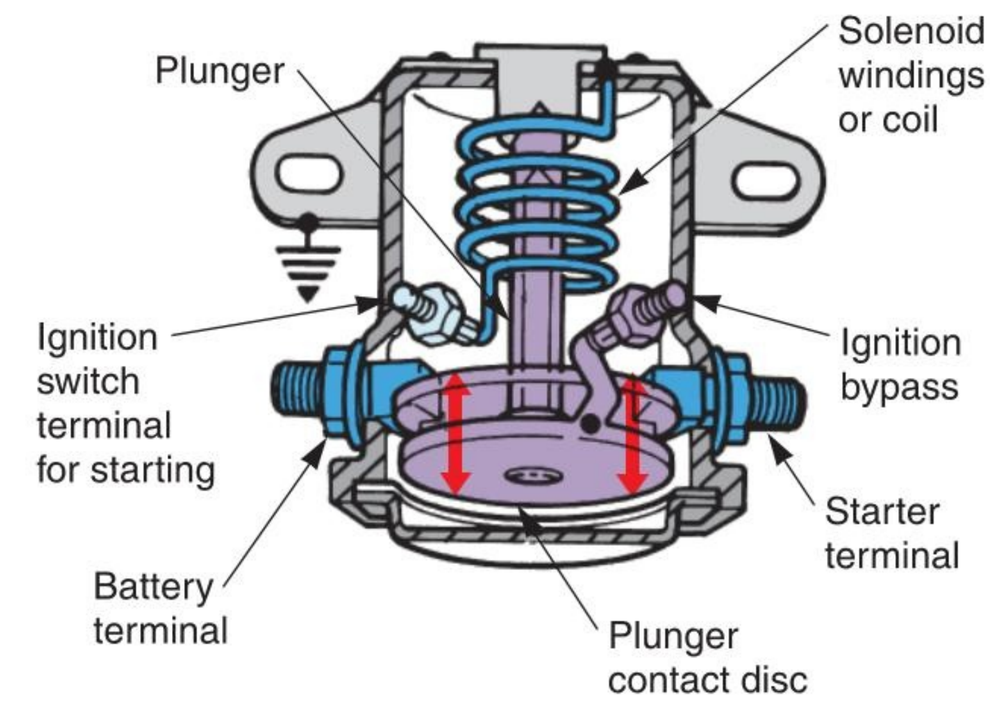
Robert Bosch

Figure 30-12. The pinion gear assembly is splined to the armature shaft. This makes the pinion gear assembly turn with the shaft. It also lets pinion gear slide on the shaft for engagement with the flywheel gear. Note how this unit also has a disc brake for stopping the pinion after disengagement.

Starter Solenoid

The starter solenoid is a high-current relay. It makes an electrical connection between the battery and the starting motor. The starter solenoid is similar to other relays but is capable of handling much higher current levels. See **Figure 30-13**.

The starter solenoid may be located on the starting motor or away from it. When mounted on a body panel (away from starter), the solenoid simply makes and breaks



Ford

Figure 30-13. Study the construction of a 12-volt starter solenoid. One small terminal connects to the ignition start switch. Larger terminals connect to the battery and starting motor. The plunger movement pulls the disc into contact with two battery contactor terminals to activate the starter.

Copyright Goodheart-Willcox Co., Inc.

electrical connections. When mounted on the starter, it also slides the pinion gear into the flywheel ring gear.

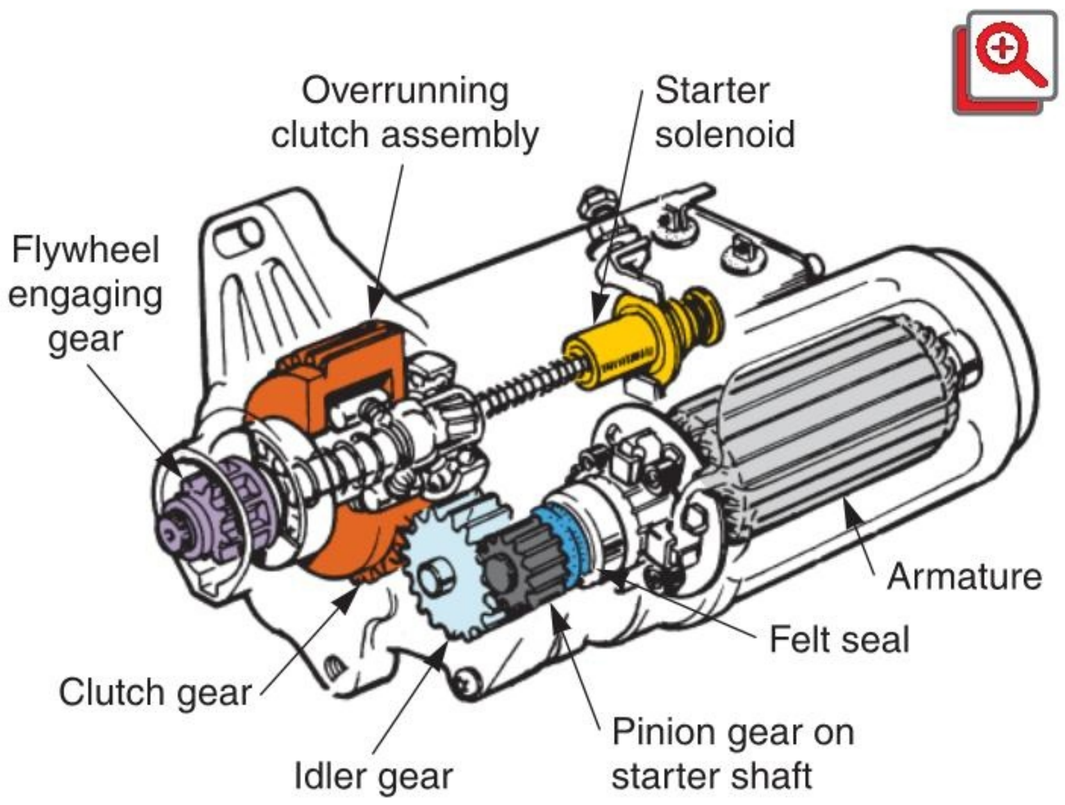
With the ignition key in start position, a small amount of current flows through the ***solenoid windings***. A magnetic field is produced that pulls the solenoid plunger and disc into the coil windings. This causes the ***solenoid disc*** to touch both of the high-current terminals, completing the battery-to-starter circuit. A current of 150–200 amps flows through the solenoid to the starter.

When the ignition key is released, current is disconnected from the solenoid windings. The magnetic field collapses, and the plunger is free to slide out of the windings. This opens the disc-to-terminal connection. The open connection stops current to the starter, and the starter motor shuts off.

Reduction Gearing

The planetary gearset is used to provide reduction. A ***reduction starter*** is sometimes used to further increase the rotating force applied to the engine flywheel. It uses an extra set of gears to improve the gear reduction, as in **Figure 30-14**.

The 12-volt starter pinion gear drives an idler gear. The idler gear drives a larger gear on the overrunning clutch assembly. This allows higher armature speed and higher torque output to the flywheel. More constant engine cranking speeds are produced by a reduction starter.



Honda

Figure 30-14. A reduction starter uses extra gears to increase motor torque. A gear on the armature shaft turns the idler gear. The idler turns a larger gear on the clutch for gear reduction. The exposed gear turns the flywheel gear.

12-Volt Starting Motor Types

Starting motors are classified by type of pinion gear engagement. There are two main 12-volt starter types: movable pole shoe starting motors and solenoid-actuated starting motors. Both types are illustrated in **Figure 30-15**.

A ***movable pole shoe starting motor*** uses a drive yoke to move the pinion gear into contact with the flywheel gear. The drive yoke is hinged on the starter frame and links a movable pole shoe to the pinion gear, **Figure 30-15A**.

When the starter is activated, the magnetic field of the motor pulls the movable pole shoe downward. Then, lever action of the drive yoke pushes the pinion gear outward on its shaft. This causes pinion gear engagement as the armature begins to spin. When the motor is shut off, a spring moves the pinion gear and pole shoe into the released position.

A ***starter-actuated solenoid*** has a plunger that moves a shift lever to engage the pinion gear. The solenoid is mounted on the side of the starter field frame. With this starter design, the solenoid completes the battery-to-starter circuit and also operates the pinion gear. See **Figure 30-15B**.

12-Volt Neutral Safety Switch

A ***neutral safety switch*** prevents the engine from cranking unless the shift selector is in neutral or park. It keeps the starting system from working when the transmission is in gear. The switch provides a safety feature to prevent the car from starting while in gear.

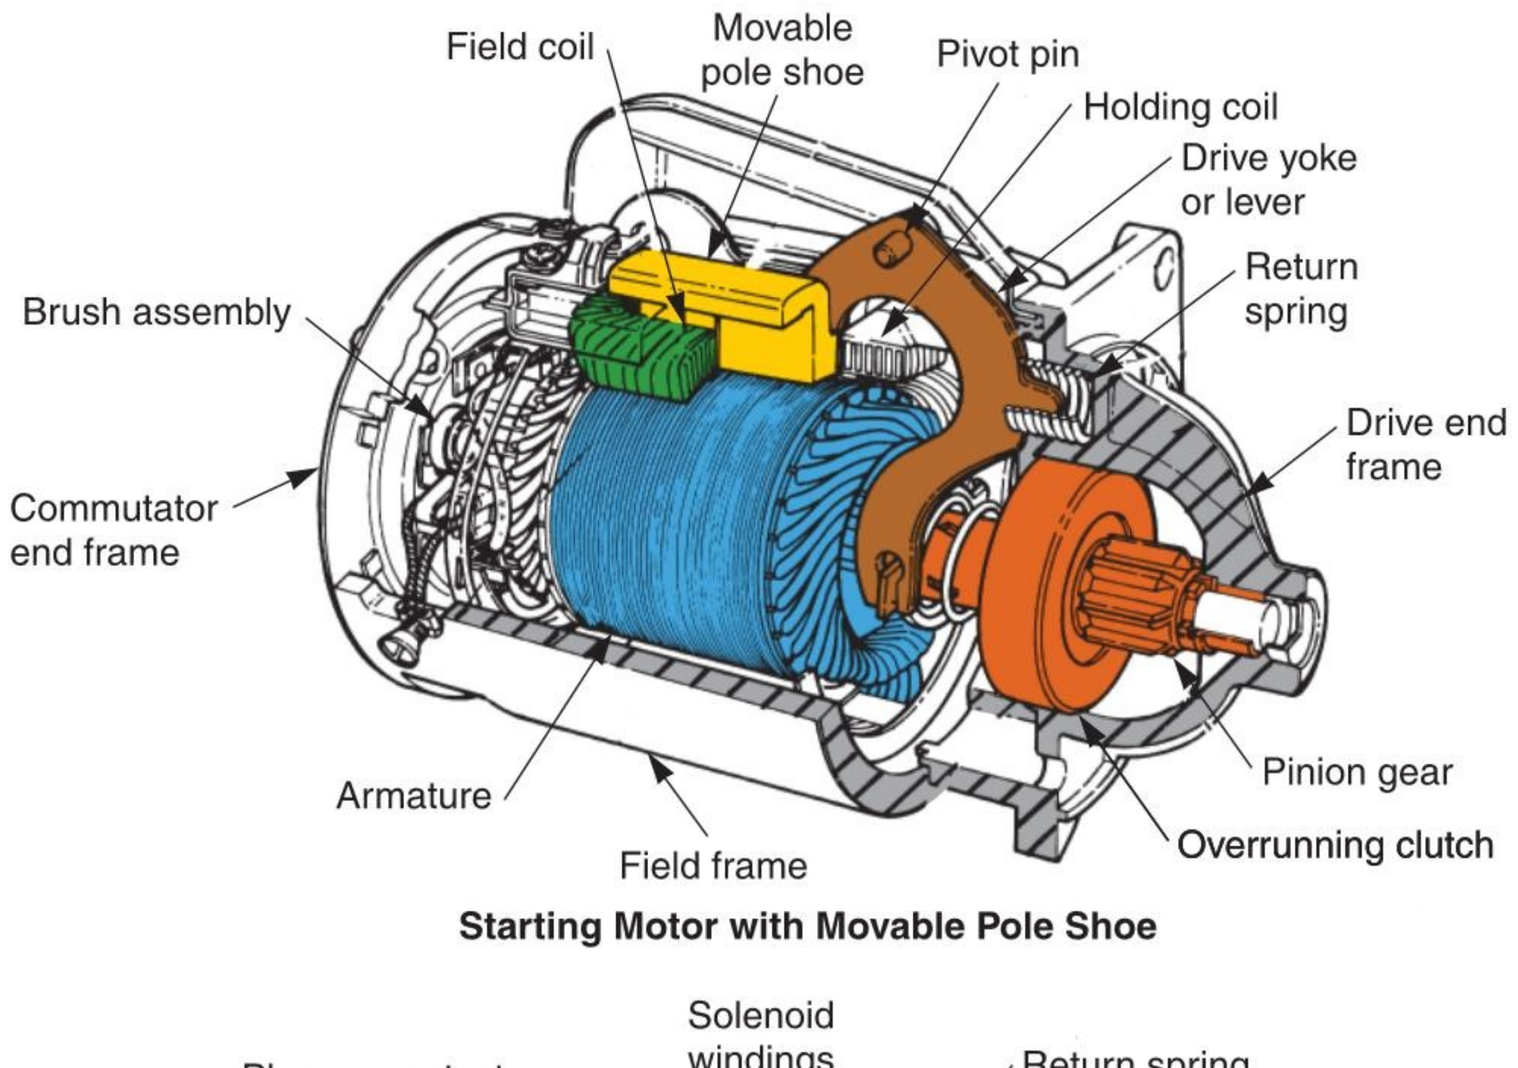
Cars with automatic transmissions commonly have a neutral safety switch. The switch may be mounted on the shift lever mechanism or on the transmission.

Neutral Safety Switch Operation

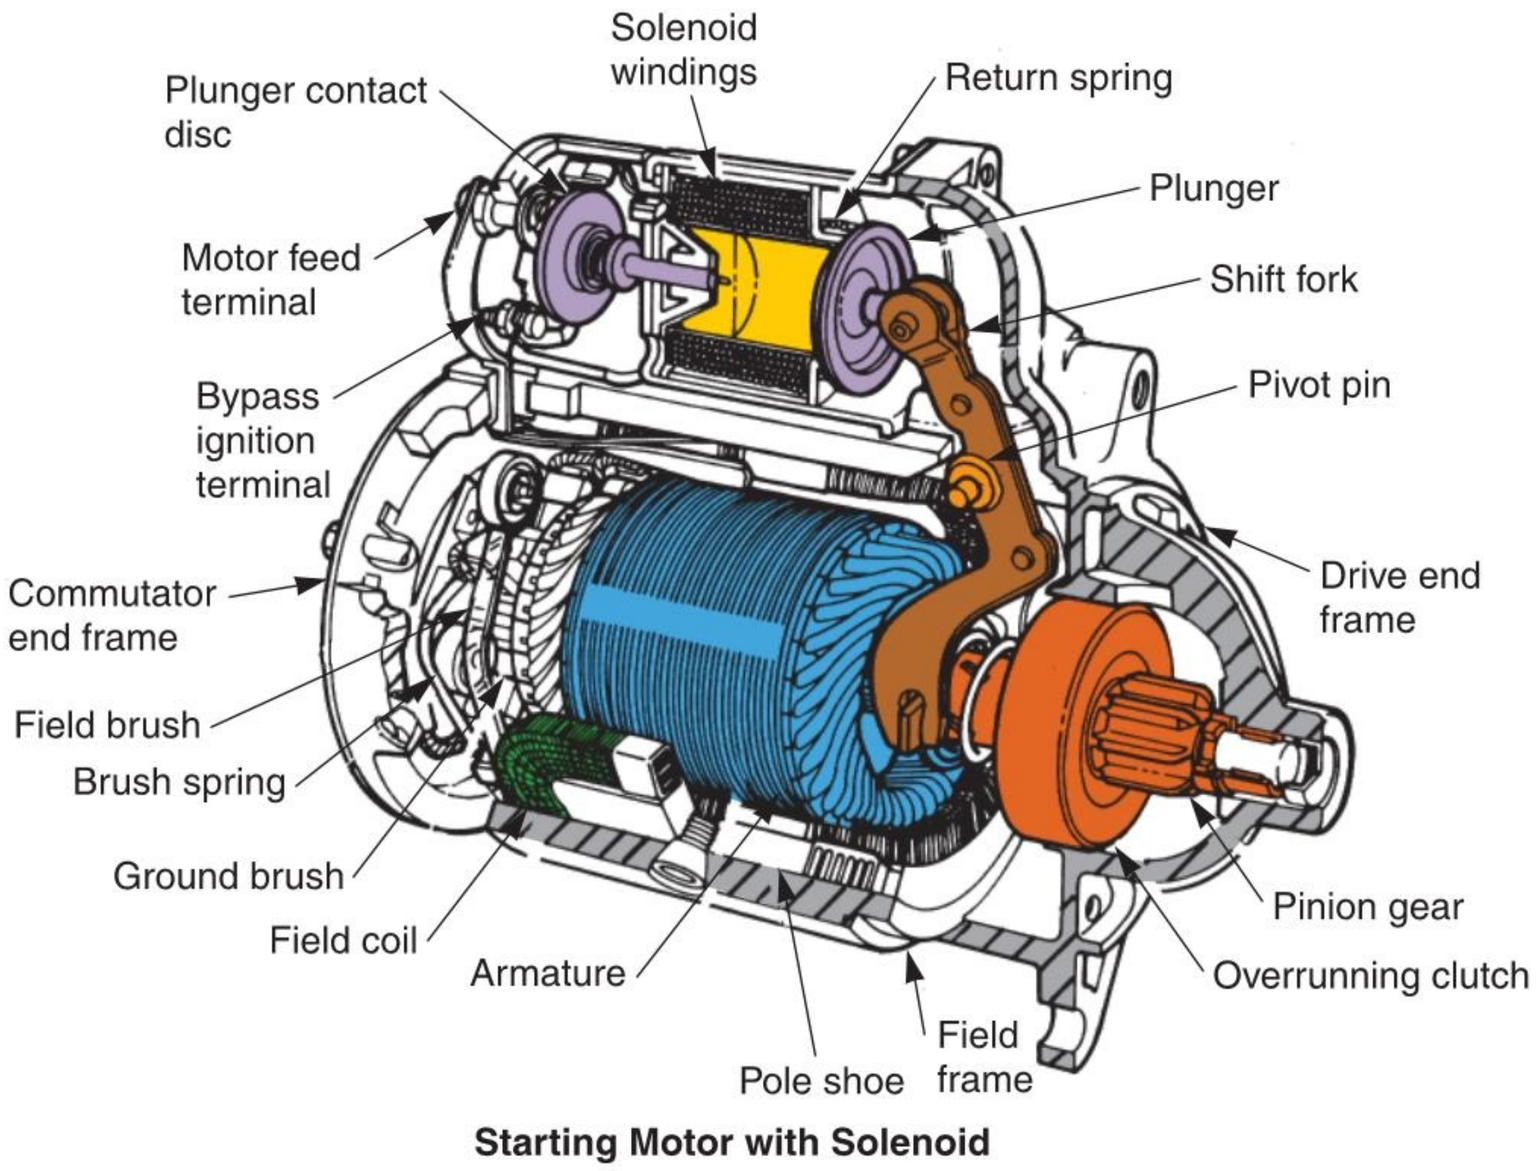
The neutral safety switch is wired into the circuit going to the 12-volt starter solenoid. When the transmission is in drive or reverse, the neutral safety switch is open (disconnected). This prevents current from activating the solenoid and starter when the start switch is turned to start.

With the transmission in park or neutral, the neutral safety switch is closed (connected). Current can flow to the 12-volt starter when the start switch is turned.

Copyright Goodheart-Willcox Co., Inc.



Starting Motor with Movable Pole Shoe



Starting Motor with Solenoid

Ford

Figure 30-15. Compare two common types of 12-volt starting motors.

Tech Tip

In most late-model cars, the brake light switch is wired into the same control circuit as the neutral safety switch. You must have the transmission in park (or neutral) and press the brake pedal for the starting motor to energize.

12-Volt Starter Relay

A ***relay*** is a device that opens or closes one circuit by responding to an electrical signal from another section of a circuit. Most modern starting systems use a relay between the ignition switch (start button) or the ECM and the 12-volt starter solenoid.

Copyright Goodheart-Willcox Co., Inc.

A starter relay uses a small current flow from the start switch or ECM to control a slightly larger current flow to the starter solenoid. This further reduces the load on the ignition key switch. A 12-volt starter relay circuit is shown in **Figure 30-16**.

Starter Relay Operation

When the ignition switch is turned to start, current flows into the relay. This closes the relay contacts. The contacts complete the circuit to the solenoid windings and the starting system operates.

When the key is released, the relay opens. This stops the solenoid current to disengage the starting motor.

ECM-Controlled 12-Volt Starting Circuit

An ***ECM-controlled starting circuit*** automatically energizes and de-energizes the 12-volt starting motor as soon as engine sensors detect fuel combustion and the resulting rapid increase in crankshaft rpms (speed sensor signal). The engine control module and body control module operate the 12-volt starting circuit automatically.

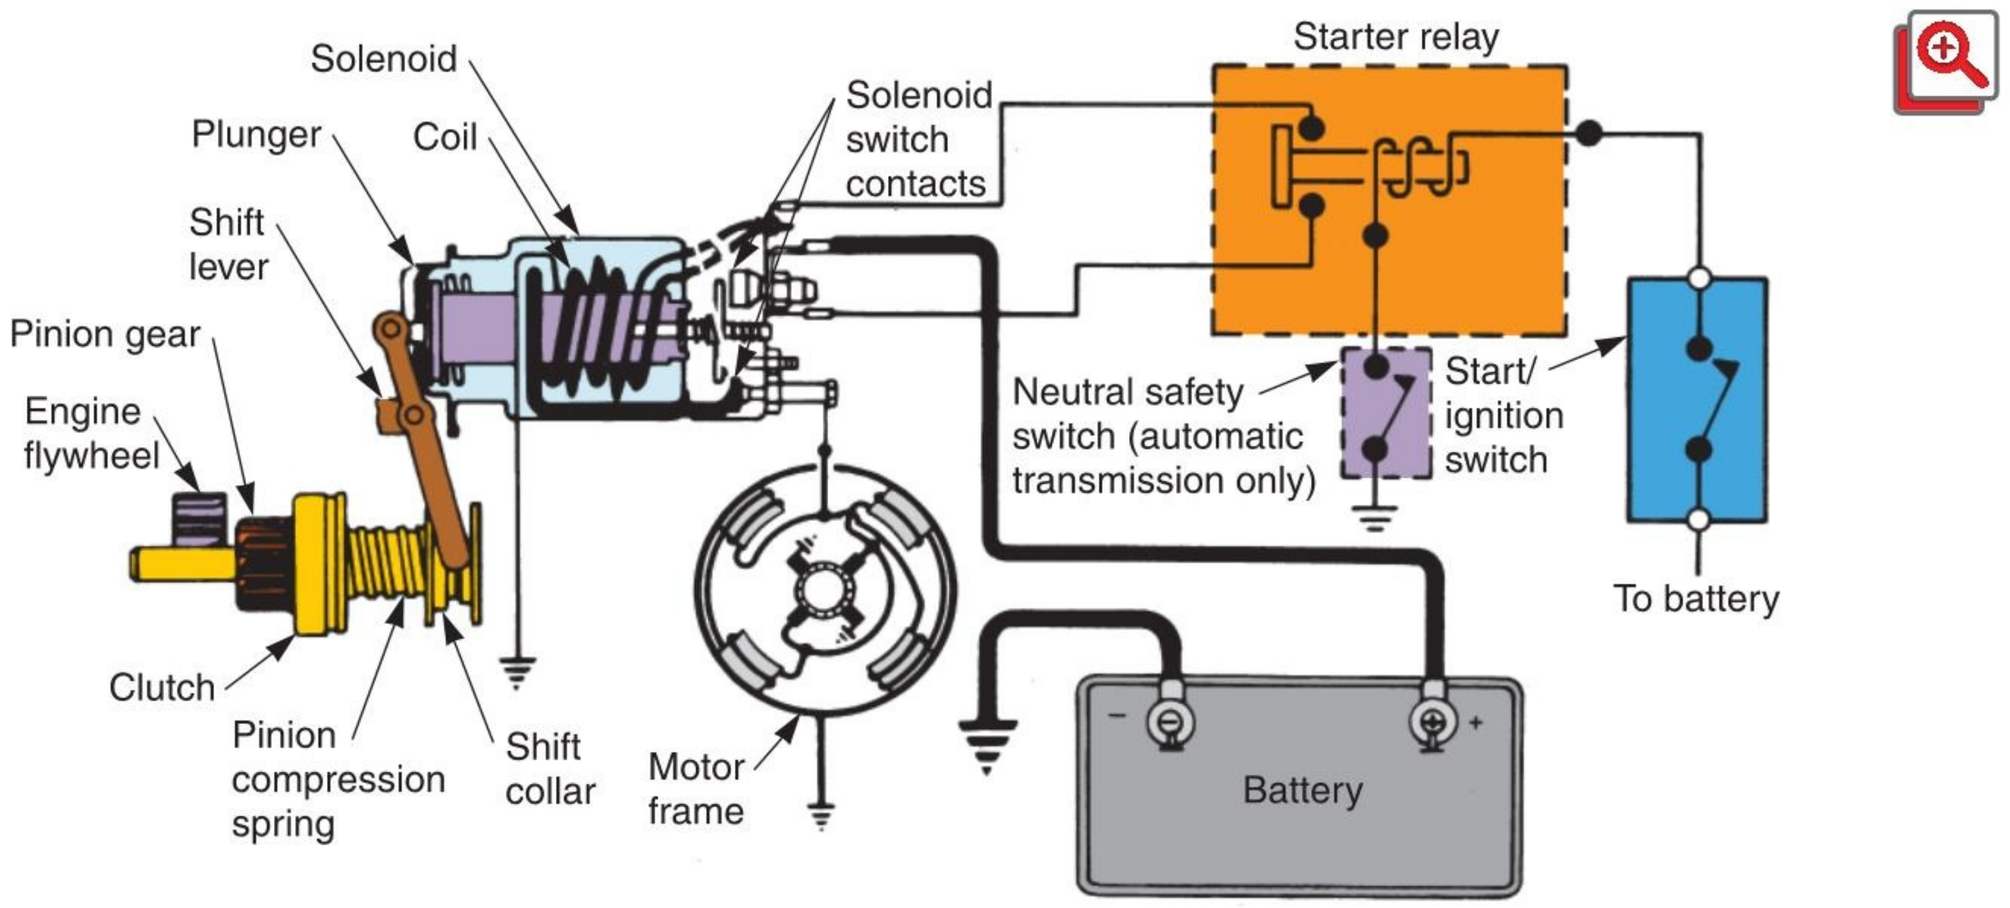
If a driver accidently holds the start key or start button too long, newer hybrids protect the starter pinion gear from damage caused by excessive speed. Most late-model starting systems are programmed to open the circuit between the ignition switch and the starter solenoid whenever the engine is running. This prevents the driver from accidentally engaging the starting motor and grinding its pinion gear into the flywheel gear when the flywheel gear is spinning at high speeds.

Hybrid Starting Systems

Early-model hybrids used a 12-volt starting system and a separate high-voltage propulsion system. Since this design added weight and complexity to the vehicle, most late-model hybrids use the motor-generator to crank the engine for starting.

A late-model hybrid starting system includes the following components:

- Motor-generator—The motor-generator serves as a high-torque motor for rotating the engine crankshaft.
- HV power cables—Three HV power cables connect the HV power control module to the motor-generator. Two HV power cables connect the HV battery to the HV power control module.
- Hybrid control module—The hybrid control module detects a need to start or stop the engine.
- HV power control module—The HV power control module converts dc into three-phase ac for the motor-generator. If the vehicle does not have a separate hybrid control module, the HV power control module determines when the engine should be started and sends three-phase ac to operate the motor-generator for engine startup.
- Engine control module (ECM)—The engine control module activates the fuel and ignition systems so the engine will start and run.



Chrysler

Figure 30-16. Study the complete manual starting system circuit. This circuit has a 12-volt starter relay. The relay further decreases the amount of current flowing through the ignition start switch. Also note how the relay winding is wired to the neutral safety switch.

Copyright Goodheart-Willcox Co., Inc.

The motor-generator armature (rotor) can be attached directly to the engine crankshaft. Refer to **Figure 30-17**. The motor-generator can also be connected to the engine through the transmission or transaxle. In this arrangement, the HV power control module and the hybrid control module must lock the torque converter clutch and the transmission motor-generator clutch so the motor-generator can spin the engine crankshaft for starting.

Motor-generators easily spin the engine crankshaft. Many hybrid starting systems are very quiet when engaged. When driving, it is difficult to tell when the HV starting system fires up the engine.

Hybrid Starting System Operation

In a hybrid, the internal combustion engine runs only when it is needed. The engine will be shut off when braking, coasting, going downhill, or when the vehicle is stopped. It is wasteful to run the internal combustion engine when its power is not needed.

The hybrid control module monitors operating conditions to determine when the internal combustion engine should be started. If the hybrid control module determines that the engine should be started, it signals the HV power control module to start the engine for propulsion and HV battery recharging. It also signals the engine control module to provide fuel and spark for engine starting and running. The HV power control module then applies voltage to the stator windings of the motor-generator to rotate the armature and the engine crankshaft.

Common reasons for starting the engine include a need to recharge the HV battery, a demand for more power during acceleration, high-speed operation, or an engine that has not been started for an extended period of time (too much driving in all electric mode).

Honda

Figure 30-17. In many hybrid designs, the motor-generator rotor is mounted directly onto the engine crankshaft flange. If three-phase current is fed to the stator coils by the HV power control module, the rotor magnets, armature, and crankshaft will be spun easily until the engine fires.

Green Tech

Recycling Batteries

Today's lead-acid batteries typically contain a large percentage of recycled materials. This is because lead-acid batteries are recycled and some of their materials can be reused. Less new material needs to go into a new battery. Several automotive shops collect and send dead batteries to off-site recycling facilities. Used batteries can be stored for up to a year before being recycled. It is best to store used lead-acid batteries inside, away from the drainage system and any source of ignition. Cracked batteries should be contained, and any spills from a battery crack should be cleaned up as quickly as possible.

Summary

- A 12-volt starting system uses battery power and an electric motor to turn the engine crankshaft for engine starting.
- A starting motor converts electrical energy from the battery into mechanical or rotating energy to crank the engine.
- A commutator serves as a sliding electrical connection between the motor windings and the brushes.
- A field winding is a stationary set of windings (insulated wire wrapped in circular shape).

Copyright Goodheart-Willcox Co., Inc.

- A permanent-magnet starter uses special high-strength magnets in place of conventional field windings.
- A starter pinion gear is a small gear on the armature shaft that engages a large ring gear on the engine flywheel.
- A starter overrunning clutch locks the pinion gear in one direction and releases it in the other.
- A starter solenoid is a high-current relay that makes an electrical connection between the battery and starting motor.
- A reduction starter is sometimes used to further increase the rotating force applied to the engine flywheel.
- A neutral safety switch prevents the engine from cranking unless the shift selector is in neutral or park.
- A 12-volt starter relay uses a small current flow from the start switch to control a slightly larger current flow to the starter solenoid.
- An ECM-controlled starting circuit automatically energizes and de-energizes the 12-volt starting motor as soon as the engine sensors detect fuel combustion and the resulting rapid increase in crankshaft rpms (speed sensor signal).
- A hybrid starting system includes a motor-generator, HV power cables, hybrid control module, HV power control module, and engine control module (ECM).
- The HV power control module converts dc into three-phase ac for the motor-generator. If a vehicle does not have a separate hybrid control module, the HV power control module determines when the engine should be started and sends three-phase ac to operate the motor-generator for engine startup.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

12-volt starting system
armature core
armature motor shaft
battery
brushes
commutator
ECM-controlled starting circuit
engine control module (ECM)
engine starting system
field windings
ignition switch
like charges
magnetic field
movable pole shoe starting motor
neutral safety switch
overrunning clutch
permanent-magnet starters
pinion gear
pole shoes
reduction starter
relay
solenoid disc
solenoid windings
start switch
starter-actuated solenoid
starter armature
starter relay
starter solenoid
starting motor
unlike charges

Activities

1. If possible, obtain an unserviceable 12-volt starter motor from a shop or junkyard. Carefully disassemble and clean the components. Mount and label them for a classroom display.
2. Research the advantages and disadvantages of installing a rebuilt 12-volt starter (rather than a new one) in a vehicle. Report to the class.
3. Inspect a hybrid vehicle's starting system. Find out if it uses a 12-volt starting motor or the hybrid motor-generator to crank the engine for starting. Write a report on the hybrid starting system using factory service information as a reference.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List and describe the six major parts of a 12-volt starting system.
2. What is the purpose of the starting motor?
3. Which of the following is *not* part of a starting motor?
   (A) Armature.
   (B) Field winding.
   (C) Commutator.
   (D) Slip ring.
4. List the four parts of a starter armature.
5. The housing around the starting motor pinion gear is called the _____.
   (A) center frame
   (B) brush end frame
   (C) drive end frame
   (D) field frame
6. What is the function of the starter pinion gear?
7. The _____ allows the pinion gear to turn the flywheel ring gear for starting.

Copyright Goodheart-Willcox Co., Inc.

8. The _____ is a high-current relay that completes the circuit between the battery and the starting motor.
9. Describe how a movable pole shoe starting motor operates.
10. A starter-actuated solenoid has a(n) _____ that moves a shift lever to engage the pinion gear.
11. Why is a reduction starter sometimes used?
12. The _____ keeps the engine from cranking unless the shift selector is in neutral or park.
13. List the five major components of a hybrid starting system.
14. Three HV power cables connect the HV power control module to the motor-generator. True or False?
15. Which of the following detects a need to start or stop the engine in a hybrid starting system?
    (A) Motor-generator.
    (B) ECM.
    (C) Hybrid control module.
    (D) None of the above.

ASE-Type Questions

1. Which of the following converts electrical energy from the battery into mechanical or rotating energy to crank the engine?
   (A) Solenoid.
   (B) Pinion gear.
   (C) Starting motor.
   (D) All of the above.
2. Which of the following serves as a sliding electrical connection between motor windings and brushes?
   (A) Solenoid.
   (B) Armature.
   (C) Pole piece.
   (D) Commutator.
3. A starter armature consists of each of these *except:*
   (A) shaft.
   (B) flange.
   (C) windings.
   (D) commutator.
4. Which device locks a pinion gear in one direction and releases it in the other?
   (A) Roller retainer.
   (B) Starter solenoid.
   (C) Flywheel ring gear.
   (D) Overrunning clutch.
5. When reviewing starter motor classifications, Technician A says starters are grouped by type of pinion gear engagement. Technician B says starters are grouped by type of armature. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Which of the following uses a plunger to move a shift lever that engages the pinion gear?
   (A) Reduction starter.
   (B) Movable pole shoe.
   (C) Starter-actuated solenoid.
   (D) Permanent-magnet starter.
7. Technician A says a neutral safety switch prevents the starting system from operating when the transmission is in gear. Technician B says the neutral safety switch is often wired into the same control circuit as the brake light switch. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Which of the following uses a small current flow from the ignition switch to control a larger current flow to the starter solenoid?
   (A) Clutch.
   (B) Starter relay.
   (C) Reduction starter.
   (D) None of the above.
9. While discussing hybrid starting systems, Technician A says the hybrid control module activates the fuel and ignition systems so the engine will start and run. Technician B says the HV power control module converts dc into three-phase ac to operate the motor-generator for engine startup. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says a motor-generator armature can be attached directly to the engine crankshaft. Technician B says that a motor-generator armature can be connected to the engine through the transmission or transaxle for engine starting. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Chapter 31
Starting System Diagnosis, Testing, and Repair

After studying this chapter, you will be able to:

- Diagnose common 12-volt starting system troubles.
- Perform 12-volt starting system tests.
- Explain typical procedures for basic 12-volt starting system repairs.
- Remove and install a starting motor.
- Recall the general procedure for diagnosing hybrid starting system problems.
- Correctly answer ASE certification test questions on starting system diagnosis, service, and repair.

This chapter introduces the steps for diagnosing, testing, and repairing common starting system problems in both conventional 12-volt and hybrid HV starting systems. By studying this chapter, you will learn to recognize the symptoms of specific starting system problems. You will also learn the general procedures for effectively removing and replacing faulty components.

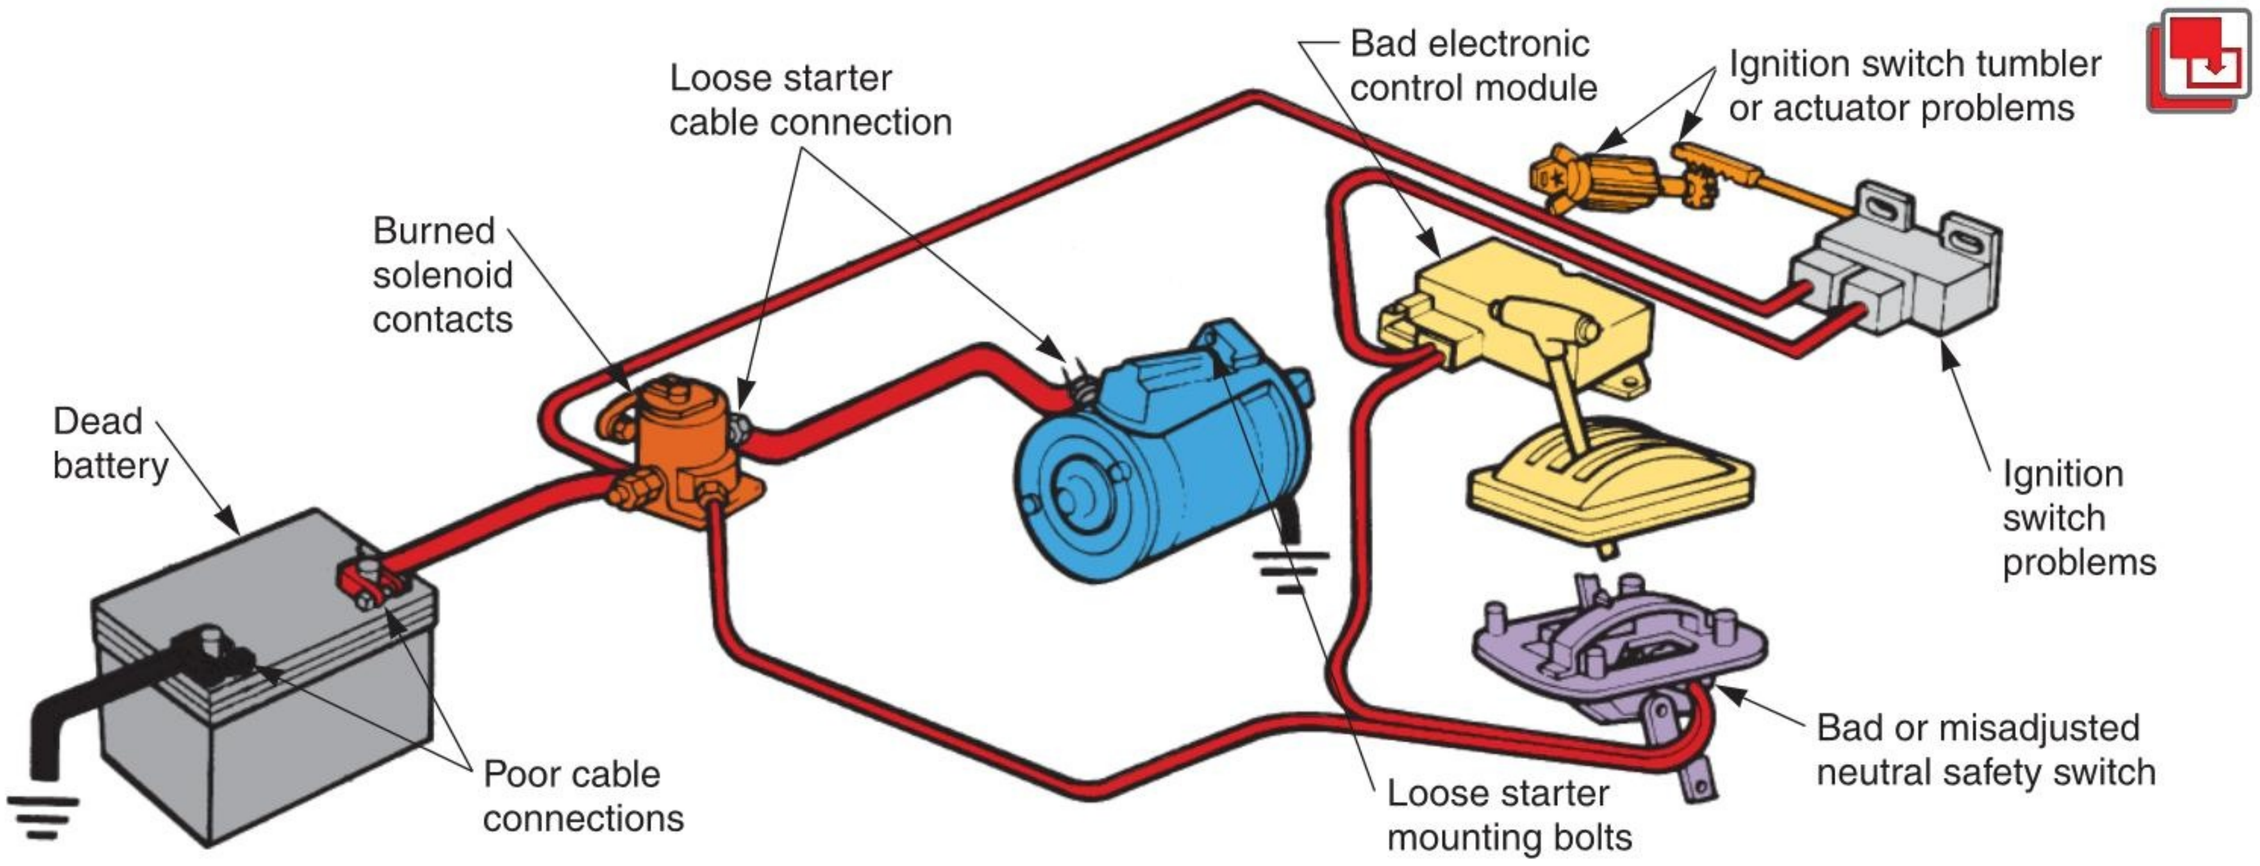
Remember that modern hybrids do not use a conventional 12-volt starting system. Instead, they use the motor-generator to crank the engine over for starting. If an HV starting system fails to function normally, voltage and current draw tests may be needed to isolate the problem location.

Starting System Diagnosis

The starting system used to be one of the simplest systems to troubleshoot and repair. The conventional starting circuit has only a few major components that can cause problems. With hybrid electric drive technology, however, finding out why the engine fails to start, or "crank," is a little more complicated.

If a 12-volt or HV starting system is not working properly, modern on-board diagnostics will provide trouble codes for most components. If any starting-related part has higher- or lower-than-normal resistance, physical damage, or wear, the car engine may not crank when the ignition key is turned or the start button is pressed. For better comprehension of starting system diagnosis and repair, this chapter will cover 12-volt starting systems before HV starting systems, **Figure 31-1**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 31-1. During initial inspection, check for these kinds of starting system troubles. A loose connection or discharged battery could keep the engine from cranking.

Common 12-Volt Starting System Problems

With a ***no-crank problem***, the engine crankshaft does not rotate when the ignition key or start button is activated. The most common causes are a dead battery, poor electrical connection, or faulty system component.

A ***slow-cranking condition*** occurs when the engine crankshaft rotates at speeds that are lower than normal. This condition is usually caused by low battery voltage, a bad starting motor, a poor battery connection, or mechanical problems.

If a buzzing or clicking sound (engine not cranking) occurs when the key is turned to start, the battery may be discharged or the battery cable connections may be poor. Low current flow causes the solenoid plunger to rapidly kick in and out, making a clicking or buzzing sound. A single solenoid click sound without engine cranking may point to a bad starting motor, burned solenoid contacts, a partially discharged battery, or engine mechanical problems, such as a locked or frozen engine. The click is usually the solenoid closing or the pinion gear contacting the flywheel gear.

A humming sound that occurs after momentary engine cranking may be due to a bad overrunning clutch or a worn pinion gear unit. Pinion gear wear can make the gear disengage from the flywheel gear too soon. This will allow the motor armature spin rapidly, producing a humming sound.

A metallic grinding noise may be caused by broken flywheel teeth or worn pinion gear teeth. The grinding may be caused as the gears clash against each other.

Normal cranking without starting is not usually caused by the starting system. There may be trouble in the fuel or ignition systems. With a diesel engine, check engine cranking speed. If cranking speed is low, the diesel may not start.

Service manual troubleshooting charts should be used when the causes of problems are hard to find. These charts are designed for the exact circuit and will often reduce the list of causes.

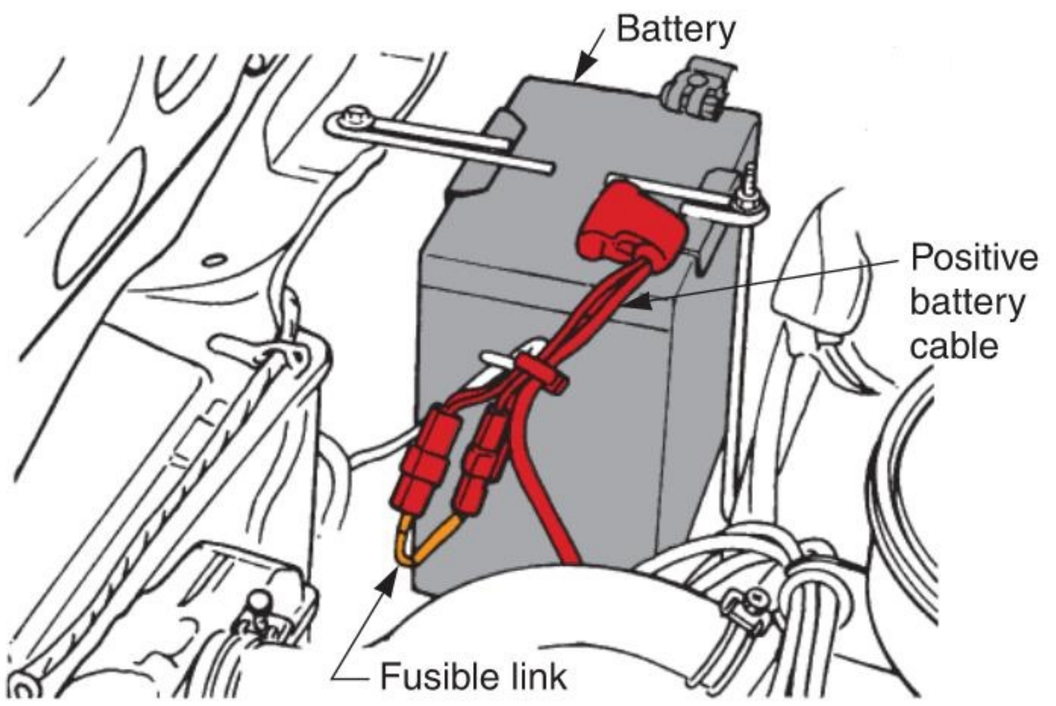
12-Volt Starting Headlight Test

A ***starting headlight test*** will quickly indicate the causes of trouble in a starting system. Turn on the headlights and try to start the engine. Note any sounds and watch the brightness of the headlights.

No cranking with no headlights points to a dead battery or an open in the electrical system. The battery connections may be bad. A burned fusible link will also kill power to most systems. A main feed wire to the fuse box could also be broken or disconnected, **Figure 31-2**.

If the headlights go out when cranking, the battery may be weak. The starting motor may be shorted. The engine could also be at fault. Dimming headlights indicate heavy current draw or poor current supply from the battery.

Copyright Goodheart-Willcox Co., Inc.



Mazda

Figure 31-2. The battery and its cables are the most common cause of improper cranking. Note the fusible link attached to the positive battery cable. It can burn during a short to protect the electrical system. If major components (lights, horn, starting system) are dead, check the fusible link.

If the lights stay bright but the engine does not crank properly, a high resistance or an open in the starting circuit is likely. The problem could be in the ignition switch, wiring, solenoid, starter cable connections, or relay.

The results of the starting headlight test will give you a general idea of the problem's cause. Further testing will be needed to pinpoint the source of the trouble. Depending on what the headlights and starter do when testing, you can decide what further tests are needed.

Checking the 12-Volt Battery

A dead or discharged 12-volt battery is one of the most common reasons the starting system fails to crank the engine properly. The starting motor draws much more current (over 200 amps with large engines) than any other electrical component. A discharged or poorly connected battery can operate the lights, but it may not have enough power to operate the starting motor.

If needed, load-test the battery as described in the chapter on battery service. Make sure the battery is in good condition and is fully charged. A starting motor will not function without a fully charged and well-connected battery.

12-Volt Starter Current Draw Test

A ***starter current draw test*** measures the current used by the starting system. It will quickly tell you about the condition of the starting motor and other system parts. If current draw is higher or lower than specifications, there is a problem.

To perform a current draw test, connect meters to measure the battery voltage and the current flow out of the battery. A load tester may also be used. See **Figure 31-3**.

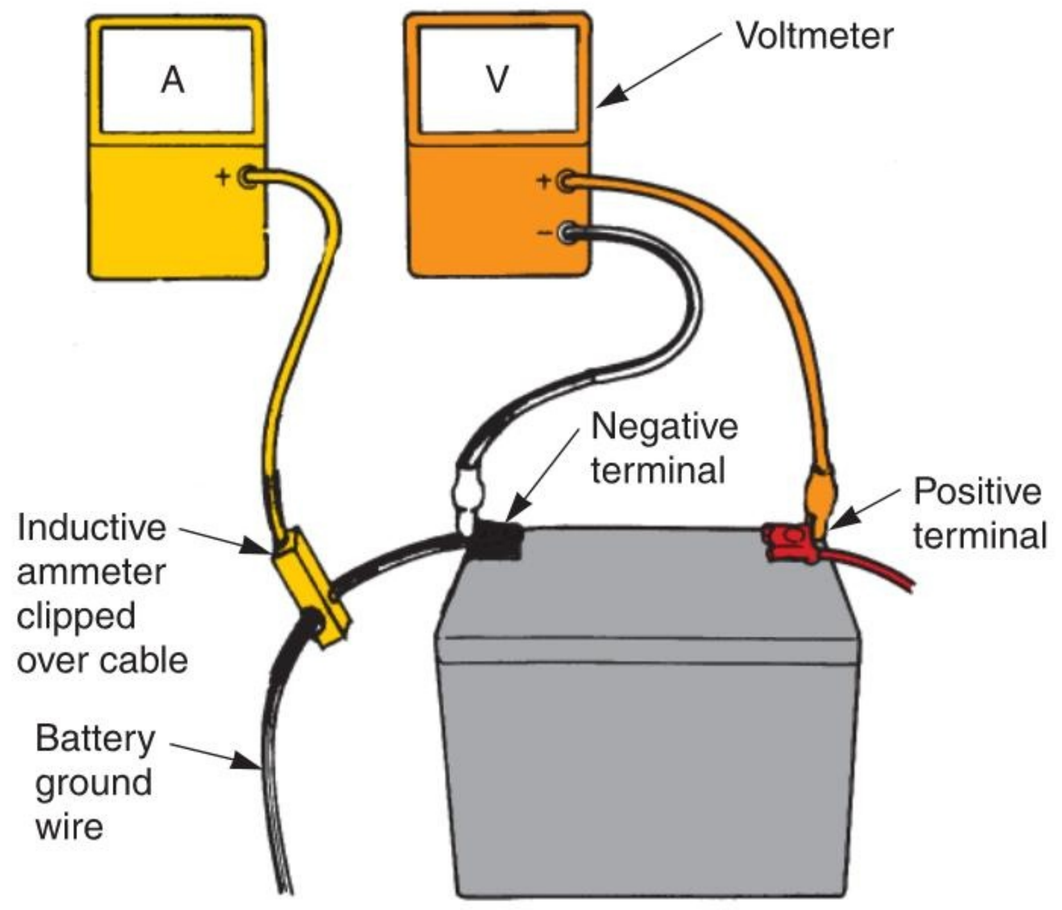
To keep the engine from starting during the test, disconnect the coil primary supply wire or ground the coil wire, **Figure 31-4**. You can also pull the fuse for the electric fuel pump if this is easier (direct ignition systems).

With a diesel engine, you must disable the injection system. You may have to disconnect the fuel shutoff solenoid. Check a shop manual for details.

Caution

Do not crank the engine for more than 15–30 seconds, or starter damage may result. If cranked too long, the starter could overheat. Allow the starter to cool for a few minutes if more cranking time is needed.

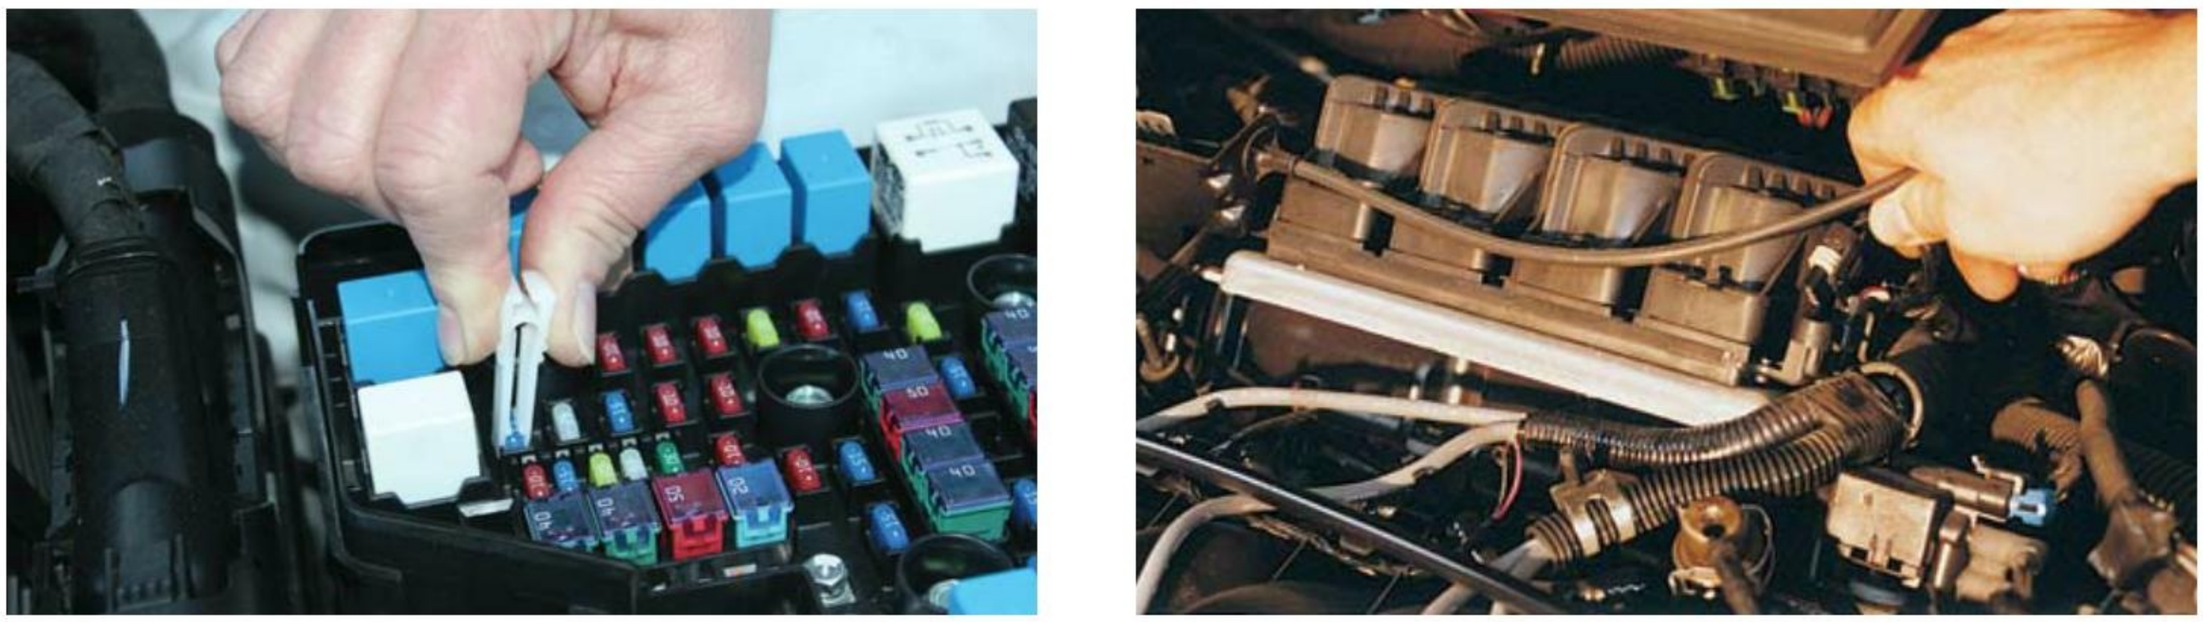
Crank the engine and note the voltage and current readings. If they are not within specifications, something is wrong in the starting system or the engine.



Honda

Figure 31-3. A voltmeter and an ammeter can also be used to measure starter current draw. A voltmeter reading is needed to compare different battery conditions. If current draw is not within specifications, there are starting system troubles.

Copyright Goodheart-Willcox Co., Inc.



A B

Honda

Figure 31-4. To keep the engine from running during a starter current draw test, disable the fuel or ignition system. A—To disable the fuel system, remove the fuel pump fuse. B—With a coil pack, disconnect the primary wires to disable the ignition system.

Further tests are needed. **Figure 31-5** contains a troubleshooting chart and lists the average current draw values for various engine sizes.

Average Current Draw	
Engine Displacement	**12-Volt System Max. Current**
Most 4–6 cylinders	125–175 amps
Under 300 C.I.D.	150–200 amps
Over 300 C.I.D.	175–250 amps

Cranking Circuit Troubleshooting Chart		
Cranking Voltage	**Cranking Amps**	**Possible Problem**
Voltage okay	Current okay	System okay
Voltage okay	Current low, engine cranks slowly	Starter circuit connections faulty
Voltage low	Current low, engine cranks slowly	Battery low
Voltage low	Current high	Starter motor faulty

Marquette

Figure 31-5. This chart shows typical current draw values for different engine sizes. Ignore initial readings until the engine has cranked for a few seconds. Then current draw will stabilize. Study meter readings and the trouble chart.

12-Volt Starting System Voltage Drop Tests

Voltage drop tests quickly locate a part with higher-than-normal resistance. These tests provide an easy way of checking circuit condition. You do not need to disconnect wires and components to perform voltage drop tests. See **Figure 31-6**.

Insulated Circuit Resistance Test

An ***insulated circuit resistance test*** checks all parts between the positive battery terminal and the starting motor for excess resistance.

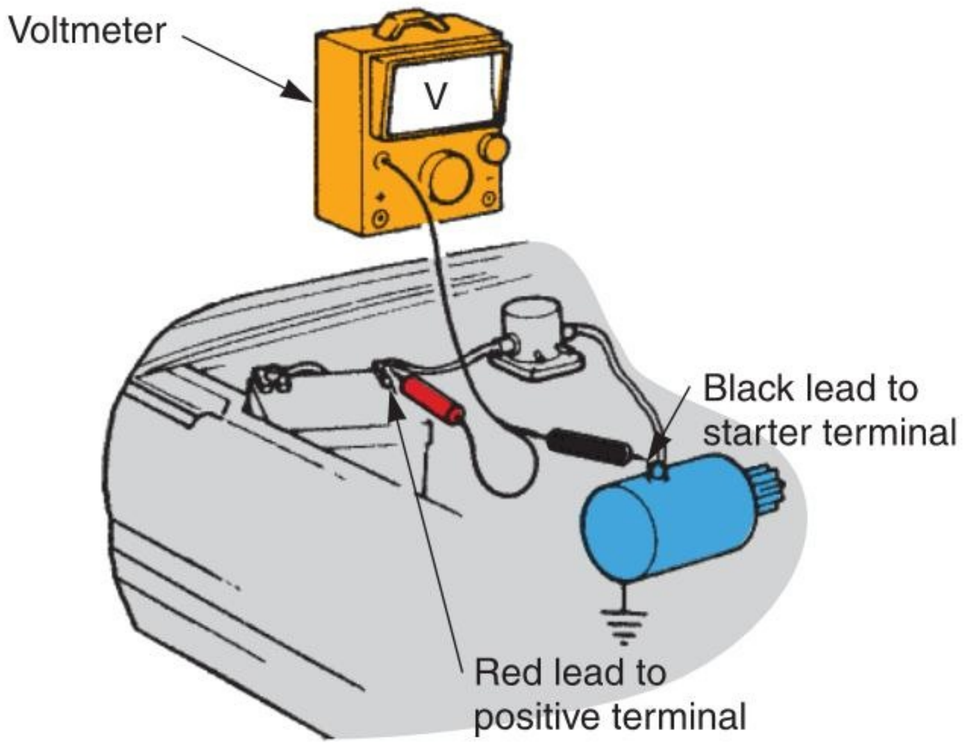
Service Procedure

To perform an insulated circuit resistance test:

1. Touch your voltmeter probes on the positive battery terminal and the starting motor input terminal.
2. Disable the ignition or injection system.
3. Crank the engine and observe the voltmeter reading.

The voltmeter should not read over 0.5 volts. If voltage drop is greater than 0.5 volts, there is excess resistance in the circuit. There may be loose electrical connections, burned or pitted solenoid contacts, or other problems. Test each part individually.

Copyright Goodheart-Willcox Co., Inc.



Insulated Circuit Resistance Test

Starter Ground Circuit Test

A ***starter ground circuit test*** checks the circuit between the starting motor ground and the negative battery terminal.

Service Procedure

To perform a starter ground circuit test:

1. Touch the voltmeter leads to the battery negative terminal and the starter end frame.
2. Crank the engine and note the meter reading.
3. If the reading is higher than 0.5 volts, check the voltage drop across the negative battery cable. The engine may not be grounded properly.
4. Clean, tighten, or replace the cable as needed.

12-Volt Battery Cable Service

A battery cable problem can produce symptoms similar to those caused by a dead battery, bad solenoid, or weak starting motor. If the cables do not allow enough current flow, the starter will turn slowly or not at all.

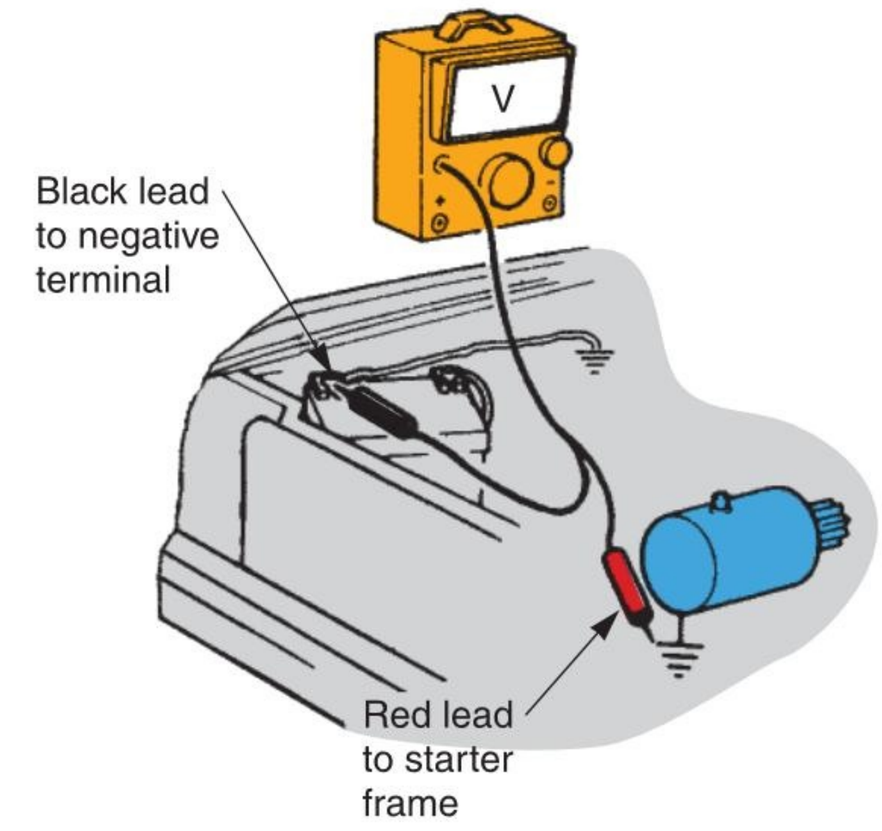
Testing Battery Cables

Battery cables can be damaged by acid corrosion, road salt, improper maintenance, and overtightening of electrical connections. Corrosion between the battery cable connectors and the battery terminals can add resistance in the starting motor circuit. Poor connections between the cable connectors and the battery terminals can also prevent the charging system from sending current through the battery cells for regeneration or recharging.

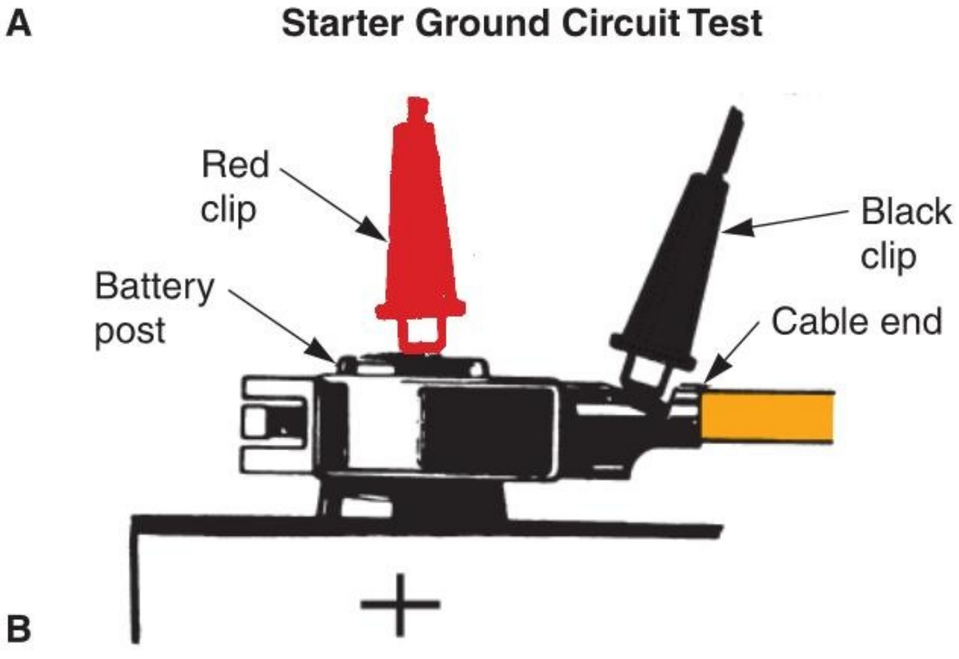
Inspect the battery cables and the cable connectors. While wearing work gloves, grab and try to wiggle the battery cable connections. Vibration, heat, and corrosion will often loosen the battery connections and cause a wide array of symptoms.

To test a battery cable on the vehicle, connect a voltmeter lead between the cable connectors. Do not allow the test leads to touch the battery terminals or ground, or a false reading will result. If necessary, use small alligator clips to secure the leads to the cable end connectors.

Crank the engine and note the voltage drop reading across the cable. Good battery cables will show



A **Starter Ground Circuit Test**



B

Chrysler

Figure 31-6. Voltage drop tests are a quick way of checking circuit resistance without disconnecting wires. A perfect electrical connection would have zero ohms. A—Voltage drop measurements provide a fast way of finding poor electrical conditions. B—Check battery terminals for corrosion and high resistance by measuring voltage drop.

Copyright Goodheart-Willcox Co., Inc.

less than a 0.1 volt drop. If the voltage drop is 0.1 volt or more, there is a high resistance between the cable and the cable connector.

To test a battery cable that has been removed from the vehicle, thoroughly clean the metal surfaces of the cable end connectors. Cleaning will ensure accurate meter measurement. Set your meter to measure resistance. Connect the meter leads between the two cable end connectors. A large-diameter battery cable should show almost no resistance, typically less than 0.2Ω per foot at room temperature. Refer to a wire resistance chart for the size of the battery cable being tested. A higher reading might be due to poor cable end connections adding resistance to the battery cable.

Repair or replace a battery cable if it shows more than a few ohms of resistance. Cleaning and resoldering the battery cable end connectors will often fix a poorly conducting battery cable.

A battery cable connection test checks for high resistance between the battery cable end connector and the battery post.

Service Procedure

To do a ***battery cable connection test***:

1. Connect a voltmeter to the battery post and to the cable end connector.
2. Measure the voltage drop across the connections while cranking the engine.
3. If any cable shows a high voltage drop (above 0.3 volts) during cranking, clean and tighten its connections.
4. Retest the connection. If the voltage drop is still high, repair or replace the cable.

Replacing Battery Cables

When replacing battery cables, make sure the new cables are the same as the old ones. Compare cable length and diameter. Lead terminals are better than steel terminals. The soft lead will more easily conform to the shape of the battery terminal.

When tightening the connections on the ends of battery or starter cables, only snug down the fasteners. Many of the threaded studs, bolts, and nuts are made of soft metal. They can strip and break easily.

Starter Solenoid Service

A bad starter solenoid can cause a variety of problems, including no cranking (with or without a click) or slow cranking. It can also keep the engine and starting motor running or prevent the starting motor from disengaging from the engine.

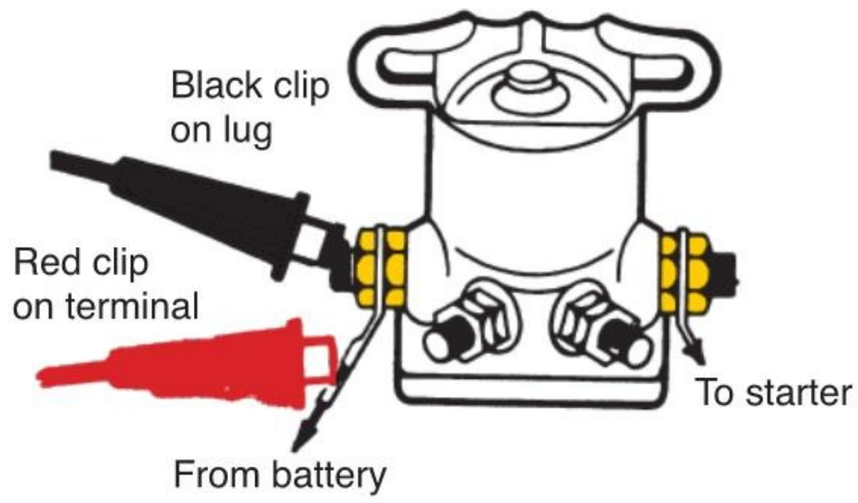
Usually, the large disc-shaped contact will burn and pit. The contact can develop high resistance that reduces current flow to the starter. An open or shorted solenoid winding can keep the contact from closing. No click will occur, and the engine will not crank.

Testing the Starter Solenoid

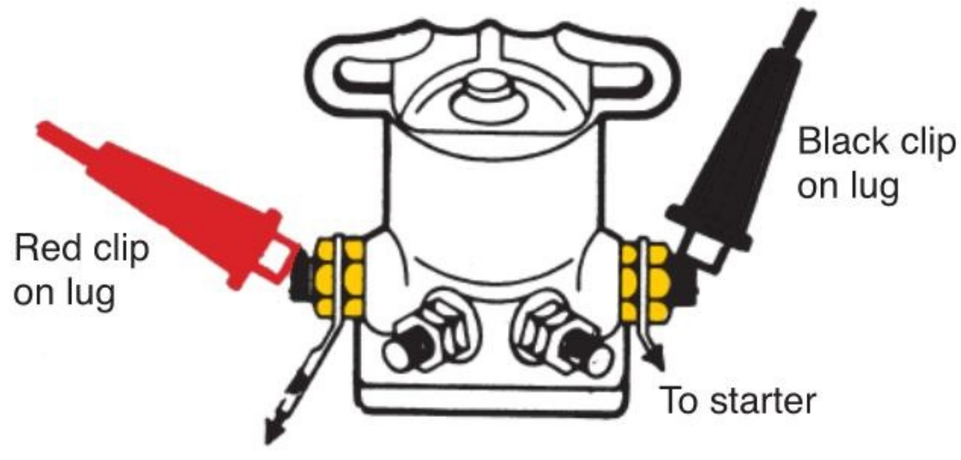
To test the solenoid, connect a voltmeter as shown in **Figure 31-7**. This will measure the voltage drop and resistance of the solenoid lugs and contacts. Crank the engine and note the voltmeter readings. If either voltage measurement is above 0.3 volts, tighten the cable connections or replace the solenoid.

Replacing the Starter Solenoid

To replace a solenoid that is mounted away from the starter, simply remove the cables and wires. Unbolt the solenoid from the fender well and install the new one.



Check Solenoid Lug-to-Cable Connection



Check Disc Contact and Terminal Condition

Marquette

Figure 31-7. Check the starter solenoid as shown.

Copyright Goodheart-Willcox Co., Inc.

If the solenoid is a starter-mounted unit, the starter must be removed from the engine. Then, the solenoid can be unscrewed from the starting motor and replaced. The procedures for removing, assembling, and installing a starter are covered later.

Warning

Before disconnecting the positive cable from a starter solenoid, make sure the battery has been disconnected. If you short this cable to ground, a powerful electric short will result. This could damage parts or cause burns.

Ignition Switch Service

A bad ignition switch (starter feed section of switch) can prevent the starter solenoid from working normally. It can also keep the solenoid from releasing. The contacts in the ignition switch can wear or burn, causing either an open (no-cranking problem) or a short (engine cranks all the time).

Testing the Ignition Switch

To test an ignition switch, touch a test light to the starter solenoid start (S) terminal. See **Figure 31-8**. If the ignition switch is good, the test light will glow when the key is turned to start the engine. The test light should go out when the key is released.

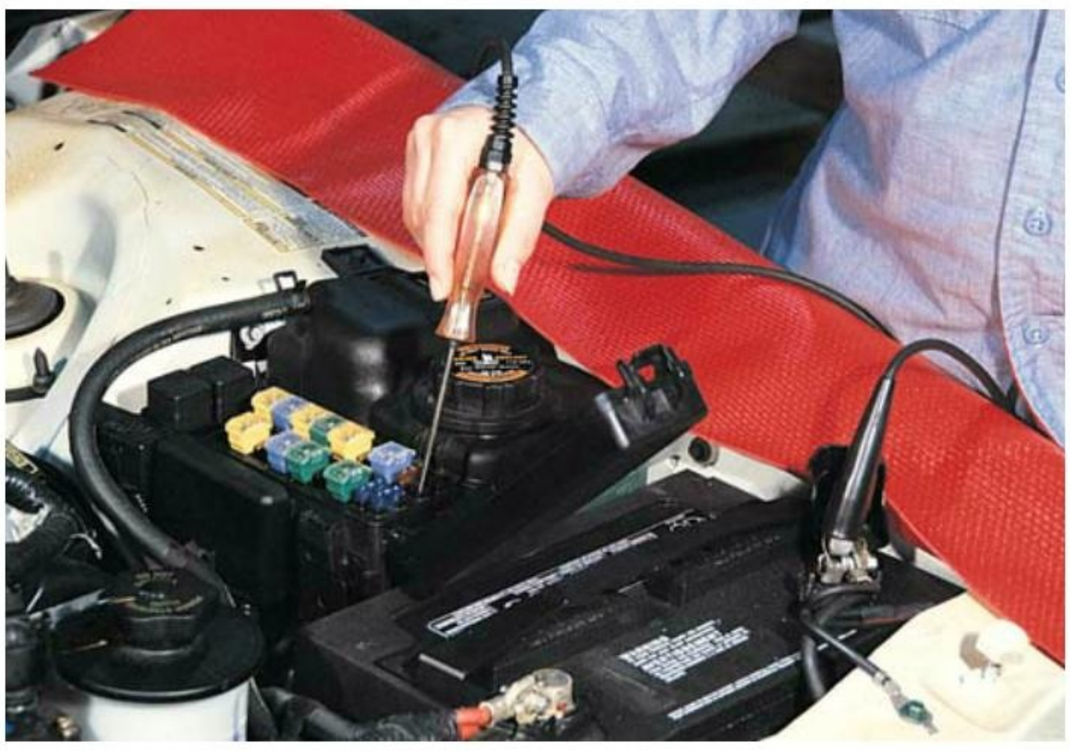


Figure 31-8. Use a test light to quickly check for power in an electric circuit. Connect the alligator clip to ground and touch the tip to the circuit. The light will glow if there is power in the circuit. To prevent component damage, do not use a conventional test light on an electronic circuit.

If the test light on the solenoid does not glow, either a wire in the ignition switch circuit is open or the ignition switch is defective. Test the wires coming out of the ignition switch to eliminate the possibility of a bad wire.

If the test light on the solenoid glows in both the start and run positions, the ignition switch is probably shorted. The engine would crank all the time.

These are simplified tests. You will need to use your own judgment and a service manual to perform more detailed tests.

12-Volt Starter Relay Service

A bad starter relay will keep power from the starter solenoid. This will prevent engine cranking. The winding or the contact points in the relay could be faulty. If the relay is bad, you will not hear the solenoid click and engage.

To test a starter relay, use a test light to check for voltage going into and coming out of the relay terminals. Refer to a wiring diagram for test points. Replace the relay if needed.

Neutral Safety Switch Service

A misadjusted or bad neutral safety switch can also keep the engine from cranking when the key is turned to start. If the neutral safety switch is open, current cannot flow from the ignition switch to the starter solenoid.

Before testing the switch, move the transmission gear shift lever into various positions while trying to start the engine. The switch may close, letting the starter operate. If the starter begins to work, the neutral safety switch may only need adjustment.

Warning

Make sure to press down on the vehicle's brake pedal when checking a neutral safety switch. If the switch is worn or faulty, the engine could try to start while the vehicle is in drive or reverse. If this happens, the brakes would be needed to keep the vehicle from moving.

Testing the Neutral Safety Switch

To test a neutral safety switch, touch a 12-volt test light to the switch output wire connection while moving the transmission shift lever. The light should glow as the shift lever is slid into *Park* and *Neutral*. The test light should not glow when the shift lever is in other positions. If the neutral safety switch does not complete its circuit in *Park* and *Neutral*, but does complete its circuit in other gear positions, it may be defective.

Copyright Goodheart-Willcox Co., Inc.

Before condemning the neutral safety switch, check the mechanism that actuates the switch. There should be a prong or other device that operates the neutral safety switch. If the actuating mechanism is working properly, try to adjust the switch as outlined in the following section. If the switch still will not work properly, it must be replaced. After replacing a defective neutral safety switch, the new unit must be adjusted.

Adjusting the Neutral Safety Switch

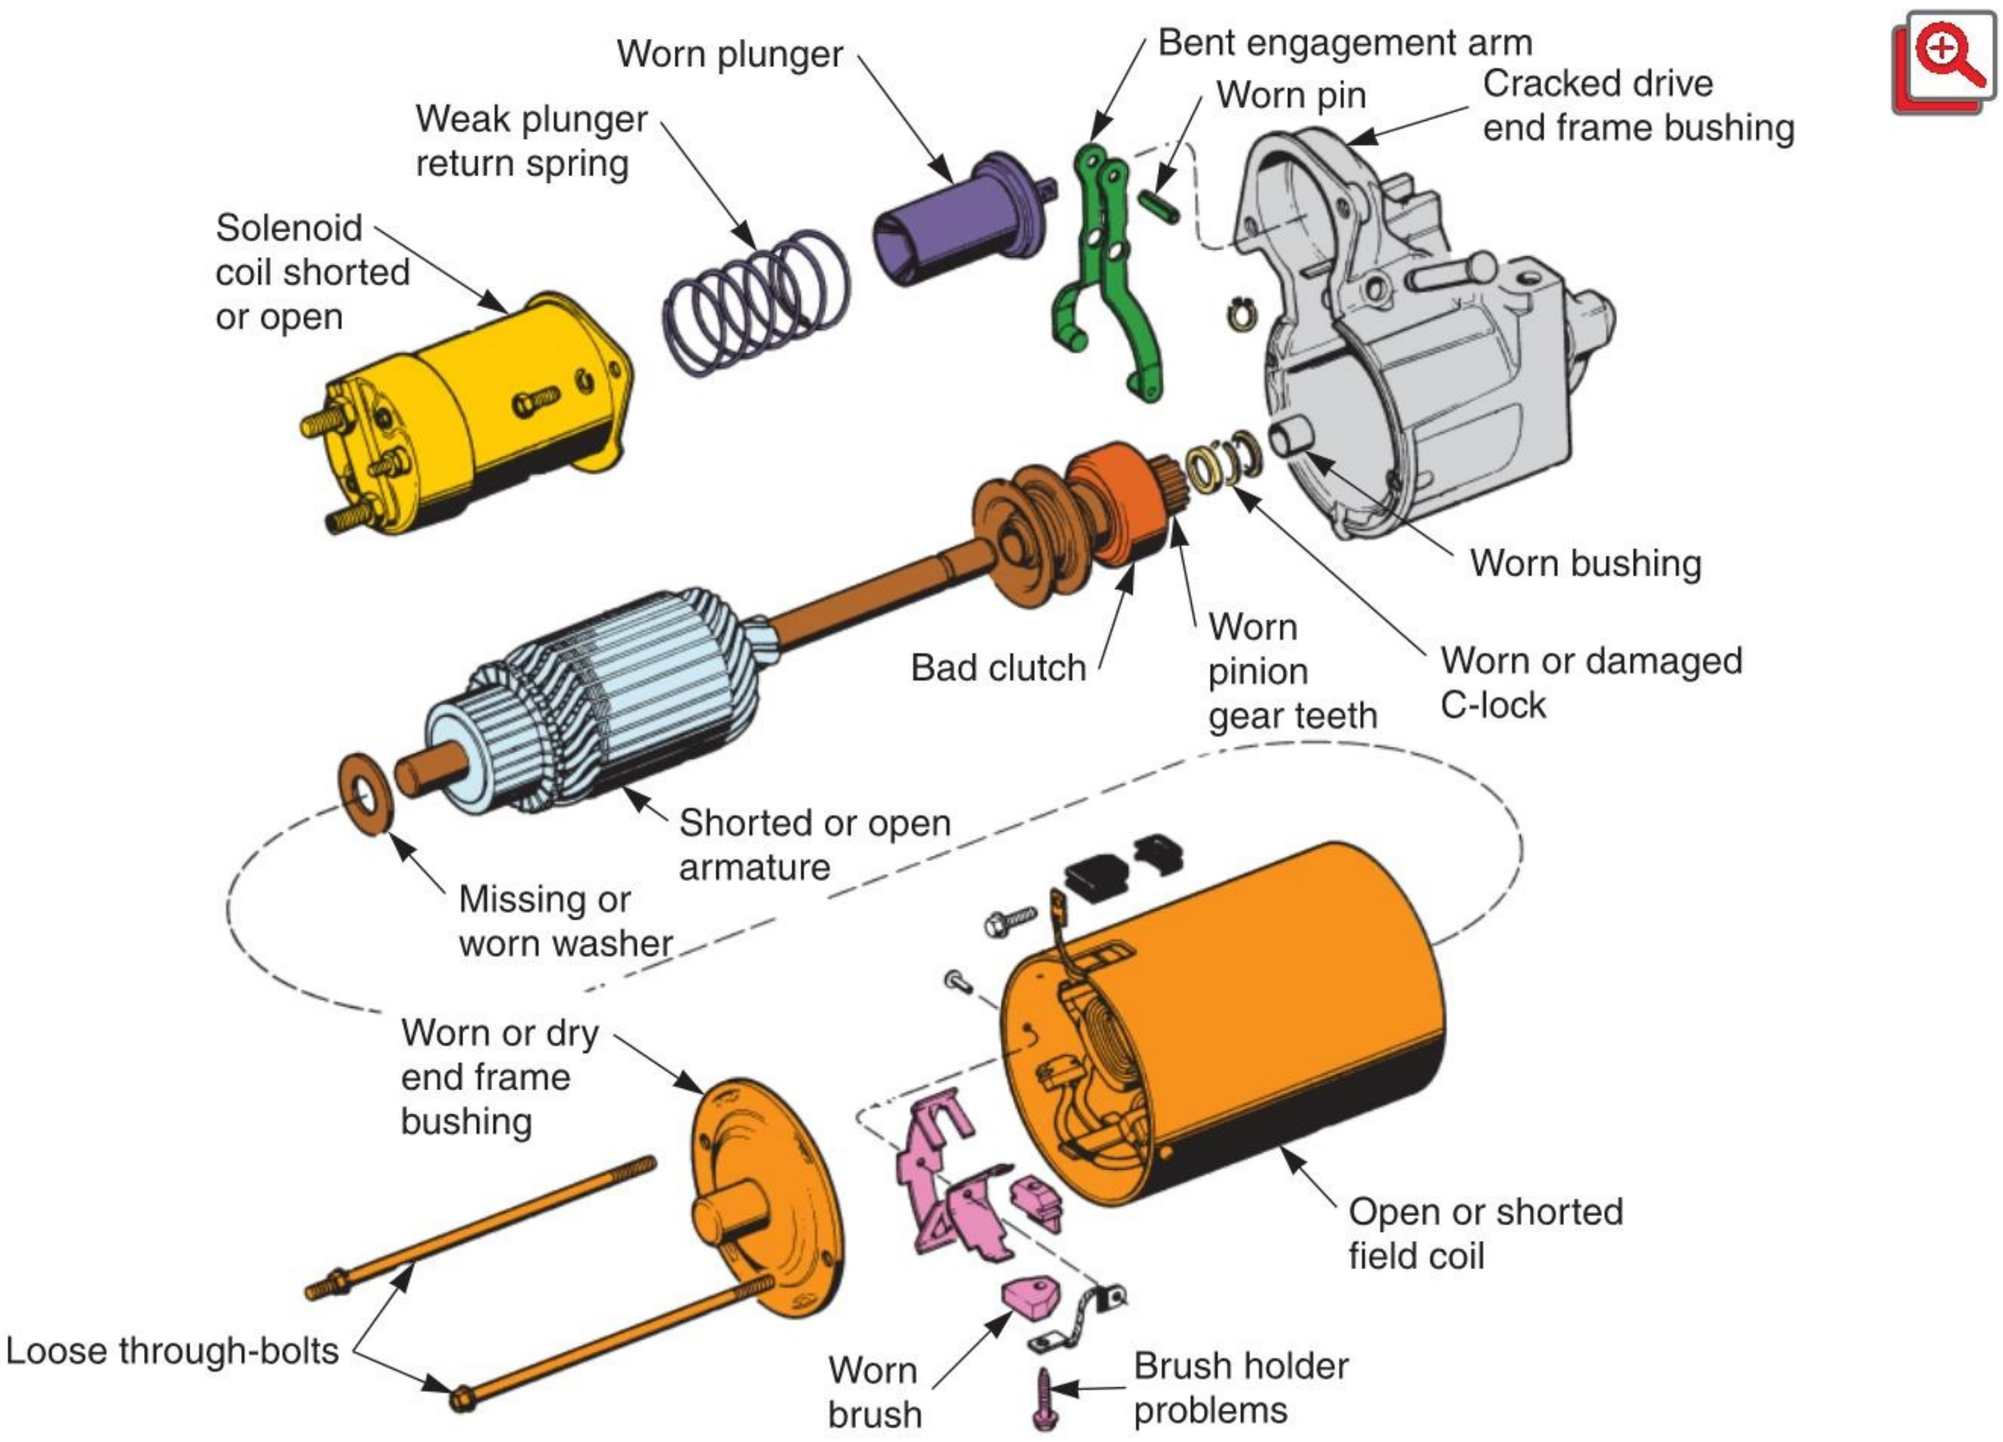
To adjust a neutral safety switch, loosen the fasteners holding the switch. The switch may be located on the steering column, shift lever, or transmission. With the switch loosened, place the shift selector into park. While holding the ignition switch to start, slide the neutral switch on its mount until the engine cranks. Without moving the switch, tighten its hold-down screws. This should allow the engine to start only with the shift lever in park or neutral. Check operation after adjustment.

12-Volt Starter Service

A faulty starting motor can cause a wide range of symptoms: slow cranking, no cranking, overheating of starter cables, and abnormal noises while cranking. If the battery, cables, solenoid, and other starting system parts are good but the engine does not crank properly, the starter may be bad. See **Figure 31-9**. A current draw test and other tests will help you determine whether the starting motor should be removed for further inspection and testing.

12-Volt Starting Motor Removal

Before deciding to remove the starting motor, inspect it closely for problems. Check that the starter-to-engine bolts are tight. Loose starter bolts can upset motor operation by causing a poor ground or incorrect pinion gear meshing. Make sure all wires on the motor and solenoid are tight. If no obvious problems are found, the starter should be removed.



Goodheart-Willcox Publisher

Figure 31-9. Study the kinds of problems that require repair versus replacement of a starting motor. Solenoid and pinion gear problems can be repaired. Motor problems normally require a new or rebuilt starting motor.

Copyright Goodheart-Willcox Co., Inc.

Service Procedure

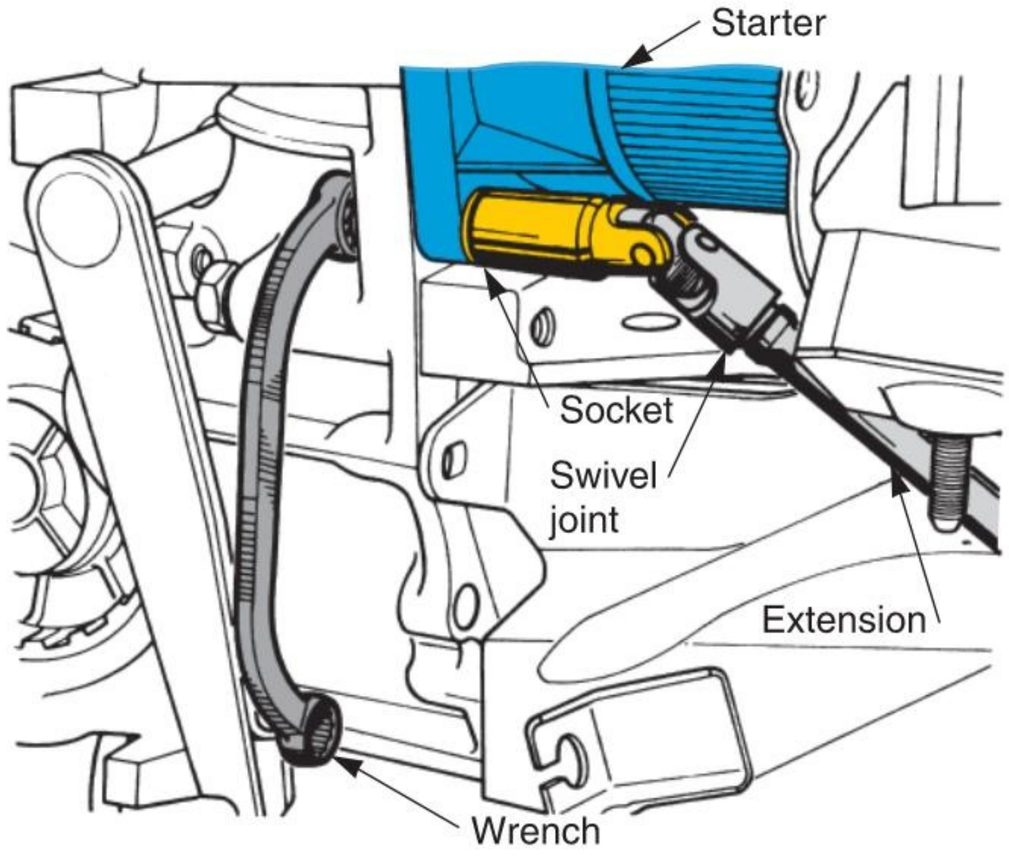
To remove a starter:

1. Disconnect the negative cable on the battery to avoid accidental cranking.
2. Unbolt the battery cable, solenoid wires (starter-mounted solenoid type), and any braces on the starting motor. See **Figure 31-10**.
3. Unscrew the mounting bolts while supporting the weight of the motor. Look at **Figure 31-11**.

Starter shims may be used to adjust the space between the pinion gear and the flywheel ring gear. During starter removal, always check for shims. They must be returned to the same place during reassembly. If the shims are not replaced, the pinion and flywheel gears will not mesh properly. A grinding noise will result, and the pinion and flywheel gears may be damaged.

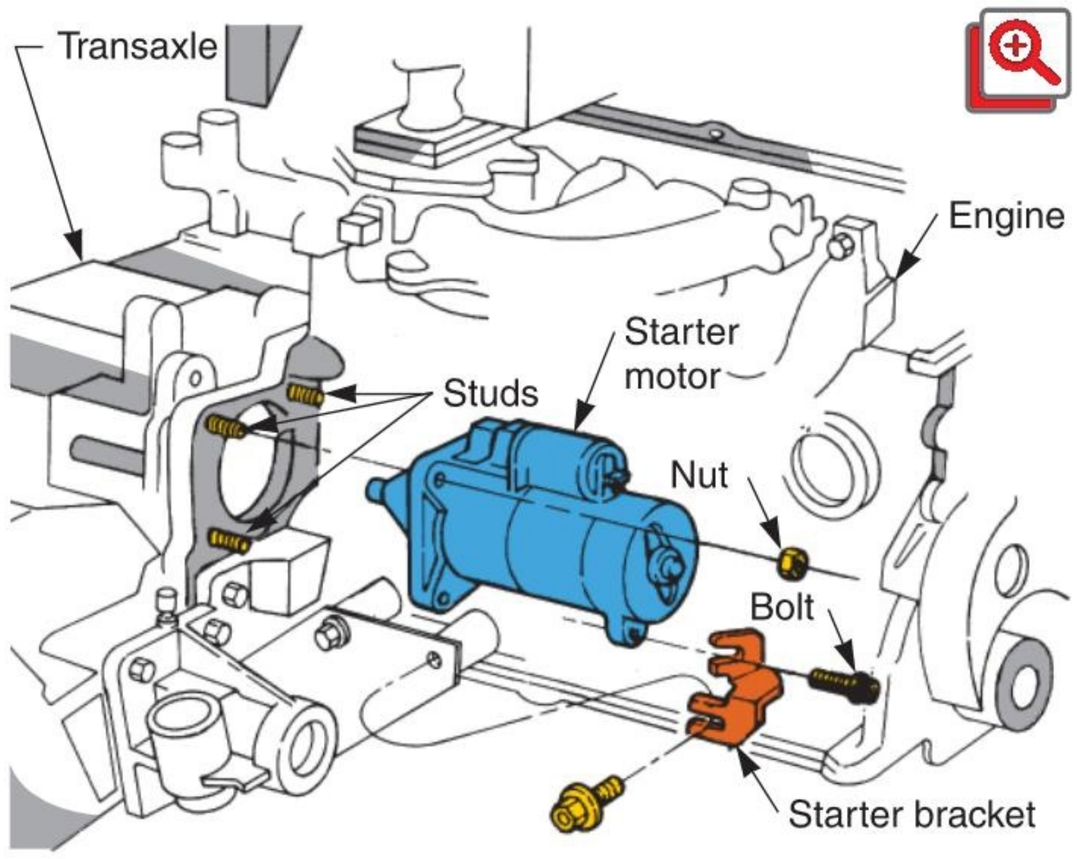
Tech Tip

In a few late-model engines, the starting motor is located under the engine intake manifold. You must remove the manifold to service the starting motor on these engines. Usually, only a few easy-to-reach bolts secure the intake manifold.



Chrysler

Figure 31-10. When starting motor fasteners are hard to reach, a swivel, extension, and ratchet may help.



Chrysler

Figure 31-11. To remove a starter, remove fasteners, wires, and brackets or heat shields. Hold the starter firmly because it is fairly heavy.

12-Volt Starting Motor Rebuild

A ***starting motor rebuild*** typically involves:

1. Disassembling the starting motor.
2. Cleaning parts and inspecting them for wear or damage.
3. Replacing brushes, bushings, and other worn or damaged parts.
4. Polishing or turning the commutator.
5. Lubricating, reassembling, testing, and installing the starting motor.

Many shops do not rebuild starting motors. Instead, they purchase and install new or factory-rebuilt units. The cost of labor is too high to make in-shop rebuilding economical. Also, the factory-rebuilt units will have a limited warranty.

Tech Tip

When the starter must be repaired, you may only need to disassemble a section of the starter. For example, a worn pinion gear can make the starter disengage before engine start-up. The clutch will freewheel before the engine has cranked. The pinion gear assembly can be replaced without complete starting motor disassembly. By removing only the drive end frame and a C-lock, the brushes and the other end of the motor can usually be left together.

Copyright Goodheart-Willcox Co., Inc.

12-Volt Starting Motor Installation

Install the starter in the reverse order of removal. Make sure that any spacer shims are replaced between the motor and the engine block. If these shims are left out, the pinion gear may not mesh with the flywheel gear properly.

If the starter has a solenoid on it, connect the wires on the solenoid before bolting the starter to the engine. Torque the starter mounting bolts to specifications. Replace any brackets or shields and reconnect the battery. Crank the engine several times to check starting motor operation.

Hybrid Starting System Diagnosis

Late-model hybrids have an extensive list of trouble codes for the main components of the engine starting system. OBD systems will indicate problems with the motor-generator, HV power control module, HV battery, and many other components. Usually, stored trouble codes will indicate which circuit is not functioning normally. See **Figure 31-12**. The

OBD II Hybrid Propulsion Diagnostic Trouble Codes (P0AXX)

instrument panel combination meter will also indicate poor electrical drive performance during all-electric (motor-generator driven) acceleration and regenerative braking.

Your scan tool will indicate the source of the problem if any starting circuit voltage, current, or resistance is not within specifications. If HV battery voltage, motor-generator current draw, HV power control module voltage, or current output is low or high, the OBD system will tell you where to start your tests.

Motor-Generator Problems

Late-model hybrid vehicle HV starting systems are very dependable. They use industrial-sized three-phase motor-generators that can crank an engine using a fraction of their rated motor horsepower. Since motor-generators are designed to propel the weight of the whole vehicle at highway cruising speeds, they seldom cause an engine no-start problem. However, after several hundred thousand miles of operation, motor-generator bearings can wear and fail in service.

Motor-generator clutch problems can keep the HV motor from cranking the engine, even if the motor is functioning normally. If a transaxle clutch is used to link the motor armature to the engine crankshaft, the traction motor can require reduction gears to multiply torque. This will allow smaller traction motors to easily rotate the engine reciprocating assembly for starting. Failure of the motor-generator clutch and these transmission gears can also appear to be a motor-generator failure.

Hybrid control module and HV power control module problems can sometimes prevent the HV starting system from cranking the engine for starting. Trouble codes will direct you to the failed control module circuit for further tests.

Diagnostic Case Study

Concern: Mr. Figueroa stopped by the shop with a question about his car. "My engine just won't turn over," he says. "It will click, but nothing happens!" Duff explains that it is impossible to diagnose the problem without looking at the vehicle. Mr. Figueroa agrees to have the vehicle towed to the shop for a proper diagnosis.

Cause: After pushing the car into the shop, Duff turns the key to start in an attempt to verify the problem. As Mr. Figueroa explained, the starter clicks but the starting motor does not turn the engine over. Duff suspects that the problem is a faulty solenoid on the starting motor and assigns the job to one of his apprentice technicians.

The apprentice technician uses a stethoscope to verify Duff's initial diagnosis. He places the stethoscope on the starter solenoid and is able to hear the solenoid closing when the key is turned to start. This tells him that current is reaching the solenoid from the ignition switch. The technician then checks the voltage drop across the solenoid terminals while the key is turned. The voltage drop is excessive, indicating a faulty solenoid.

Correction: The technician removes the starter and solenoid. He notices that a few teeth on the flywheel ring gear are worn but knows that this problem would not cause the starter to fail. After disassembling the starter, the technician finds that the large round contact inside the solenoid is burned, preventing current flow from the battery to the starting motor windings.

The technician calls Mr. Figueroa to get his approval before making the repairs. He explains that a faulty solenoid is causing the no-crank problem but warns Mr. Figueroa that a few teeth on the flywheel ring gear are worn down and may cause further cranking problems. Mr. Figueroa tells the technician to replace the starter and solenoid, but he does not okay flywheel ring gear replacement because of the added cost.

The technician installs a new starter and solenoid. He then starts the vehicle several times to make sure the problem has been fixed. As he prepares Mr. Figueroa's invoice, the technician notes that he warned the customer about the ring gear wear. He also notes that Mr. Figueroa chose not to have the repair done.

Summary

- In a no-crank problem, the engine crankshaft does not rotate properly with the ignition key at start. The most common causes are a dead battery, poor electrical connection, or faulty system component.
- A solenoid buzzing or clicking sound, without cranking, is commonly due to a discharged battery or poor battery cable connections.
- A starting system humming sound, after momentary engine cranking, may be due to a bad starter overrunning clutch or a worn pinion gear unit.
- A starter metallic grinding noise may be caused by broken flywheel teeth or pinion gear teeth wear.
- A dead or discharged battery is one of the most common reasons the starting system fails to crank the engine properly.
- A starter current draw test measures the current used by the starting system. This will tell you about the condition of the starting motor and other system parts.
- Voltage drop tests will quickly locate a part with higher-than-normal resistance.
- An insulated circuit resistance test checks all parts between the positive battery terminal and the starting motor for excess resistance.
- A starter ground circuit test checks the circuit between the starting motor ground and the negative battery terminal.
- A battery cable problem can produce symptoms similar to a dead battery, bad solenoid, or weak starting motor.
- A bad starter solenoid can cause a range of symptoms, including no cranking (with or without a click) or slow cranking. It can also keep the engine or starting motor from shutting off.
- A bad ignition switch (starter feed section of switch) can prevent the starter solenoid from working normally.
- A misadjusted or bad neutral safety switch can keep the engine from cranking when the key is turned to start.
- If the battery, cables, solenoid, and other starting system parts are good but the engine does not crank properly, the starter may be bad. A current draw test and other tests will help determine whether the starting motor requires further inspection and testing.
- Starter shims may be used to adjust the space between the pinion gear and the flywheel ring gear. During starter removal, always check for shims.
- A starting motor rebuild typically involves disassembly of starting motor; cleaning and inspection for part wear or damage; replacement of brushes, bushings, and any other worn or damaged parts; polishing or turning of commutator; lubrication, reassembly, testing, and installation of starting motor.
- OBD systems will indicate problems with hybrid components, including the motor-generator, HV power control module, and battery stack. Stored trouble codes will usually indicate which circuit is not functioning normally.
- You must use high-voltage, high-current tests to pinpoint the problem when a hybrid engine fails to crank and start.
- Motor-generator clutch problems can keep the HV motor from cranking the engine, even if the motor is functioning normally.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

battery cable connection test
insulated circuit resistance test
no-crank problem
slow-cranking condition
starter current draw test
starter ground circuit test
starter shims
starting headlight test
starting motor rebuild
voltage drop tests

Activities

1. Demonstrate the use of a voltmeter in making voltage drop tests to detect excessive resistance in starting system components.
2. Make a video recording to show a procedure that would be hard to demonstrate for a class, such as starting motor removal and installation. Narrate the finished video and play it for the class.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What are the most common causes of a no-crank problem?
2. List two causes of a buzzing or a clicking sound from the starter solenoid.
3. List two causes of a humming sound after momentary engine cranking.
4. What commonly causes a metallic grinding noise during starting?
5. Summarize how a starting headlight test is performed.
6. Why is a starter current draw test used?
7. A high voltage drop in the starting system could indicate:
   (A) high resistance.
   (B) a loose electrical connection.
   (C) a corroded or burned terminal.
   (D) All of the above.
8. How do you test the battery cables?
9. List two symptoms of a bad starter solenoid.
10. A bad ignition switch can keep the starting motor from working and can also make the engine crank all the time. True or False?
11. How do you adjust a neutral safety switch?
12. Motor-generator clutch problems can keep the HV motor from cranking the engine. True or False?

ASE-Type Questions

1. A metallic grinding noise can be caused by each of the following *except:*
   (A) clashing gears.
   (B) broken flywheel teeth.
   (C) pinion gear tooth wear.
   (D) broken main feed wire.
2. After performing a starting headlight test, Technician A says the resulting bright lights and no-crank condition indicate starting circuit high resistance. Technician B says the test results suggest an open starting circuit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Which of the following tests measures the number of amps used by a starting system?
   (A) Starter current draw test.
   (B) Starter ground circuit test.
   (C) Insulated circuit resistance test.
   (D) All of the above.
4. A battery cable problem produces symptoms similar to each of the following *except:*
   (A) bad solenoid.
   (B) dead battery.
   (C) weak starter motor.
   (D) brush holder problem.
5. Which of the following is not an indication of a bad starter solenoid?
   (A) Slow cranking.
   (B) Clicking without cranking.
   (C) Cranking without starting.
   (D) No cranking and no clicking.
6. When removing a starter motor, which of the following should be done first?
   (A) Disconnect the battery.
   (B) Mark the end frames.
   (C) Unbolt the battery cable from the starter.
   (D) Remove any solenoid fasteners.
7. An ignition switch is being tested with a test light. When connected to the solenoid start terminal, the light glows when the key is in the start position and the run position. Technician A says the switch is working properly. Technician B says the ignition switch is most likely shorted. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

8. Technician A says a bad starter relay will keep power from the starter solenoid. Technician B says a faulty neutral safety switch can prevent current from flowing from the ignition switch to the starter solenoid. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says a starter rebuild generally involves replacing brushes, bushings, and other damaged parts. Technician B says the commutator is typically polished or turned during a starter rebuild. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. The HV starting system in a hybrid vehicle will not crank the engine for starting. Technician A says the problem could be caused by a faulty HV power control module. Technician B says the problem could be caused by a faulty hybrid control module. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Chapter 32
Charging System Technology

After studying this chapter, you will be able to:

- Describe the construction of major 12-volt charging system components.
- Explain charging system indicators and instrumentation.
- Explain the construction and operation of hybrid charging systems.
- Compare the operation of a 12-volt charging system to that of a hybrid charging system.
- Correctly answer ASE certification test questions that require a knowledge of charging system fundamentals.

In previous chapters, you learned how a 12-volt starting motor or a hybrid motor-generator uses battery power to crank the engine. The starting motor consumed electricity and partially discharged the battery.

In this chapter, you will learn how the charging system re-energizes the battery and supplies electricity for all the car's other electrical systems. This chapter will prepare you for the next chapter on testing and repair of 12-volt and hybrid charging systems.

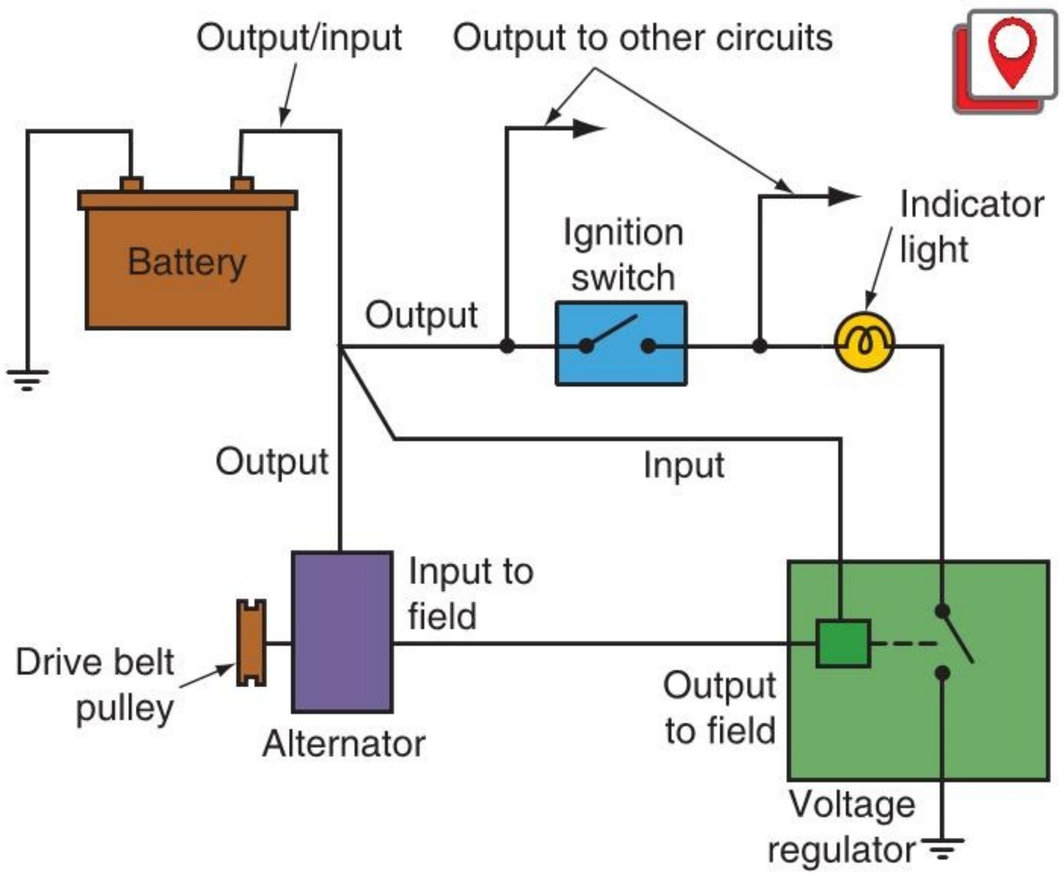
12-Volt Charging System Functions

The ***charging system*** performs several functions:

- It recharges the battery after engine cranking or after the use of electrical accessories with the engine shut off.
- It supplies all the vehicle's 12-volt electricity when the engine is running.
- It provides a 13-15 volt output, which is slightly higher than a battery fully-charged at 12.6 volts.
- It changes current and voltage output to meet different electrical loads.
- It provides smooth dc for the proper function of all of the vehicle's electronic circuits.

A basic 12-volt charging circuit is shown in **Figure 32-1**. When the engine is not running, the battery feeds current to the vehicle's electrical system. When the engine starts, a belt spins the alternator, causing the alternator to produce an electrical output. Current then flows back to the battery and into other electric circuits of the vehicle.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 32-1. This is a basic charging circuit. The alternator output is wired to the battery and to the vehicle's electrical system.

12-Volt Charging System

The major parts of a typical 12-volt charging system include:

- ***Alternator***—An alternator is an ***ac generator*** that uses mechanical (engine) power to produce electricity.
- ***Voltage regulator***—A voltage regulator is an electronic device that controls the voltage and current output of an alternator. The engine control module serves as the voltage regulator on late-model vehicles.
- ***Drive belt***—The drive belt links the engine crankshaft pulley with the alternator pulley to drive the alternator.
- ***Charge indicator***—A charge indicator often includes an ammeter, voltmeter, or warning light that informs the driver of problems with the charging system.
- ***Charging system harness***—The charging system harness is wiring that electrically connects the components together.
- ***Battery***—A 12-volt battery provides current to initially energize and smooth dc current output from the alternator.
- ***ECM***—The ECM usually monitors 12-volt charging voltage to alter rotor field strength and alternator current output to prevent overcharging and battery damage.

During engine cranking, the battery supplies all the electricity used by the automobile. Then, when the engine starts running, the charging system takes over to provide current to the vehicle's electrical systems.

The engine crankshaft pulley and alternator drive belt spin the alternator pulley. This turns the alternator and causes it to produce electricity. See **Figure 32-2**.

The voltage regulator keeps alternator output at a preset ***charging voltage*** (13–15 volts). Since this is higher than battery voltage (12.6 volts), current flows back into the battery and recharges it. Current also flows to the ignition system, electronic fuel injection system, on-board computers, radio, navigation, cell phone, or any other device that uses electricity.

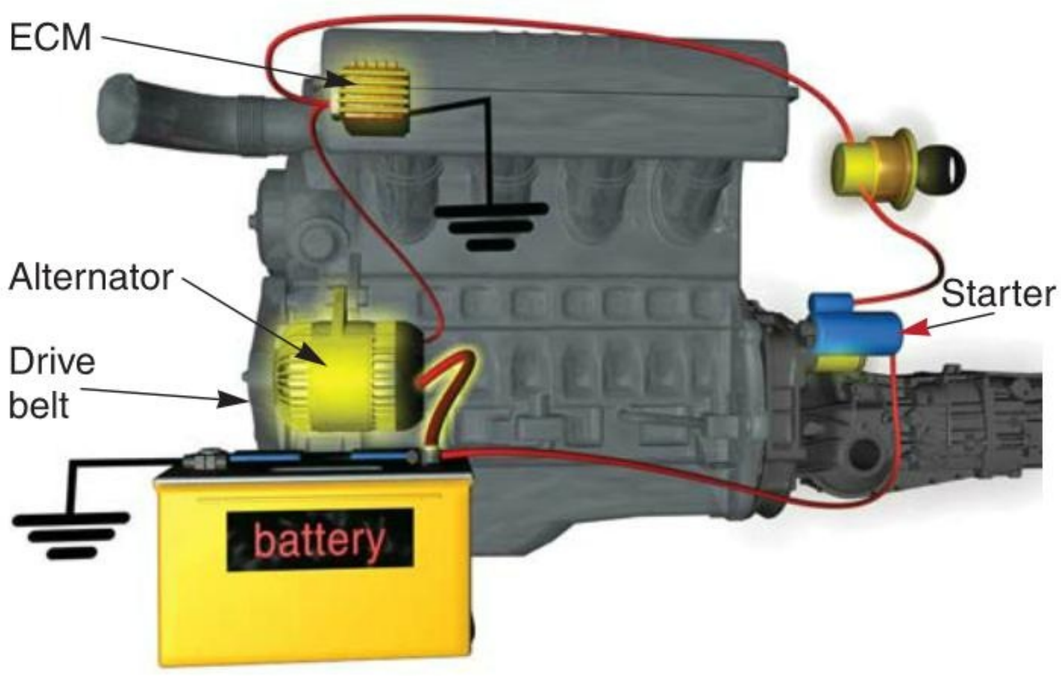
Alternator

It is very important that you understand alternator construction and operation. This information is essential to properly diagnose, test, and repair 12-volt starting systems.

The two main parts of a simplified alternator are the rotor and stator. The rotor is located in the center of the alternator housing. It creates a rotating magnetic field. The alternator drive belt turns the rotor, making the field rotate.

The stator is a stationary set of windings that surrounds the rotor. It is the output winding in the alternator. When the rotor spins, its strong magnetic field cuts across the stator windings. This induces current in the stator windings. If the stator windings are connected to a load (a lightbulb, for example), the load would operate (glow).

The simple alternator shown in **Figure 32-3** produces an alternating current (ac) output. Alternating current flows one way, and then the other. As the rotor turns into one stator winding, current is induced in one direction. Then, when the same rotor pole moves into



Goodheart-Willcox Publisher

Figure 32-2. The charging system recharges the battery and supplies electricity when the engine is running.

Goodheart-Willcox Publisher

Figure 32-3. A basic alternator operation shows a rotating magnetic field moving across the stationary windings. Current is induced in the windings and out to the load. When the rotating field turns one-half turn, the polarity of the windings is reversed. This causes current to flow out to the load in the opposite direction. Alternating current is produced.

the other stator winding, current reverses and flows out in the other direction. See **Figure 32-4**.

An automobile electrical system is designed to use direct current (dc), which flows in one direction only. It cannot use the alternating current as it comes out of the alternator's stator. Therefore, the alternator current must be rectified (changed) into direct current before entering the vehicle's electrical system.

Discussed in earlier chapters, a diode is an electronic device that allows current flow in only one direction. It serves as an "electric check valve." When a diode is connected to a voltage in such a way that current passes through the diode, the diode is said to be forward biased.

A ***forward-biased diode*** acts as a conductor. When a diode is connected to a voltage in such a way that current does not pass through, it is said to be reverse biased. A ***reverse-biased diode*** acts like an insulator. **Figure 32-5** illustrates diode action.

If a diode were placed on the stator output of our simple alternator, current would only flow out through the circuit in one direction.

A single diode would not use all of the alternator's output, however. Also, it would result in pulsing direct current, not smooth current flow. Therefore, an alternator uses several diodes connected into a rectifier circuit.

The main components of a typical alternator, pictured in **Figure 32-6**, include:

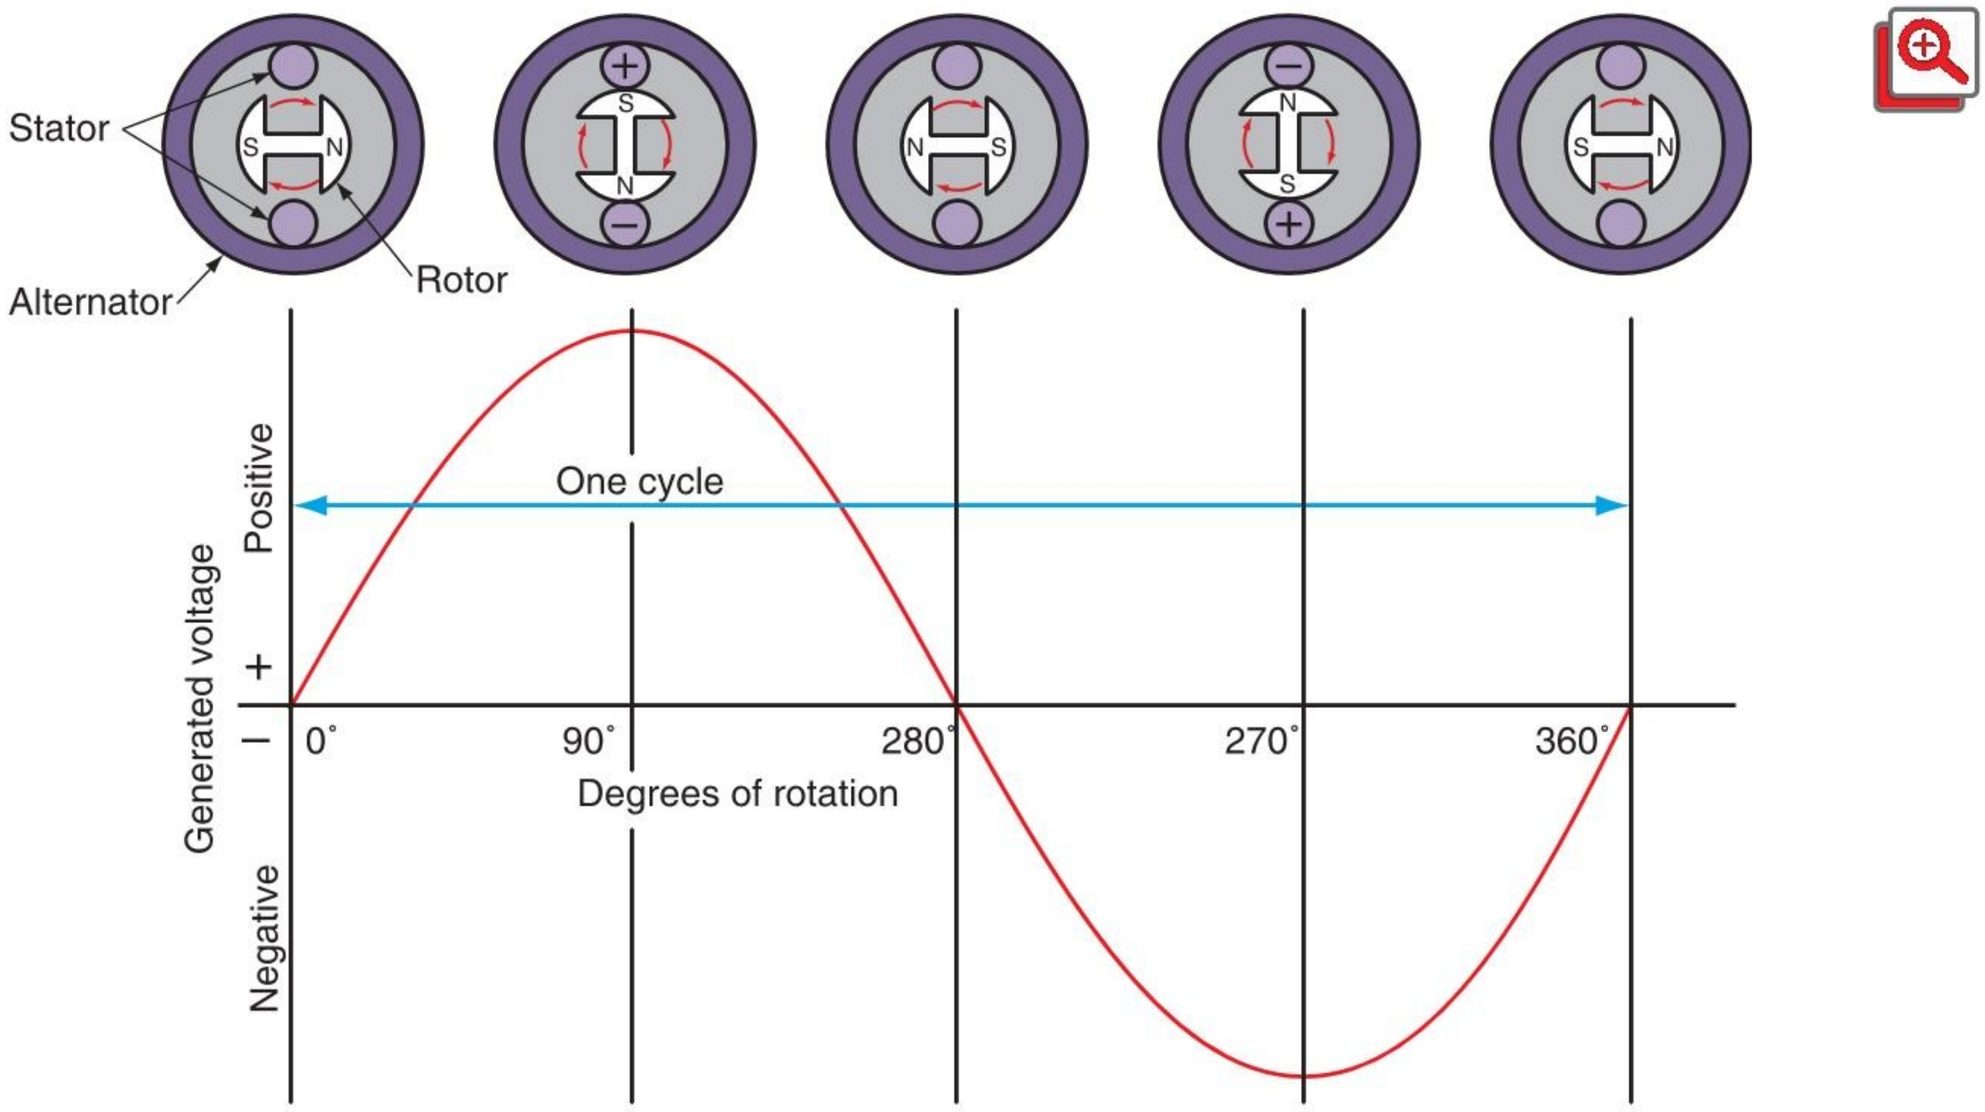
- Rotor—A rotor assembly consists of field windings, claw poles, rotor shaft, and slip rings.
- Brush assembly—The brush assembly includes the brush housing, brushes, brush springs, and brush wires.
- Rectifier—The rectifier assembly consists of diodes, a heat sink or diode plate, and electrical terminals.
- Stator—The stator assembly has three stator windings (coils), a stator core, and wires for the rectifier circuit.
- Alternator housing—The alternator housing is made up of the drive end frame, slip ring end frame, and end frame bolts.
- Fan and pulley—A fan and pulley assembly includes a fan, spacer, pulley, lock washer, and pulley nut.
- Voltage regulator—The voltage regulator is an electronic, small-voltage control circuit chip mounted in or on the rear housing of an alternator. In some cases, the engine control module serves as the voltage regulator.

Alternator Rotor Assembly

An ***alternator rotor assembly*** consists of field windings mounted on a shaft. Two claw-shaped pole pieces surround the field windings to increase the magnetic flux or the magnetic field strength.

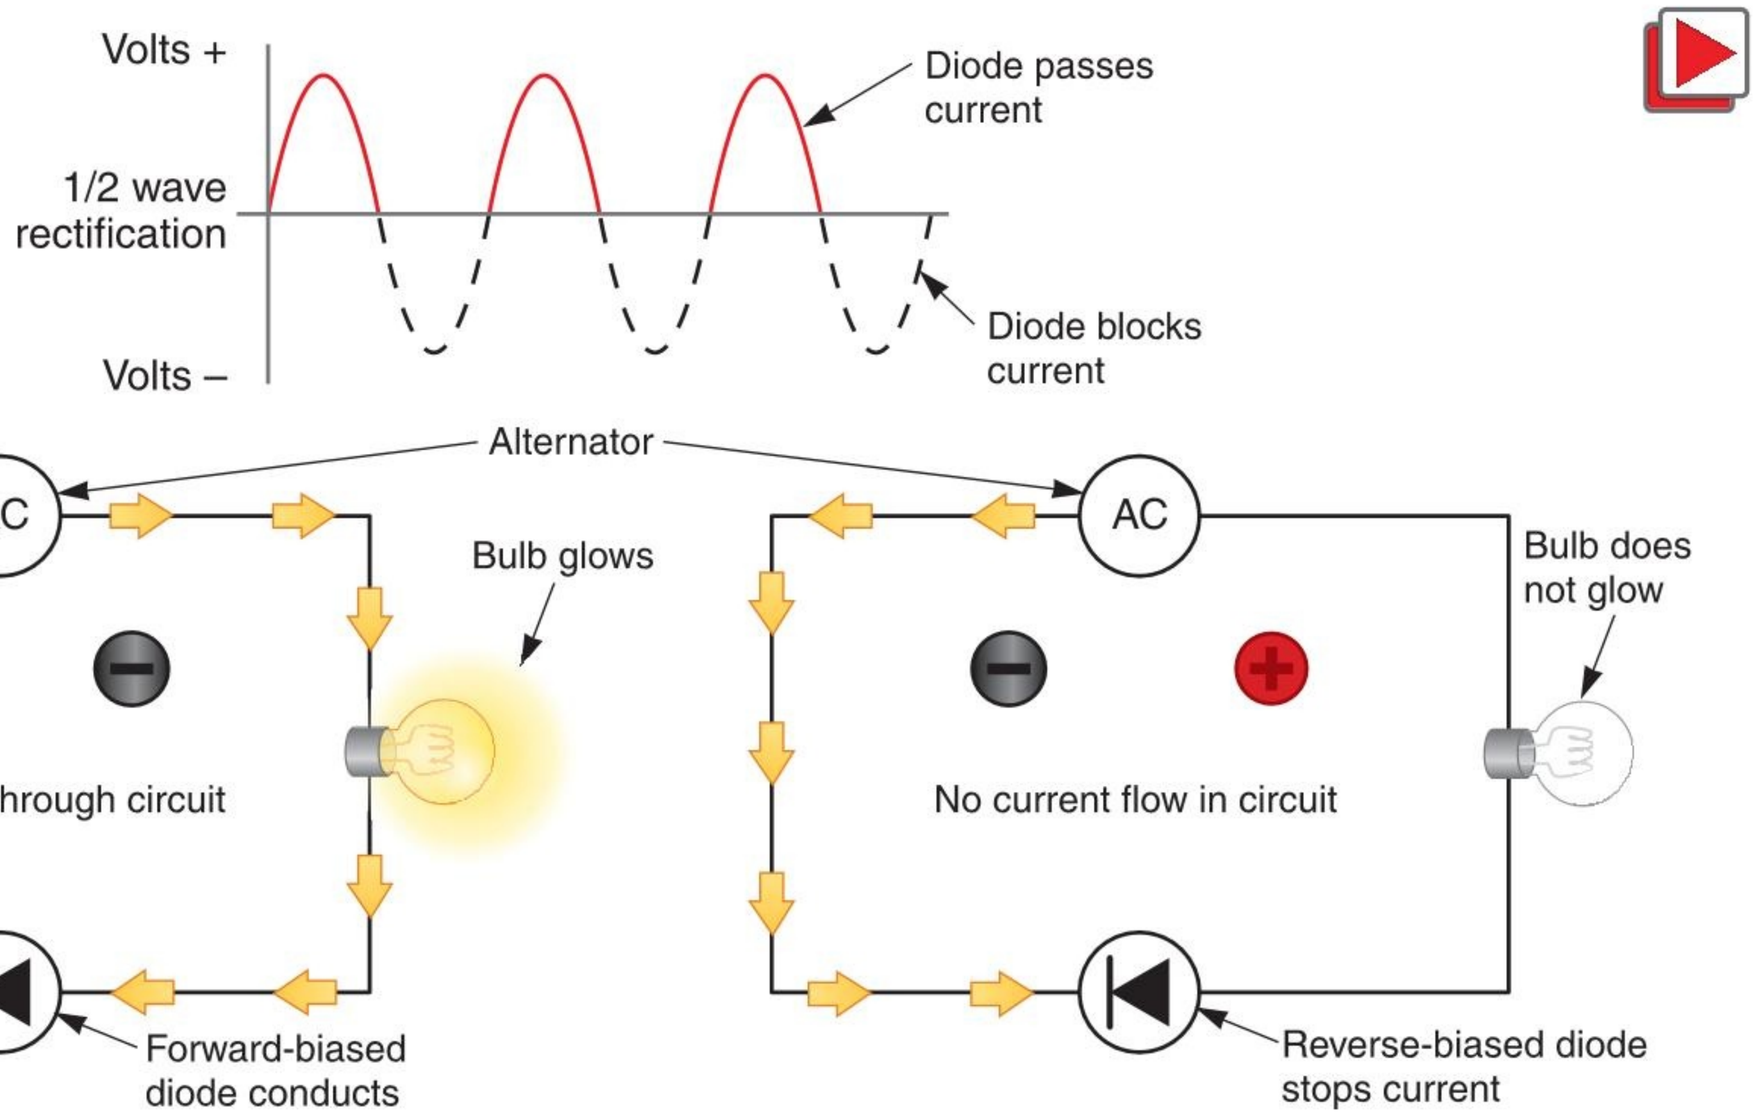
The fingers on one of the pole pieces produce S (south) poles. The fingers on the other pole piece form N (north) poles. As the rotor spins inside the alternator, the alternating polarity (north-south-north-south) produces an alternating current. This is illustrated in **Figure 32-7**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 32-4. The spinning magnetic field induces current into the stationary windings of the stator. As the north and south poles of the spinning field cut across the stationary windings, an output current is generated. The sine wave represents the reversing polarity or reversing current flow.



Goodheart-Willcox Publisher

Figure 32-5. This simple circuit shows action of a diode. When the alternator output places forward bias on diode, current passes through circuit. With reverse bias, the diode prevents current flow. The bulb would only glow on the positive output wave from the alternator.

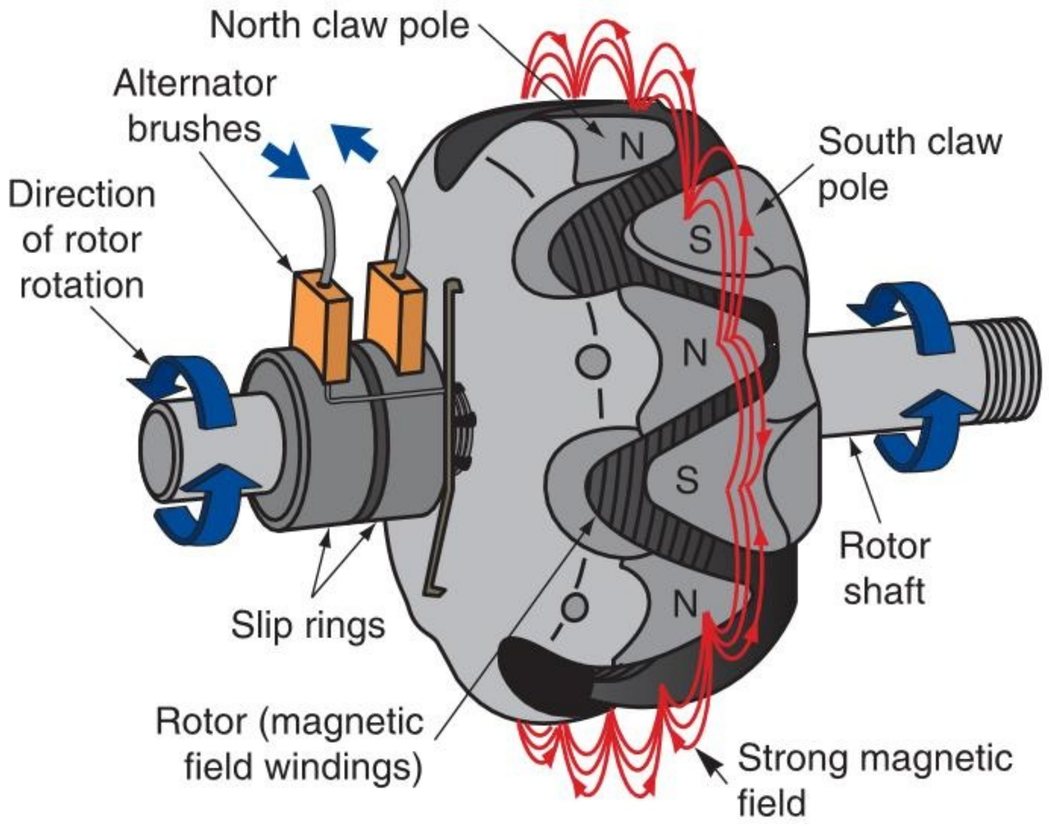
Ford

Figure 32-6. This exploded view shows the major parts of an alternator. Study the names of the parts and the general construction.



Goodheart-Willcox Publisher

Figure 32-7. The rotor has claw poles that surround its windings. This produces a strong magnetic field that induces current into the stator. Note the north and south poles of the claws.

Alternator Bearings

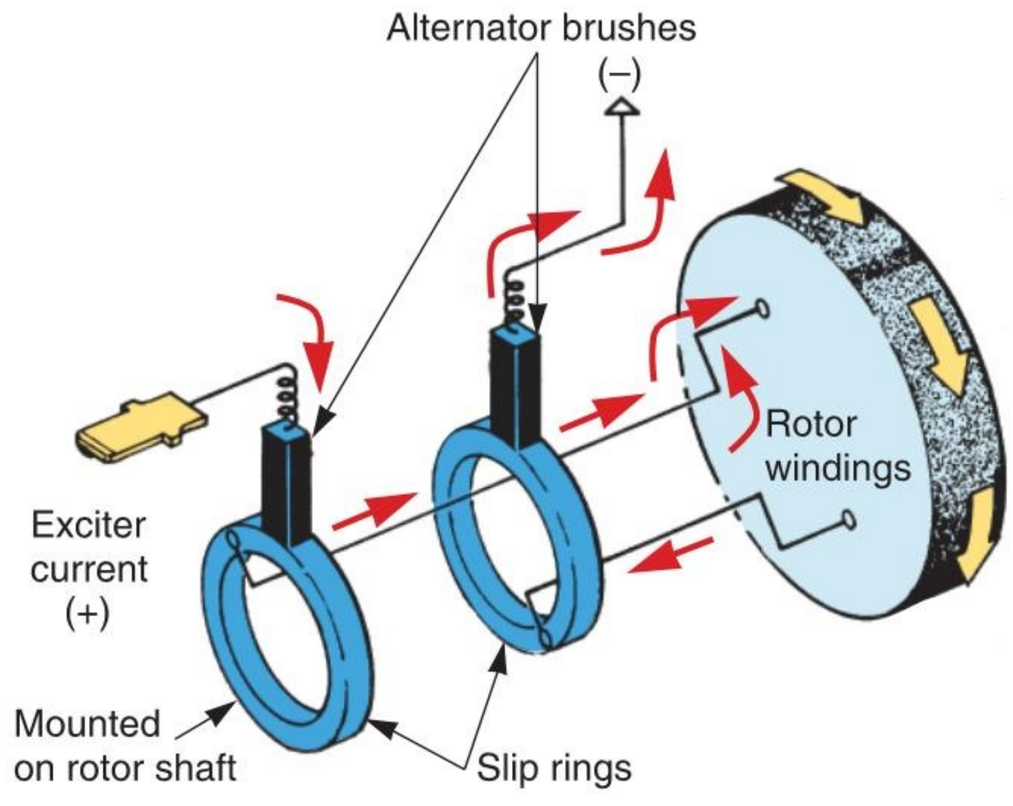
Alternator bearings (needle or ball types) are commonly used to produce a low-friction surface for the rotor shaft. These bearings support the rotor shaft as it spins inside the stator and alternator housing.

The alternator bearings are normally packed with grease. The front bearing is frequently held in place with a small plate and screws. The rear bearing is usually press-fit into place. The average service life of alternator bearings is about 10 years or 100,000 miles (160,934 km).

Slip Rings and Brushes

Alternator slip rings are mounted on the rotor shaft to provide dc current to the rotor's field windings. Each end of the field windings connects to one of the slip rings. Battery voltage is needed to excite the field windings, producing a magnetic field. See **Figure 32-8**.

Alternator brushes ride on the slip rings to make a sliding electrical connection. The brushes feed battery current into the slip rings and field windings. Small ***brush springs*** hold the brushes in contact with the slip



Motorola

Figure 32-8. Brushes and slip rings allow current to be fed into rotor windings. This excites windings to produce a rotating magnetic field.

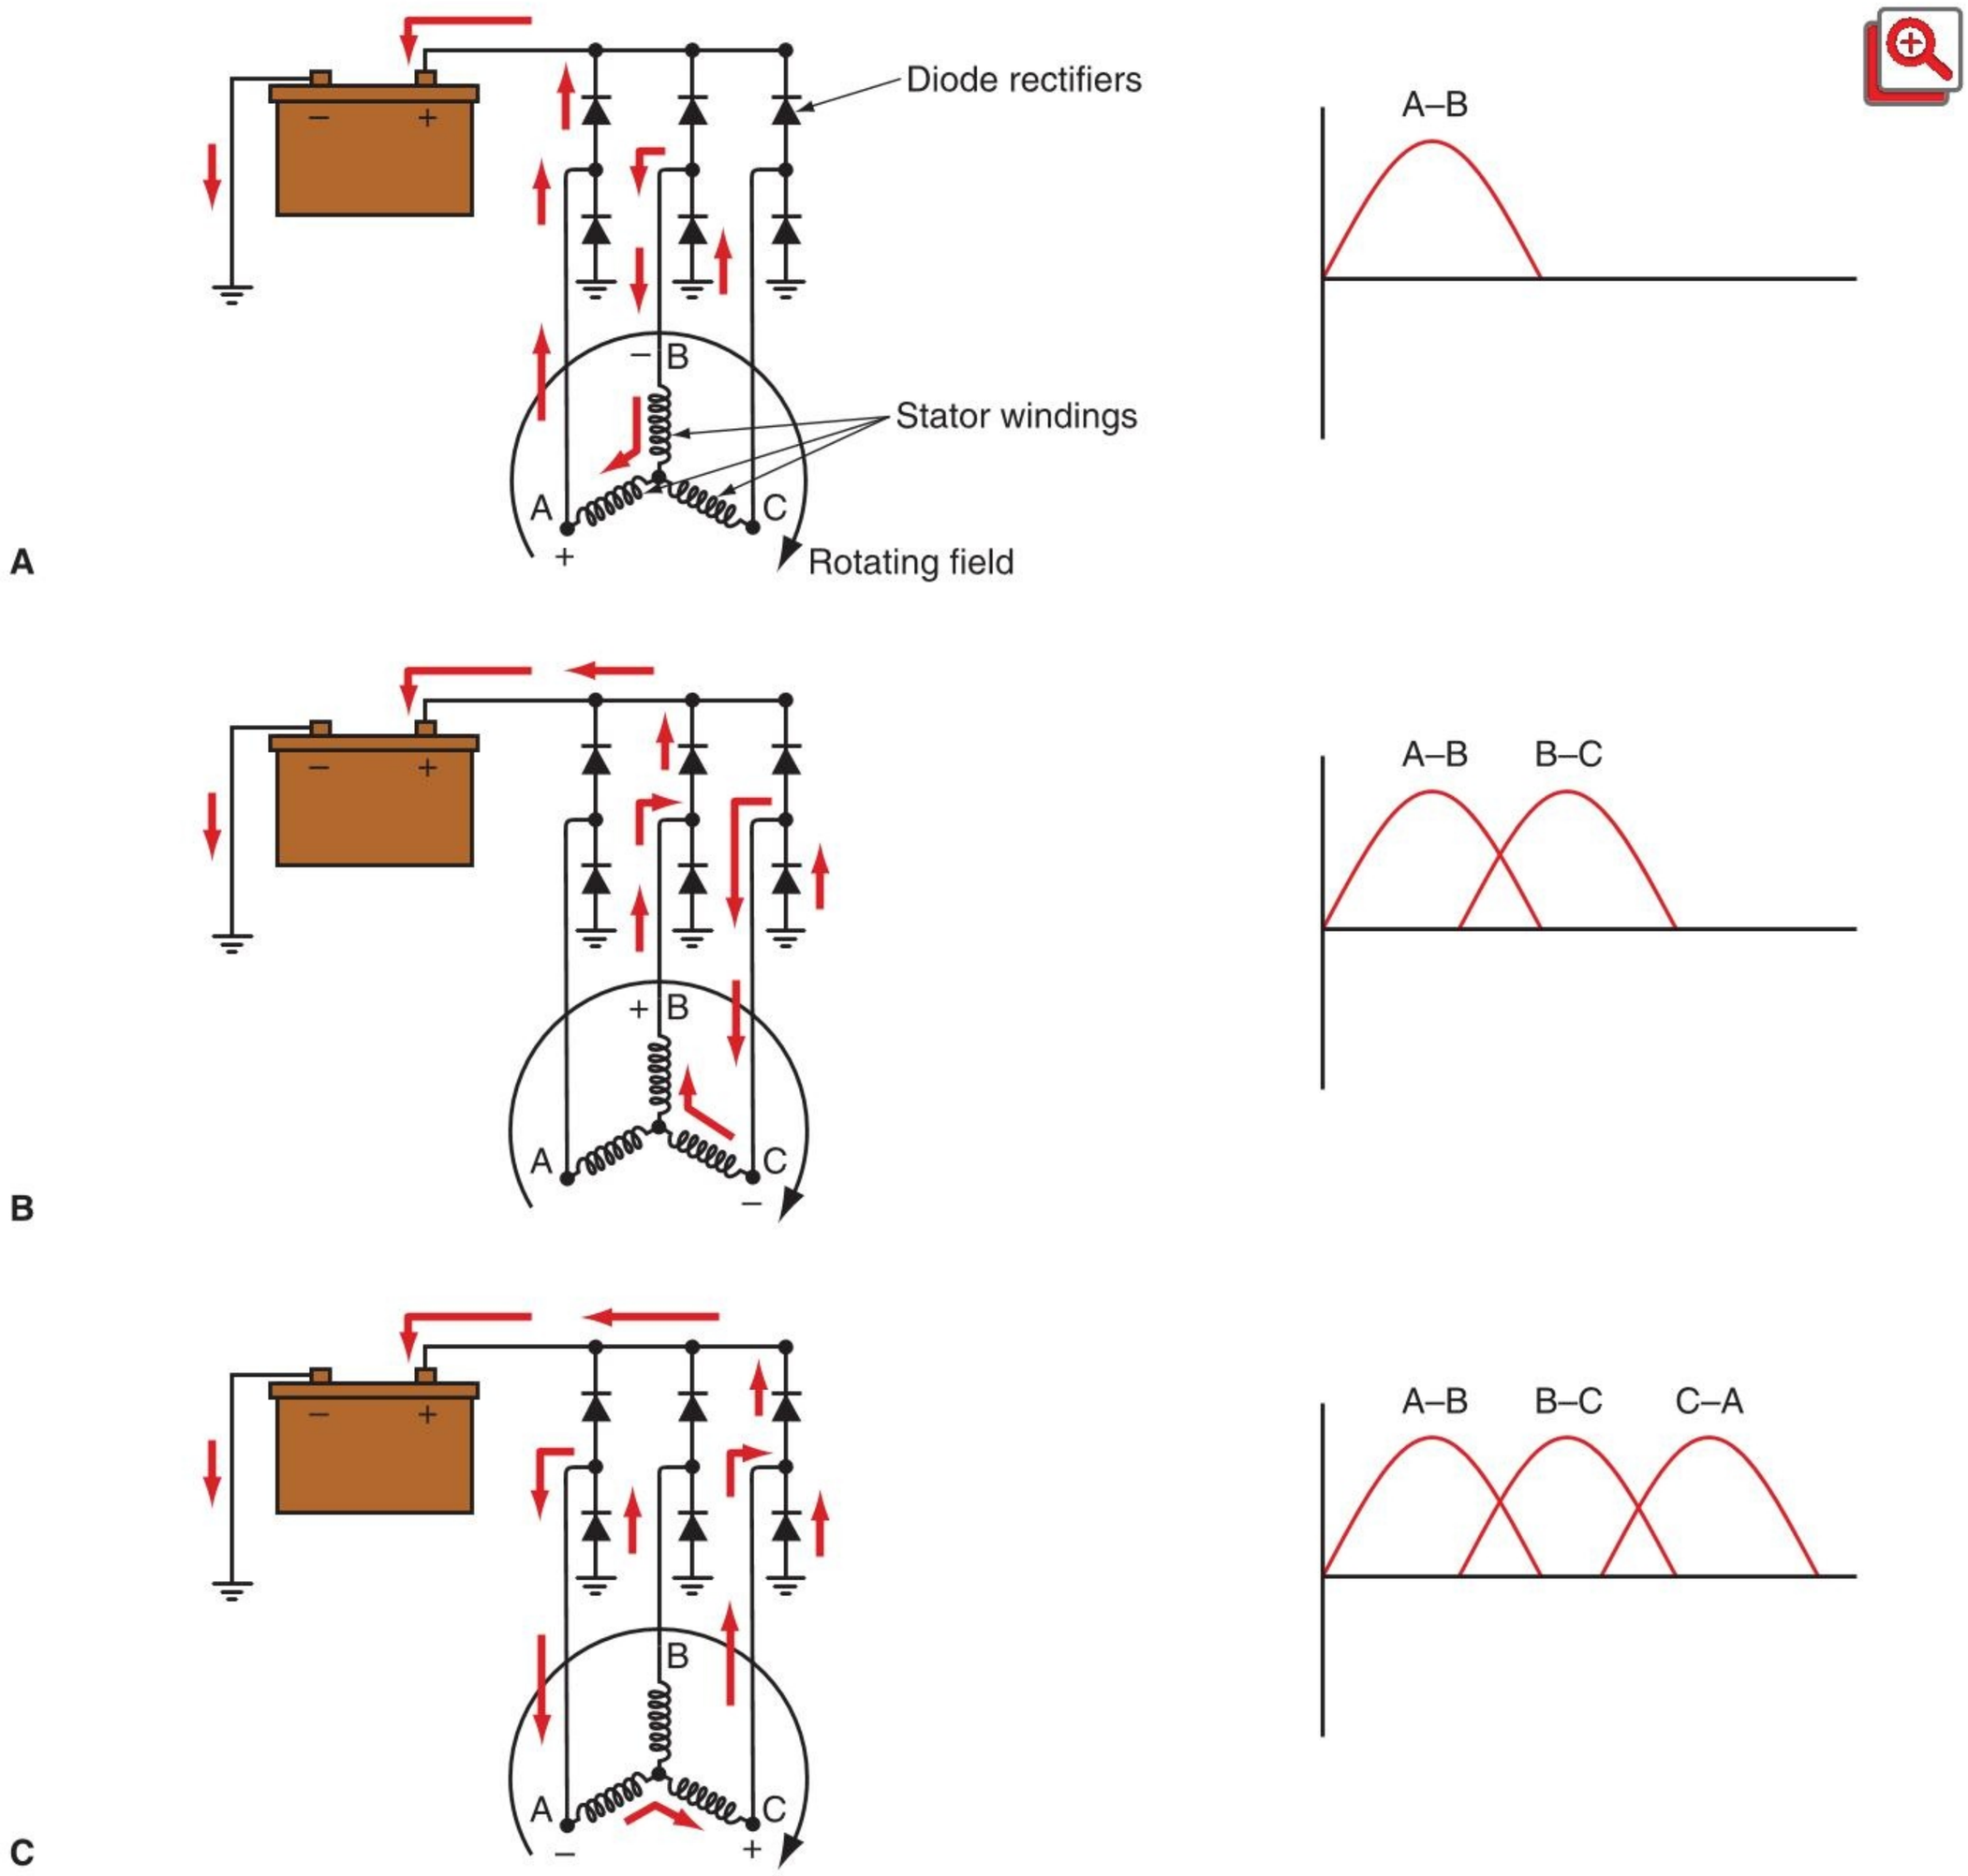
Copyright Goodheart-Willcox Co., Inc.

rings. Current flow into the field windings is low. Therefore, the brushes are small compared to motor brushes.

Alternator Rectifier

An ***alternator rectifier***, also called a ***diode assembly***, commonly uses six diodes to convert stator current (alternating current) to direct current. The diodes are usually wired as shown in **Figure 32-9**. The rectifier provides ***full-wave rectification*** (changes both positive and negative polarities into direct current) as the north and south poles of the rotor claws pass the stator windings.

A ***diode trio*** may be used to supply current to the rotor field windings. In a diode trio, three diodes are



Goodheart-Willcox Publisher

Figure 32-9. These diodes convert ac into dc. As the rotor turns, only two stator windings and two diodes are active at a time. A—Winding A and B are active and form a series circuit. Current flows from winding A, through one diode, and to the positive post of the battery. It returns through one diode to winding B. B—Current flows from winding B, through one diode, and to the positive post of the battery. It returns through one diode to winding C. C—Current flows from winding C, through one diode, and to the positive post of the battery. It returns through one diode to winding A.

Copyright Goodheart-Willcox Co., Inc.

connected to the field windings through a connection in the voltage regulator. The stator output feeds the diode trio.

The ***rectifier diodes*** are mounted in a ***diode frame*** or ***heat sink*** (metal mount for removing excess heat from electronic parts). Three positive diodes are press-fit in an insulated frame, and three negative diodes are mounted in an uninsulated or grounded frame. A stator with an attached rectifier is shown in **Figure 32-10**.

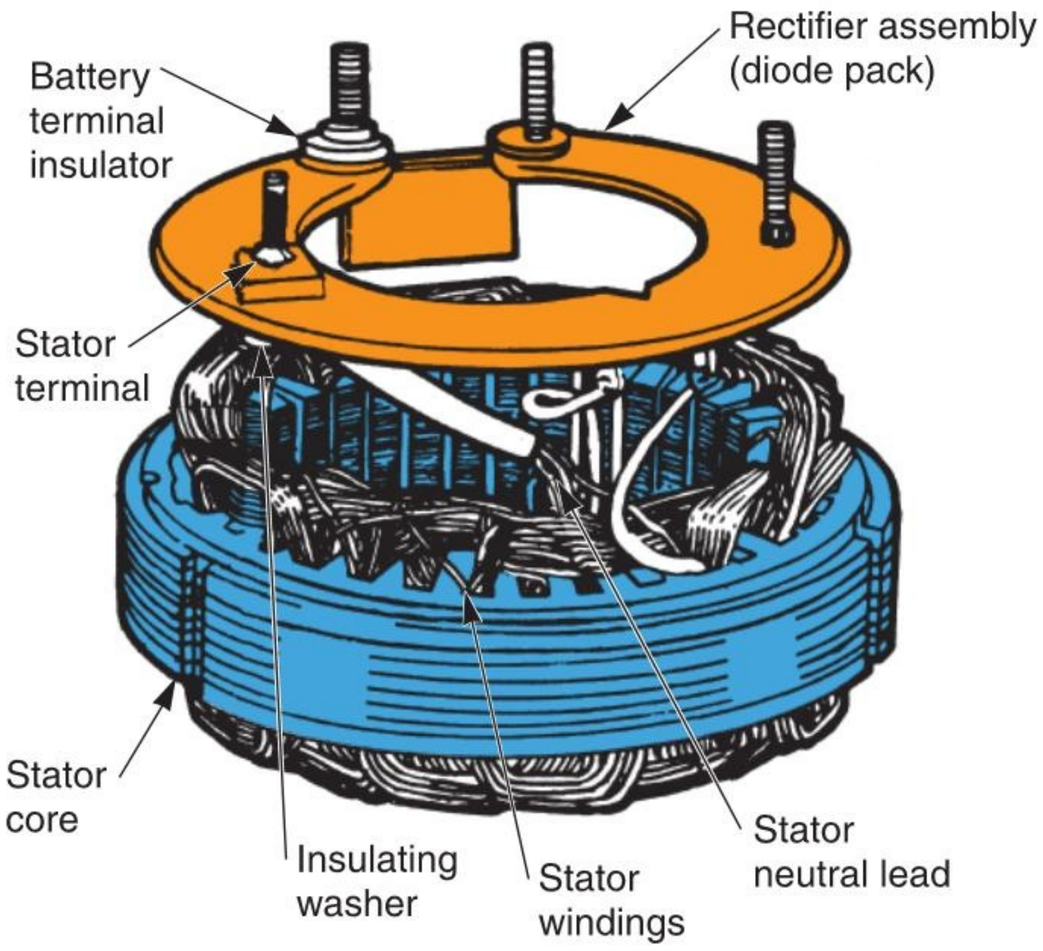
Alternator Stator

The ***alternator stator*** consists of three sets of windings. Each set is wrapped around a laminated iron core. The iron core is used to concentrate and strengthen the field around the stator windings. The stator produces the electrical output of the alternator. The stator windings connect to the rectifier.

Alternator Fan

To provide forced-air cooling for the alternator, an ***alternator fan*** is mounted on the front of the rotor shaft. Normally, the fan is located between the pulley and the front bearing. Look at **Figure 32-11**.

As the rotor and shaft spin, the whirling alternator fan helps draw air through and over the alternator. This cools the windings and diodes to prevent overheating and damage.

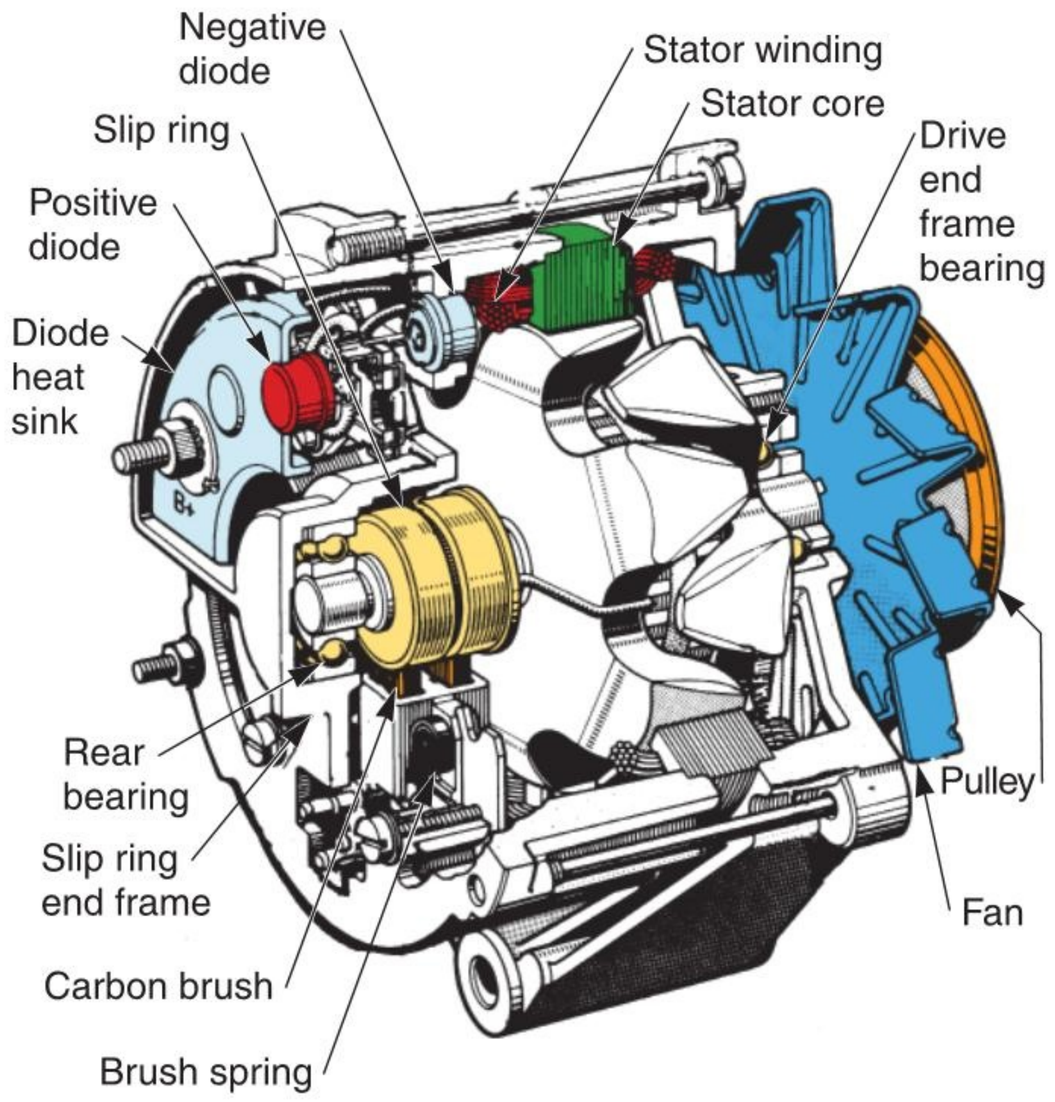


Ford

Figure 32-10. The rectifier assembly consists of six diodes in heat sink. Wires from the stator windings connect to the rectifier. An iron core around the stator windings increases induction.

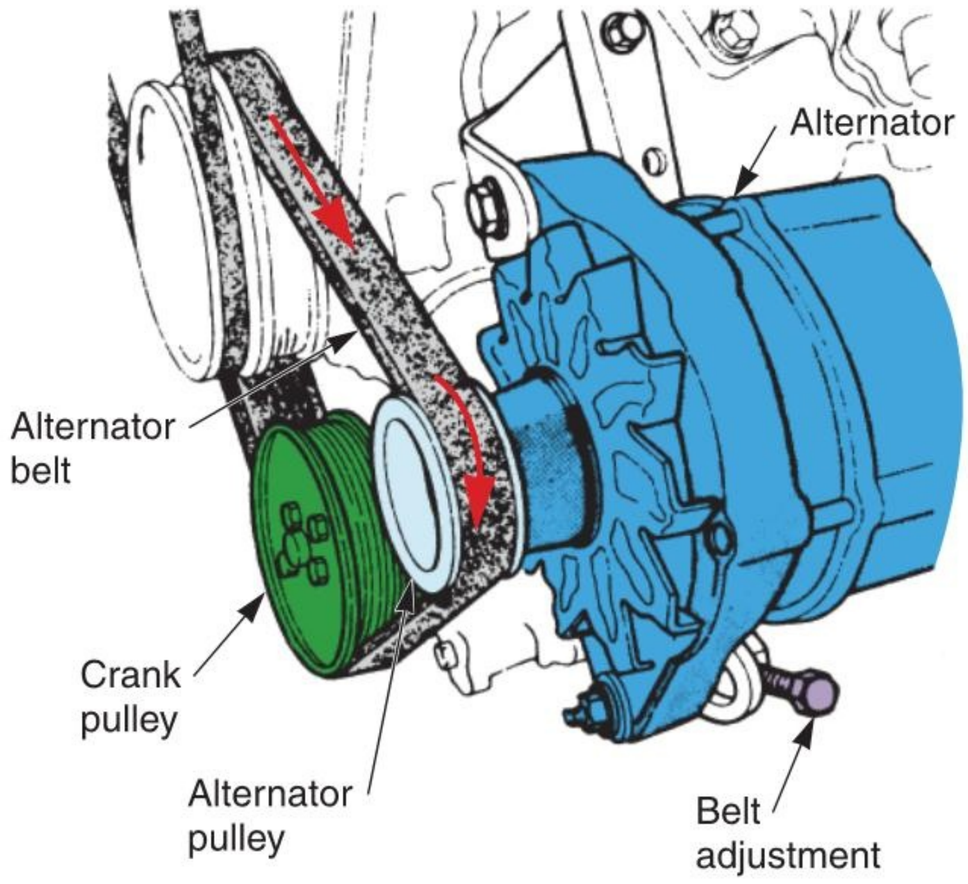
Alternator Pulley and Belt

An ***alternator pulley*** provides a means of spinning the rotor through the use of a belt. The pulley is secured to the front of the rotor shaft by a large nut. See **Figure 32-12**.



Bosch

Figure 32-11. This cutaway view shows many of the parts already discussed. Note the construction.



Sun Electric

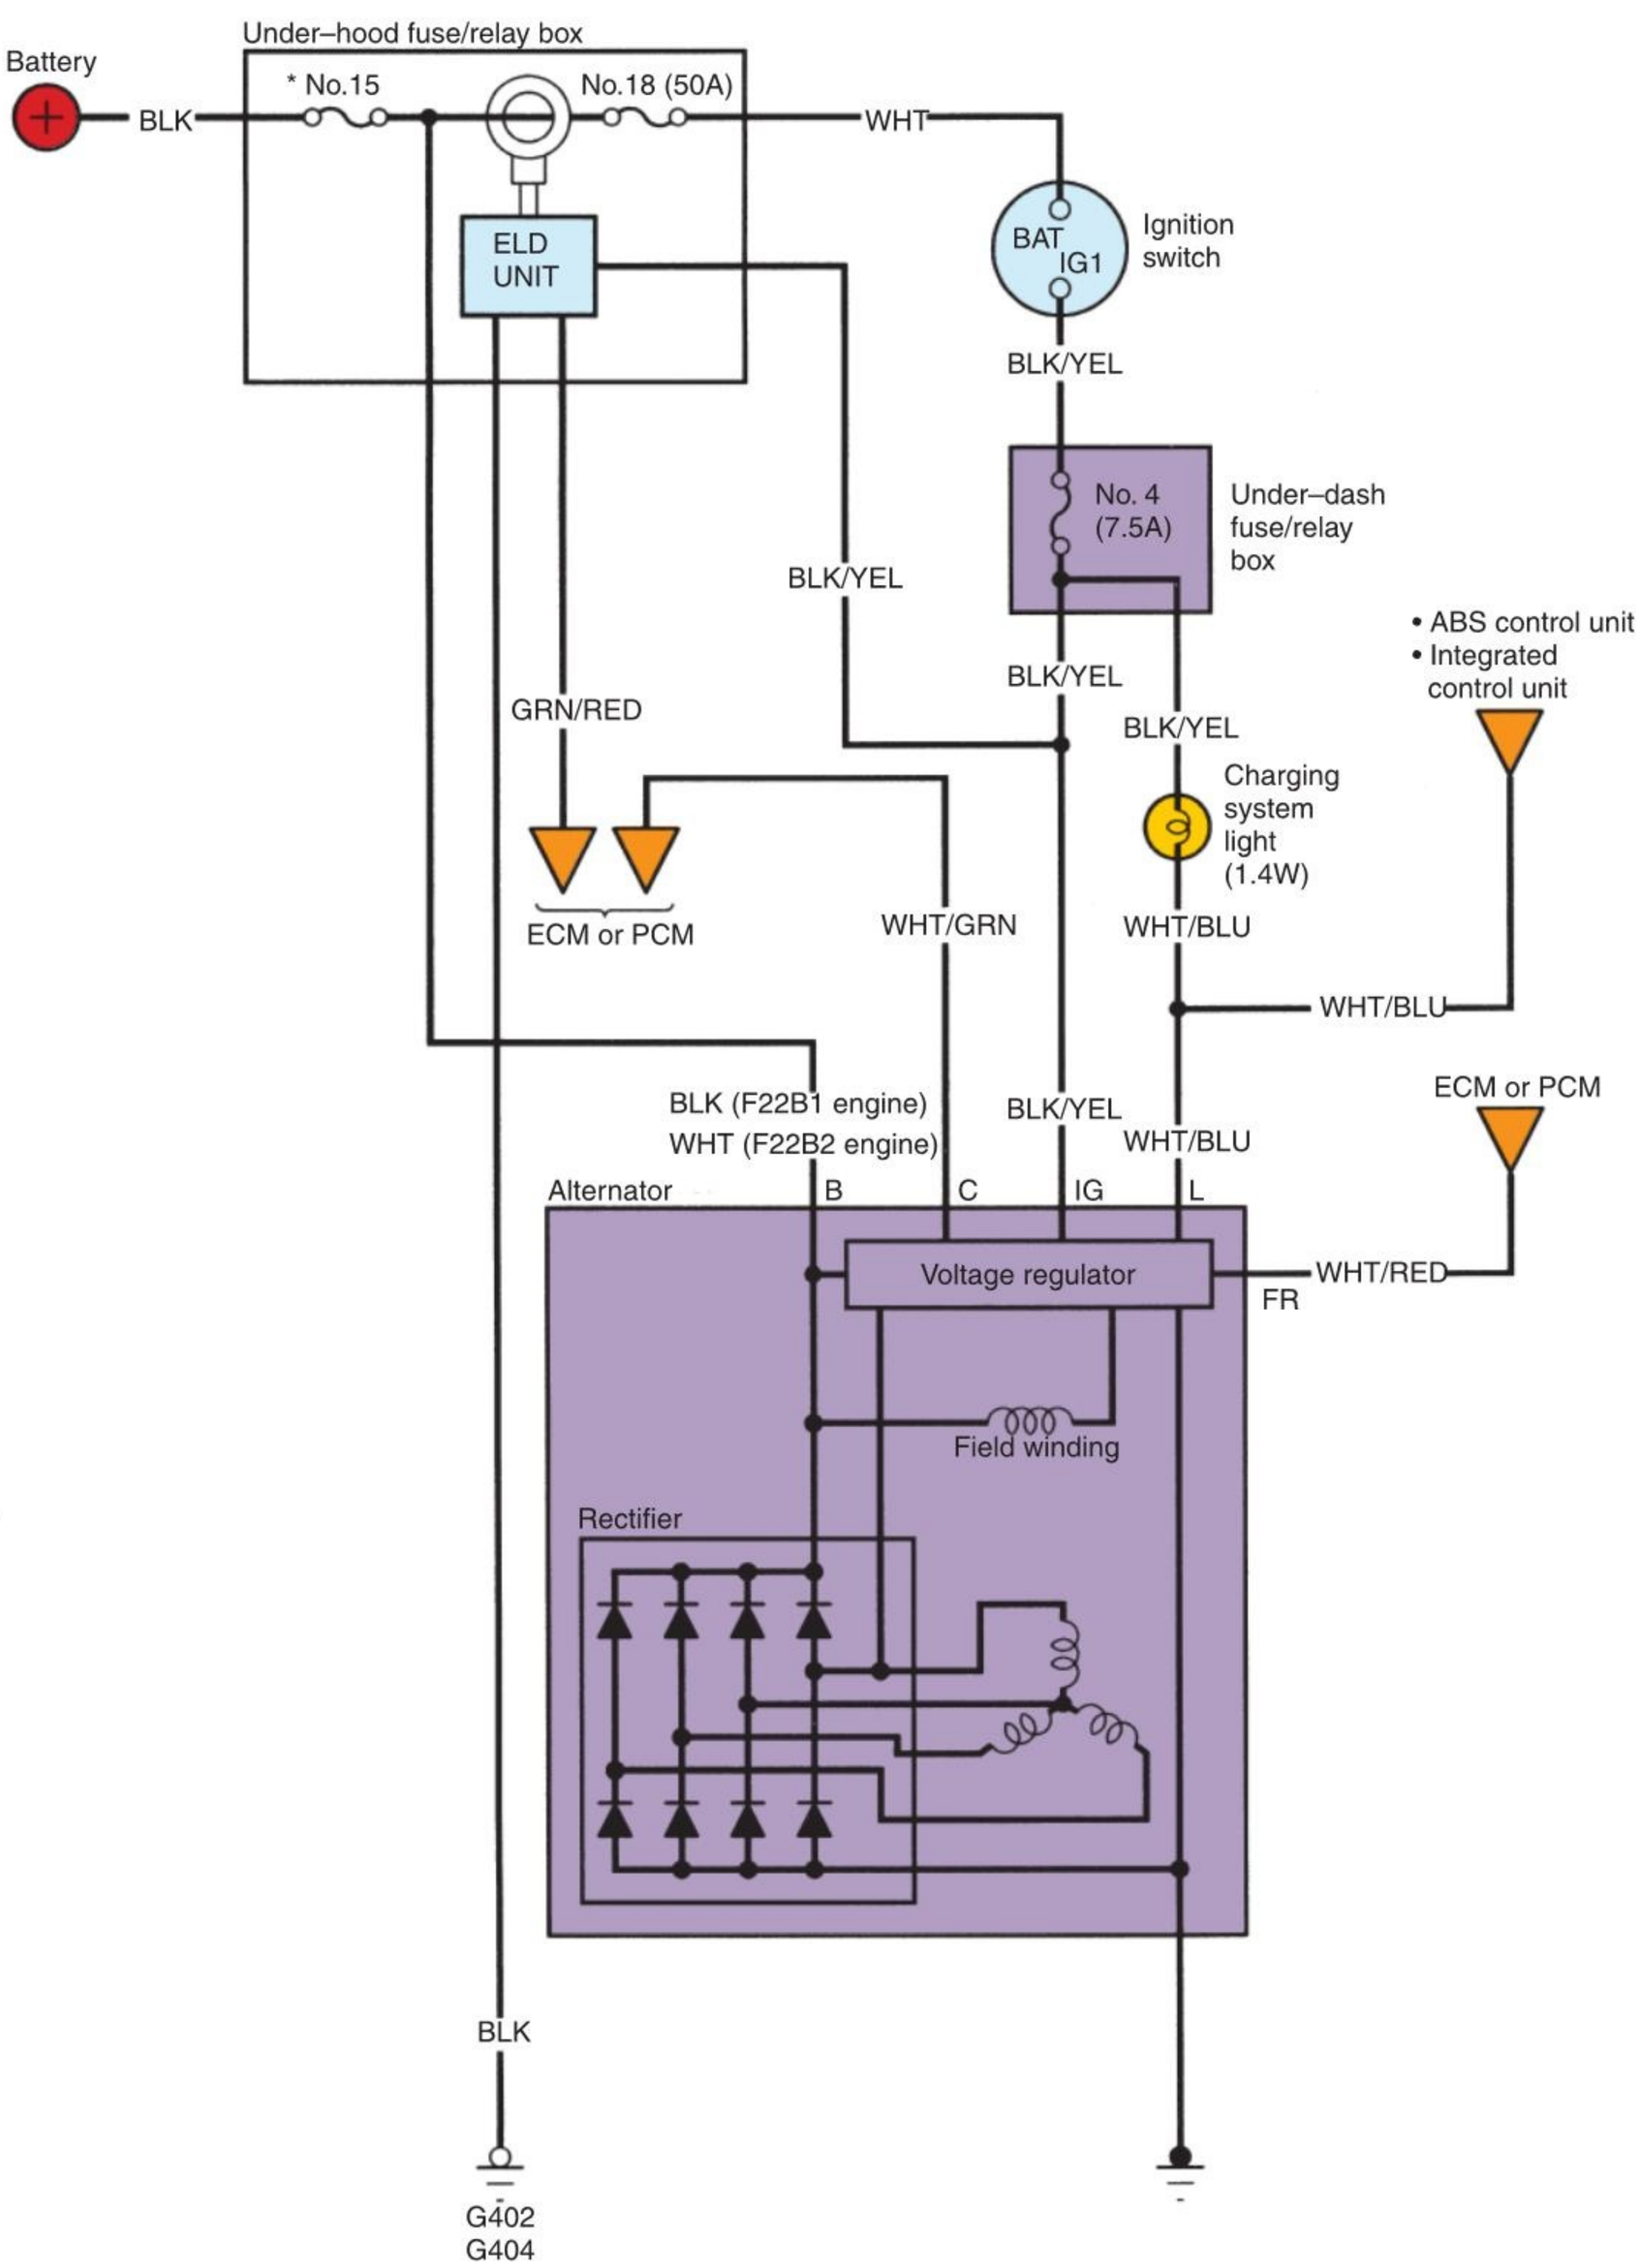
Voltage Regulator

A voltage regulator uses an electronic circuit to control alternator output by changing the amount of current flowing through the rotor's field windings. Any change in field winding current changes the field strength acting on the stator (output) windings. In this way, the voltage regulator can maintain a preset charging voltage of 13–15 volts. See **Figure 32-13**. The regulator can be mounted inside or on the back of the alternator.



Honda

Figure 32-13. Charging system schematic diagram. The voltage regulator is an unserviceable miniature electronic circuit. Note other connections.

Copyright Goodheart-Willcox Co., Inc.

An electronic voltage regulator is a sealed unit and cannot be repaired. The electronic circuit must be sealed because it can be damaged by moisture, excessive heat, and vibration. Usually the circuit is surrounded by a rubber-like gel for protection.

An ***integral voltage regulator*** is mounted inside or on the rear of the alternator. It is the most common type used on today's vehicles. The integral regulator is small, efficient, and dependable. In many cases, the engine control module serves as the voltage regulator.

Voltage Regulator Operation

To increase alternator output, the voltage regulator allows more current into the rotor's field windings. This strengthens the magnetic field around the rotor. More current is then induced in the stator windings, increasing alternator output.

To reduce alternator output, the voltage regulator places more resistance between the battery and the field windings. Magnetic field strength drops and less current is induced in the stator windings.

Alternator speed and electrical load determine whether the regulator increases or decreases charging output. If the load is high or the rotor speed is low (engine idling), the regulator will sense a drop in system voltage. The regulator then increases field winding current until a preset output voltage is obtained. If the load drops or rotor speed increases, the opposite occurs.

ECM Charging System Monitoring and Control

The engine control module or the power train control module is sometimes used to supplement or replace the conventional voltage regulator to more precisely control the charging circuit.

The control module can monitor charging system output and react to changing operating conditions. For example, the module can shut the alternator off at wide-open throttle for better vehicle acceleration, saving several horsepower. It can more accurately control charge rate, allowing the use of a smaller, lighter battery. The module can also monitor system operation to simplify diagnosis and repair by producing trouble codes and problem descriptions.

Basically, the computer controls the duty cycle of the alternator's field. The ***duty cycle*** is the percentage of time that current is fed to the alternator's field windings. A duty cycle of 50% is normal. With a large electrical load, the duty cycle would be high (long) to make the alternator produce high output. At low engine and alternator speeds with a high load, the regulator may use a 90% duty cycle (on time) to produce an output to meet the high load.

Modern electronic voltage regulators, either integral or in-computer types, can also progressively switch on charging voltage. If the full load of the alternator were to come on instantly, it could lug the idling engine down. Voltage regulator switching is very fast (about 400 cycles per second) to help prevent radio noise.

Battery Thermistor

In some systems, a ***battery thermistor*** is used to measure battery temperature so the charging system can alter charging output as needed. Generally, a cold battery requires more voltage for recharging than a hot battery. The battery thermistor is often mounted on the positive battery cable. It rests against the battery so it can measure battery temperature.

Fail-Safe Circuit

Some late-model charging systems have ***fail-safe circuits***, which disconnect alternator output if voltage levels become too high. This protects all the on-board electronics from being damaged by high voltage. The fail-safe circuit is designed into the voltage regulator. If the alternator stops working for no apparent reason, suspect this circuit, which is located in the electronic voltage regulator chip.

Alternator Drive Belt

An ***alternator drive belt***, powered by the crankshaft pulley, turns the alternator pulley and rotor. One of three belt types may be used: V-belt, cogged V-belt, or ribbed belt. These are pictured in **Figure 32-14**.

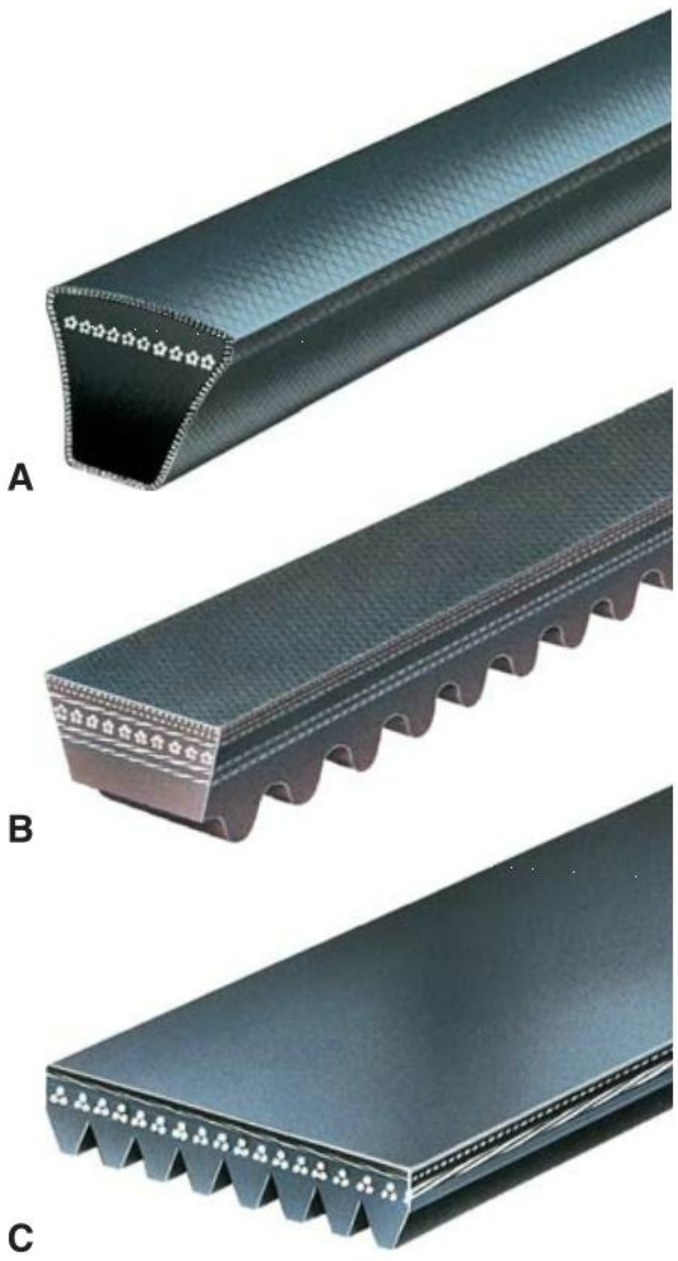
Covered in other chapters, these types of belts are also used to drive the power steering pump, air conditioning compressor, water pump, and other units.

Charge Indicators

A charge indicator informs the driver of the operating condition or output of the charging system. There are three basic types of charge indicators:

- ***Warning light***—A warning light glows if alternator output is below a specified level.
- ***Voltmeter indicator***—The voltmeter measures voltage output of alternator.

Copyright Goodheart-Willcox Co., Inc.



Gates

Figure 32-14. There are three types of belts. A—Conventional V-belt. B—Cogged V-belt. C—Ribbed belt.

- ***Ammeter indicator***—The ammeter measures current flow to and from the battery.

These indicators are mounted in the dash or instrument cluster of the car. Normally, all cars have at least a charge indicator light that signals a failed charging system.

Alternator Warning Light

An ***alternator warning light*** is wired into the charging system so that it will glow when alternator output drops to a specified level. **Figure 32-15** shows one circuit using an alternator warning light.

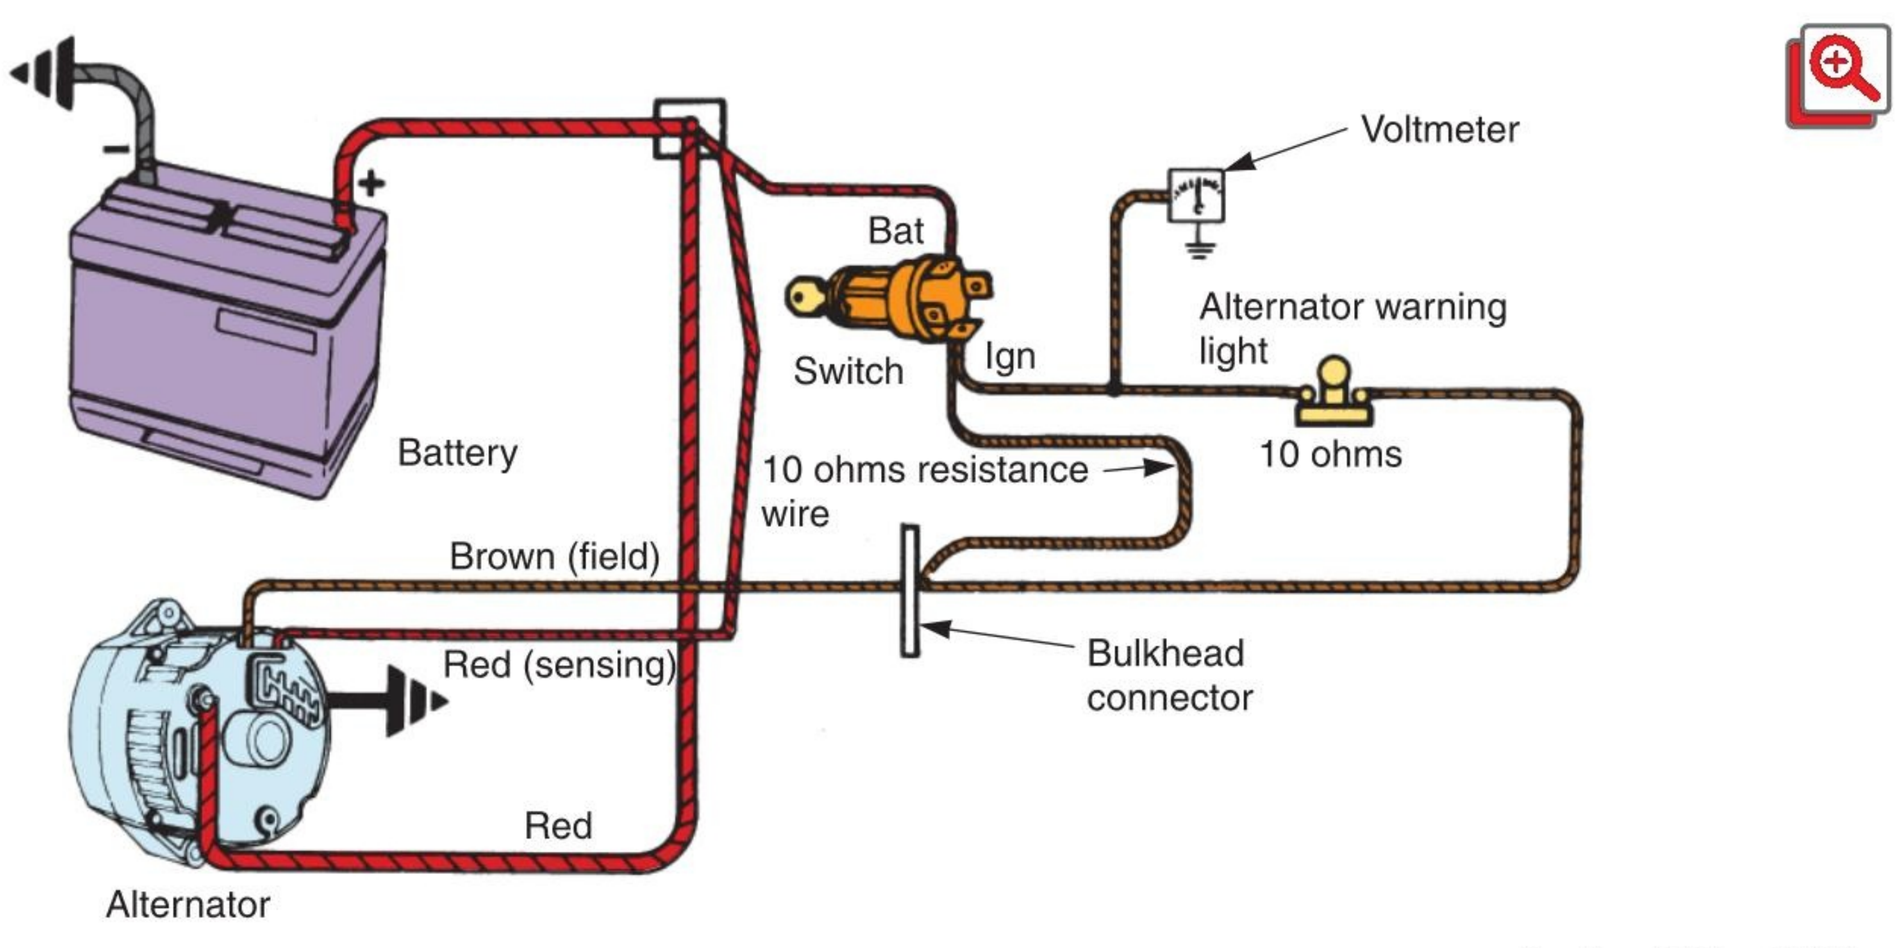
If problems develop in the charging system, the field current, trying to increase alternator output, will increase enough to light the indicator bulb. If the charging system is in good operating condition, current flow through the field will be too low to light the bulb.

Voltmeter Indicator

A voltmeter indicator can also be used to warn the driver of charging system problems. The voltmeter reads the system voltage when the engine is running.

A battery has 12.6 volts when fully charged. To recharge the battery, alternator output must be higher than the battery voltage. Alternator output is normally 13–15 volts.

The voltmeter indicator simply shows voltage, which is an indicator of current output and charging system condition. If the voltmeter reading drops to battery voltage or below, the charging system has problems. If the voltmeter reading is too high, overcharging can occur. ***Overcharging*** results when excess current



Goodheart-Willcox Publisher

Figure 32-15. The charging circuit shows connections for an alternator warning lamp and voltmeter.

Copyright Goodheart-Willcox Co., Inc.

is forced through the battery. Battery overheating damage can result after extended overcharging. This problem is often due to a faulty voltage regulator.

Hybrid Charging Systems

Many hybrid vehicles do not have a conventional alternator. Instead, these vehicles use the motor-generator to recharge a high-voltage battery and, sometimes, a conventional 12-volt battery.

The major parts of a hybrid charging system, **Figure 32-16**, include:

- Motor-generator—A motor-generator uses braking energy or engine power to produce electricity.
- Hybrid instrumentation—This instrument panel display shows the battery state of charge, power regeneration, power remaining, etc.
- HV power control module—The HV power control module converts high-voltage ac to 12 volts dc, and controls ac charging current from the motor-generator.
- HV battery—The HV battery provides huge amounts of stored electrical energy for engine starting and propulsion.
- Hybrid control module—The hybrid control module coordinates information flow from the HV power control module and other computers to control the hybrid charging systems.

When a hybrid vehicle has been driven its maximum range on electric power alone, it will start the internal combustion engine to partially recharge the battery, propel the car, and operate conventional 12-volt circuits. The hybrid control module will signal the HV power control module to harness the energy from the engine-powered motor-generator and route it to the HV battery. The HV power control module rectifies the alternating current coming out of the motor-generator and outputs smooth dc through the orange power cables to the HV battery. Today's HV power control modules also step down and rectify the high-voltage ac.

In the Rearview Mirror

Until the late 1960s, motor cars used large mechanical contact-point voltage regulators to control alternator voltage and current output. These large sheet-metal-encased components used a coil, a set of relatively large contact points, and resistors to control generator or alternator output. This type of regulator has long been replaced by electronic units. Back then, if the system was not charging, you could often tap on the side of the voltage regulator to free the points and get the system charging again.

Summary

- The major parts of a 12-volt charging system include: an alternator, voltage regulator, drive belt, charge indicator, charging system harness, battery, and ECM.
- The battery provides current to initially energize and smooth dc current output from the alternator.
- An alternator is an ac generator that uses mechanical (engine) power to produce electricity.
- The alternator rotor assembly is located in the center of the alternator housing, and creates a rotating magnetic field.
- The alternator stator is a stationary set of windings that surrounds the rotor that carries the current generated.
- The voltage regulator keeps alternator output at a preset charging voltage (13–15 volts). An ECM is sometimes used to supplement or replace the conventional voltage regulator to more precisely control the charging circuit.
- A charge indicator can be an ammeter, voltmeter, or warning light. Indicators inform the driver of the operating condition or output of the charging system.
- The major parts of a hybrid charging system include a motor-generator, hybrid instrumentation, HV power control module, HV battery, and hybrid control module.

Activities

1. Vehicles from different manufacturers use various belt arrangements to drive the alternator. Identify at least three different belt arrangements and sketch them. Label each sketch with vehicle make and engine type.
2. A diode is sometimes called “an electrical check valve.” Make sketches to show why it received that name.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What are four of the functions of a 12-volt charging system?
2. List and explain the seven major parts of a 12-volt charging system.
3. The alternator is a device for changing mechanical energy into _____ energy.
4. Explain the function of alternator's rotor and stator.
5. What is a *diode*?
6. What are *forward-biased diodes* and *reverse-biased diodes*?
7. List and describe the seven main components of an alternator.
8. An alternator _____ consists of field windings mounted on a shaft.
9. Alternator brushes ride on _____ to feed current to the field windings.
10. The alternator _____ changes alternating current into direct current.
    (A) transistor
    (B) rectifier
    (C) stator
    (D) regulator
11. An alternator _____ consists of three groups of windings and produces the electrical output of the alternator.
12. A voltage regulator controls alternator output by changing the amount of current flowing through the _____.
13. The voltage regulator keeps alternator output at a preset charging voltage of approximately _____ to _____ volts.
14. A(n) _____ voltage regulator is an electronic unit mounted inside or on rear of alternator.
15. Alternator _____ and electrical _____ determine whether the regulator increases or decreases charging output.
16. A(n) _____ may be used to measure battery temperature so the charging system can alter charging output as needed.
17. List and describe two types of charge indicators.
18. Name the major parts of a hybrid charging system.

ASE-Type Questions

1. Technician A believes that once an engine starts running, the engine crankshaft pulley powers the alternator to supply electricity to a car's electrical systems. Technician B feels a battery is a car's sole electrical supplier. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
2. Charging system voltage is approximately:
    (A) 12.6 volts.
    (B) 13–15 volts.
    (C) 16–19 volts.
    (D) 20–25 volts.
3. Which of the following is *not* a component of a typical 12-volt charging system?
    (A) Voltage regulator.
    (B) Drive belt.
    (C) Battery.
    (D) Ignition switch.
4. The component that is turned by the alternator drive belt and creates a rotating magnetic field is the:
    (A) rotor.
    (B) stator.
    (C) rectifier.
    (D) diode trio.
5. Alternator design is being discussed. Technician A says the stator is a stationary set of windings that is surrounded by the rotor. Technician B says the stator is the output winding in the alternator. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
6. To reduce alternator output, the voltage regulator places more resistance between the:
    (A) battery and the field windings.
    (B) rotor and the stator.
    (C) alternator pulley and the stator.
    (D) alternator brushes and slip rings.
7. Which of the following is *not* a type of alternator belt?
    (A) V.
    (B) Ribbed.
    (C) Cogged V.
    (D) Integrated.

Copyright Goodheart-Willcox Co., Inc.

8. When fully charged, an automotive battery has:
   (A) 12.6 volts.
   (B) 13–15 volts.
   (C) 16–19 volts.
   (D) 20–25 volts.
9. Which of the following components do hybrid vehicles use to recharge the HV battery?
   (A) HV power control module.
   (B) Motor-generator.
   (C) Alternator.
   (D) Battery thermistor.
10. Which of the following components steps down and rectifies the high-voltage ac used in hybrid charging systems?
   (A) HV power control module.
   (B) Hybrid control module.
   (C) Motor-generator.
   (D) Voltmeter.

Copyright Goodheart-Willcox Co., Inc.

Chapter 33
Charging System Diagnosis, Testing, and Repair

After studying this chapter, you will be able to:

- Inspect a 12-volt and high-voltage (HV) charging system to locate obvious troubles.
- Diagnose 12-volt charging system troubles.
- Test 12-volt charging system with a voltmeter, load tester, and scope.
- Remove and reinstall an alternator.
- Diagnose high voltage hybrid charging system problems.
- Correctly answer ASE certification test questions on charging system service.

This chapter begins by summarizing the types of troubles that occur in 12-volt charging systems. You will learn how to perform fundamental tests that help locate problems. Then, the chapter covers parts removal, disassembly, repair, and reassembly. This should give you a sound background in the most common types of charging system service and repair jobs.

In addition to being able to service conventional 12-volt charging systems, you should know how to troubleshoot and repair the charging systems found in hybrid vehicles. Remember, the hybrid's HV charging system uses voltage produced by the motor-generator to recharge the HV battery, and steps down HV battery voltage to 12 volts dc for use in conventional circuits. Refer to **Figure 33-1**.

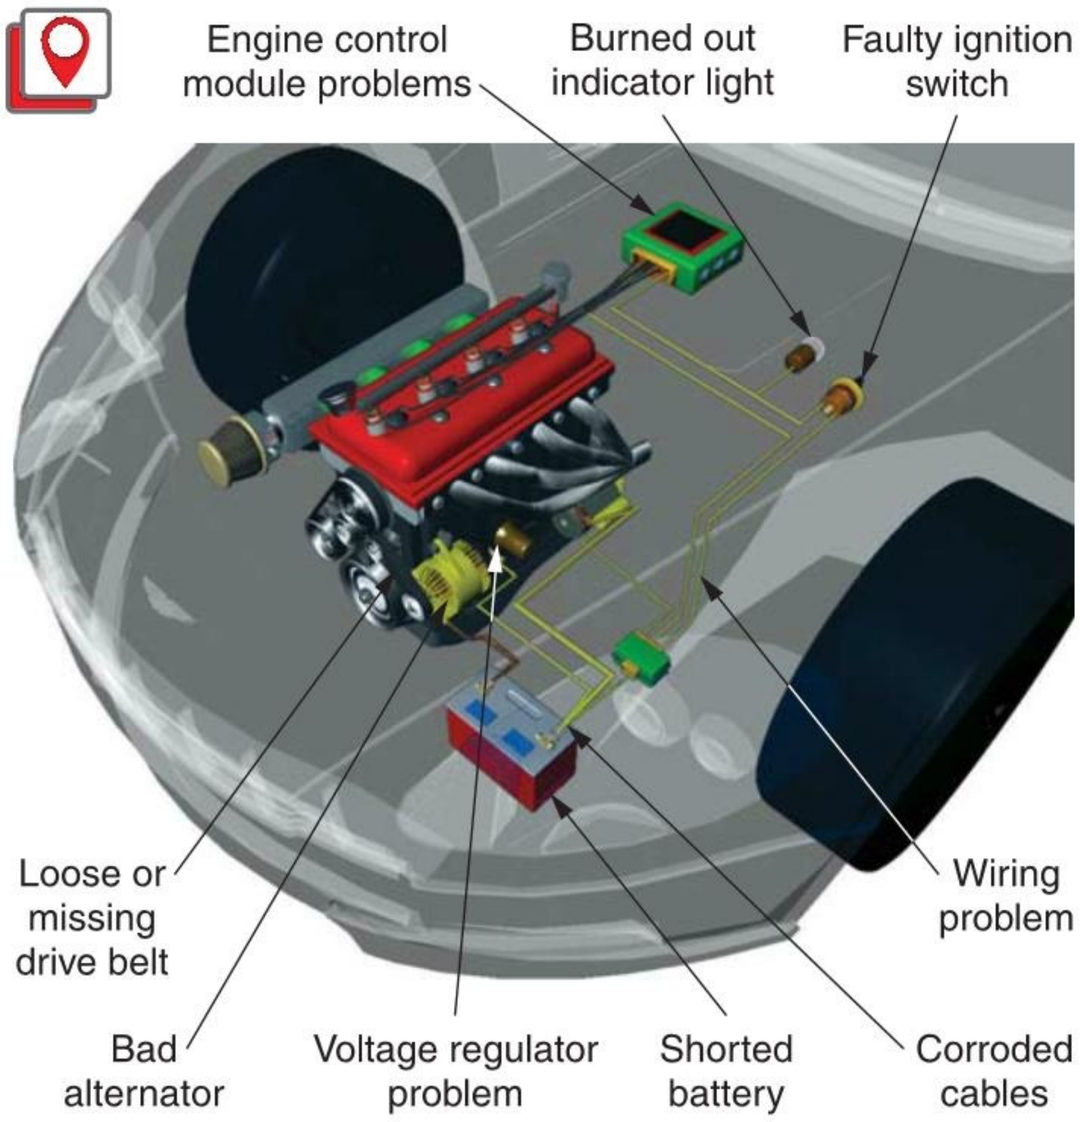
12-Volt Charging System Diagnosis

Although a 12-volt charging system has only two major parts (alternator and regulator), troubleshooting can be difficult. Sometimes, another system's fault (bad starting motor, defective battery, computer failure, or faulty wiring) will appear to be caused by problems in the charging system.

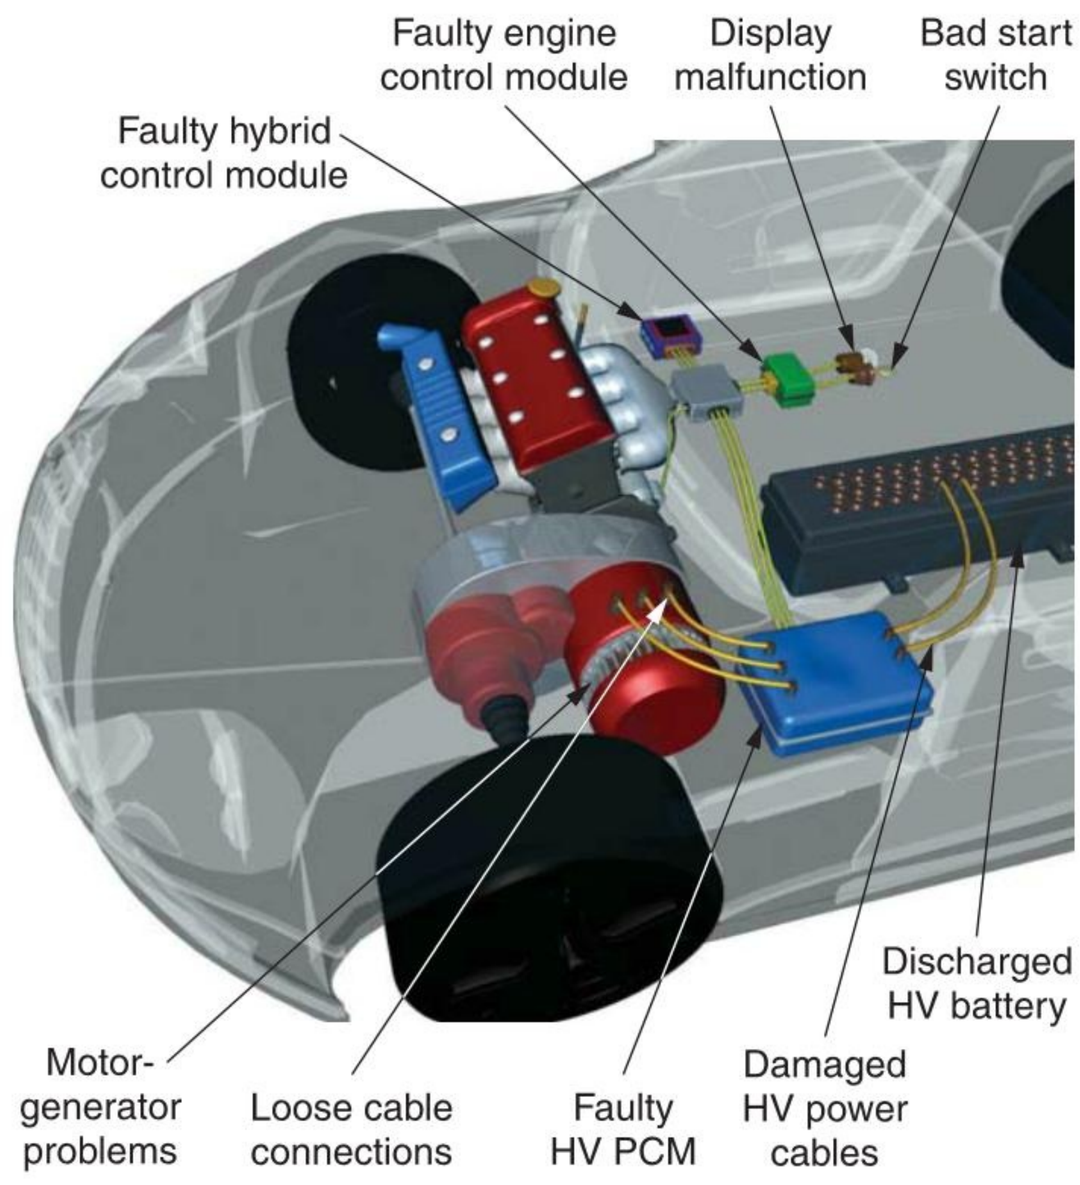
There are four common symptoms of charging system problems:

- Dead battery—A dead battery will crank the engine slowly or it will not crank the engine at all.
- Overcharged battery—An overcharged battery is rare, but occurs when the battery has a low electrolyte level or gets too hot from current flow back through the battery.
- Abnormal noises—Abnormal noises include dry alternator bearing noise, belt squealing, and solenoid buzzing when trying to start the engine with a discharged battery.

Copyright Goodheart-Willcox Co., Inc.



12-Volt Charging System Problems



Hybrid Charging System Problems

Goodheart-Willcox Publisher

Figure 33-1. Note common problems in 12-volt and HV charging systems. Some of these could be found during your initial visual inspection and test drive.

- Indicator shows problem—An indicator will glow or otherwise signal a problem when there is an incorrect charge voltage reading.

Verify these problems by starting or trying to start the engine. It is possible that the symptoms have been misinterpreted by the service writer or customer. For example, a problem described as a no-charge condition may really be a shorted starting motor, parasitic battery drain, bad battery, or other trouble.

Warning

Some late-model cars are equipped with a heated windshield. When the windshield is being heated, the alternator produces 110 volts ac. This is enough voltage to cause electrocution. Keep this in mind when working on this type system.

Preliminary Inspection

A preliminary inspection of the components and connections will help determine the source of the charging system problem.

Service Procedure

To perform a preliminary inspection of the charging system:

1. Open the hood and visually inspect the parts of the 12-volt charging system.
2. Check for battery-related problems, such as loose battery cables, a discharged battery, corroded terminals, a low water level, or a damaged battery case.
3. Make sure the belt tension is adjusted to specifications. A loose alternator drive belt may squeal or flap and prevent normal charging.
4. Check the condition of the alternator drive belt. Look for cracks, glazing (hard, shiny surface), grease or oil contamination, and deterioration, **Figure 33-2**.
5. Check for loose or corroded electrical connections, shorted wires (missing insulation), and other wiring problems. In particular, check the electrical connections on the back of the alternator.

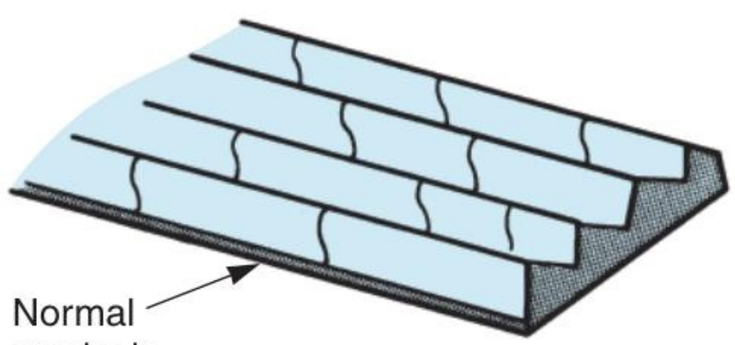
Copyright Goodheart-Willcox Co., Inc.

6. Wiggle the wiring harness from the alternator to the firewall or ECM while the engine is running. If the indicator light goes out or the indicator gauge begins to read properly when a wire is moved, the problem is in that area of the wiring.

Tech Tip

Connect a voltmeter across the battery terminals while wiggling charging system wires. If the meter fluctuates to a higher voltage when a wire is wiggled, you have found the bad electrical connection.

7. With the engine running, listen closely for abnormal noises in the alternator. If necessary, use a stethoscope to listen for dry, noisy alternator bearings. Try to detect internal grinding (worn, dry bearings), whining (leaking diodes or overcharging), or any other unusual sounds.



Snap-on Tool Corp.

Figure 33-2. Inspect belts closely for wear, deterioration, and damage. Replace belt, if needed.

Scanning 12-Volt Charging Systems

On most vehicles with self-diagnostic systems, you can connect a scan tool to the vehicle to aid in troubleshooting. The scan tool will display charging voltage, battery temperature, and other data useful in finding problems. Capabilities vary with each model; refer to the service manual or scanner instructions for details.

12-Volt Charging System Precautions

Observe the following rules when working on a charging system. These precautions will help prevent possible damage to electrical/electronic systems.

- Disconnect the battery before removing any charging system component. If a ***hot wire*** (current-carrying wire) touches a ground, parts could be ruined.
- Disconnect the battery before connecting it to a battery charger. A voltage surge or high voltage can damage electronic components in the alternator, regulator, and other computerized systems.
- Never reverse polarity. If the battery or jumper cables are connected backwards, serious electrical damage can occur. Reversing polarity can damage the diodes in the alternator, ruin regulator circuitry, and burn electronic components in other computer systems.
- Do not operate the alternator with the output wire disconnected. If the alternator is operated with the output wire disconnected, alternator voltage can increase above normal levels. Alternator or charging circuit damage could result.
- Never short or ground any charging system terminal unless instructed to do so by a shop manual. Some circuits can be grounded or shorted without damage; others will be seriously damaged. Refer to a service manual when in doubt.

12-Volt Charging System Tests

Charging system tests should be done when symptoms point to low alternator voltage and current. These tests will quickly determine the operating condition of the charging system. There are several common charging system tests, including the following:

- Scan tool test—This test allows charging system voltage values to be viewed using the scan tool's datastream capabilities.
- Load test—This test involves using a load tester to check the current and voltage output of the charging system.

Copyright Goodheart-Willcox Co., Inc.

- Scope tests—These tests involve using a scope to analyze voltage waveforms produced by the charging system.
- Voltmeter test—This test is used to quickly check the general output of a charging system.
- Circuit resistance tests—These tests measure resistance in insulated and ground circuits of the system.

Scan Tool Test

With modern OBDII vehicles, you can access alternator charging voltage values with your scan tool or diagnostic tablet. Start and idle the engine. Turn on all electrical accessories (headlights, AC, stereo, interior lights) to load the alternator. Use the scan tool menu to access datastream values and scroll to the alternator or charging system live voltage readings. With all accessories on, an alternator output of at least 13 volts indicates normal operation. If the output reading drops to 12.6 volts or less, the alternator is bad and is not producing enough current to keep the battery charged.

Tech Tip

Most modern laptop computers and diagnostic tablets have a scope function. The scope function will convert datastream voltage readings into live scope waveforms for advanced troubleshooting. Remember that smooth DC is required for the proper operation of ECMs and their sensor circuits.

Load Test

A ***load tester*** provides the most accurate method of checking a charging system. See **Figure 33-3**. It will measure both system current and voltage while applying a load to the system.

Before testing the charging system, it is common practice to check the condition of the battery. Although charging system problems often show up as a dead battery, you must not forget that the battery itself may be bad. Measure the battery's state-of-charge and perform a battery load test. This will ensure that the battery is not affecting your charging system tests.

A ***charging system load test*** measures alternator/regulator current and voltage output under its maximum load.

Goodheart-Willcox Publisher

Figure 33-3. Modern, digital load testers may or may not have an inductive, clip-on current clamp.

Service Procedure

To check charging system output with a load tester:

1. Connect the tester leads, as described by the manufacturer. With modern testers, fasten the two large alligator clips to the battery terminals (red to positive, black to negative). With some loader testers, you must clip an inductive (clip-on) amps pickup around the insulation on the negative battery cable.

Tech Tip

Procedures differ with each tester design. Check the tester's operating instructions when in doubt.

2. Set the load tester controls to their proper positions and values.
3. Attach a vent hose to the exhaust and start the engine.
4. Set the load control on the tester until the ammeter displays the alternator's rated amperage. Do not exceed the alternator's output rating in amps. Do not let the voltage drop below the full battery voltage of 12.6 volts. (You do not want to load the battery, just

Copyright Goodheart-Willcox Co., Inc.

the alternator. At 12.6 volts, current flow into and out of the battery will be minimal.)
5. Note the alternator output current (amps) at 12.6 volts.
6. Turn off the load control and evaluate your readings.

Compare the test amps reading to the alternator's output specifications. If alternator output current is low, suspect a bad alternator/regulator assembly.

Alternator output current specifications for charging systems depend on the size (maximum amp rating) of the alternator.

Tech Tip

Alternator current specifications are sometimes stamped on the alternator housing. If not, look up the alternator specifications in the service manual.

Scope Tests

A charging system ***scope test*** involves analyzing the alternator voltage waveform for signs of abnormal ripple, interference, and "dirty dc." Abnormal voltage ripple is an indication of bad alternator diodes.

Service Procedure

To scope a 12-volt alternator charging system:
1. Connect the red scope test lead to the alternator battery (output) terminal.
2. Ground the other scope lead.
3. Start the engine and observe the scope trace (waveform). The charging system should produce a relatively smooth dc voltage trace with minimum ripple. Look at **Figure 33-4**.

Voltmeter Test

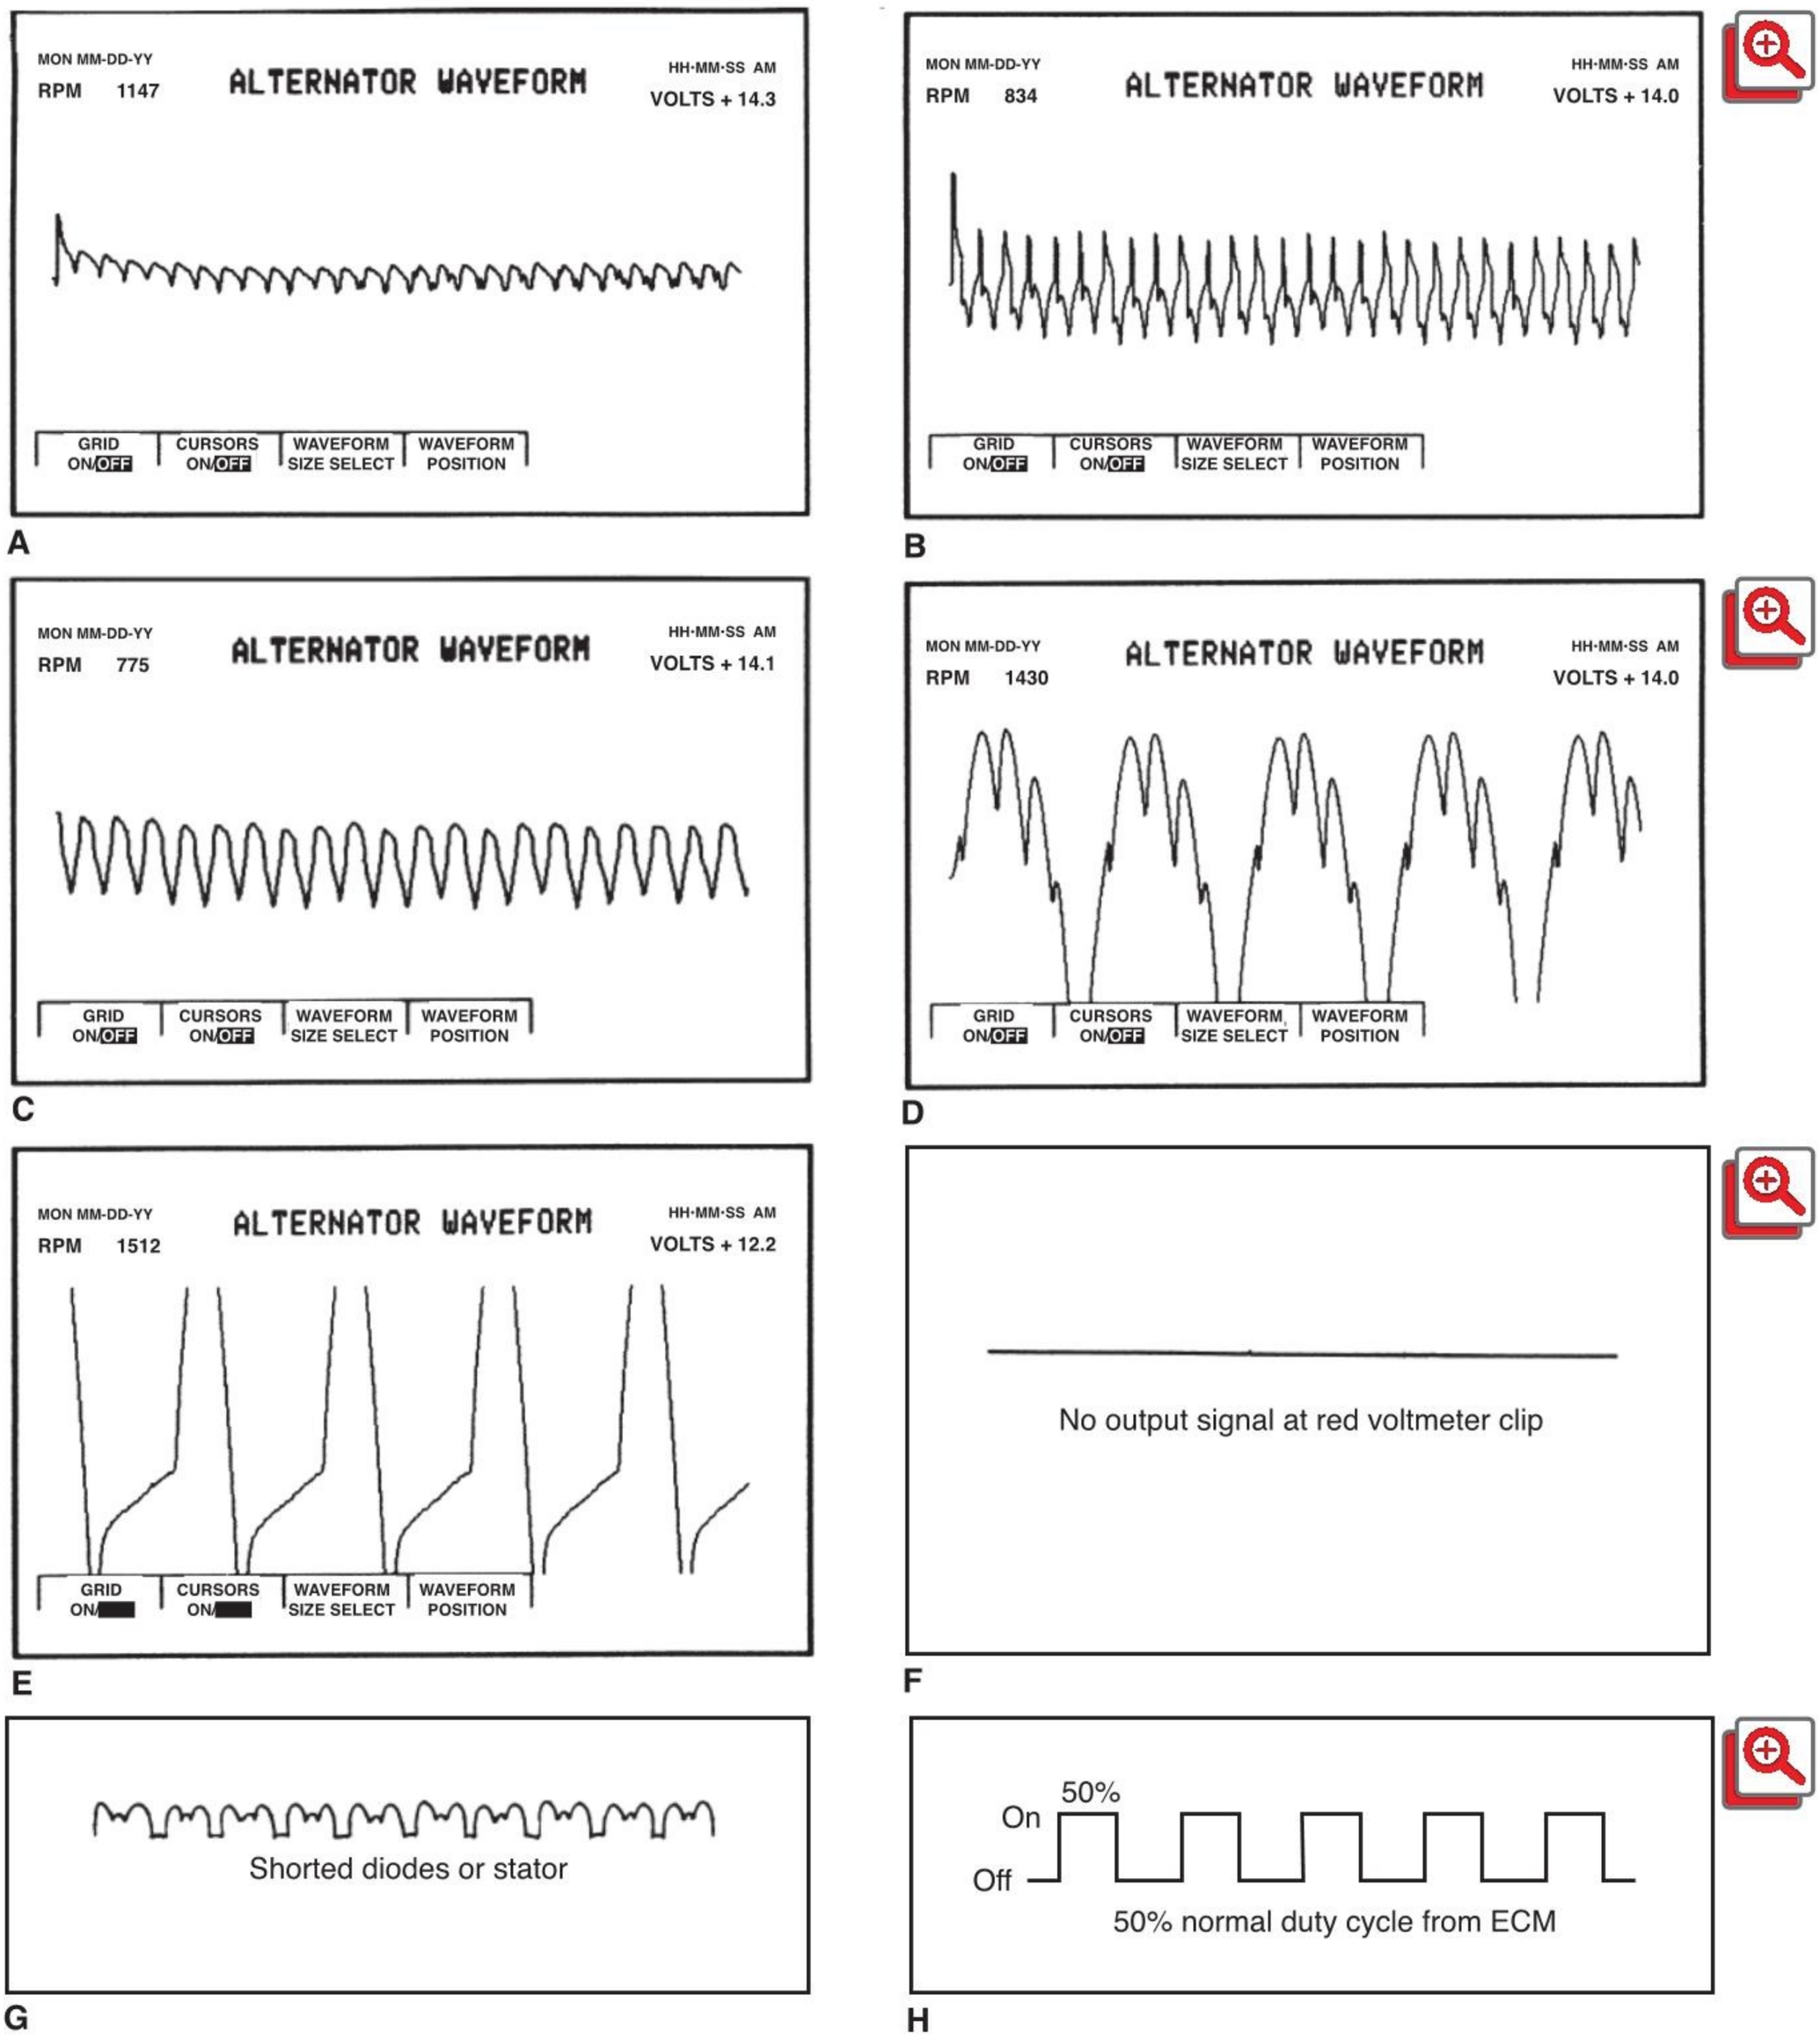
A voltmeter can also be used to quickly test the general output of a charging system. It will measure charging system voltage with a vehicle accessory load (all electrical accessories *on*). The voltage reading will be a good indicator of system condition. If charging system output voltage is not above battery voltage, the battery is not being recharged and a problem exists. Typical charging system voltmeter tests are shown in **Figure 33-5**.

Service Procedure

To use a common voltmeter to test a charging system:
1. Charge the battery, if it was drained before testing.
2. Set the voltmeter to read low voltage.
3. Connect the voltmeter test leads across the battery terminals.
4. Measure and record battery ***base voltage*** (battery voltage with everything off). This reading will compensate for any variation in the condition of the battery and accuracy of your meter. With a good, fully-charged battery, the base voltage reading should be around 12.6 volts. Look at **Figure 33-6**.
5. Start the engine and record the ***no-load voltage***. The no-load voltage is the battery voltage with the engine running and the electrical accessories off. The voltmeter reading should increase from the base reading, but not by more than 2–3 volts. For example, if your base voltage is 12.5 volts, your no-load voltage reading should be 13–14.5 volts. If the no-load voltage is more than 2–3 volts higher than base voltage, the alternator is overcharging the battery. Either the voltage regulator, ECM, or wiring is bad.
6. Turn on all electrical accessories (air conditioning, blower, stereo, headlights, etc.) to load the charging system, and record the load voltage. The ***load voltage*** test shows if the charging system is providing current for all the electrical units and still has enough current to recharge the battery.
7. Calculate ***charge voltage*** using the formula: Load voltage – base voltage = charge voltage. So, 14.5 volts – 12.6 base volts = 1.9 volts dc.

Charge voltage should be at least 0.5 volts with the engine at warm idle. The load voltage must be higher than the base voltage for battery charging. No-load voltage must be within specifications.

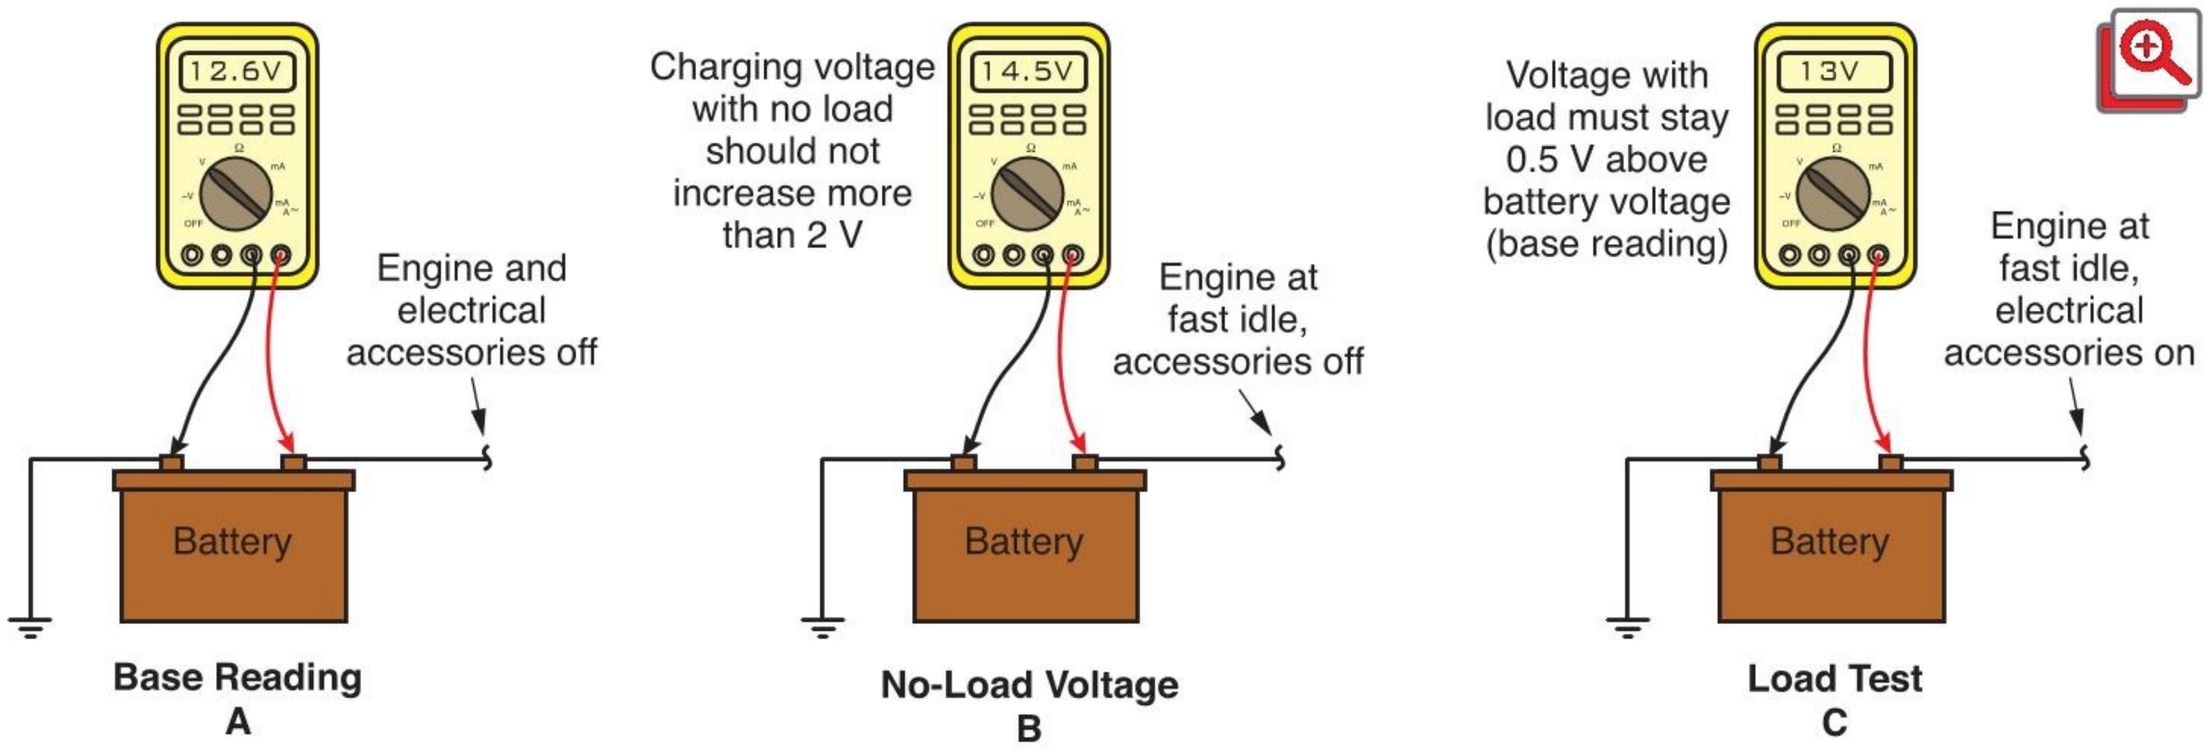
Copyright Goodheart-Willcox Co., Inc.



Snap-on Tool Corp.

Figure 33-4. An oscilloscope can be used to check for faulty diodes and other problems before alternator removal. A—Normal alternator waveform with typical output. Note the small, regularly spaced, even ripples. B—This is a normal light-load alternator waveform for some electronic regulators using duty cycles to control output. Slightly higher inductive peaks and spikes can be normal with other systems. C—Normal alternator waveform with heavy load. It is similar to A, but has a higher amplitude ripple from increased current output. D—This alternator waveform shows an open diode causing high spikes. E—This waveform is due to one open diode and one shorted diode. F—A solid straight line at zero on the scope screen indicates no output from the alternator. G—This waveform indicates shorted diodes or shorted stator windings. H—Duty cycle from ECU to alternator field windings can be checked with a scope. High load, applied from the load tester, should make the duty cycle show more "on" time. If not, suspect the computer or ECM.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 33-5. A volt-ohm-millimeter, or VOM, allows for a quick check of the general condition of a 12-volt charging system. A—Connect the meter across the battery with the engine off to check battery base voltage. Battery voltage should be almost 12.6 volts if the battery is good. B—Start the engine with all accessories *off* to take a no-load voltage reading, which should be higher than battery voltage. C—Turn on all electrical accessories and read the voltmeter again. Charge voltage must remain above battery voltage. If readings are below battery voltage, the charging system is not working.

Circuit Resistance Tests

Circuit resistance tests are used to locate wiring problems in a charging system, such as loose connections, corroded terminals, partially burned wires, and similar troubles. Resistance tests should be performed when symptoms point to problems other than the alternator or regulator. For example, if the dash indicator flashes on and off erratically or the system charges one minute then stops working, suspect a poor ground or electrical connection between the alternator, regulator, and engine or body ECM. Two common circuit resistance tests are the insulated-circuit resistance test and ground-circuit resistance test. See **Figure 33-7**.

Fluke

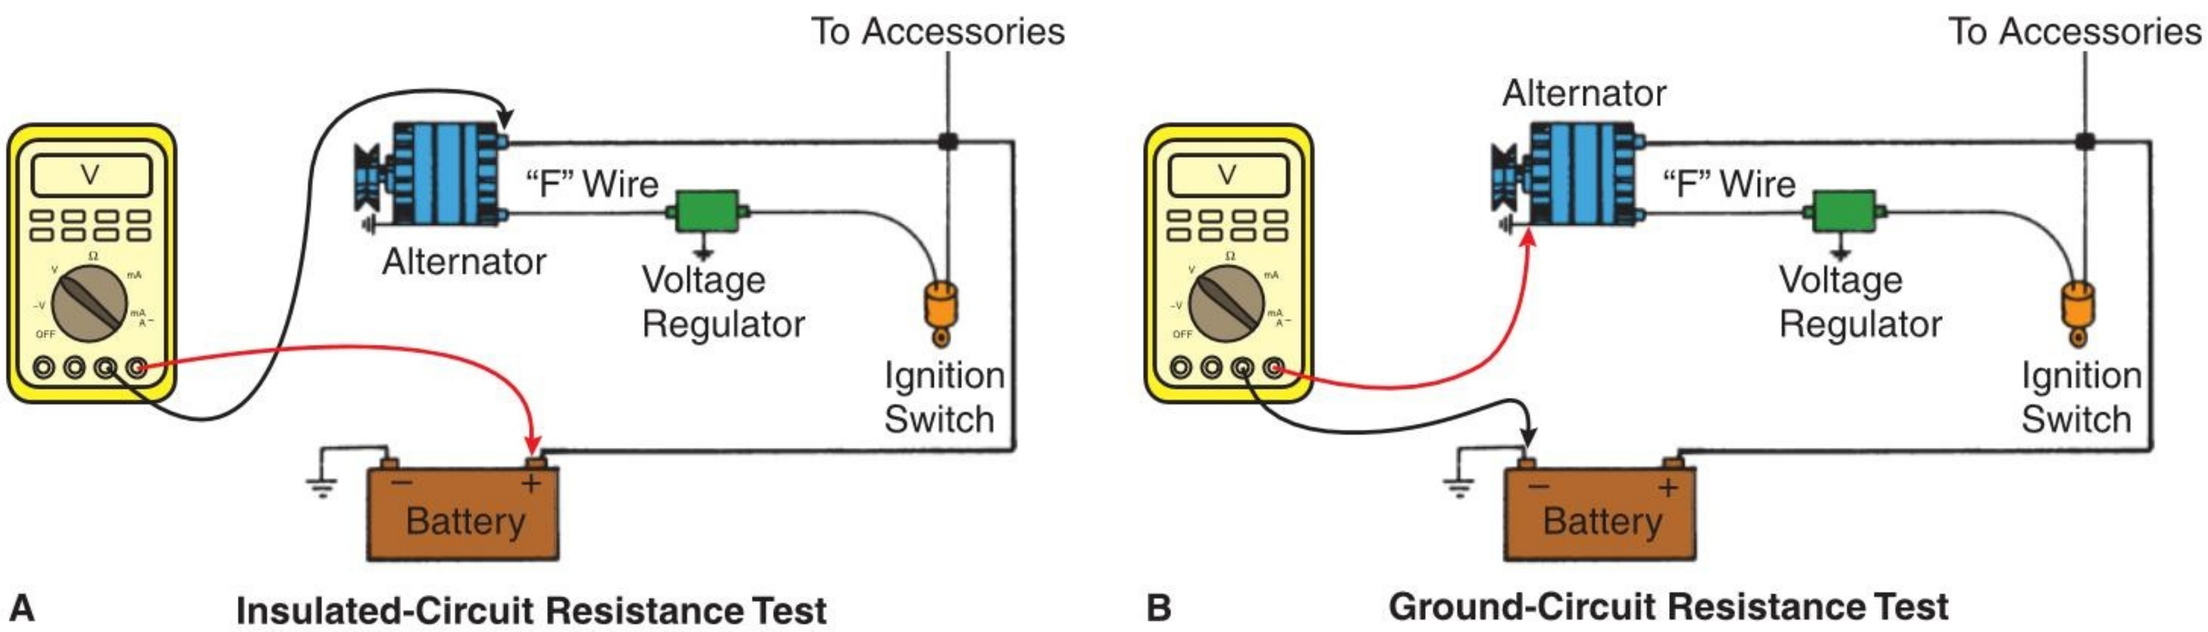
Figure 33-6. This digital voltmeter shows a base voltage reading of 12.49 volts, which is about 100% of a full charge.

Service Procedure

To do an ***insulated-circuit resistance test*** on a charging system:

1. Connect the tester across the alternator (battery) output terminal and the positive battery terminal.
2. With the vehicle running at a fast idle, set the load control to obtain a 20 amp current flow. All lights and accessories should be off.
3. Read the voltmeter. If the circuit is in good condition, the voltmeter should not read over about 0.7 volts (0.1 volt per electrical connection). If the voltage reading is higher than 0.7 volts, circuit resistance is high and a poor connection exists in that section of the charging circuit.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 33-7. Voltage drop or resistance tests will find problems in wiring. A—Connections for an insulated circuit resistance. B—Connections for a ground circuit resistance test. A voltage reading above 0.1 volts per connection indicates a resistance problem.

A ***ground-circuit resistance test*** is similar to the insulated-circuit resistance test. However, the voltmeter is placed across the negative battery terminal and alternator housing.

The voltmeter should not read over 0.1 volt per electrical connection. If the voltmeter reading is higher, look for corroded or loose connections, a burned plug socket, damaged wiring harness, or similar problems.

Alternator Service

A bad alternator will show up during your tests as a low output or unclean dc problem. Although most shops simply replace alternators that exhibit these symptoms, a few will rebuild faulty units. The following sections outline the steps for removing, rebuilding, and installing an alternator.

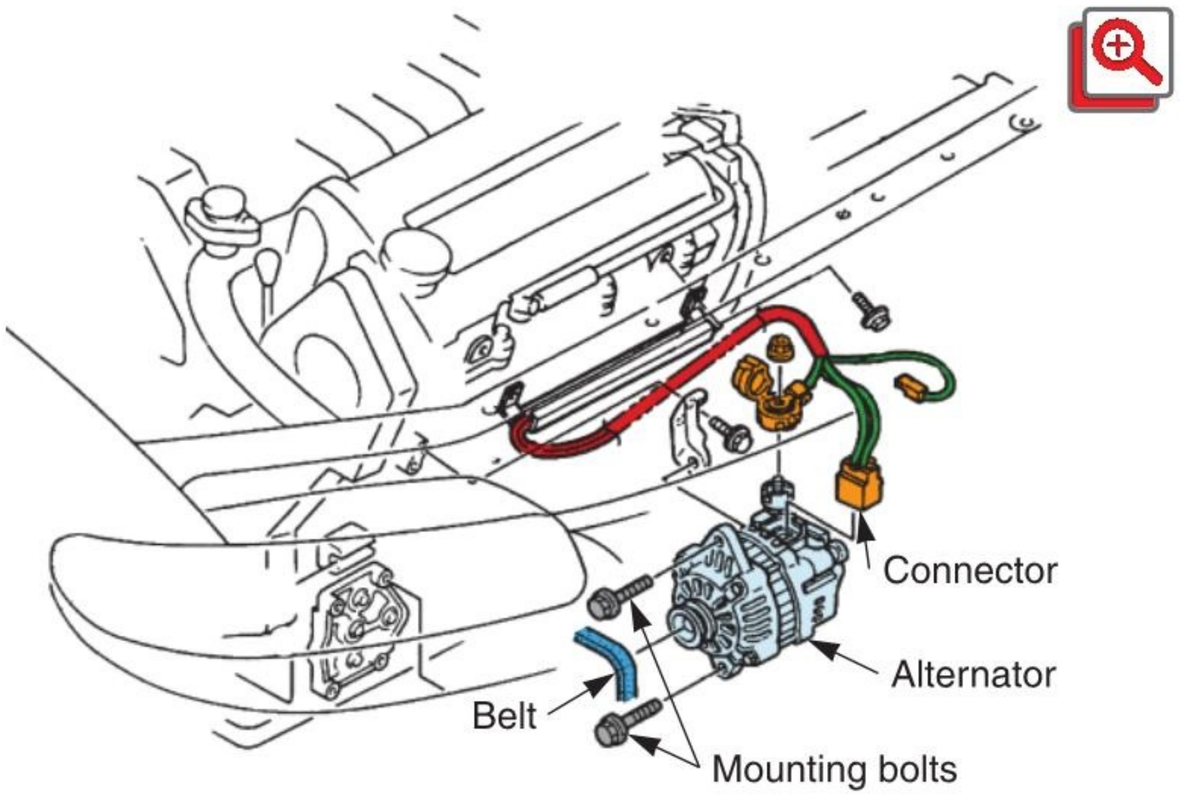
Alternator Removal

Service Procedure

To remove an alternator:

1. Disconnect the battery to prevent a major electrical short and wiring harness fire.
2. Remove the alternator belt from the drive pulley by retracting the belt tensioner with a breaker bar and socket. Try to keep the belt over and inside the other engine pulleys to simplify reinstallation.
3. Disconnect the wiring harness from the rear of the alternator. When removing the wires from the alternator, note their location and whether special insulating washers are used.
4. Remove the bolts that secure the alternator to its mounting brackets and remove the alternator from the vehicle. Sometimes it is easier to remove the alternator wires after the unit has been unbolted from the engine. See **Figure 33-8**.

Depending on vehicle design, the alternator may come out from the top, side, or bottom of the engine compartment. If it must be removed from the bottom, you may need to remove a splash shield to gain access to the bolts securing the alternator to



Mazda

Figure 33-8. When removing an alternator, first remove the belt and any parts that block access to the alternator mounting bolts. Then disconnect the wires and remove the mounting bolts.

Copyright Goodheart-Willcox Co., Inc.

its mounting brackets. If the alternator comes out from the side of the engine compartment (transverse engine mounting), you may have to remove the inner fender apron to gain access to the alternator.

Alternator Rebuild

An alternator rebuild typically involves the following steps:

1. Disassembling the alternator.
2. Inspecting and testing the rotor.
3. Inspecting and testing the stator.
4. Testing the diodes.
5. Replacing the rotor, stator, or diodes if they are defective.
6. Replacing the bearings.
7. Replacing the brushes.
8. Reassembling and testing the alternator.

As mentioned previously, most shops do not rebuild alternators. Instead, they purchase new or rebuilt units. The cost of labor is generally too high to make in-shop rebuilding economical. Alternator rebuild parts are often no longer available. Also, rebuilt units will have a limited warranty.

Alternator Installation

With the battery still disconnected, fit the alternator onto the engine. Install the alternator mounting bolts, torque them to specifications, and reconnect the wiring harness.

Check the condition of the alternator belt and replace it, if needed. Slip the belt over the engine and alternator pulleys, making sure the belt is aligned properly on each pulley.

Hybrid Charging System Service

In a high-voltage hybrid electrical system, the HV power control module (HV PCM) normally generates different voltage levels for the various vehicle electrical systems. It will often have connectors for outputting 13–15 volts dc for conventional circuits, 45–110 volts dc for heated windshield circuits, and a voltage slightly higher than HV battery voltage for recharging the HV battery. Proper operation of the hybrid charging system can often be verified by studying the diagnostic information displayed by the vehicle's dash instrumentation. See **Figure 33-9**.

Scanning Hybrid Charging Systems

Depending on the make and model of the vehicle, your scan tool, laptop computer, or diagnostic tablet will indicate problems in the HV charging system. Diagnostic codes will indicate problems with any high-voltage component or circuit that is affecting HV battery charging voltage.

Late-model hybrid vehicles will output hundreds of trouble codes for almost every circuit, ECM, and component in the entire electrical/electronic system. The following are the most common problems with an HV charging system:

- Bad HV PCM—The HV PCM can have problems in its converter circuits, inverter circuits, high-power relays (contactors), transformers, diodes, and power transistors. Since the HV PCM performs so many electrical functions, it will sometimes trip trouble codes. Most scan tool readouts will indicate which circuit in the HV PCM is not functioning normally.
- Bad motor-generator—The motor-generator can fail to output normal 3-phase voltage and trip various trouble codes. For example, if one stator coil winding breaks open, the motor-generator will still work, but will not generate adequate voltage in that phase. Normally, the hybrid control module will completely disable the electric drive train when any problem with the motor-generator is found.
- Failed hybrid control module—The hybrid control module will generate trouble codes indicating something is wrong with the control module itself or its connecting circuits.
- Loose or corroded HV power cables—Faulty HV power cables, a common problem, can affect charging system performance and trip motor-generator, HV battery, or HV PCM codes. Loose HV cable connections can overheat and burn, increasing circuit resistance even more. Bad HV cable connections can affect motor-generator or electric drive performance.
- Bad HV battery—Late-model hybrids can detect a weak HV battery and will trip a trouble code if the HV battery fails to take or hold a proper electrical charge.

When test driving a hybrid vehicle in the electric mode, it is best to drive up a small hill. This will increase the load on the motor-generator and draw more current from the HV battery. Compare electric

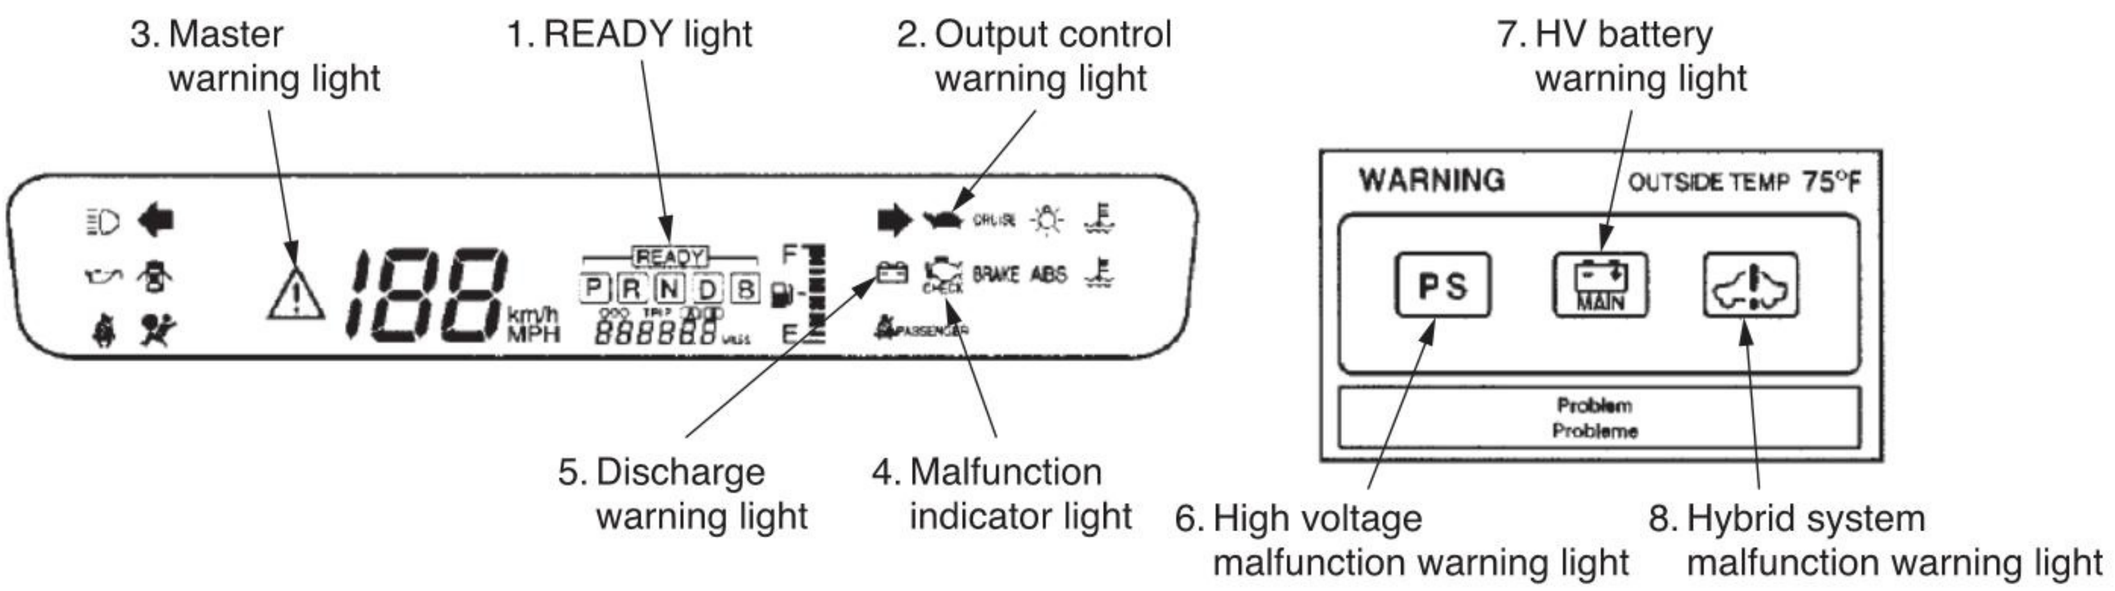
Copyright Goodheart-Willcox Co., Inc.

drive and charging circuit performance to that of a known good vehicle and system. If the battery of a hybrid or electric vehicle is not being recharged normally with a home charger or by driving in the recharge mode, further tests are needed to verify diagnostic trouble codes in vehicle memory.

Tech Tip

To become properly trained to diagnose and repair a hybrid charging system, you should attend factory training courses or read manufacturer instructions on the specific make and model of hybrid vehicle. Hybrid vehicle designs, operation, and repair procedures vary.

Instrument Cluster



Center Meter **Multi Information Display**

1. READY Light	Turns on when the ignition switch is turned to START to indicate that the vehicle is ready to drive.
2. Output Control Warning Light	Turns on when the remaining HV battery charge becomes insufficient at R range or when there is an abnormal temperature rise in the HV battery due to continuous driving under heavy loads. It may also light when the HV battery temperature is low (after starting at low temperatures). The hybrid system output is limited while this light is on. • Travel at reduced speeds (avoid sudden acceleration) while the light is lit.
3. Master Warning Light	Turns on with buzzer sounding by linked operation with warning lights “6” to “8” on the center display.
4. Malfunction Indicator Light	Turns on when there is a malfunction in the engine control system.
5. Discharge Warning Light	Turns on when there is a malfunction in the 12 V charging system (converter assembly). • If it turns on together with the master warning light and hybrid system warning light, check the diagnostic code.
6. High Voltage Malfunction Warning Light	Turns on when there is a malfunction in the HV power control module.
7. HV Battery Warning Light	Turns on when the HV battery is discharged to the lower limit.
8. Hybrid System Warning Light	Turns on when a malfunction in motor-generator, HV power control module, HV battery, or hybrid control module is detected.

Toyota

Figure 33-9. Modern hybrid and electric vehicles provide an abundance of diagnostic information through the dash instrumentation. Note all the indicator lights on this instrument cluster.

Diagnostic Case Study

Concern: Mr. Howard brings his 2011 Ford Mustang to the shop, complaining that it has to be jump started every time he wants to drive it. He adds that he bought and installed a new battery to correct the no-start problem, but the car still will not start properly after a couple of days of driving.

Cause: Duff inspects the alternator belt, the alternator, the alternator wiring, and the battery connections. Not finding a problem during the visual inspection, Duff turns the repair over to the shop's electrical technician.

The technician charges the battery in preparation for electrical tests. He connects a voltmeter across the battery terminals. The meter shows a base voltage reading of 12.6 volts, indicating that the battery is fully charged.

The technician then checks no-load voltage. He starts the engine, makes sure all the electrical accessories are off, and runs the engine at fast idle. At fast idle, the voltmeter still reads 12.6 volts, indicating that the charging system is not functioning properly. Further testing shows that the alternator is not putting out the required voltage.

Correction: The technician removes the bad alternator and orders a rebuilt unit. He then reinstalls the alternator and rechecks charging system voltage. After determining that the system is working properly, he releases the vehicle to the customer.

Summary

- Sometimes, another system's fault (bad starting motor, defective battery, computer failure, or faulty wiring) will appear to be caused by problems in the charging system.
- There are four common symptoms of charging system problems: dead battery, overcharged battery, abnormal noises, and an indicator showing a problem.
- A preliminary inspection of the components and connections will help determine the source of the charging system problem.
- Take the necessary precautions when working on a charging system to prevent possible damage to electrical/electronic systems.
- Charging system tests should be done when symptoms point to low alternator voltage and current. Common charging system tests include the scan tool voltage readings, load test, scope tests, voltmeter test, and circuit resistance tests.
- A bad alternator will show up as a low voltage and current output problem during charging system tests. This may be caused by a bad alternator rotor, bad alternator stator, bad alternator diodes, worn alternator bearings, or worn alternator brushes.
- The most common problems with an HV charging system include the following: bad HV PCM, bad motor-generator, failed hybrid control module, loose or corroded HV power cables, and a bad HV battery.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

base voltage
charge voltage
charging system load test
charging system tests
circuit resistance tests
ground-circuit resistance test
hot wire
insulated-circuit resistance test
load tester
load voltage
no-load voltage
scope test

Activities

1. Make a poster for classroom display showing the steps involved in checking a charging system with a voltmeter.
2. Using the Internet, price a new or rebuilt alternator for a vehicle of your choice. Then, use a flat rate manual to determine how many hours of labor a customer should be charged to replace the alternator on the vehicle chosen. Assuming a shop labor rate of $60 per hour and a part markup of 15%, prepare an estimate showing the total parts and labor charges for replacing the alternator.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Name four common symptoms caused by charging system problems.
2. List and explain five 12-volt charging system service precautions.
3. List and explain five common 12-volt charging system tests.
4. All of the following are steps in a charging system visual inspection *except:*
   (A) checking battery terminals for corrosion.
   (B) listening for abnormal noises in the alternator.
   (C) checking the condition of the alternator drive belt.
   (D) checking the operation of the neutral safety switch.
5. Alternator current specifications can be found in service literature or are sometimes stamped on the _____.
6. A scope test on a charging system involves analyzing an alternator voltage waveform for signs of abnormal ripple or interference. True or False?
7. What is the purpose of charging system circuit resistance tests?
8. When measuring the battery base voltage with a voltmeter, the vehicle engine should be _____ and all the accessories should be turned _____.
   (A) fast idling; on
   (B) running; on
   (C) off; off
   (D) running; off
9. All of the following steps may be part of an alternator rebuild *except:*
   (A) testing the diodes.
   (B) resurfacing the clutch plate.
   (C) replacing the brushes.
   (D) inspecting and testing the rotor.
10. List five common problems that occur in HV charging systems.

ASE-Type Questions

1. When working on charging systems, all of the following precautions should be taken *except:*
   (A) never reverse polarity.
   (B) always polarize the alternator.
   (C) never short system terminals.
   (D) detach the battery before part removal.
2. Each of these is a common 12-volt charging system test *except:*
   (A) scan tool charging voltage test.
   (B) circuit resistance tests.
   (C) alternator mounting test.
   (D) charging system load test.
3. Charging system tests are performed using a(n):
   (A) VOM.
   (B) scope.
   (C) load tester.
   (D) All of the above.
4. During a 12-volt charging system voltmeter test, all electrical accessories are *on* when checking:
   (A) base voltage.
   (B) load voltage.
   (C) no-load voltage.
   (D) All of the above.
5. When recording no-load voltage, the voltmeter reading should increase from the base reading by no more than:
   (A) 1–2 volts.
   (B) 2–3 volts.
   (C) 5–6 volts.
   (D) 8–10 volts.
6. To check a HV charging system, Technician A says to use on-board diagnostics and a scan tool, laptop, or diagnostic tablet. Technician B says to check data stream values to gain more information on the performance of the HV charging system. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. What is the best way to be trained to service a specific HV charging system?
   (A) Attend factory or manufacturer classes and read their service instructions.
   (B) Search the Internet for service information.
   (C) Read posts from hybrid vehicle forums on the Internet.
   (D) Read service magazines that discuss hybrid repairs.
8. Hybrid vehicle charging system problems are being discussed. Technician A says that an HV battery that will not hold a proper electrical charge will set a diagnostic trouble code. Technician B says that loose HV cable connections will not affect electric drive train performance. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Charging System Diagnosis

Condition	Possible Causes	Correction
No charge.	1. Alternator drive belt loose or broken. 2. Voltage regulator fusible link blown. 3. Sticking or worn commutator brushes. 4. Loose or corroded connection. 5. Rectifiers open. 6. Charging circuit open. 7. Open circuit in stator winding. 8. Field circuit open. 9. Defective field relay. 10. Defective voltage regulator. 11. Open isolation diode. 12. Open resistor wire. 13. Slipping drive pulley. 14. Oil soaked brushes. 15. Corroded or loose brush connections. 16. Seized bearings.	1. Tighten or replace belt. 2. Install new fusible link. 3. Free or replace brushes. 4. Clean and solder connections. 5. Correct cause and replace rectifiers. 6. Correct as needed. 7. Replace stator. 8. Test and correct as required. 9. Replace relay. 10. Replace voltage regulator. 11. Replace diode. 12. Replace resistor wire. 13. Install new key and tighten. 14. Replace brushes. 15. Clean and tighten connections. 16. Replace bearings. Check shaft for damage.
Low or erratic rate of charge.	1. Loose drive belt. 2. Open stator; grounded or shorted turns in stator windings. 3. High resistance in battery terminals. 4. High resistance in charging circuit. 5. Engine ground strap loose or broken. 6. Loose connections. 7. Defective rectifier. 8. Dirty, burned slip rings. 9. Grounded or shorted turns in rotor. 10. Brushes worn. Brush springs weak.	1. Tighten belt. 2. Replace stator. 3. Clean and tighten terminals. 4. Repair cause of high resistance. 5. Tighten or replace strap. 6. Tighten connections. 7. Replace rectifier. 8. Turn slip rings. 9. Replace rotor. 10. Replace brushes and/or springs.
Excessive rate of charge.	1. Faulty voltage regulator ground. 2. Defective voltage regulator. 3. Alternator field winding grounded. 4. Open rectifier. 5. Loose connections.	1. Ground regulator properly. 2. Replace regulator. 3. Repair grounded field winding. 4. Replace rectifier. 5. Tighten connections.
Noise.	1. Drive belt slipping. 2. Drive pulley loose or misaligned. 3. Mounting bolts loose. 4. Worn bearings. 5. Dry bearing. 6. Open or shorted rectifier. 7. Sprung rotor shaft. 8. Open or shorted stator winding. 9. Alternator fan dragging. 10. Excessive rotor end play. 11. Out-of-round or rough slip rings. 12. Hardened brushes.	1. Tighten belt. 2. Tighten or align pulley. 3. Tighten mounting bolts. 4. Replace bearings. 5. Lubricate or replace as required. 6. Replace rectifier. 7. Install new rotor. 8. Test. Replace stator as needed. 9. Adjust fan clearance. 10. Adjust for correct end play. 11. Turn slip rings. 12. Replace brushes.

Chapter 34
Ignition System Technology

After studying this chapter, you will be able to:

- Explain the operating principles of any type of automotive ignition system.
- Sketch the primary and secondary circuits of an ignition system.
- Identify and describe the function of major ignition system components.
- Compare ignition coil, spark plug, and ignition circuit variations.
- Distinguish between coil pack and direct ignition systems.
- Explain the need for accurate ignition timing control.
- Correctly answer ASE certification test questions that require knowledge of ignition system theory and design.

In recent years, different types of ignition systems have been developed to enhance performance, increase efficiency, improve dependability, and reduce the emissions of gasoline engines. Ignition systems in late-model vehicles use a crankshaft position sensor and a computer or an ignition control module (ICM) to determine when to fire each spark plug.

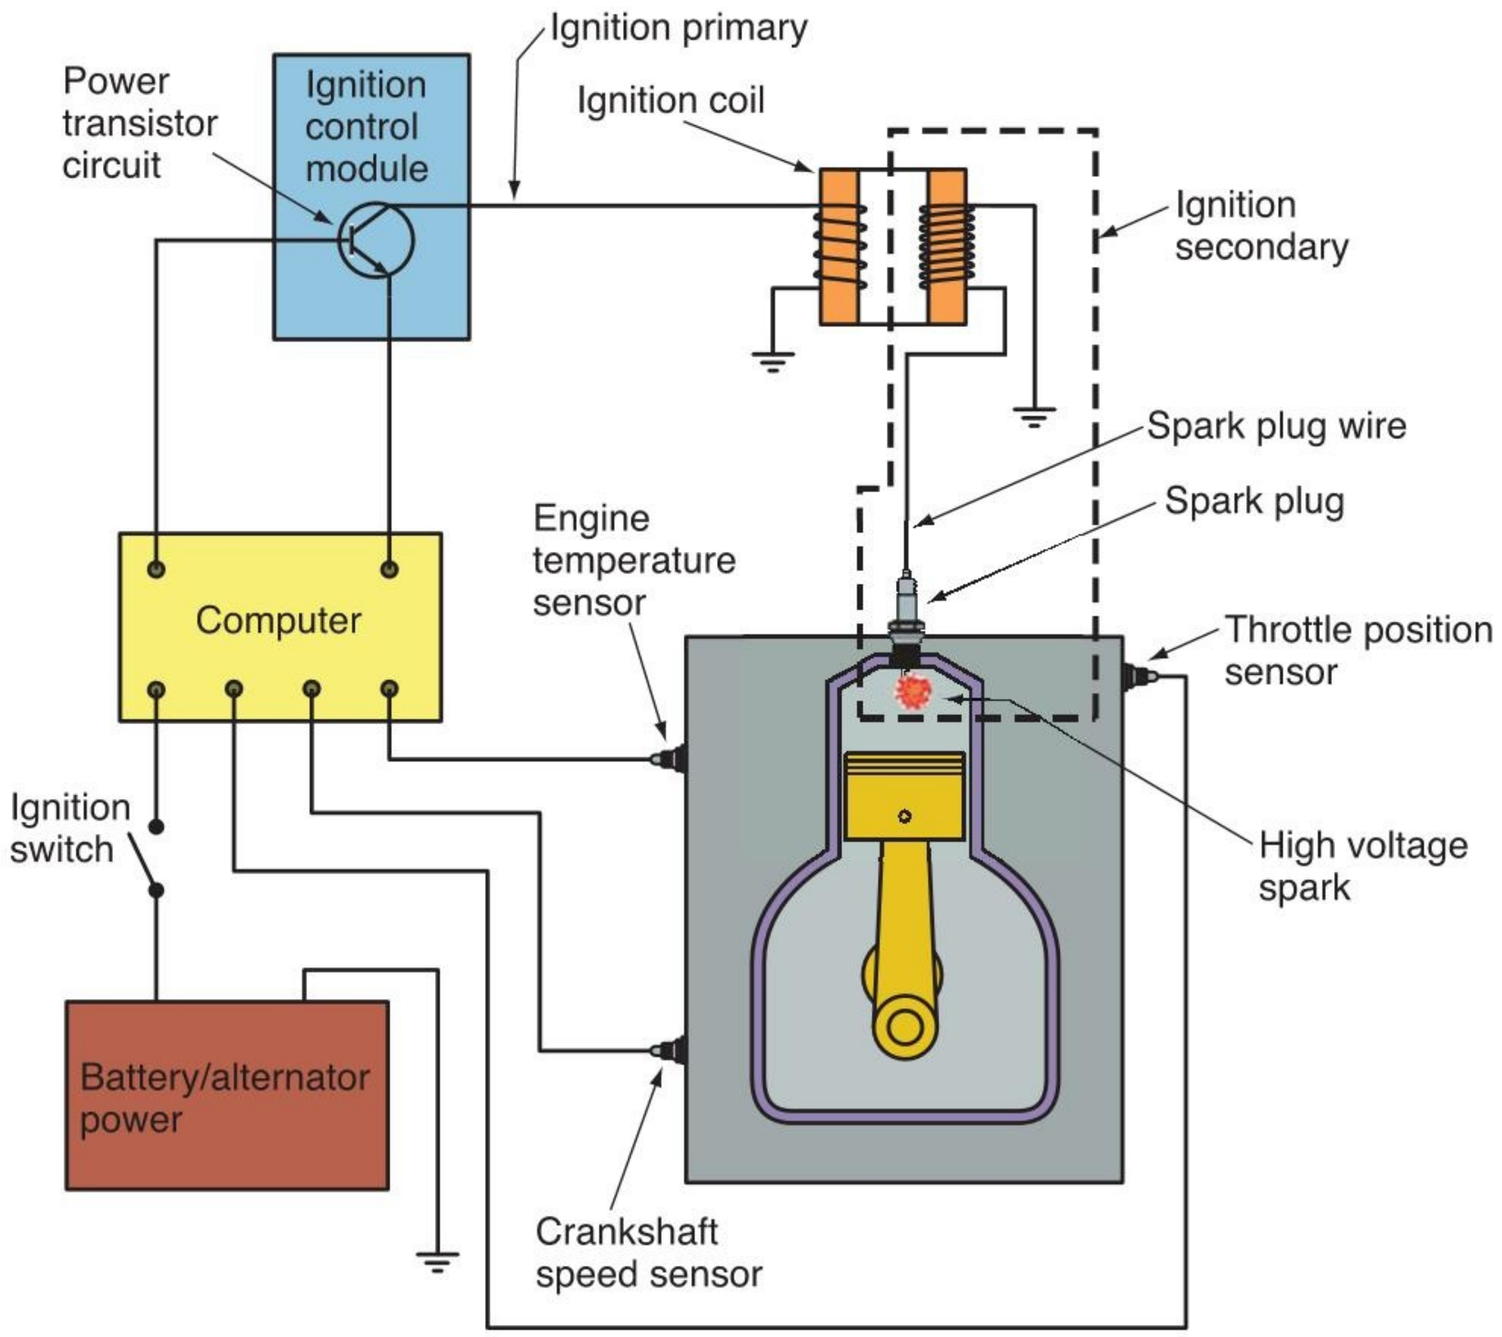
Ignition System Fundamentals

An ***ignition system*** amplifies battery voltage (12.6 volts) or charging system voltage (13 to 15 volts) to over 40,000 volts and delivers this voltage to the spark plugs at the right time. Refer to **Figure 34-1**. Gasoline engines need an ignition system to initiate combustion on the power stroke. Diesels are compression ignition engines and do not need an ignition system to start combustion.

The following are the basic parts of an ignition system:

- Crankshaft position sensor—A crankshaft position sensor is usually a magnetic pickup coil that detects engine speed to "fire" the ignition coil properly.
- Primary wires—The primary wires feed low voltage to components in the ignition system.
- Ignition control module—An ignition control module is an electronic circuit used with the crankshaft position sensor to make and break current to the ignition coil.
- Ignition coil—The ignition coil serves as a step-up transformer that increases battery voltage to 100,000 volts or more.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 34-1. These are the basic parts of an ignition system. The crankshaft speed sensor sends a low voltage signal to the computer and other engine sensors. The computer then signals the ignition control module, which amplifies the signal to make and break current flow to the ignition coil. When the amplifier shuts off the current to the ignition coil, the ignition coil fires and produces high voltage for the spark plug.

- Spark plugs—The spark plugs convert high-voltage current into an electric spark, or arc, in the engine combustion chamber to burn the engine's fuel.
- Secondary wires—The secondary wires have thick insulation for carrying high-voltage current to the spark plugs without arcing or leaking to ground.
- Ignition switch—The ignition switch is the key-operated or push-button switch that feeds battery voltage to the ECM, ignition coil(s), and other components.

Ignition System Operation

The ignition system supply voltage is fed to the ignition system by the battery or alternator. The battery provides electricity for starting the engine. After the engine is running, the alternator supplies a slightly higher voltage to the battery and the ignition system.

When the driver turns the ignition key to the *Start* position, current is fed to the ignition coils by the ignition control module. The current energizes the coil windings with a strong magnetic field. The starting motor turns the crankshaft, trying to make the engine fire and run. This causes the position sensor to produce voltage signals that correspond to engine speed.

The ***ignition control module (ICM)*** uses signals from the engine control module and the crankshaft position sensor to determine when to stop (and start) the current flow through an ignition coil. When the ICM stops the current, the ignition coil feeds high-voltage current to the spark plug. This causes an electric arc between the spark plug electrodes, igniting the air-fuel mixture in the combustion chamber. Combustion makes the engine start, and the driver or ECM can then cut power to the starting motor. This stops and disengages the starting motor, but still allows ignition system operation. When the driver turns the key to the *Off* position, the current is shut off to the ignition module and coil, and the engine stops running.

Copyright Goodheart-Willcox Co., Inc.

As you will learn, an actual ignition system is much more complex than the one just described. Automotive engines have multiple cylinders, and the timing of the sparks must vary with operating conditions.

Primary and Secondary Circuits

The two main sections of an ignition system are the primary and secondary circuits. In **Figure 34-1**, the primary circuit includes all the components and connections outside the dotted box.

The ***primary circuit*** consists of all the components and wires that operate on low 12-volt dc from the battery, alternator, or current from the HV power control module. Small, conventional wires carry primary currents.

The ***secondary circuit*** includes all the parts that carry high-voltage current. It consists of the wires and parts between the coil output windings and the spark plug ground. The secondary wiring must have thick insulation to prevent leakage or arcing of the high secondary operating voltage. The ***secondary operating voltage*** of the ignition system ranges from 4,000–100,000 volts, depending on the system design.

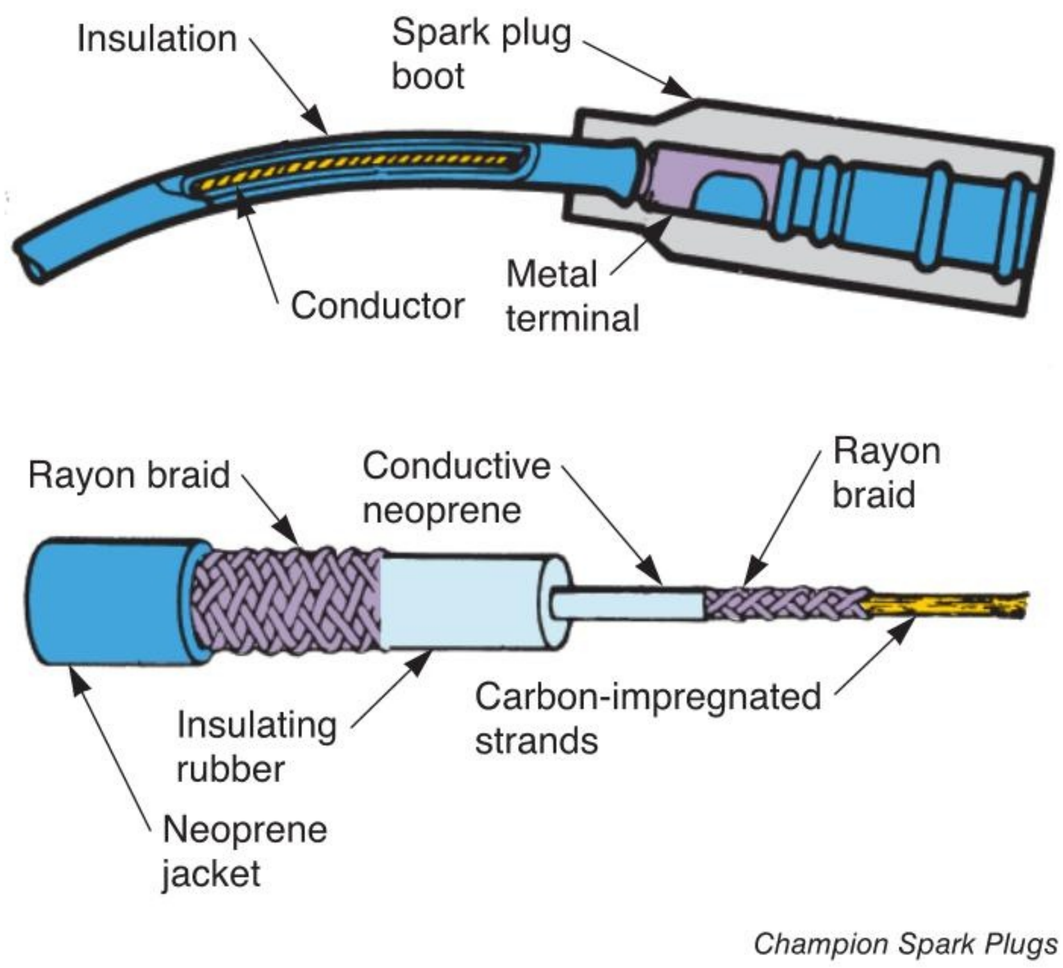
Ignition System Supply Voltage

The ***ignition system supply voltage*** is fed to the ignition system by the battery, alternator, ignition ECM, or HV power control module. On late-model vehicles, these sources feed voltage through the engine control module or the power train control module. The 12-volt or HV battery provides electricity for starting the engine. After the engine is running, the alternator or HV power control module supplies a slightly higher voltage to the electrical and ignition system.

Secondary Wires

Secondary wires, or ***spark plug wires***, carry the high-voltage current produced by the ignition coils. Insulated ***boots*** usually fit over both ends of the secondary wires to protect the metal connectors from corrosion, oil, and moisture.

Resistance wires are now used for secondary wire applications because they contain internal resistance, which helps prevent radio interference. Resistance wires consist of carbon-impregnated strands and rayon braids. Look at **Figure 34-2**. Also called ***radio suppression wires***, resistance wires have about 10,000 ohms of resistance per foot.



Champion Spark Plugs

Figure 34-2. Secondary wire has very thick insulation. Spark plugs contain carbon-impregnated strands that increase internal wire resistance, to prevent radio interference noise in the stereo speakers.

Tech Tip

Most late-model engines have one ignition coil mounted directly to each spark plug. This eliminates the need for secondary wires and improves ignition system dependability. A short resistance spring often conducts high voltage from the direct ignition coil to the spark plug center electrode.

Spark Plugs

Spark plugs use ignition coil high voltage to ignite the fuel mixture. A secondary voltage between 4,000 and 28,000 volts is needed to make current jump the gap at the spark plug electrodes. This is much lower than the coil's output voltage potential discussed earlier.

The following are the basic parts of a spark plug:

- ***Center terminal (center electrode)***—The center terminal (center electrode) conducts electricity into the combustion chamber.
- ***Grounded side electrode***—The grounded side electrode causes the electricity to jump the gap and return to the battery through frame ground.
- ***Ceramic insulator***—The ceramic insulator keeps the high voltage at the plug wire from shorting to ground before producing a spark in the engine cylinder.

Copyright Goodheart-Willcox Co., Inc.

- ***Steel shell***—The steel shell supports the other parts of the plug and has threads for screwing the plug into the engine cylinder head.

Spark Plug Reach

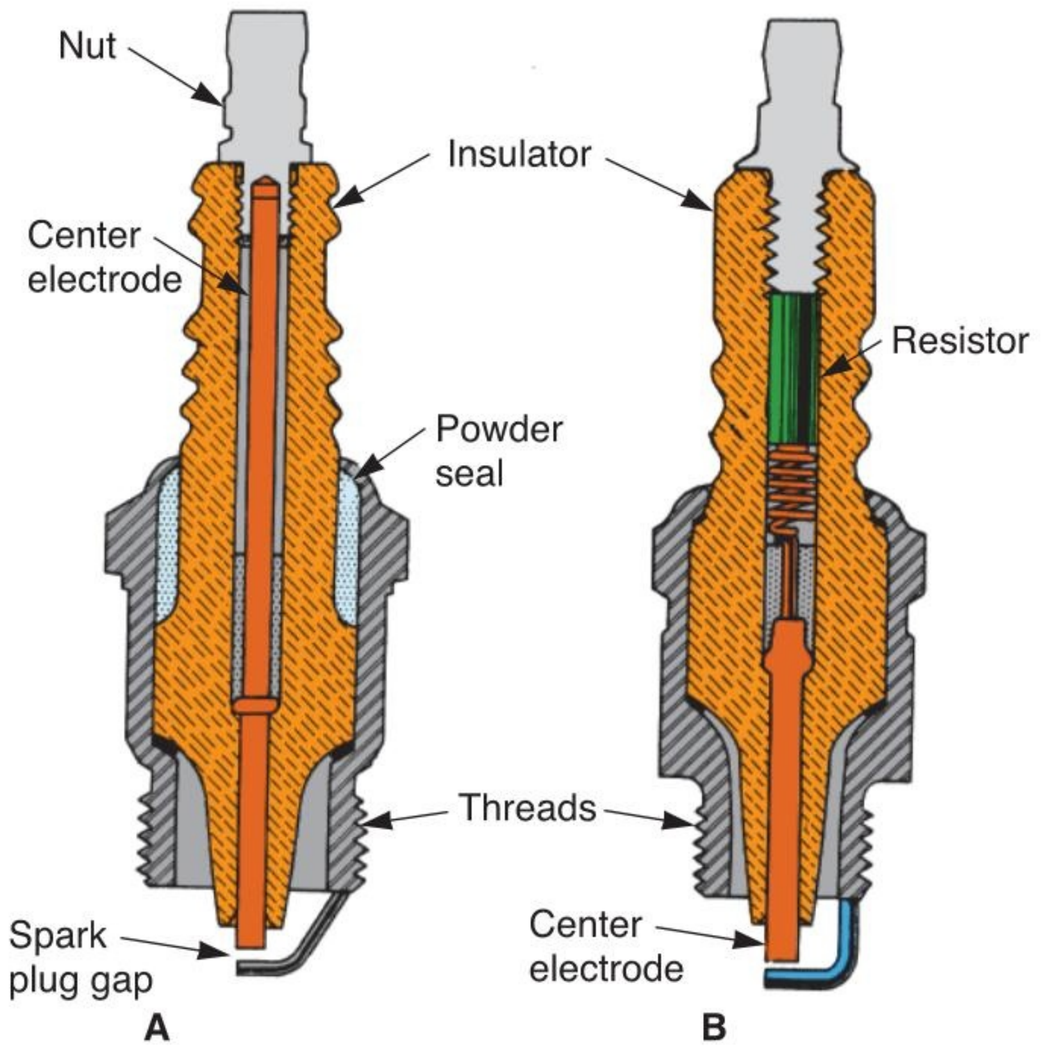
Spark plug reach is the distance between the end of the plug threads and the seat or sealing surface on the plug shell. Refer to **Figure 34-3**. Spark plug reach determines how far the spark plug extends through the cylinder head.

If spark plug reach is too long, the plug electrode may be struck by the piston at top dead center (TDC). If reach is too short, the plug electrodes may not extend far enough into the chamber, and combustion efficiency may be reduced.

Resistor and Non-Resistor Spark Plugs

A ***resistor spark plug***, like a resistance secondary wire, has internal resistance (around 10,000 ohms) to reduce static in radios and television sets. Most vehicles require resistor plugs.

A ***non-resistor spark plug*** has a solid metal rod that forms the center electrode. This type of plug is not commonly used, but it is found in some racing and off-road applications. Refer to **Figure 34-4**.

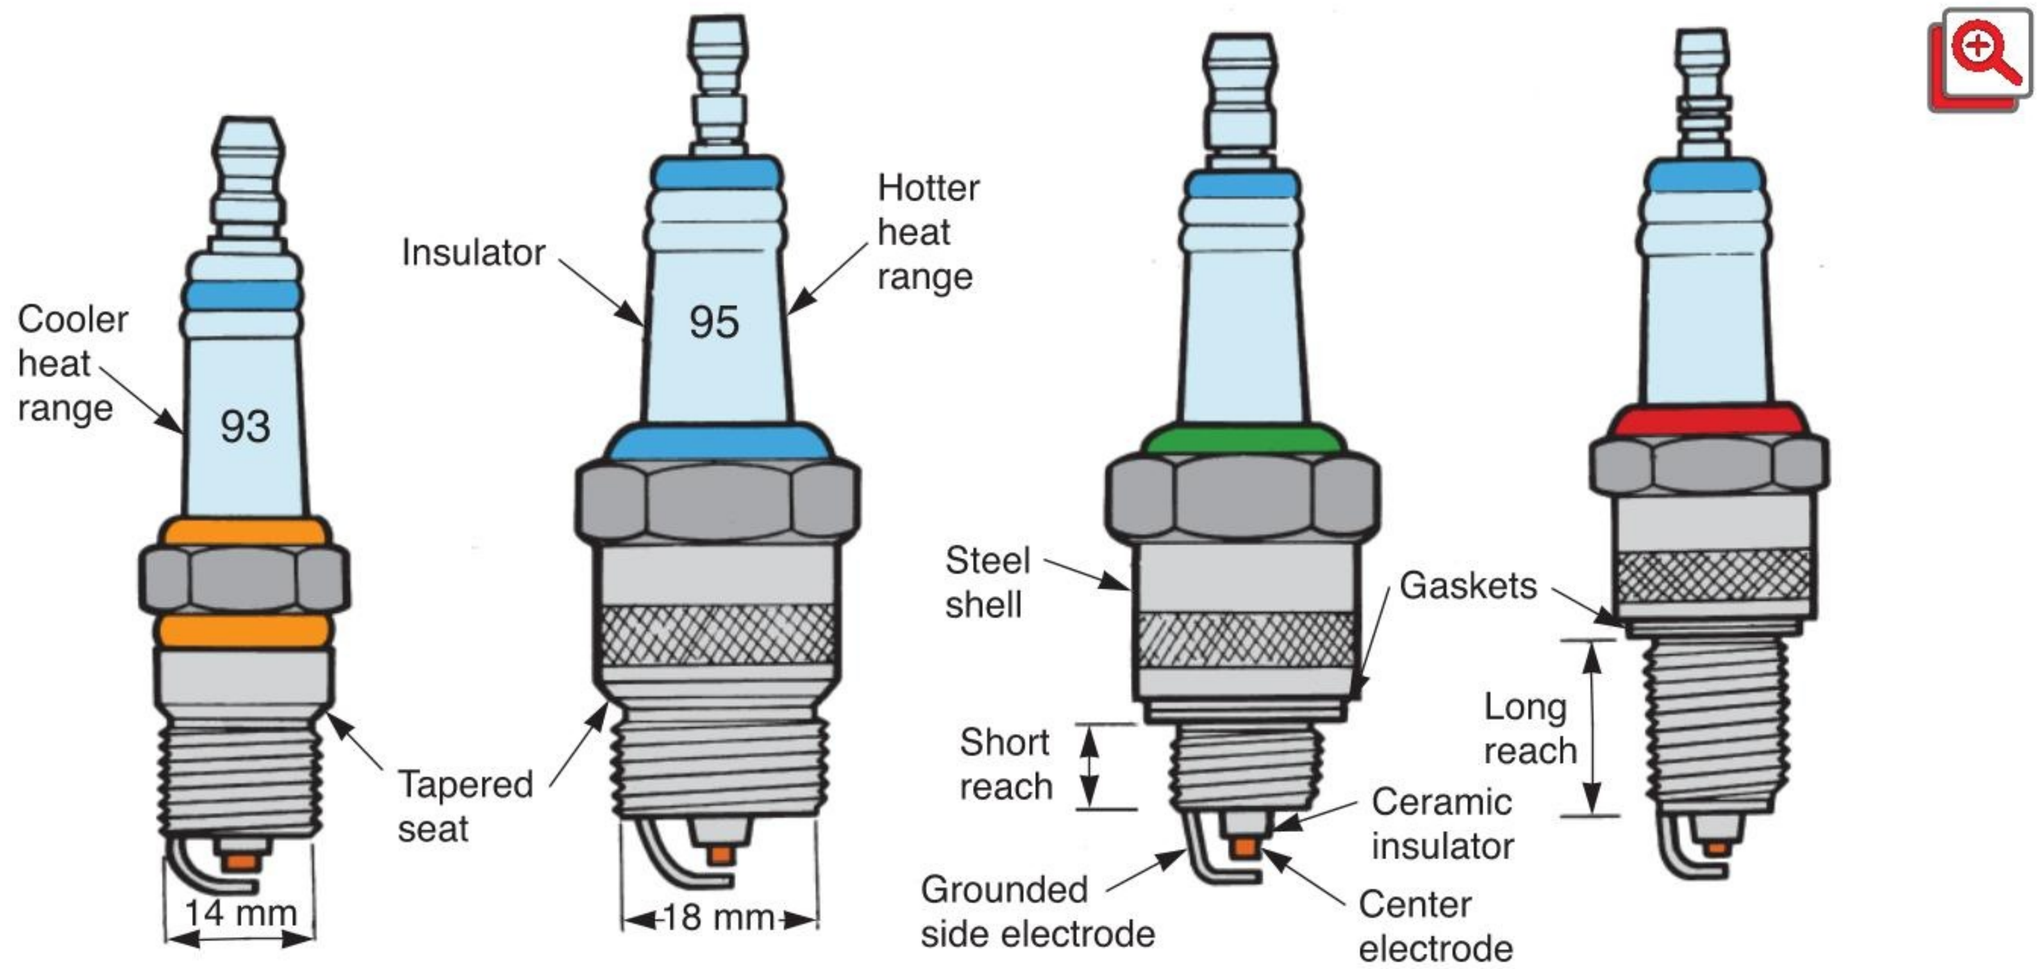


Ethyl Corp.

Figure 34-4. Cutaway shows the internal parts of racing and street spark plugs. A—Non-resistor spark plugs have a solid metal center electrode for a hotter spark, and are used for off-road racing. B—Resistor spark plugs have a small radio-suppressing resistor between a two-piece center electrode. Resistance plugs are required to avoid inducing a clicking sound into nearby car stereos.

Spark Plug Gap

Spark plug gap is the distance between the center and the side electrodes. Normal gap specifications



Chrysler

Figure 34-3. Compare spark plug variations. Small 14 mm plugs are commonly used in today's engines. Larger 18 mm plugs are used in older engines. Spark plug reach is the length of the plug threads.

Copyright Goodheart-Willcox Co., Inc.

range from 0.030″–0.080″ (0.76 mm–2.0 mm). Smaller spark plug gaps are used on older cars. Larger spark plug gaps are used with electronic and computerized ignition systems to produce a "hotter spark."

Spark Plug Heat Range

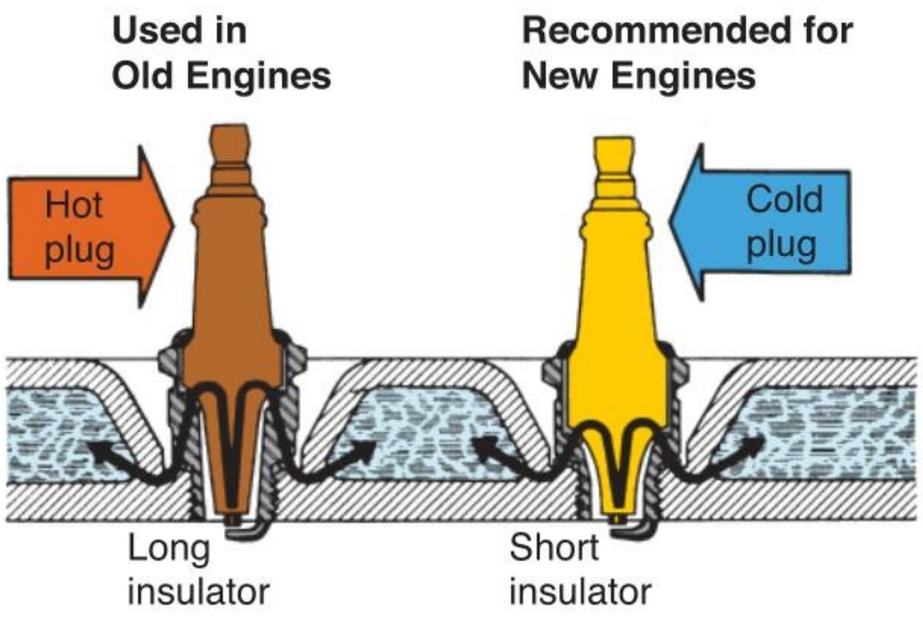
Spark plug heat range is a rating of the operating temperature of the spark plug tip. Plug heat range is basically determined by the length and diameter of the insulator tip, and the ability of the plug to transfer heat into the cooling system. Refer to **Figure 34-5**.

A ***hot spark plug*** has a long insulator tip and tends to burn off deposits. This provides a self-cleaning action.

A ***cold spark plug*** has a shorter insulator tip; its tip operates at a cooler temperature. A cold plug is used in engines that operate at high speeds. The cooler tip helps prevent tip overheating and preignition.

Auto manufacturers normally recommend a specific spark plug heat range for their engines. The heat range is normally coded and given as a number on the plug insulator. Generally, the larger the number on the plug, the hotter the spark plug tip. For instance, a 52 plug would be hotter than a 42.

The only time you should deviate from plug heat range specifications is when abnormal engine or driving conditions are encountered. For example, a hotter plug may be installed in a worn out, oil-burning engine. The hotter plug helps burn off oil deposits, which prevents spark plug oil fouling.



Ethyl Corp.

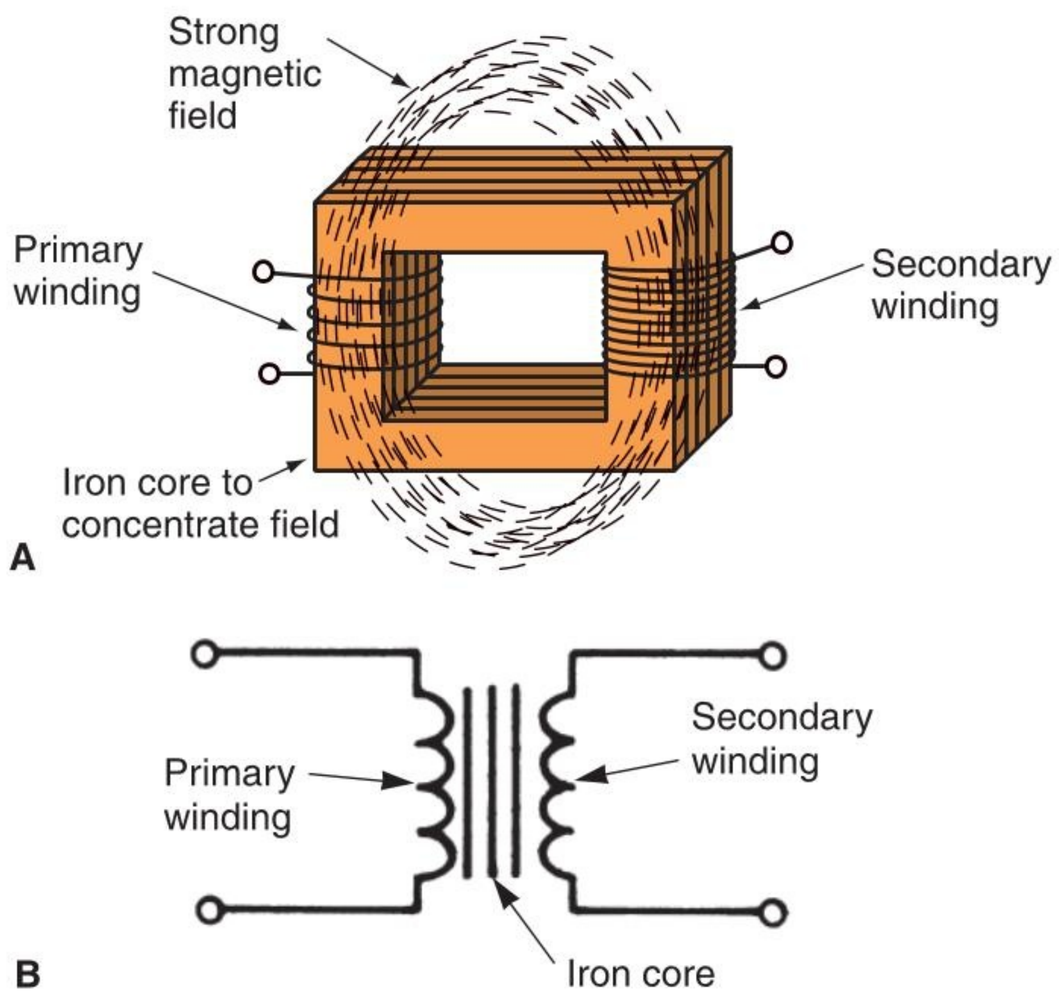
Figure 34-5. A hot plug has a long insulator that prevents heat transfer into the water jackets. It will burn off oil deposits in high-mileage engines. A cold plug has a shorter insulator for high-speed operation and higher cylinder temperatures.

Ignition Coils

The ***ignition coil*** is a pulse-type transformer capable of producing the short bursts of high-voltage current that pass through the secondary wires (if used) and jump the spark plug gaps. It contains two sets of ***windings*** (insulated wire wrapped in circular pattern). The ***primary windings*** are made up of several hundred turns of heavy wire wrapped around or near the secondary windings. The ***secondary windings*** consist of several thousand turns of very fine wire located inside or near the primary windings. Both windings are wrapped around an iron core and are housed inside the coil case. See **Figure 34-6**.

The ignition systems in older engines contain spark plugs with relatively small gaps. These systems operate at about 4,000–8,000 volts. With today's wider spark plug gaps and leaner fuel mixtures, more voltage is needed to make the electricity surge through all parts of the ignition system. Ignition systems in late-model vehicles operate at about 15,000 volts, depending on ignition system design and condition.

If everything is in good condition, the ignition coil operates below its potential maximum output voltage. This keeps some voltage in reserve. The ***ignition coil open-circuit voltage*** (maximum voltage potential) ranges from 40,000–100,000 volts in late-model designs.



Goodheart-Willcox Publisher

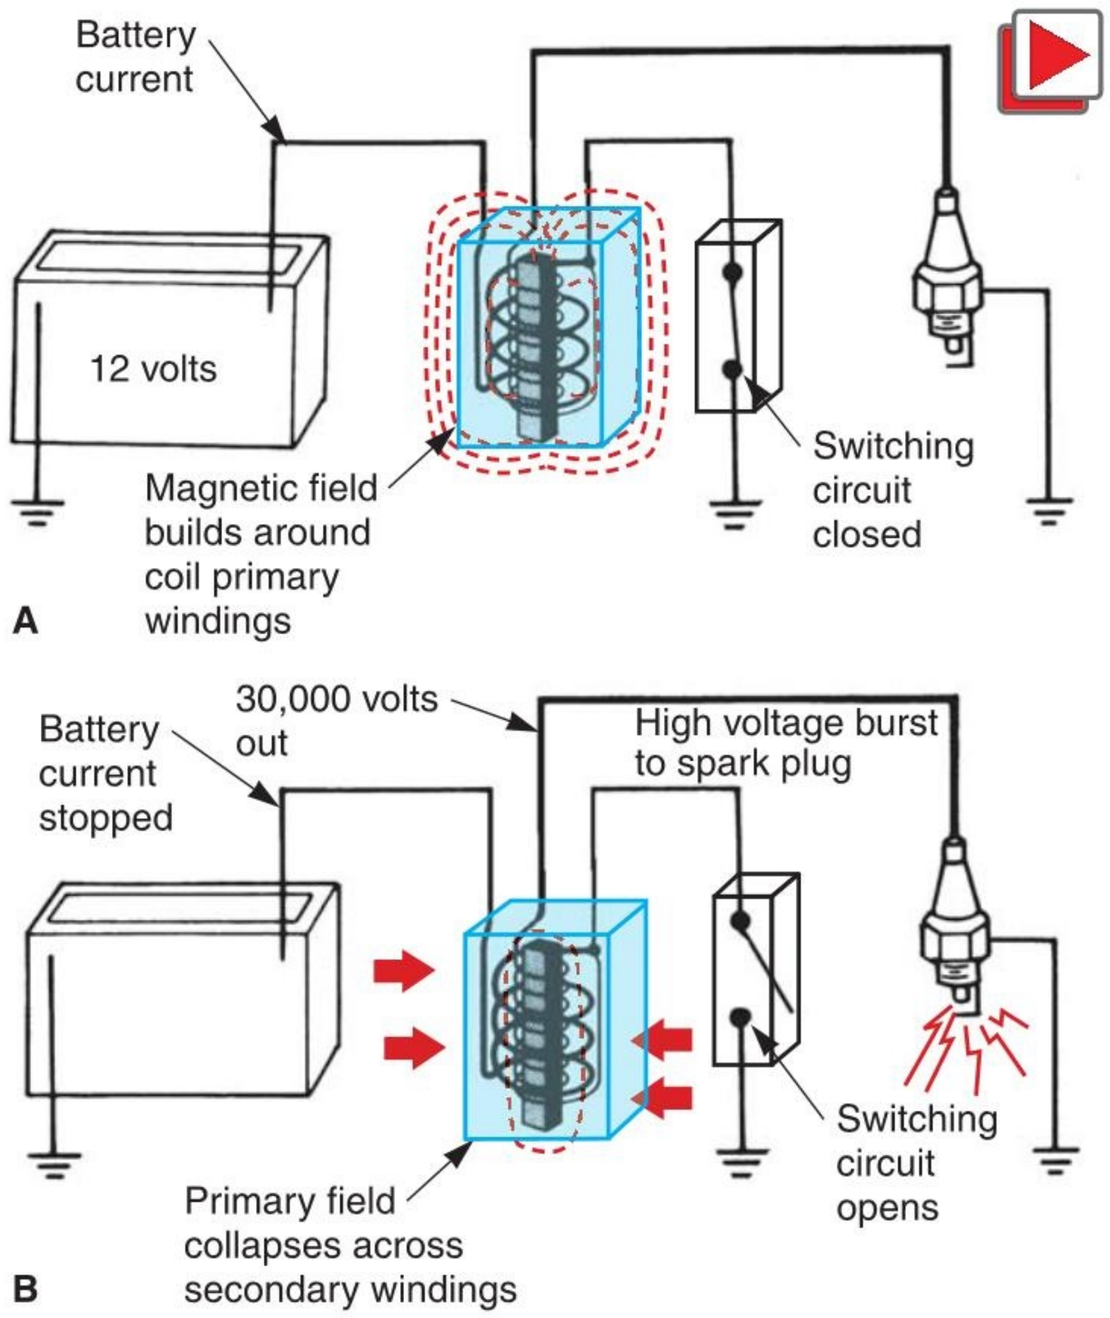
Figure 34-6. Study an ignition coil. A—The ignition coil is a step-up transformer that can increase a 12-volt input into an output of almost 100,000 volts. B—Note how the schematic symbol for an ignition coil relates to its construction.

Copyright Goodheart-Willcox Co., Inc.

Ignition Coil Operation

When battery current flows through the ICM and primary windings of the ignition coil, a strong magnetic field is generated. The action of the iron core helps concentrate and strengthen this field. Look at **Figure 34-7**.

When the current flowing through the coil's primary windings is interrupted by the ICM, the magnetic field collapses across the secondary windings. Since the secondary windings have more turns than the primary windings, up to 60,000 volts is induced in the secondary windings. High voltage shoots out of the high-voltage terminal of the coil, traveling through the secondary circuit to a spark plug.

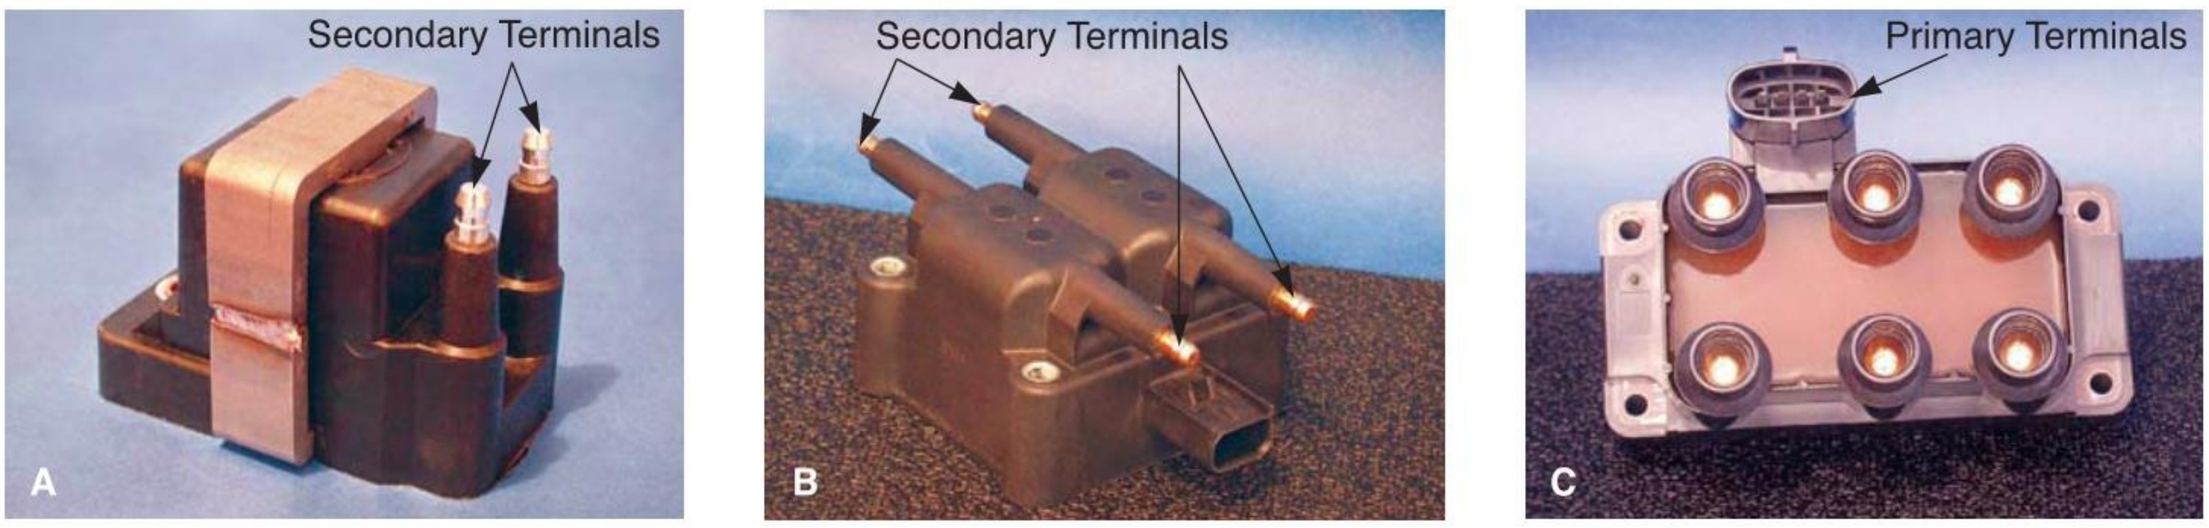


Saab

Figure 34-7. Study the operation of a typical ignition coil. A—With the switching device (electronic circuit or contact points) closed, current flows through the ignition coil primary windings. A strong magnetic field builds around both coil windings and the iron core. The primary magnetic field saturates secondary windings with magnetic energy. B—When the switching device opens, current flow stops and the magnetic field collapses through the secondary windings. This induces a high-voltage surge of electricity in the secondary windings. When the high-voltage surge reaches the spark plug, it arcs across the plug's gap to the ground electrode.

Ignition Coil Designs

With today's computer-controlled ignition systems, ignition coils can be more complex than those used in the past. Depending on ignition system design, an engine can have one or more ignition coils. Very old ignition systems have one coil that serves all engine cylinders. Coil pack ignition systems have one coil for every two engine cylinders. Direct ignition systems have one coil for every engine cylinder. A ***coil pack*** consists of several ignition coils combined into one assembly, **Figure 34-8**. As you will learn, this type of coil is used in coil pack ignition systems. No coil wire is needed with a coil pack. The spark plug wires are connected from the coil pack to the spark plugs. Each coil in the coil pack is wired so that it fires two spark plugs at the same time. As illustrated in **Figure 34-9**, each end of the coil's secondary winding is connected to a spark plug wire. Then, when the primary magnetic field collapses across the secondary winding, a high-voltage, low-current surge is induced in both spark plug wires. Current flows across each spark plug gap



Goodheart-Willcox Publisher

Goodheart-Willcox Publisher

Figure 34-9. Waste-spark ignition coils are wired so they fire two spark plugs simultaneously. One spark plug starts combustion on the power stroke. The other spark plug produces a wasted spark. It does nothing since the electric arc or spark occurs during the engine exhaust stroke.

with the opposite polarity. The engine ground connects the two spark plugs.

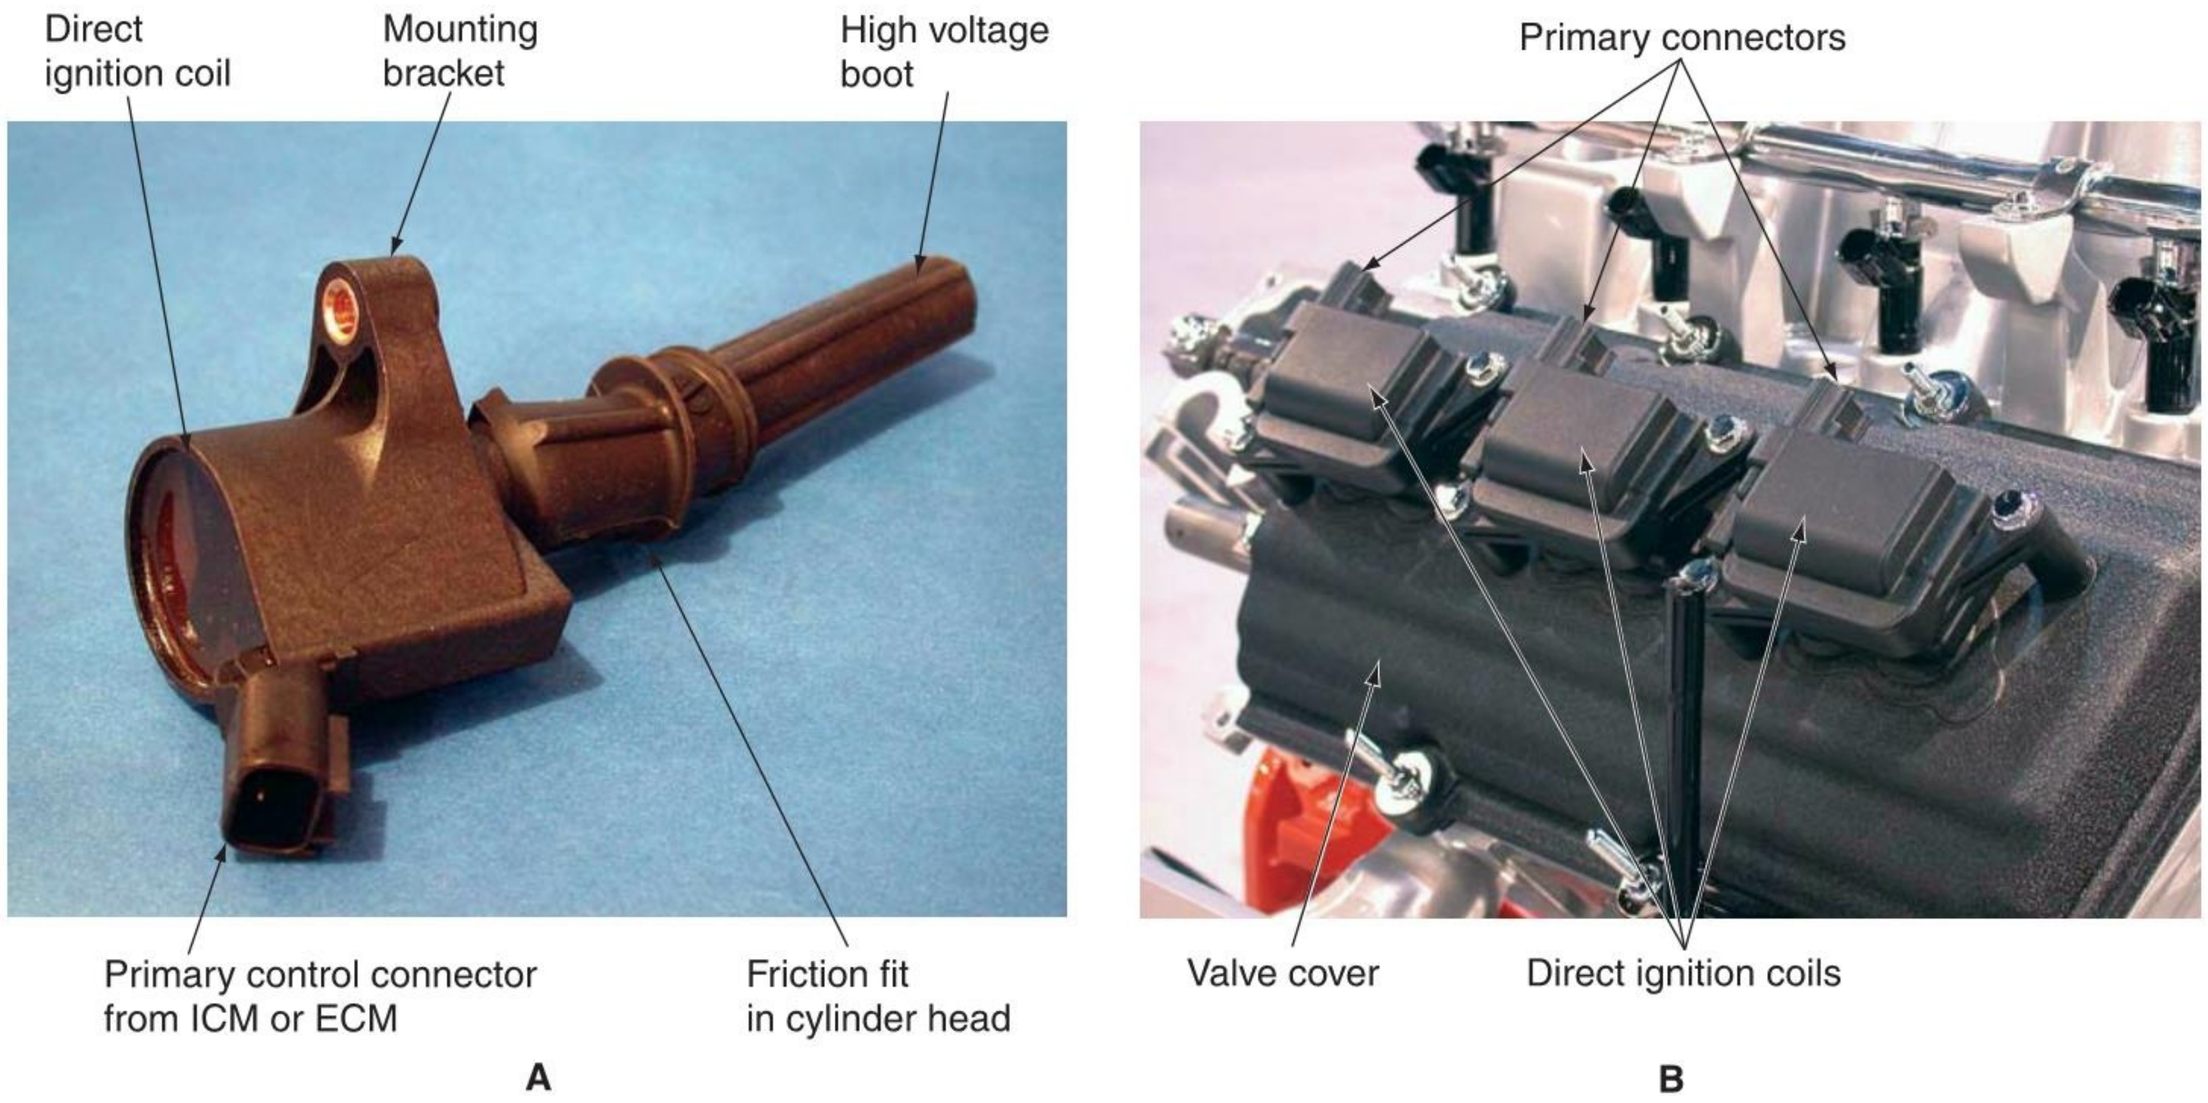
The ***direct ignition coil*** bolts directly over the top of the spark plug on top of the engine. A direct ignition coil fires only on the power strokes for maximum voltage and combustion efficiency. One direct ignition coil is required for each spark plug. Two wires connect to each direct ignition coil from the ICM or directly from the engine ECM. Refer to **Figure 34-10**.

Coil Pack Ignition System

A ***coil pack ignition***, also called a distributorless ignition system or a computer-coil ignition system, uses multiple ignition coils, a coil control unit, engine sensors, and a computer (engine control module) to operate the spark plugs. See **Figure 34-11**.

An ***electronic coil module*** consists of two or more ignition coils and a coil control unit (electronic circuit) that operates the coils. Each coil in the coil module serves two cylinders. Therefore, a four-cylinder engine would have a coil module with two ignition coils and a six-cylinder engine would need a coil module with three ignition coils.

The coil control unit performs about the same function as the ignition control module in an electronic



Goodheart-Willcox Publisher

Figure 34-10. A direct ignition coil is designed to operate only one spark plug. A—The direct ignition system has ignition coils mounted directly on top of the spark plugs. One coil is used for each spark plug. No plug wires or conductor strips are needed. B—Note how the direct ignition coils bolt to the valve cover of this engine.

Copyright Goodheart-Willcox Co., Inc.

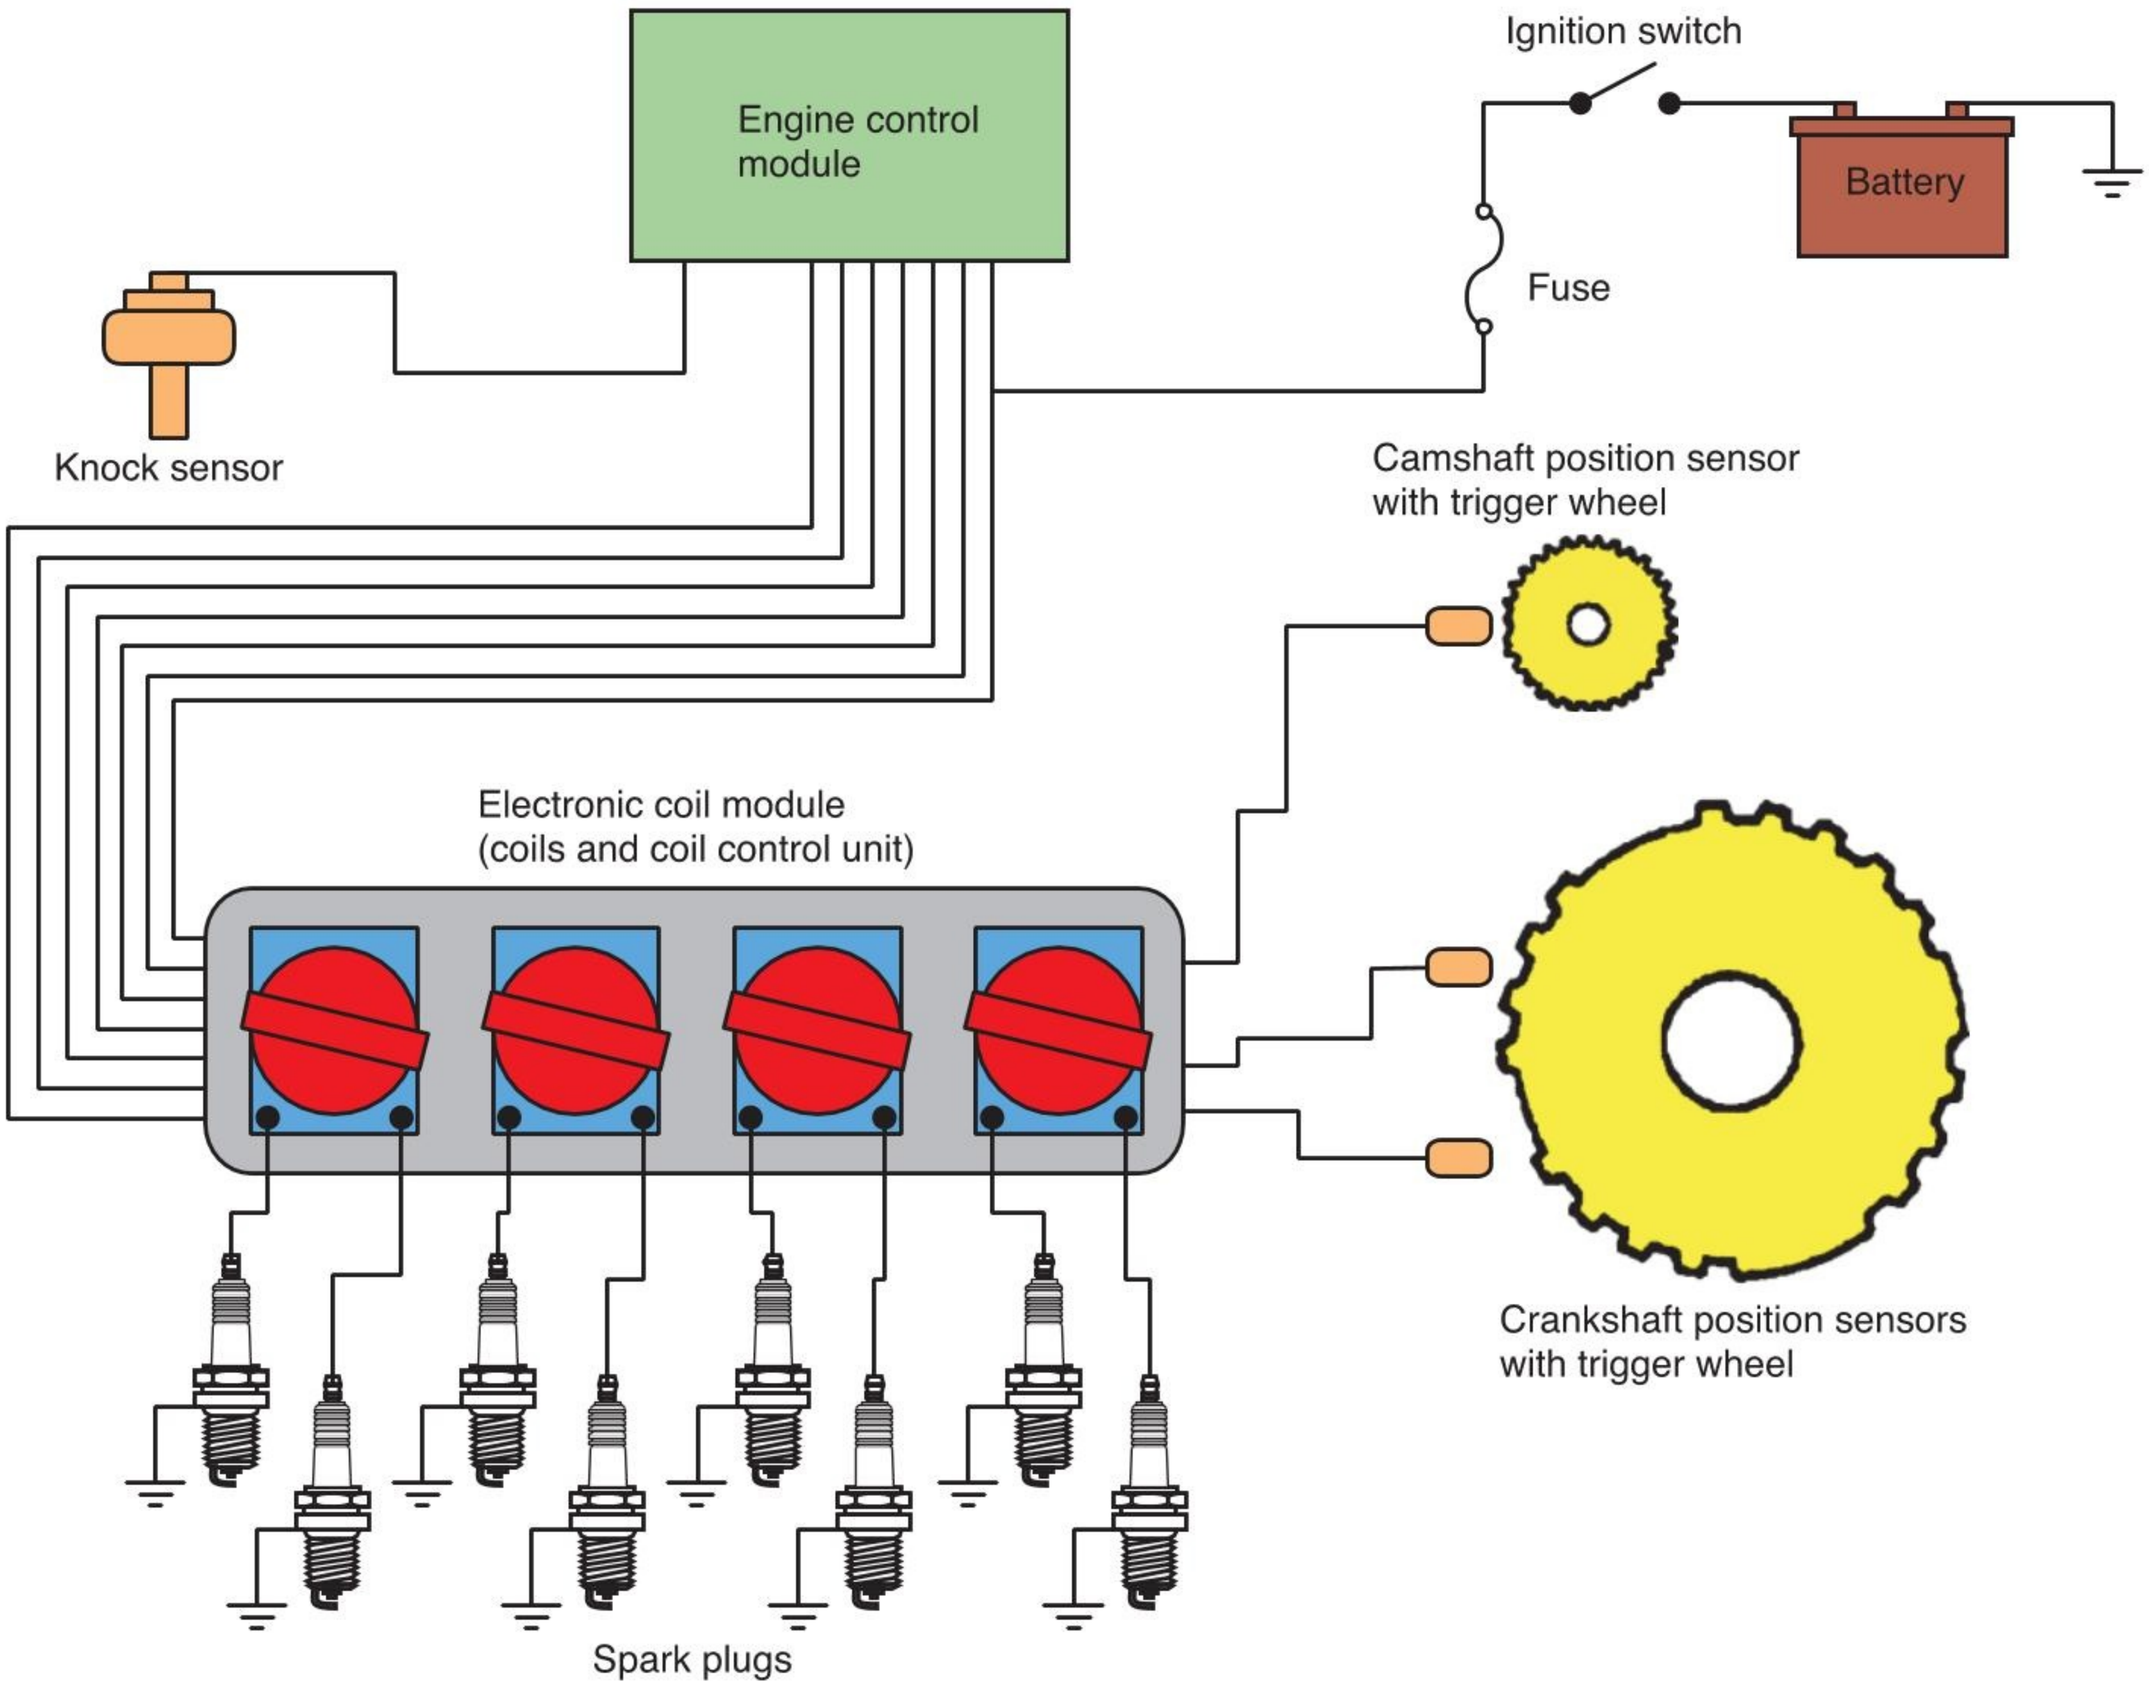
ignition. It is more complex, however, because it must analyze data from engine sensors and the computer.

A camshaft position sensor sends electrical pulses to the coil control unit, providing data on camshaft and valve position. The crankshaft position sensor feeds pulses to the control unit that show engine speed and piston position. A knock sensor may be used to allow the system to retard timing if the engine begins to ping or knock.

Figure 34-12 illustrates how a coil pack ignition system works. The on-board computer (engine or ignition control module) monitors engine-operating conditions and controls ignition timing. Sensor data is also fed to the coil control unit.

When the computer and sensors (including the crankshaft position sensor) send correct electrical pulses to the coil control unit, the control unit fires one of the ignition coils. Since the secondary output of each coil is wired to two spark plugs, both plugs fire. One spark plug arc produces the power stroke. The other arc does nothing (waste-spark) because its cylinder is on the exhaust stroke—burned gases are simply being pushed out of the cylinder. Because the arc in the cylinder on the exhaust stroke has no effect on engine operation, coil pack ignition systems are often called ***waste-spark ignition systems***.

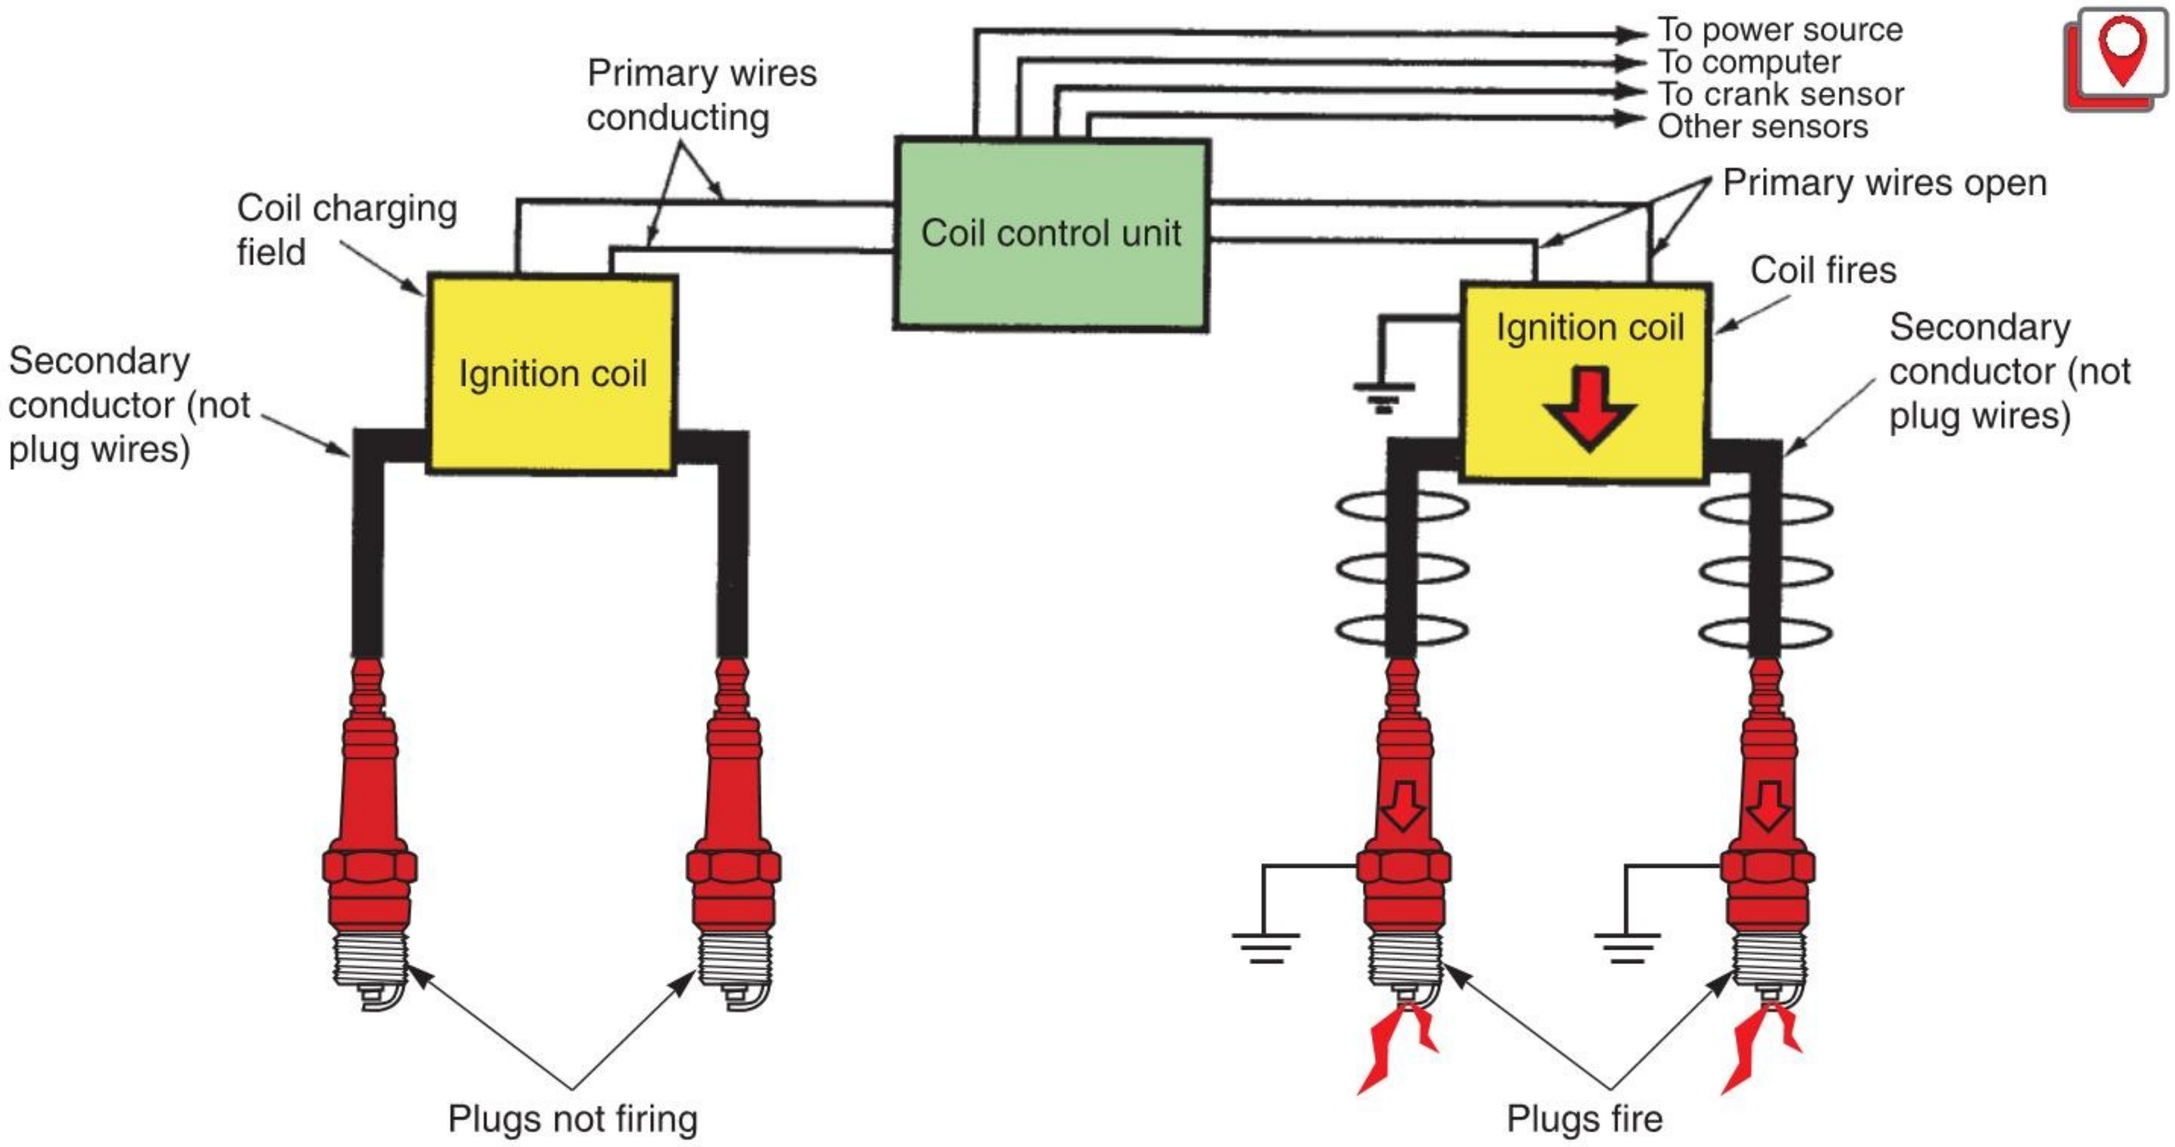
When prompted by the computer and sensors, the coil control unit or engine ECM fires the next ignition coil. Another two spark plugs arc, producing one more power stroke. This process is repeated over and over as the engine runs.



Goodheart-Willcox Publisher

Figure 34-11. A coil pack ignition system has multiple coils and a coil control unit. Crankshaft and camshaft position sensors feed data to the control unit. Each ignition coil fires two spark plugs.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 34-12. Simplified illustration of a coil pack ignition. The coil control unit uses various sensor inputs to determine when to fire one of the ignition coils. When one coil fires, two spark plugs fire. One plug produces a power stroke and the other does nothing since its cylinder is on the exhaust stroke. Two coils operate the ignition for a four-cylinder engine. Three coils are needed for a six-cylinder engine.

Direct Ignition System

In a ***direct ignition system***, one coil assembly is mounted directly above each spark plug, **Figure 34-13**. This eliminates the need for spark plug wires. It also allows the use of smaller ignition coils. The other components in a direct ignition system (ECM, sensors, etc.) are the same as those used in a coil pack ignition system.

There is some confusion in the industry about the terms *coil pack ignition* and *direct ignition*. A coil pack ignition system has secondary wires between the coils and spark plugs. In a direct ignition system, one ignition coil is mounted over the top of each spark plug. There is no need for spark plug wires, just a short secondary conductor from the coil secondary output to the spark plug terminal. Study the direct ignition system wiring diagram in **Figure 34-14**.

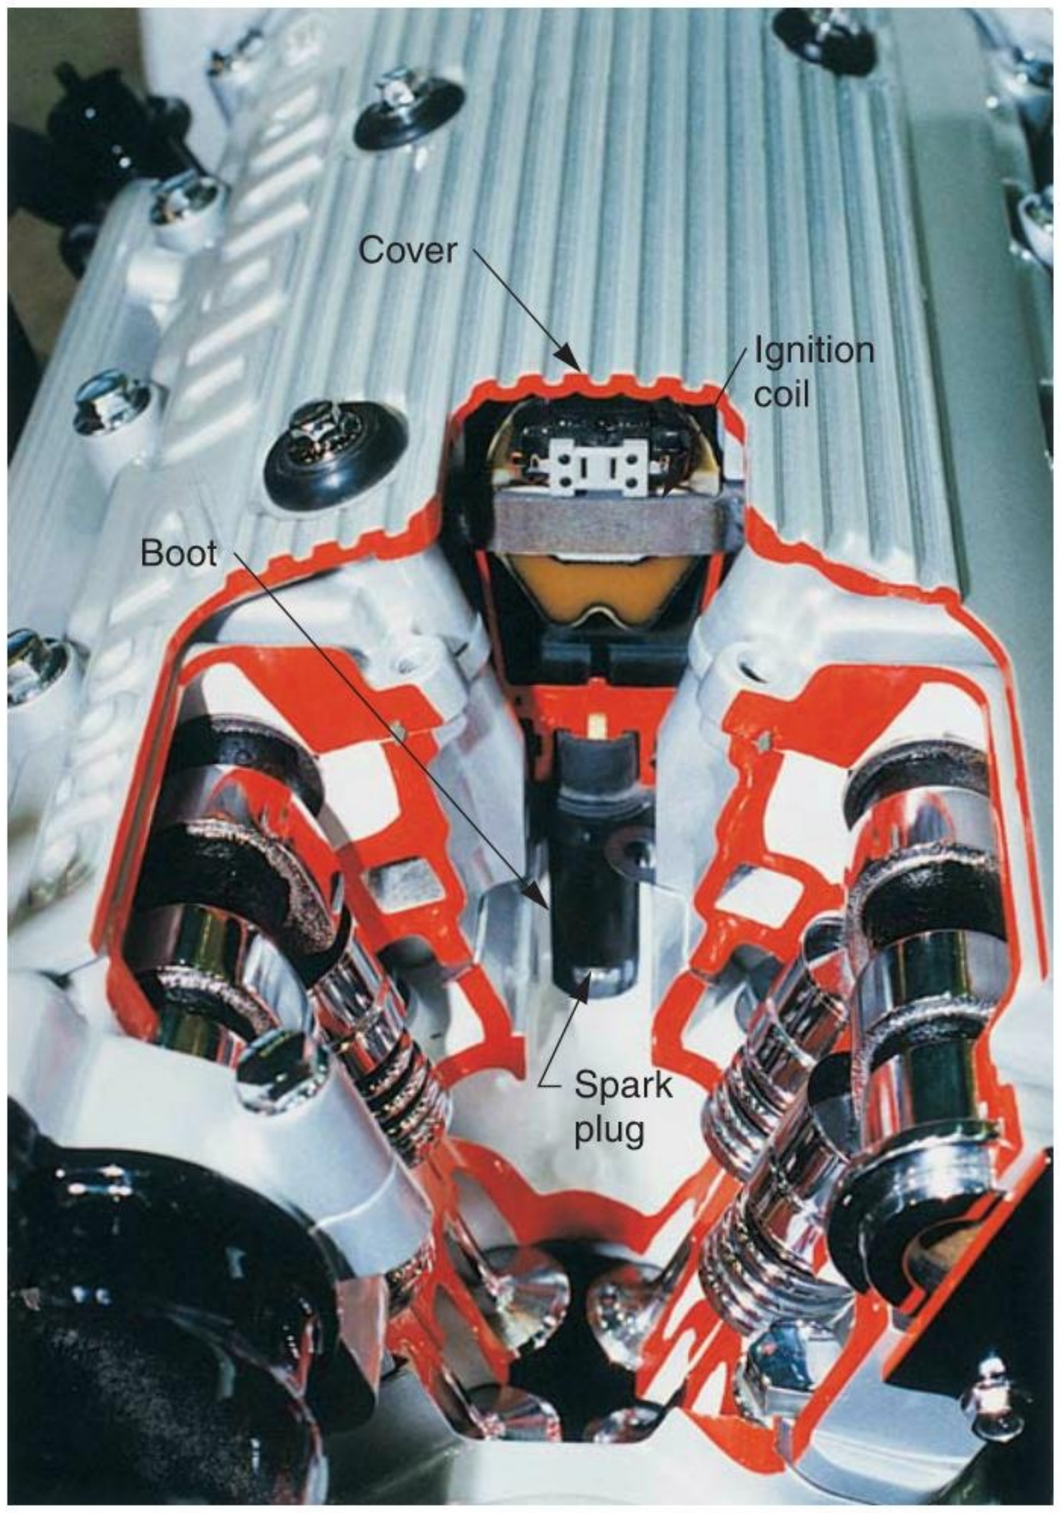
Tech Tip

In some multi-coil ignition systems, the engine control computer measures the time needed to charge each ignition coil. Charge time varies with each coil's resistance/inductance and with the output voltage from the alternator or HV power control module. The ECM uses this charge time to determine the ignition coil on-time for optimum spark plug arc duration and spark timing.

Ionization Knock Sensing

In some cases, an ***ionization knock sensing*** system is used to detect abnormal combustion and knocking. In these systems, the coil computer prompts the ignition coil to send a low-voltage discharge across the spark plug gap immediately following combustion. The quality of combustion affects the resistance across the plug gap by varying the degree of ionization (process by which atoms gain or lose electrons) in the gases between the plug's electrodes.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 34-13. This engine cutaway shows a coil mounted over a spark plug.

Consequently, the quality of combustion influences the strength of the discharge across the gap. The computer uses feedback from the discharge to determine if the spark advance or the supercharger or turbocharger boost should be modified to reduce knocking. A conventional knock sensor is not needed on an engine with an ionization knock sensing system.

Dual Spark Plug Ignition

A few engines have a ***dual spark plug ignition system***. In this type of system, two spark plugs are used in each cylinder. For instance, a four-cylinder engine would use eight spark plugs. One plug is located near the intake valve and the other is near the exhaust valve. Dual plugs help ensure better ignition and combustion of the air-fuel mixture.

In some dual spark plug systems, one ignition coil is used to fire both spark plugs in a given cylinder at the same time, similar to a coil pack ignition. Other systems contain a separate coil for each plug. This results in two very powerful electric arcs that can ignite and burn fuel more completely, especially at high engine speeds and boost levels.

Multiple Discharge Ignition

A ***multiple discharge ignition system*** fires the spark plugs more than once during each power stroke. By producing a series of sparks, the multiple discharge system helps ensure more complete burning of the fuel charge. This type of ignition system is commonly used on racing engines and on some late-model engines with direct fuel injection. Each ignition coil can be fired hundreds of times or more per power stroke.

Distributor Ignition Systems

An ignition distributor is used in older ignition systems. An ignition distributor, **Figure 34-15**, typically has several functions:

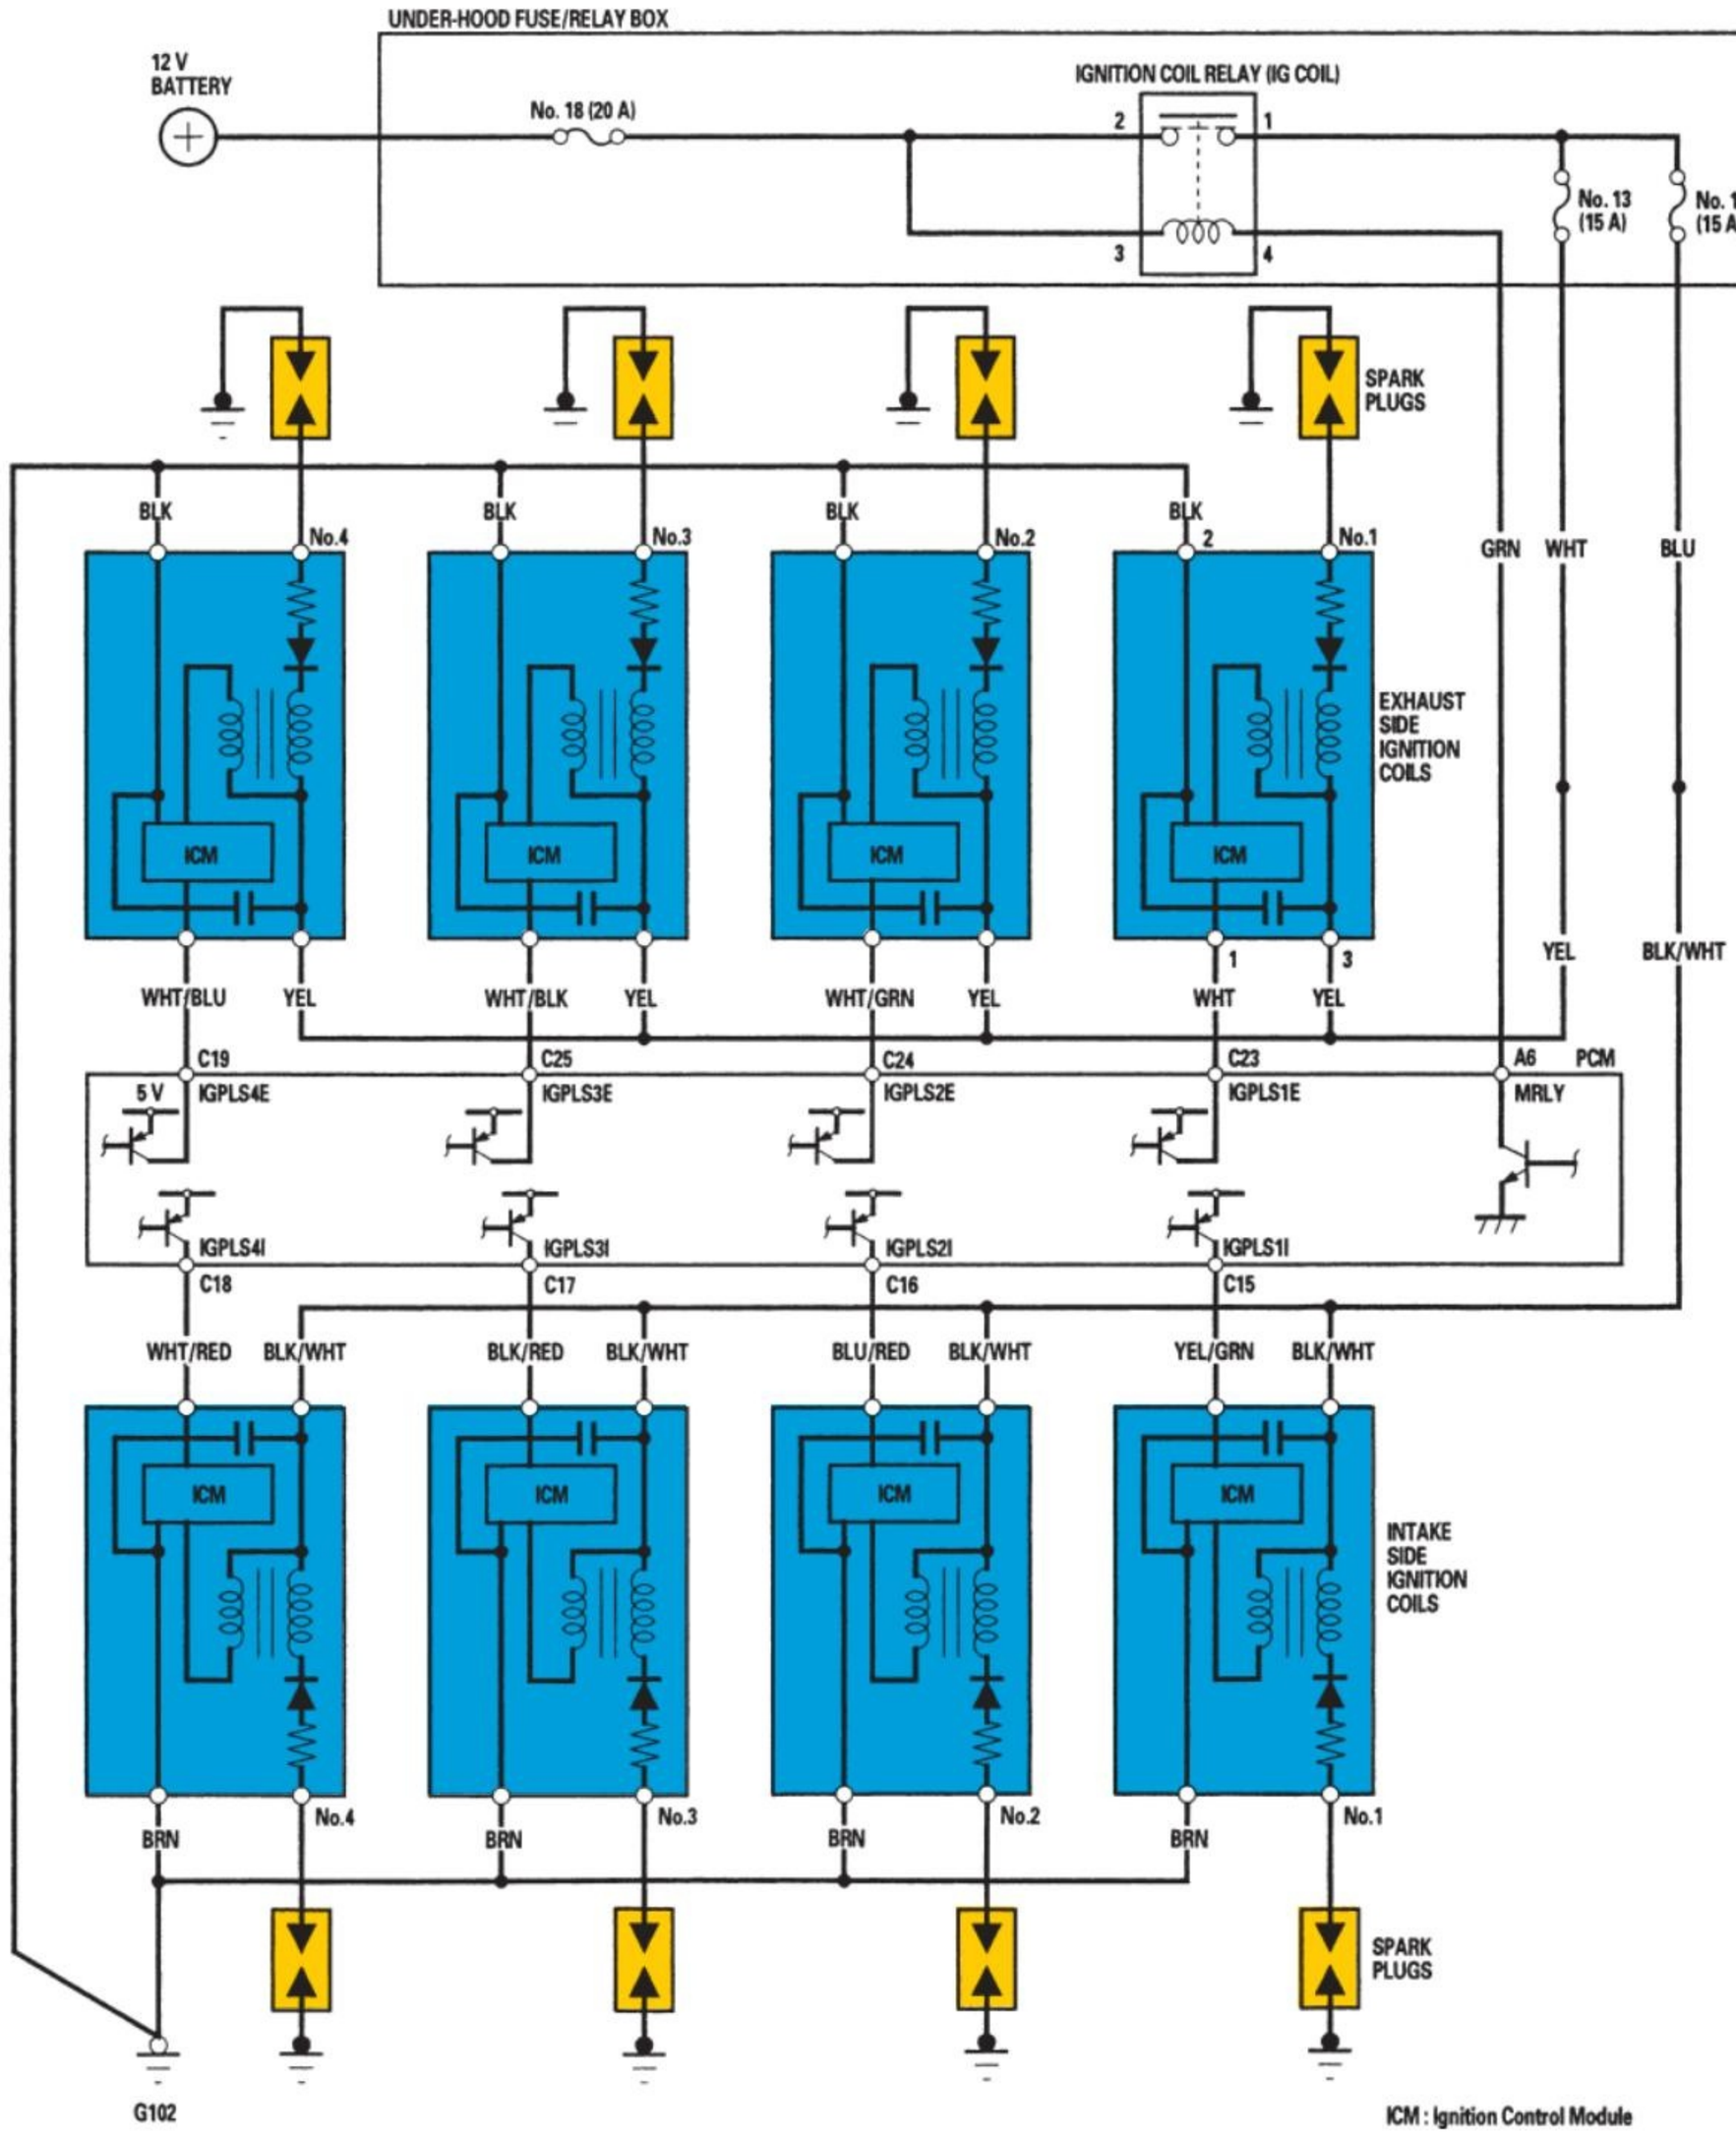
- It actuates the *on*/*off* cycles of current flow through the ignition coil primary windings.
- It distributes the coil's high-voltage pulses to the spark plug wires.
- It causes the spark to occur at each plug earlier in the compression stroke as engine speed increases and vice versa.
- It changes spark timing with changes in engine load. As more load is placed on the engine, the spark timing must occur later in the compression stroke to prevent spark knock (abnormal combustion).
- Sometimes, the bottom of the distributor shaft powers the engine oil pump.
- Some distributors (unitized distributors) house the ignition coil and electronic switching circuit in one assembly.

Engine Firing Order

Engine firing order refers to the sequence in which the spark plugs fire to cause combustion in each cylinder. A four-cylinder engine may have one of two firing orders: 1-3-4-2 or 1-2-4-3. The cylinders are numbered 1, 2, 3, and 4, starting at the front of the engine. In this way, you can tell which cylinders will fire in sequence. Firing orders and cylinder numbers for V-6 and V-8 engines vary. See **Figure 34-16**.

The engine firing order is sometimes cast into the top of the intake manifold. When not on the manifold, the firing order can be found in a service manual.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

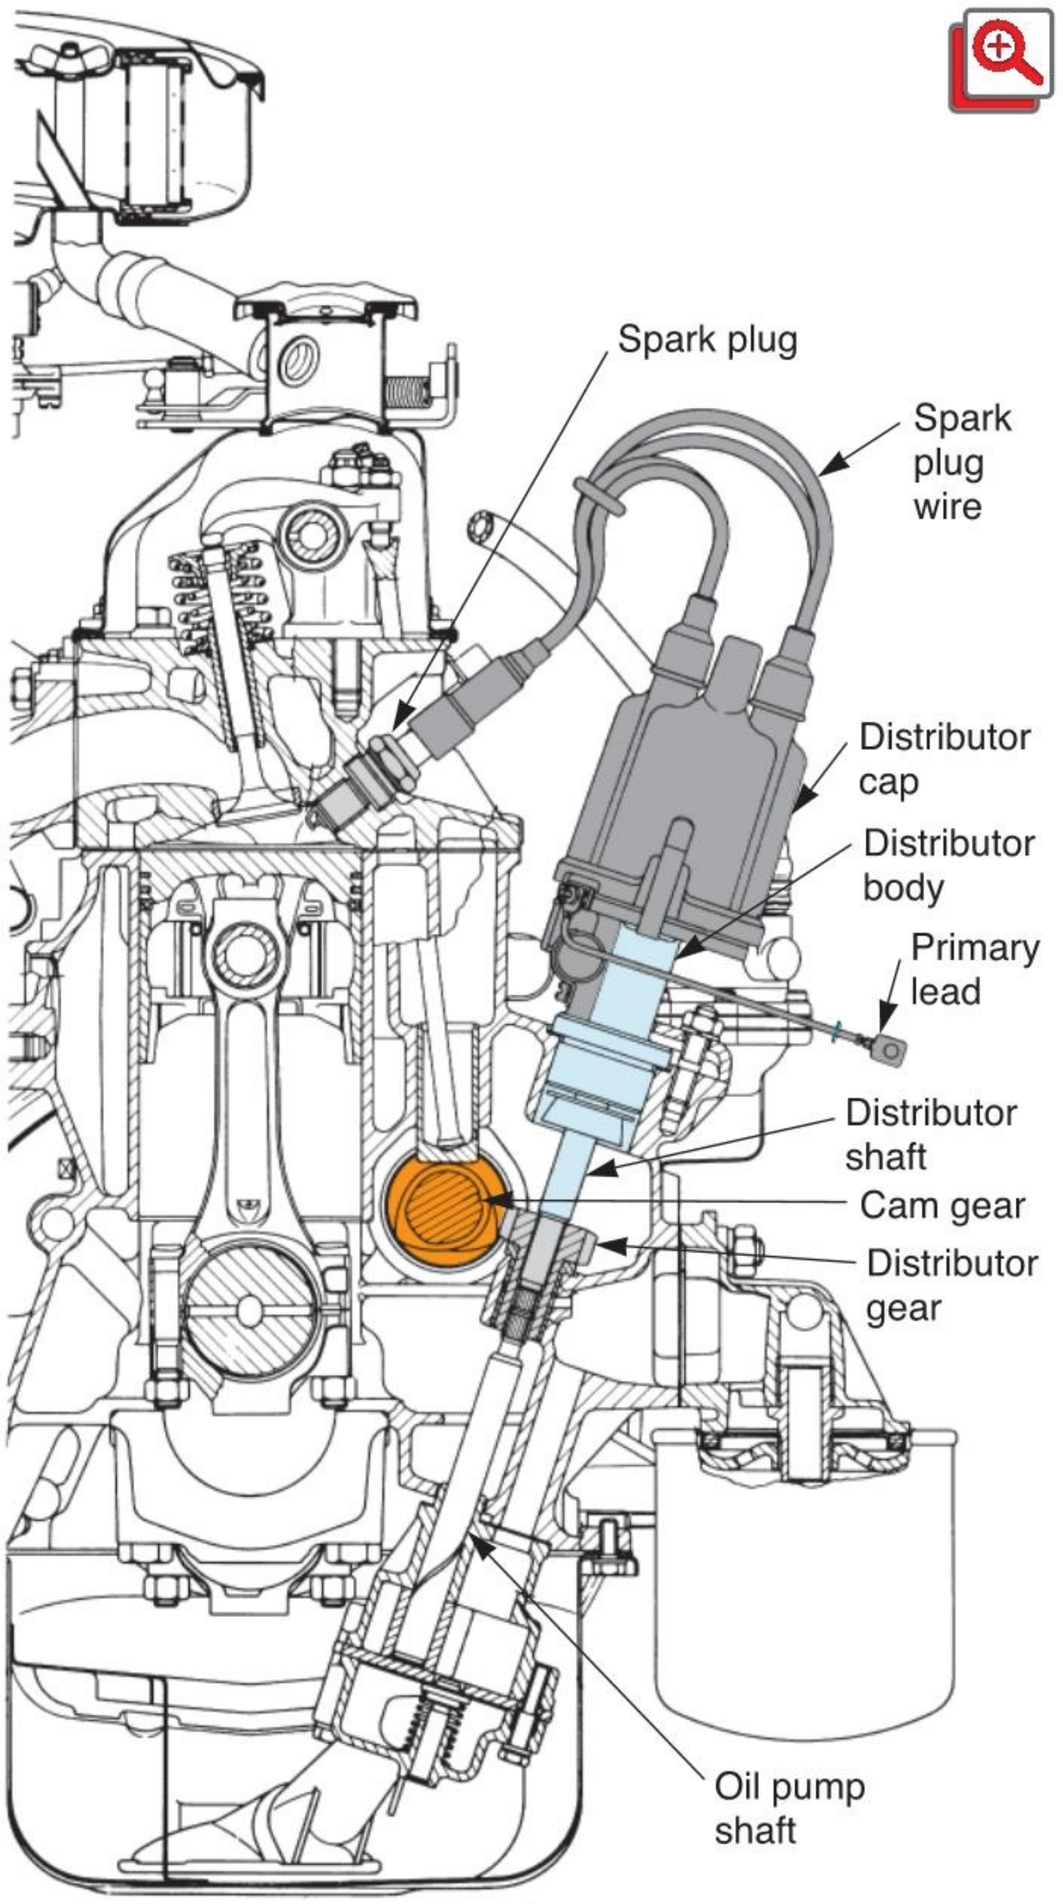
Figure 34-14. This ignition system is for a four-cylinder engine used in a hybrid vehicle. The intake-side ignition coils fire spark plugs near the intake valves, and the exhaust-side ignition coils fire spark plugs near the exhaust valves.

Ignition Timing

Ignition timing, also called ***spark timing***, refers to how early or late the spark plugs fire in relation to the position of the engine pistons. Ignition timing must change with changes in engine speed, load, air-fuel mixture, and temperature.

Timing advance occurs when the spark plugs fire sooner during the engine's compression strokes. The timing is set several degrees before top dead center (TDC). Even more timing advance is needed at higher engine speeds to give combustion enough time to develop pressure on the power stroke. See **Figure 34-17**.

Copyright Goodheart-Willcox Co., Inc.

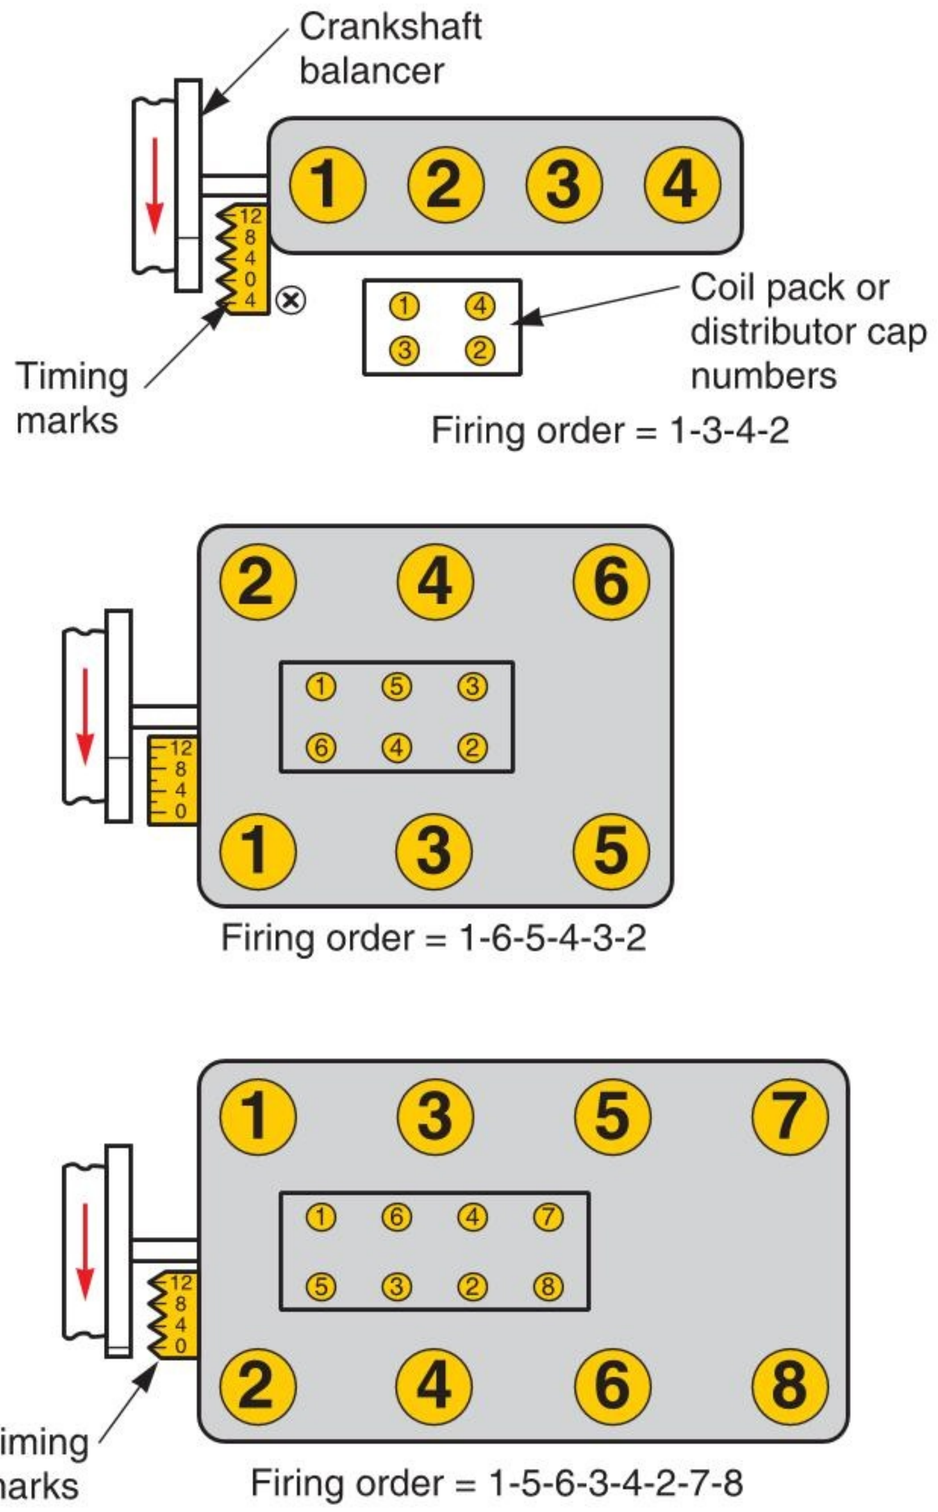


Goodheart-Willcox Publisher

Figure 34-15. The ignition distributor is usually driven by the engine camshaft. A small gear on the camshaft drives the gear on the distributor a one-half engine speed. The main purpose of the distributor is to feed coil voltage to the spark plugs.

Timing retard occurs when the spark plugs fire later during the compression strokes—opposite of timing advance. Timing retard is needed at lower engine speeds and under high load conditions. Timing retard prevents the fuel from burning too much on the compression stroke, causing a spark knock or ping (abnormal combustion).

The spark advance systems found on late-model vehicles use engine sensors, an ignition control module, and/or an engine or power train ECM to adjust ignition timing.



Mitchell Manuals and Echlin

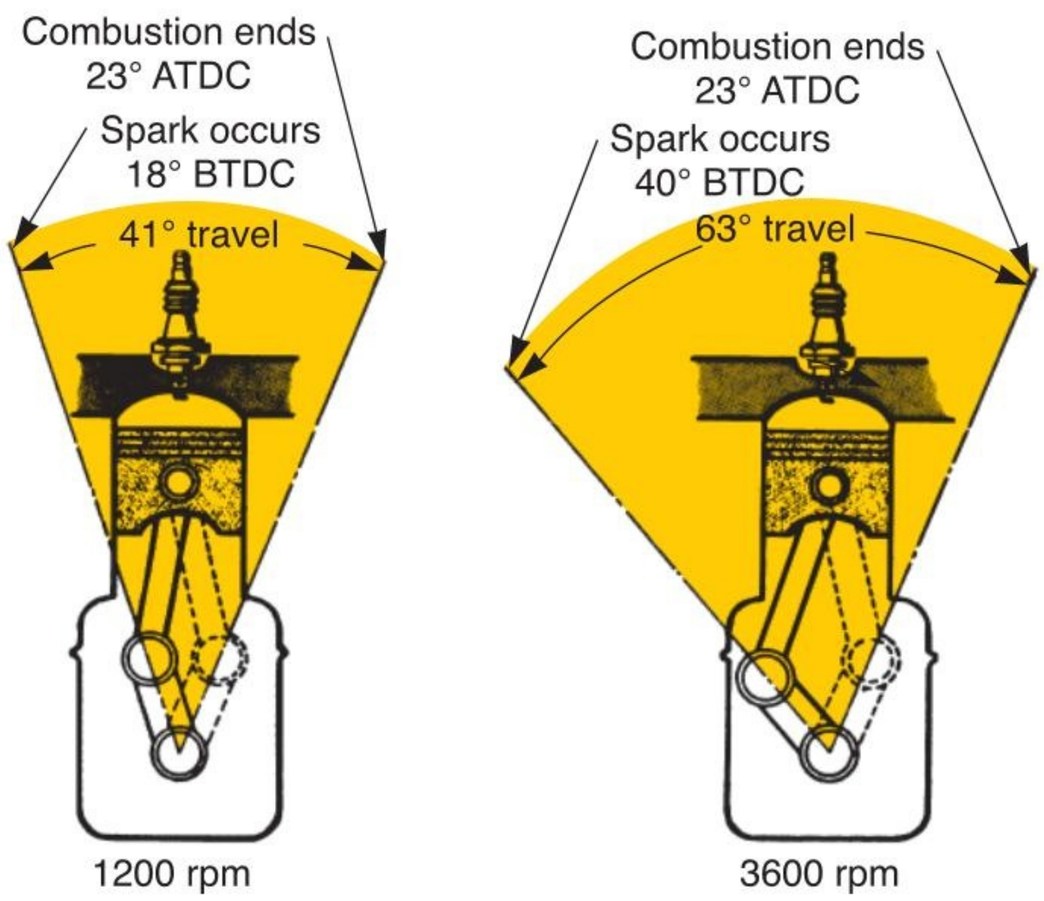
Figure 34-16. Firing order is the sequence in which the spark plugs fire inside the engine. Firing order information is used when installing plug wires, checking ignition timing, and other operations.

The ***engine sensors*** check various operating conditions and send electrical data representing these conditions to the computer. The computer can then analyze the data and change ignition timing for maximum engine efficiency.

Sensors that influence ignition timing include:

- ***Crankshaft position sensor***—Reports engine rpms to the computer.
- ***Camshaft position sensor***—Tells the computer which cylinder is on its power stroke.
- ***Manifold absolute pressure sensor***—Measures engine intake manifold vacuum, an indicator of load.
- ***Intake air temperature sensor***—Checks temperature of air entering the engine.

Copyright Goodheart-Willcox Co., Inc.



Sun Electric Corp.

Figure 34-17. Study how ignition spark timing is altered with changes in engine rpms and other conditions. Since each combustion flame period takes about the same amount of time, the electric spark at the air gap must start combustion sooner as engine speed increases. This will ensure that all the fuel is burned on the power stroke and that sufficient pressure acts on the piston.

- ***Engine coolant temperature sensor***—Monitors the operating temperature of the engine by measuring the temperature of the engine coolant.
- ***Knock sensor***—Allows the computer to retard timing when the engine pings or knocks.
- ***Throttle position sensor***—Notes the position of the throttle.

The ECM receives input signals (different current or voltage levels) from these sensors, and it can measure battery voltage to compensate for voltage variations due to battery state-of-charge, accessory loads, etc. It is programmed (preset) to adjust ignition timing to meet different engine operating conditions. The ECM may be mounted under the dash, on the air cleaner, on the fender inner panel, or under a seat.

For an example, imagine a car or light truck traveling down the highway at 55 mph (88 km/h). The crankshaft sensor detects moderate engine rpms. The throttle position sensor detects part throttle. The intake air and coolant temperature sensors detect normal operating temperatures. The manifold absolute pressure sensor detects high vacuum. The sensors send signals representing these values and conditions to the ECM.

Based on the sensor signals, the ECM circuitry calculates that the engine needs almost maximum spark advance. It then advances timing so the spark occurs several degrees before TDC on the compression stroke. This ensures that the engine attains high fuel economy on the highway. There is enough time for all the fuel to burn and produce maximum pressure on the downward motion of the pistons.

If the driver began to pass a car and pressed down on the accelerator to open the throttle valve more, engine intake manifold vacuum would drop. A manifold absolute pressure sensor signaling this drop in intake manifold vacuum would be sent to the computer. The throttle position sensor would detect wide open throttle (WOT). Other sensor outputs would stay about the same. Based on the signals from the manifold absolute pressure sensor and the throttle position sensor, the computer would retard ignition timing to prevent spark knock or ping.

Since computer systems vary, refer to a service manual for more information. The manual will detail the operation of the specific ignition system for that make and model vehicle.

Summary

- An ignition system amplifies battery voltage (12.6 volts) or charging system voltage (13 to 15 volts) to over 40,000 volts, and delivers this voltage to the spark plugs at the right time.
- The primary circuit of the ignition system consists of all the components and wires that operate on low 12-volt dc from the battery, alternator, or current from the HV power control module.
- The secondary circuit of the ignition system includes all the components that carry high-voltage current.
- The secondary operating voltage of the ignition system can range from 4,000–100,000 volts, depending on system design.
- The spark plugs use ignition coil high voltage to ignite the fuel mixture.
- An ignition coil is a pulse-type transformer capable of producing the short bursts of high-voltage current that pass through the secondary resistance wires (if used), and jump the spark plug gap.
- A coil pack ignition system, also called a distributorless ignition, uses multiple ignition coils, a coil control unit, engine sensors, and a computer (engine control module) to operate the spark plugs.

Copyright Goodheart-Willcox Co., Inc.

- In a direct ignition system, one coil assembly is mounted directly above each spark plug, eliminating the need for spark plug wires.
- In a dual spark plug ignition system, two spark plugs are used in each cylinder.
- A multiple discharge ignition system fires the spark plugs more than once on each power stroke, which ensures more complete burning of the fuel charge.
- An ignition distributor is used on older ignition systems to distribute the coil's high-voltage pulses to the spark plug wires.
- Engine firing order refers to the sequence in which the spark plugs fire to cause combustion in each cylinder.
- Ignition timing must change with changes in engine speed, load, and temperature.
- An electronic spark advance system uses engine sensors, an ignition control module, and/or a computer (engine or power train ECM) to adjust ignition timing.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

boots
camshaft position sensor
center terminal (center electrode)
ceramic insulator
coil pack
coil pack ignition
cold spark plug
crankshaft position sensor
direct ignition coil
direct ignition system
dual spark plug ignition system
electronic coil module
engine coolant temperature sensor
engine firing order
engine sensors
grounded side electrode
hot spark plug
ignition coil
ignition coil open-circuit voltage
ignition control module (ICM)
ignition system
ignition system supply voltage
ignition timing
intake air temperature sensor
ionization knock sensing
knock sensor
manifold absolute pressure sensor
multiple discharge ignition system
non-resistor spark plug
primary circuit
primary windings
radio suppression wires
resistor spark plug
secondary circuit
secondary operating voltage
secondary windings
secondary wires
spark plug gap
spark plug heat range
spark plug reach
spark plug wires
spark plugs
spark timing
steel shell
throttle position sensor
timing advance
timing retard
waste-spark ignition system
windings

Activities

1. If you have access to a computer with a CAD or drawing program, use it to make a cross-sectional drawing of a resistor-type spark plug. Label the components and then output the drawing to a printer, if available.
2. Make a list of the various engine sensors used with an electronic spark advance system. Describe the purpose of each sensor.
3. Using a computerized service information system, identify the firing order of the spark plugs for two different makes of four-, six-, and eight-cylinder engines.
4. Make a wall chart comparing coil pack and direct ignition system types.

Review Questions

Answer the following questions using the information provided in this chapter.

1. List and explain each of the basic parts of an ignition system.
2. Define the terms *primary circuit* and *secondary circuit*.
3. An ignition system _____ is used to ignite the air/fuel mixture in the engine combustion chamber.
4. A secondary voltage between _____ and _____ volts is needed to operate a spark plug.

Copyright Goodheart-Willcox Co., Inc.

5. Why do most vehicles require resistor spark plugs?
6. Spark plug gap is the distance between the center electrode and side electrode. True or False?
7. A cold spark plug might be beneficial in an older engine that burns some oil. True or False?
8. A modern ignition coil is capable of producing an open-circuit voltage of:
   (A) 7,000–9,000 volts.
   (B) 10,000–15,000 volts.
   (C) 40,000–100,000 volts.
   (D) None of the above.
9. The primary windings of an ignition coil are several hundred turns of heavy wire. True or False?
10. When the current flowing through the ignition coil is interrupted, the magnetic field collapses and induces high voltage into the _____ windings of the coil.
11. A(n) _____ ignition system has one coil for every two engine cylinders.
12. A waste-spark ignition coil fires two spark plugs at once. True or False?
13. One coil assembly is mounted above each spark plug in the engine in a(n) _____ system.
14. An ionization knock sensing system is used to detect abnormal combustion and knocking. True or False?
15. Explain the difference between coil pack ignition and direct ignition systems.
16. All of the following are functions of a distributor in a distributor ignition system *except:*
   (A) analyzes sensor data to advance spark timing.
   (B) changes spark timing with changes in engine load.
   (C) actuates *on/off* cycles of current flow through ignition coil primary windings.
   (D) distributes the coil's high-voltage pulses to the spark plug wires.
17. The sequence in which the spark plugs operate to cause combustion in each cylinder is called _____.
18. Timing retard is needed at _____ engine speeds and under _____ load conditions.
19. An electronic spark advance system uses engine sensors, an ignition control module, and/or a computer to adjust _____.
20. Explain how an electronic spark advance system functions.

ASE-Type Questions

1. An ignition system uses this to change battery voltage into high secondary voltage:
   (A) spark plug.
   (B) bypass circuit.
   (C) ignition coil.
   (D) spark advance system.
2. Which of the following provides voltage to the battery and ignition system *after* an engine is running?
   (A) Alternator.
   (B) Condenser.
   (C) Primary circuit.
   (D) None of the above.
3. Ignition system wires that operate at battery voltage are considered part of the:
   (A) ignition coil.
   (B) primary circuit.
   (C) secondary circuit.
   (D) primary windings.
4. Which of the following spark plug components causes electricity to jump the gap and return to the battery through frame ground?
   (A) Shell.
   (B) Insulator.
   (C) Side electrode.
   (D) Center terminal.
5. Technician A says that with modern ignition coils, open-circuit voltage can reach 100,000 volts. Technician B says that average operating voltages for an ignition system are about 15,000 volts. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says that no coil wire is needed with an ignition coil pack. Technician B says that an eight-cylinder engine equipped with a coil pack system uses two ignition coil packs. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

7. A direct ignition system uses:
   (A) spark plug wires.
   (B) a distributor.
   (C) one coil per spark plug.
   (D) All of the above.
8. Technician A says a multiple discharge ignition system fires the spark plug during each of the engine's four-cycle strokes. Technician B says that a dual spark plug ignition system ensures better ignition and combustion of the air-fuel mixture than a single spark plug per cylinder system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says late-model vehicles keep ignition timing the same under varying conditions and engine speeds. Technician B says that most late-model vehicles require non-resistor spark plugs. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Which of the following is *not* a typical electronic spark advance ignition system sensor?
   (A) Vehicle height sensor.
   (B) Knock sensor.
   (C) Manifold absolute pressure sensor.
   (D) Crankshaft position sensor.

Chapter 35
Ignition System Diagnosis, Testing, and Repair

After studying this chapter, you will be able to:

- List the symptoms produced by faulty ignition system components.
- Diagnose typical ignition system problems.
- Describe common tests used to find ignition system troubles.
- Explain how to replace or repair ignition system parts.
- Describe safety practices to follow when testing or repairing an ignition system.
- Correctly answer ASE certification test questions on the diagnosis and repair of ignition systems.

An ignition system is required to ignite an engine's fuel in a gasoline or flex-fueled engine, although not in a diesel engine. If a problem exists in the ignition system, engine performance and emissions will suffer. As a service technician, you must be able to quickly and accurately correct any ignition system troubles.

Complete ignition system part failure can prevent the engine from starting. Problems caused by spark plugs, secondary wires, ignition coils, ECMs, and related wiring manifest themselves in a variety of ways (glowing indicator light in the dash, engine missing, poor fuel economy, engine spark knock, etc.). If the malfunction indicator light (MIL) is on, it should be noted on your shop's repair order so you would know to scan the vehicle first to verify the problem source before performing other tests. See **Figure 35-1**.

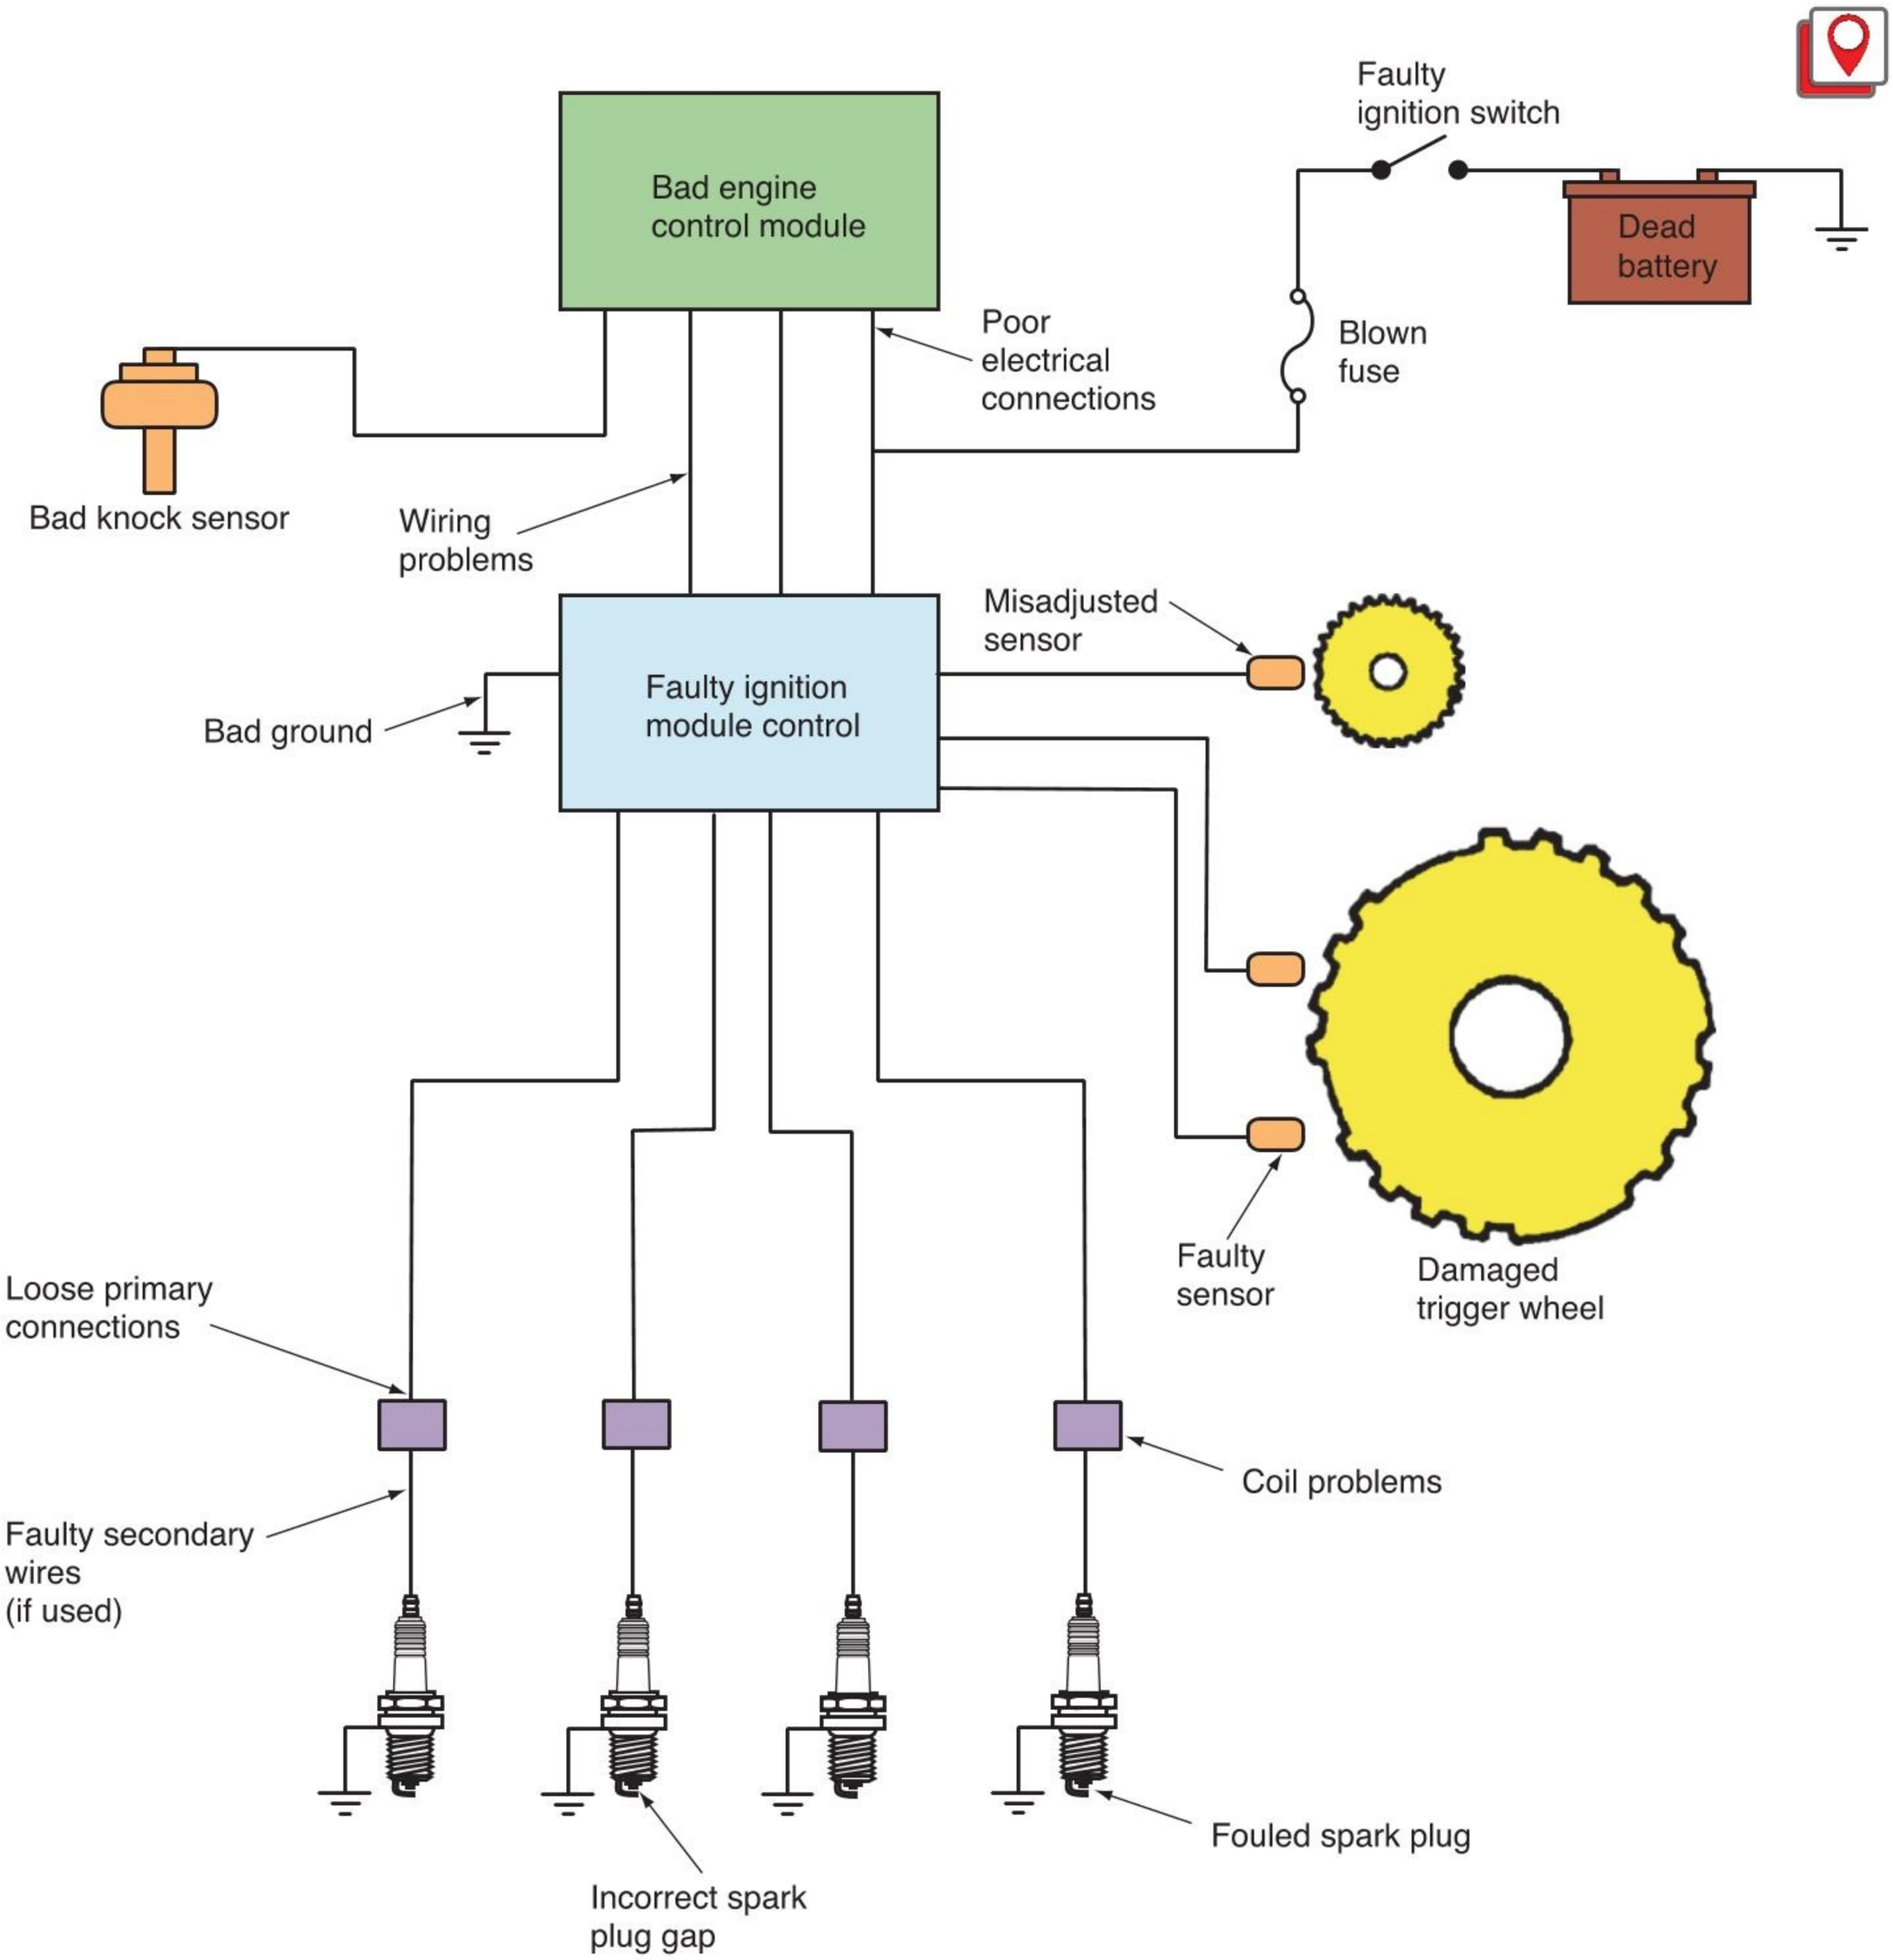
Ignition System Diagnosis

To start diagnosis, visually inspect the ignition system with and without the engine running. Look for obvious problems, such as loose primary connections to ignition coils, a disconnected spark plug, loose direct ignition coil fasteners, deteriorated secondary wire insulation, a damaged coil pack, burned ignition system control module fuse, and other troubles. See **Figure 35-2**. At the same time, look over other engine systems and try to find anything that could upset engine operation.

Scanning Ignition System Problems

After inspection is complete, connect a scan tool to the vehicle's diagnostic connector under the dash to find many ignition-related problems. Look at **Figure 35-3**.

Copyright Goodheart-Willcox Co., Inc.



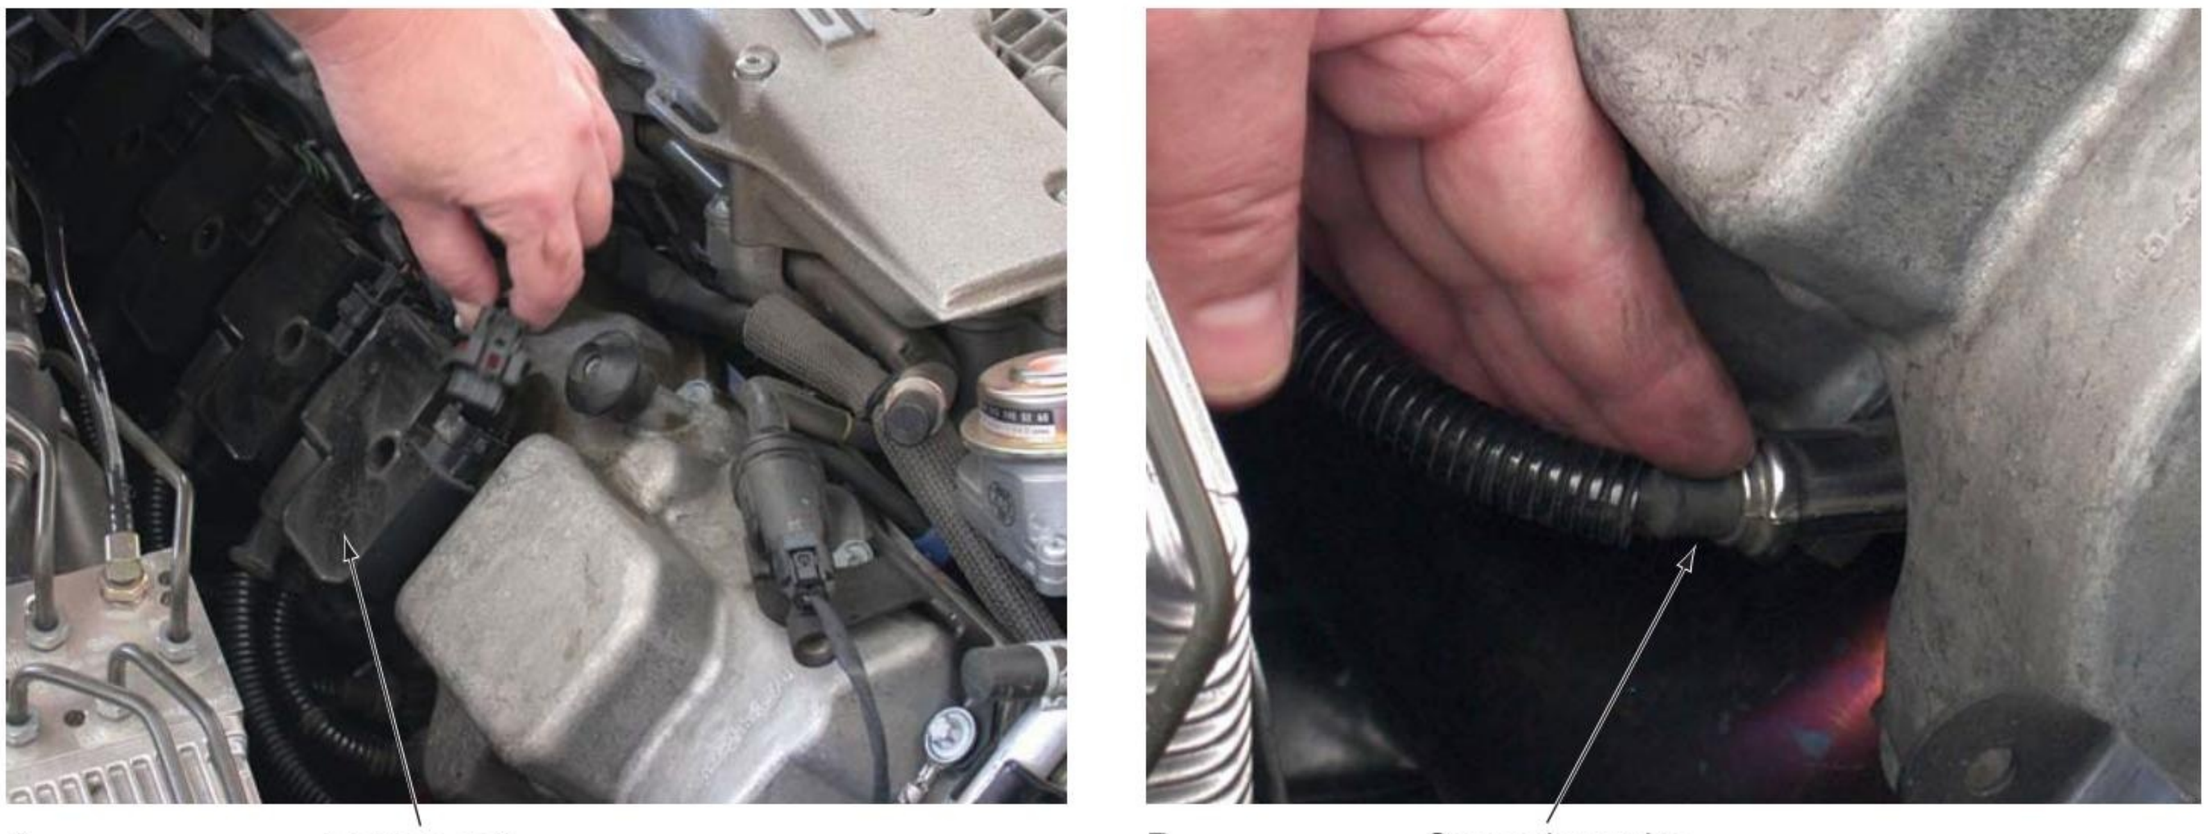
Goodheart-Willcox Publisher

Figure 35-1. Note some of the problems you will find in a modern ignition system.

The scan tool can detect troubles in the following ignition system circuits, components, and conditions:

- Crankshaft position sensor.
- Camshaft position sensor.
- Knock sensor.
- Ignition coil(s) primary circuit.
- Ignition coil(s) secondary circuit.
- Timing reference signal and timing advance circuit.
- Spark plug and coil secondary wire radio interference.
- Engine misfire (on-board computer conclusion from analyzing crank speed fluctuations, spark duration, and other circuit values and frequencies).

Copyright Goodheart-Willcox Co., Inc.



A Ignition coil **B** Secondary wire

Goodheart-Willcox Publisher

Figure 35-2. Visually inspect the ignition system with and without the engine running. A—Loose electrical connections can cause problems in the ignition system. This technician is securing a loose connector to the coil module on a direct ignition system. B—Check that the secondary wires are fully locked onto their spark plugs.

Snap-on Tool Corp.

Figure 35-3. Scan tools can find problems with ignition system sensors, ignition coils, spark plugs, engine valves, piston rings, pistons, and can even tell you which engine cylinder is missing and not firing its fuel.

Start your pinpoint tests at the component or circuit indicated by the scan tool readout. You might test the component first and then its circuit. This will depend on the specific circumstances of the symptoms, part location, and vehicle design.

If your scan tool readout displays a ***misfire code***, the engine has failed to ignite and burn its air-fuel mixture properly. Engine misfire increases exhaust emissions, fuel consumption, and engine vibration, while reducing engine power.

A misfire code indicates which engine cylinder is not producing combustion normally. Misfire can be caused by problems in the ignition system, the fuel injection system, the emission control system, or the engine itself (low compression, for example). Additional tests and more specific scan tool data are needed to pinpoint the cause of the misfire condition.

Start your meter tests at the engine cylinder indicated by the scan tool trouble code. If, for example, your scan tool indicates a misfire in the number three cylinder, check that cylinder's spark plug or direct ignition coil first.

Caution

A computerized ignition system can be seriously damaged if the wrong wire is shorted to ground, or if a meter is connected improperly. Always follow manufacturer's testing procedures.

Spark Intensity Testing

A ***spark intensity test***, or ***spark test***, checks the strength of the electric arc (spark) produced by the ignition system. It is a quick and easy way to check the general condition of the ignition system.

The spark intensity test is often used when an engine cranks, but will not start. The test will tell you

Copyright Goodheart-Willcox Co., Inc.

whether the trouble is in the fuel system ("no fuel" problem) or the ignition system ("no spark" problem). It may also be used to check the condition of the spark plug wires, ignition coils, and other secondary components.

Tech Tip

When testing a direct ignition system, it may be helpful to remove the coils and connect conventional spark plug wires between the coil output terminals and the spark plugs. This will let you connect a spark tester, an inductive tachometer, and other test instruments to the system.

Spark Test Procedures

A ***spark tester*** is a device that is used to check ignition system output voltage. It looks like a spark plug with a large air gap and an alligator clip test lead.

Service Procedure

To perform a spark intensity test:

1. Remove one of the secondary wires from a spark plug or from a suspect direct ignition coil.
2. Insert the spark tester into the wire or the coil's secondary conductor terminal.
3. Ground the spark tester by connecting the alligator clip to a good ground on the engine or unibody (frame).
4. Crank or start the engine and observe the spark at the tester's air gap. Refer to **Figure 35-4**.

Caution

Only run the engine for a short period of time with a spark plug wire or direct ignition coil off its spark plug. Unburned fuel from the dead cylinder could foul and ruin the catalytic converter after prolonged engine operation.

Snap-on Tool Corp.

Figure 35-4. A bright arc should jump the gap in the spark tester. No spark or a weak spark indicates ignition system troubles. This tests the general high voltage output of the ignition coil and any plug wire.

Spark Test Results

A strong spark (wide, bright, snapping electric arc) should jump the tester's air gap. This shows that ignition system primary and secondary voltages are good. A strong spark also indicates that the ignition coil, crankshaft position sensor, ignition control module, and other ignition system parts are functioning. If a strong spark is present, the engine no-start problem may be due to oil-fouled spark plugs, fuel system problems, ignition switch or engine troubles.

A weak spark or no spark indicates that something is wrong inside the ignition circuit. If the spark is weak at all the spark plug wires, the problem is common to all the cylinders . If you are not getting a good, hot spark, you may want to check the coil supply voltage. If a coil is not getting full battery voltage or if the coil windings partially fail, the ignition system will not produce a secondary arc at the plug tip or the arc will be too weak to start combustion.

Checking for a Dead Cylinder

A ***dead cylinder*** is an engine combustion chamber that is not igniting and burning its fuel-air mixture on that cylinder's power stroke. There may be ignition system troubles or problems in the engine itself, the fuel system, starting system, or another system.

Symptoms of a dead cylinder include a very rough idle and a puffing noise at the engine's exhaust tailpipe. A dead cylinder is considered an extreme misfire condition because none of the fuel is "firing" and burning.

Copyright Goodheart-Willcox Co., Inc.

To check for a dead cylinder in a direct ignition system, pull off the suspect cylinder's ignition coil primary connector. With older ignition designs, pull off one secondary coil or spark plug wire. On a "live" or firing cylinder, disabling the high-voltage source to one spark plug will cause engine speed to drop and the idle to become rougher. With a dead cylinder, idle smoothness and engine speed will *not* change when the high-voltage source for that cylinder is removed.

After locating the dead cylinder, check for spark and study the spark plug's condition. Also measure for low cylinder compression pressure. Today's OBD systems automatically check for engine misfire and dead cylinders by reading abnormal speed signals from the crankshaft and camshaft sensors and will set a trouble code. A dead cylinder causes the crankshaft to momentarily slow down during a few degrees of rotation when the bad cylinder is not firing and helping to spin the crankshaft.

High-Voltage Leakage Test

After prolonged service, the secondary or high-voltage ignition circuit can fail. This usually occurs due to internal high-voltage arcing that eventually burns circuit conductors. You will often find burned secondary connections inside direct and indirect (with spark plug wire) ignition coils. The insulation can burn and harden from the heat of unwanted electrical sparks in the conductors.

Service Procedure

To check an ignition system for high-voltage leakage:

1. Place a hood cover over the engine compartment to fully darken your inspection area, which will help you view any electric sparks on ignition components, **Figure 35-5**.
2. Install a vent hose over the vehicle's tailpipe.
3. Chock the wheels, put the transmission in *Park*, and set the emergency brake.
4. Start the engine.
5. While wearing rubber gloves and eye protection, place your head under the hood cover to inspect for high-voltage leakage.
6. Move the primary and secondary conductors in their connectors while looking for small sparks jumping off of components.
7. Ground a non-powered test light and move it over secondary wires and conductors. The metal probe on the test light will attract any electrical leakage and will glow.
8. Replace any components that show electrical leakage.
9. If the engine has a direct ignition, you must remove each ignition coil to inspect its high-voltage connection to its spark plug.

OTC/SPX Corp.

Figure 35-5. To check for high-voltage leakage in the ignition secondary, you must block outside light from the engine compartment. This technician is using a special cover so the area around the engine is dark. This will make small sparks easy to find.

Tech Tip

Many late-model ignition systems apply full-battery voltage to the ignition coil primary terminal. The ignition coil primary voltage is grounded by the ignition or engine electronic control module power transistor circuits.

Ignition Primary Voltage Testing

The ***ignition primary voltage test*** checks the voltage being fed to the ignition coil. If the ignition system fails a spark test, an ignition primary voltage test may help you locate the source of the problem.

Copyright Goodheart-Willcox Co., Inc.

Service Procedure

To check for proper primary voltage to the ignition coils in a direct ignition system:

1. Disconnect the primary connector to one of the ignition coils on the engine.
2. Install test jumper wires between the harness connector and the coil connector.
3. Connect your high-impedance meter leads to the bare metal conductors on the jumper wires.
4. Measure the voltage applied to the ignition coil with the ignition switch in the *Run* position. Compare the reading to specifications.

If the voltage across the ignition primary is too low or too high, you could have a problem in the coil windings. You could also have a circuit problem in the ignition module or engine module affecting applied ignition coil voltage or ECM applied ground for the ignition coil primary circuit.

Ignition Circuit Scope Testing

An oscilloscope, or scope, precisely measures the operating voltages of analog and digital signals present in a modern ignition system over specific time intervals. Study **Figure 35-6**.

OTC/SPX Corp.

Figure 35-6. A handheld scope is handy for advanced ignition system testing. It gives voltage, current, and resistance readings, and shows scope waveforms for advanced troubleshooting of the ignition system and other systems.

Often built into advanced scan tools and laptop diagnostic software, the scope uses a display screen to show slight changes in voltage over small periods of time. The technician can compare actual ignition system voltage over time, and also compare them with known good patterns. Any variance from spec voltage levels and signals in the ignition system will pinpoint problems to components or computer systems (ignition control module, engine control module, or coil control modules).

Evaluating Ignition System Test Results

After performing preliminary ignition system tests, you must evaluate the test results and narrow down the possible causes. Use your knowledge of system operation, a service manual troubleshooting chart, basic testing methods, and common sense to locate the trouble.

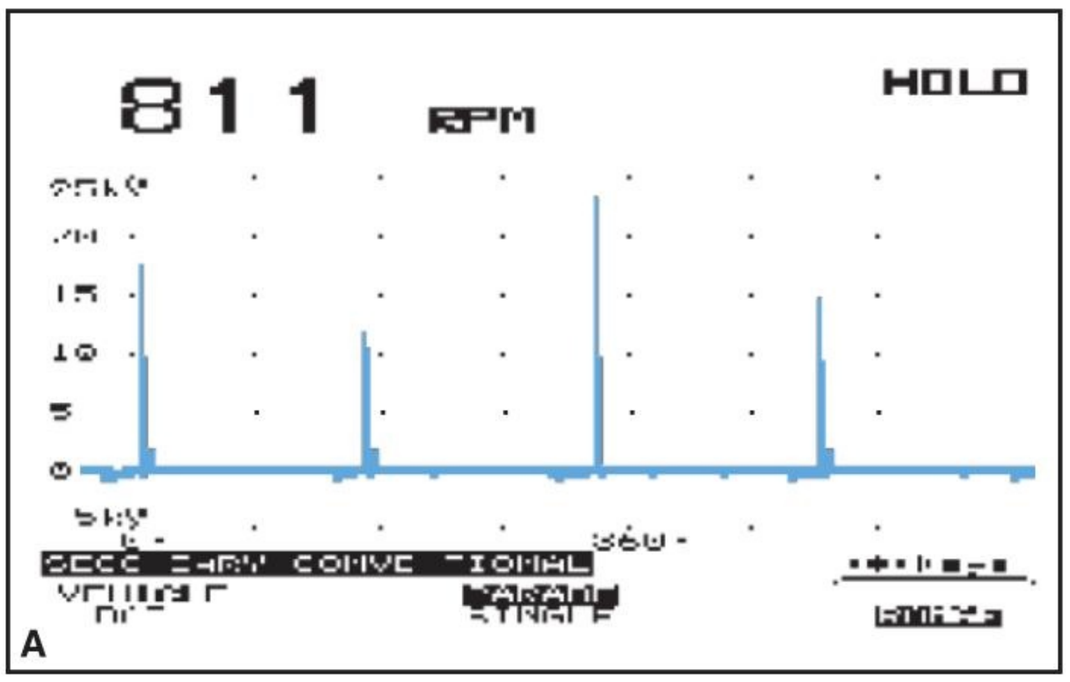
Spark Plug Service

Bad spark plugs can cause a wide range of problems, including misfiring, lack of engine power, poor fuel economy, exhaust odor, and hard starting. With a high-mileage engine, the spark plug tip can become coated with ash, oil, and other substances. This may allow high voltage to flow over the deposits and to ground without arcing or sparking. The engine may miss and stumble upon rapid acceleration.

The spark plug electrodes can also be etched away by prolonged use. The millions of electric arcs that have occurred after prolonged service tend to erode the metal inside the spark plug gap, widening the air gap. This will make it more difficult for the ignition system to produce an arc between the electrodes. Wider spark plug gaps require an increased secondary voltage, which can burn other ignition system parts (ignition module, ignition coil, etc.).

To test the spark plugs, use an oscilloscope or scan tool misfire readings. Bad plugs will show up as abnormal scope waveforms (trace or pattern) or as a misfire code. Refer to **Figure 35-7**. If a scope or advanced scan tool is not available, remove the plugs and inspect their condition.

Copyright Goodheart-Willcox Co., Inc.



Fluke

Figure 35-7. Secondary ignition system patterns can provide information on spark plug condition. A—Uneven firing lines are commonly caused by worn spark plugs. B—A short firing line is often caused by a fouled spark plug.

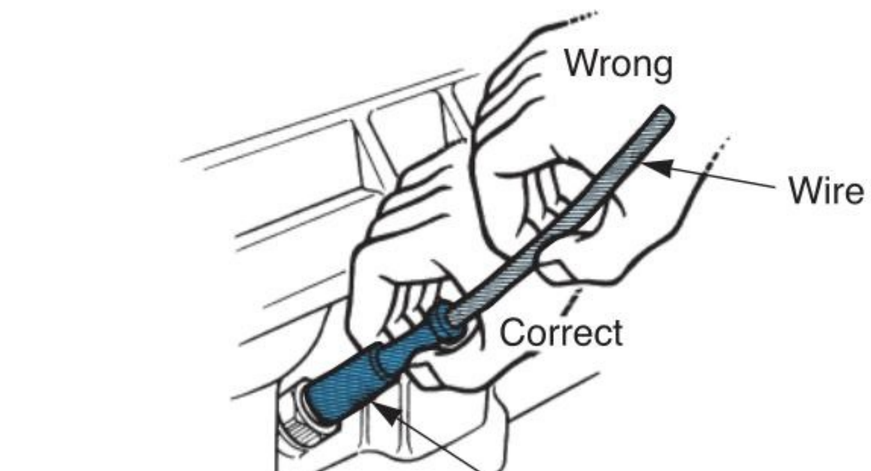
4. Use a blow nozzle to clean off any debris that has collected on top of the engine. Never allow small rocks and other debris to accidentally fall into the spark plug holes and engine cylinders.
5. Unscrew each spark plug using a spark plug socket, an extension, and a ratchet (as needed), **Figure 35-9**.
6. As you remove the plugs, lay them in order on the fender cover or the workbench. Do not mix up the plugs.
7. After all the plugs have been removed, inspect the color and condition of the electrodes to help diagnose the condition of the engine and fuel system.

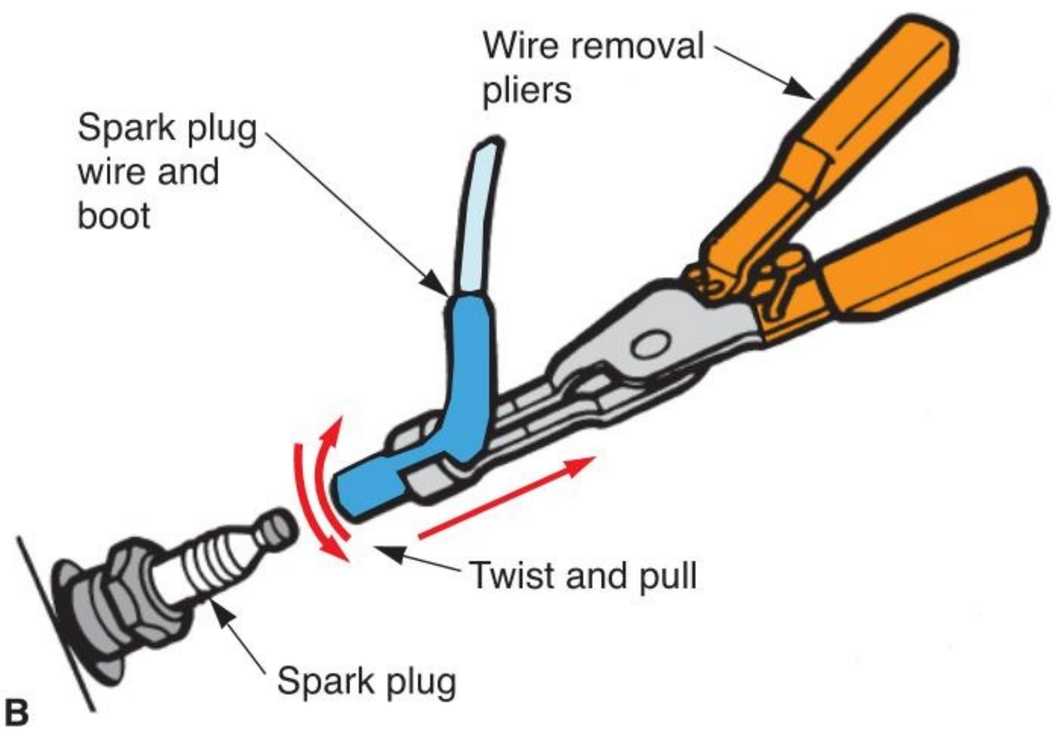
Spark Plug Removal

Service Procedure

To access the spark plugs, you must remove the ignition coils, the coil module, or the spark plug wires:

1. If the engine is equipped with direct ignition coils or a coil module, remove the screws that secure the coils or module to the engine.
2. Wiggle the coil or module while pulling it straight up. This will free each coil terminal from its spark plug terminal.
3. If the engine is equipped with spark plug wires, make sure they are numbered or located correctly in their clips. Grasp a spark plug wire by the boot and pull to disconnect it from its spark plug. See **Figure 35-8**. Twist the boot back and forth if it is stuck on the plug.

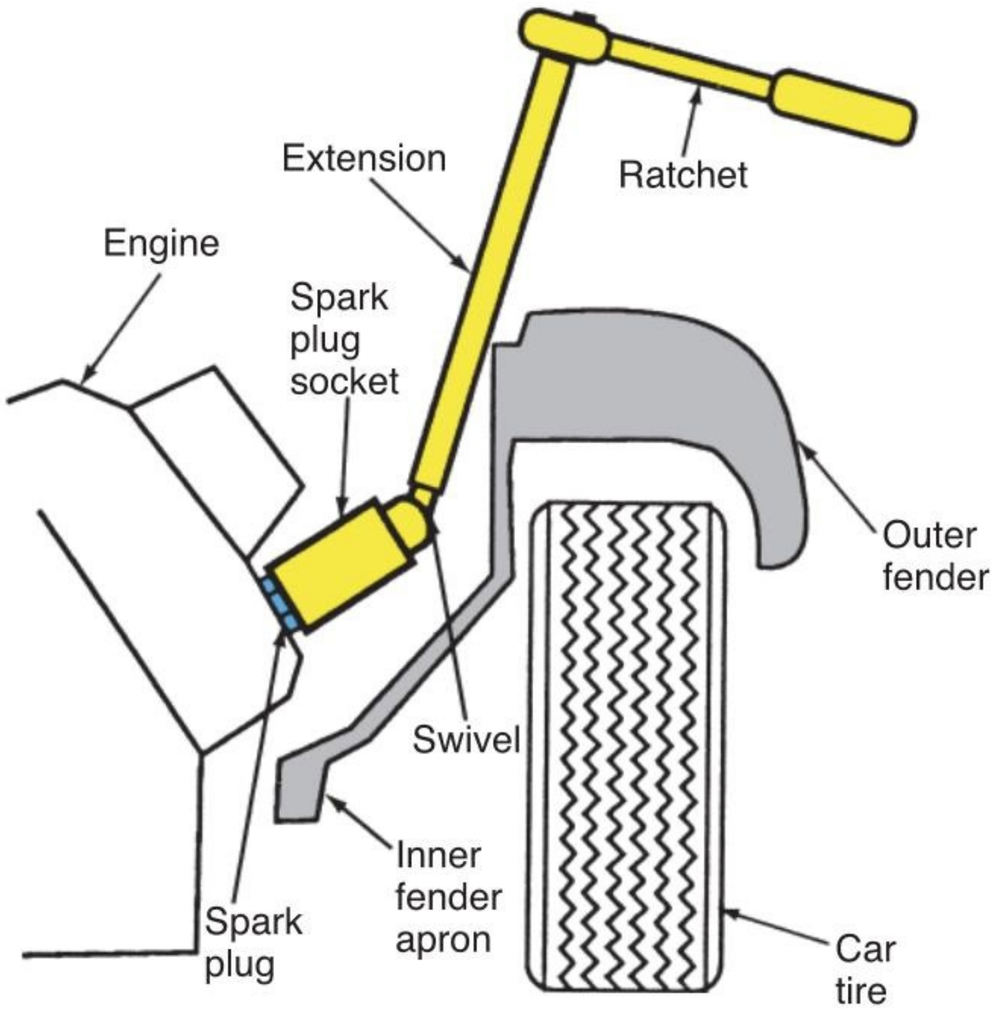




Toyota and Chrysler

Figure 35-8. When removing a spark plug wire, pull on the boot, never on the wire because its powdered carbon conductor can easily break. This would ruin the wire and cause the engine to miss after the repair. A—Sometimes you have to use your fingers to remove a spark plug wire. B—If you have enough clearance for them, use special pliers to grasp and pull on the boot.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 35-9. With today's cramped engine compartments, there is little room to reach spark plugs. A common fix is to use a swivel-type spark plug socket on a short 3/8th extension. The socket with the extension can reach around obstructions to easily remove or install spark plugs.

Reading Spark Plugs

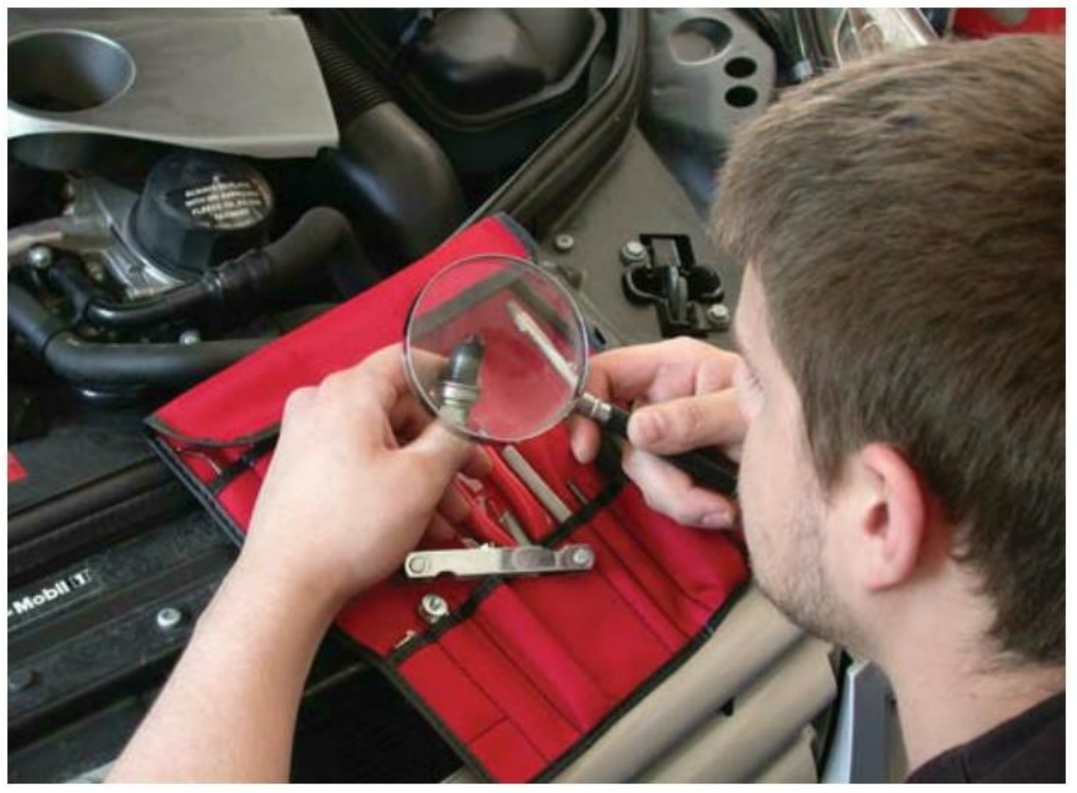
To read a spark plug, closely inspect and analyze the condition of its tip and insulator, **Figure 35-10**. This will give you information on the condition of the engine, fuel system, and ignition system.

A properly burning plug should have a brown to grayish-tan color. A black or wet plug indicates that the plug is not firing or that there is an engine problem (worn piston rings and cylinders, leaking valve stem seals, low engine compression, or rich fuel mixture) in that cylinder. Study the spark plugs in **Figure 35-11**.

Gapping Spark Plugs

Obtain the correct replacement plug (heat range and reach) recommended by the manufacturer. Then, set the spark plug gap by spacing the side electrode the correct distance from the center electrode. If the new spark plugs have been dropped or mishandled, the gap may not be within specifications.

A wire feeler gauge should be used to measure spark plug gap. Slide the specified size feeler gauge



Goodheart-Willcox Publisher

Figure 35-10. Read spark plugs by inspecting the condition of insulators and electrodes.

between the electrodes. The gauge should drag lightly as it is pulled in and out of the gap. See **Figure 35-12**.

If needed, bend the side electrode until the feeler gauge fits snugly, **Figure 35-13**. Spark plug gaps vary from approximately 0.030″ (0.76 mm) on older engines to over 0.080″ (2.03 mm) on late-model, high-energy ignition systems.

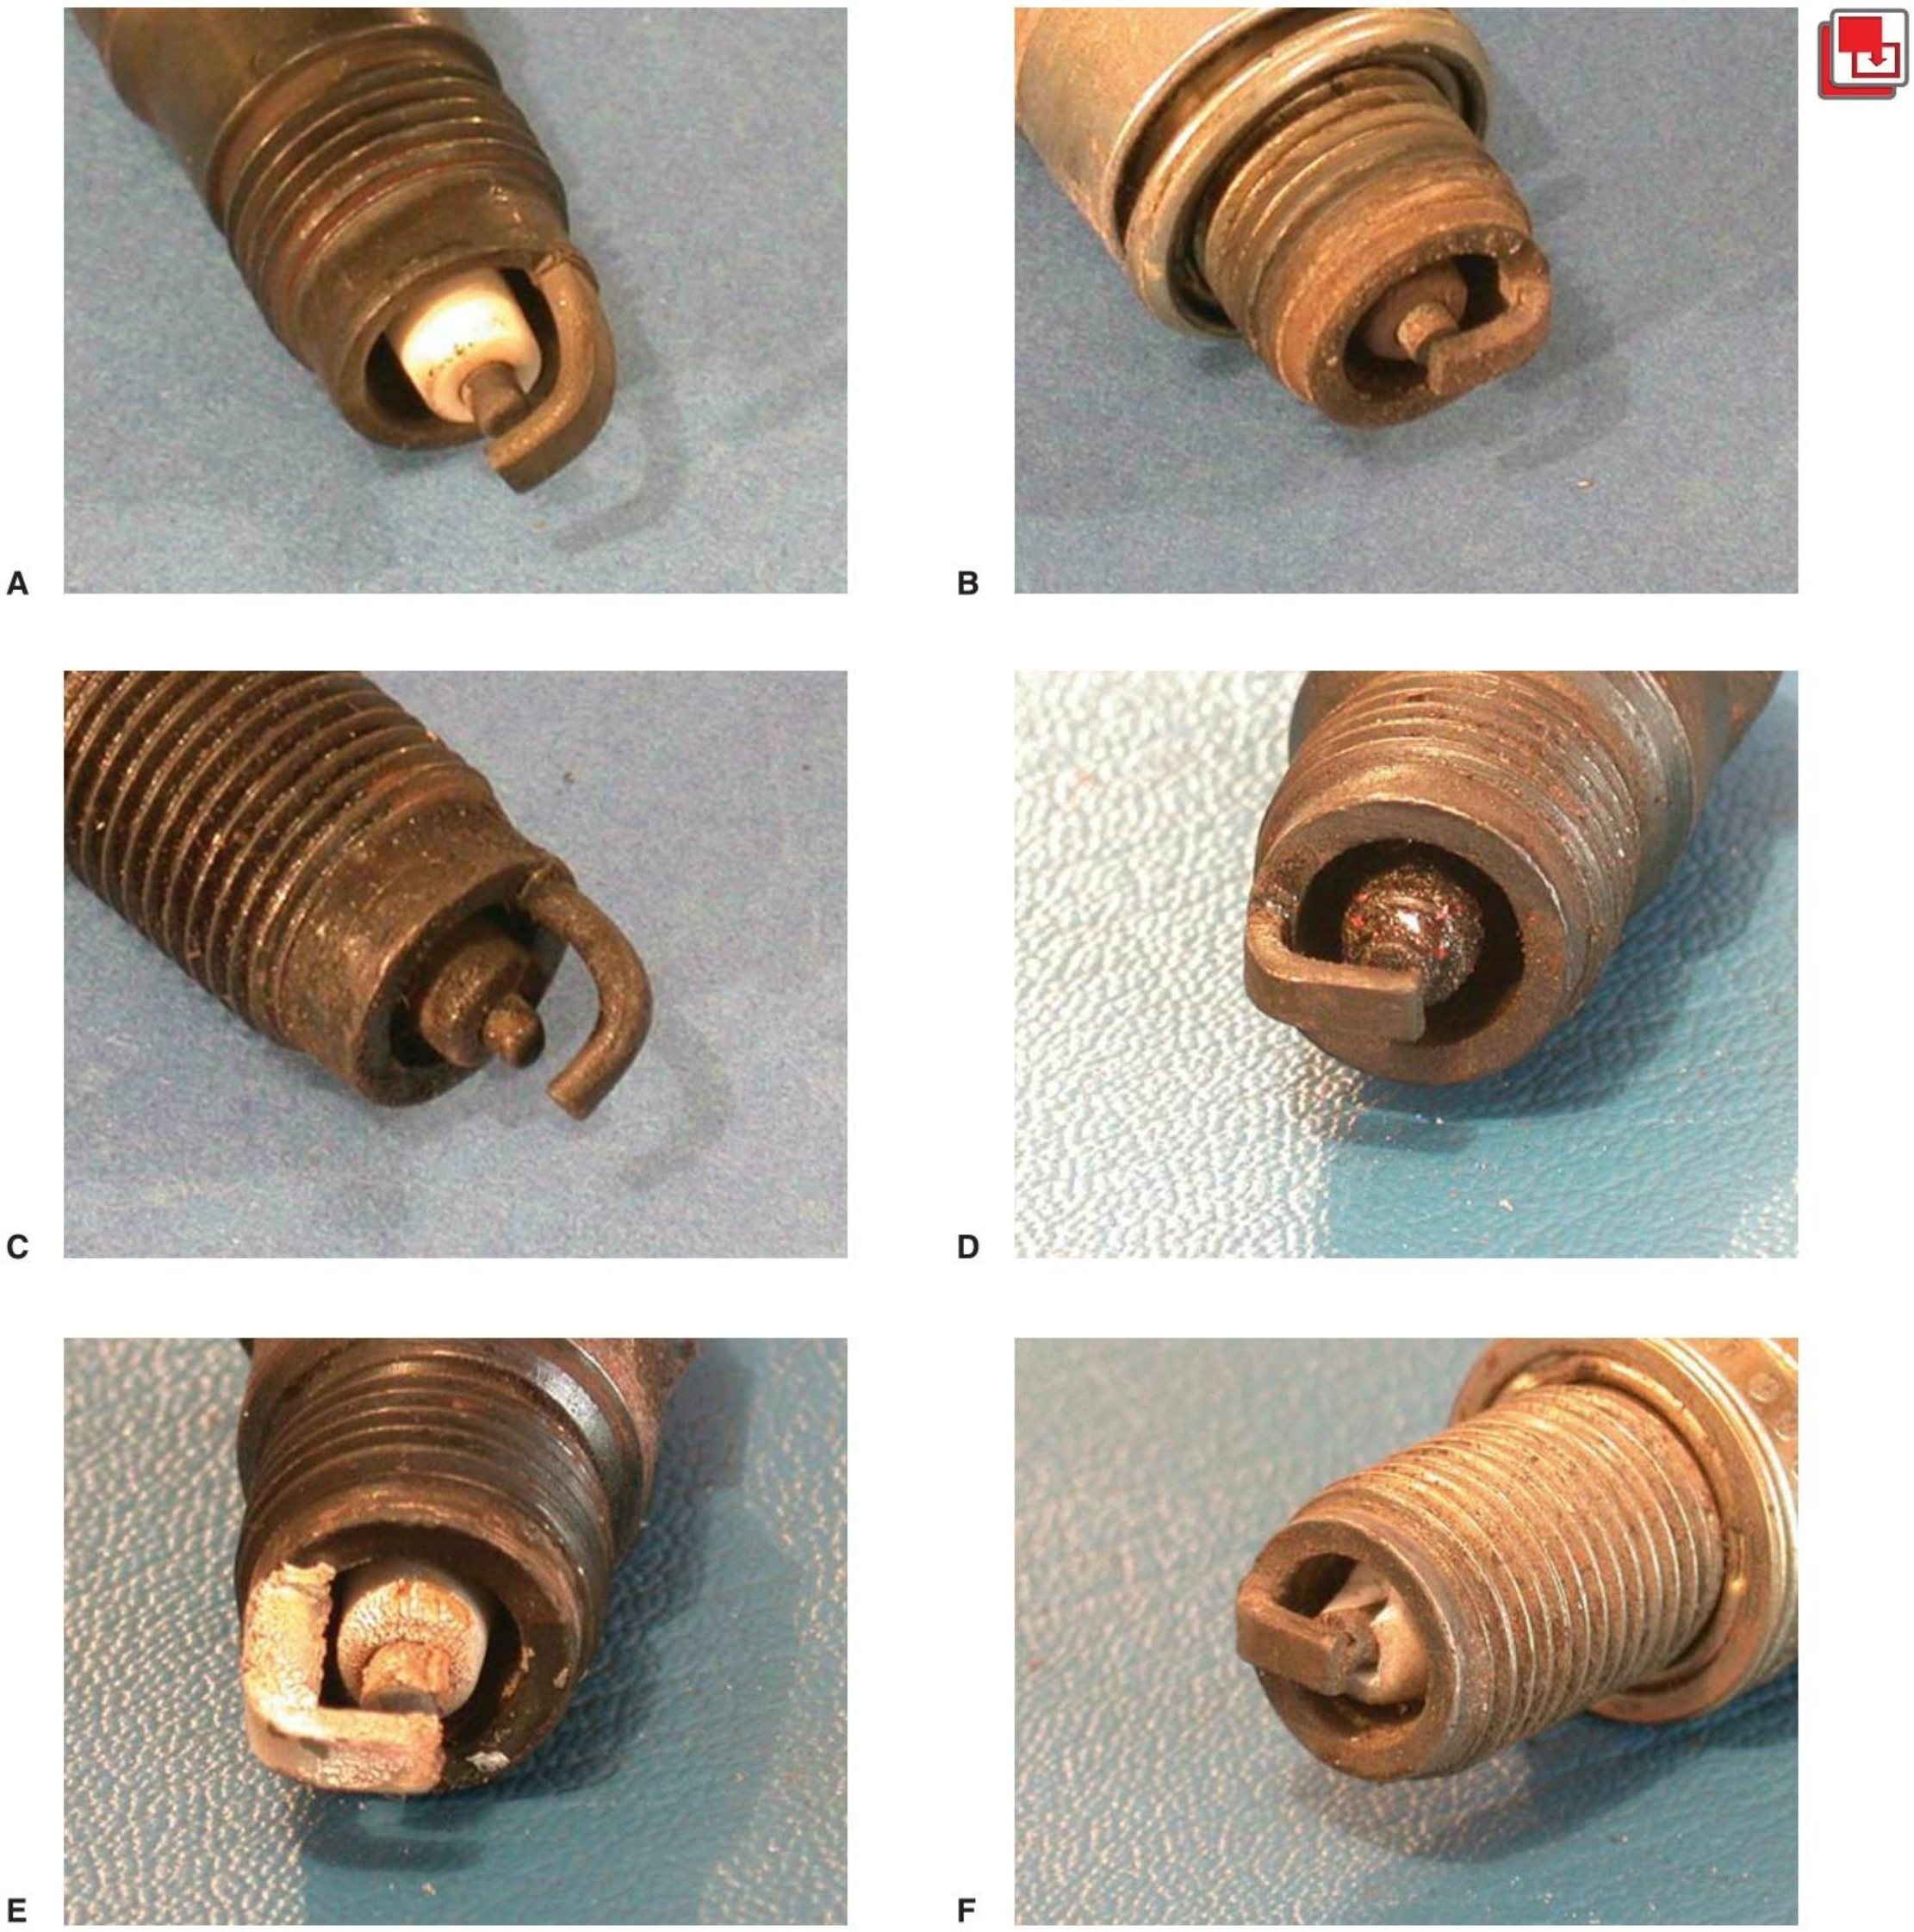
Tech Tip

Wider spark plug gaps (above 0.045″) are needed to burn lean fuel mixtures required by many late-model vehicles. Smaller spark plug gaps (around 0.025″ to 0.030″) are recommended in high-horsepower, turbocharged, and supercharged engines. An electric arc or spark cannot jump a wide air gap when extreme boost and compression pressure builds in the cylinder. A smaller spark plug gap will allow the high voltage to arc to ground to start combustion more easily, even with extreme cylinder boost pressures.

Installing Spark Plugs

Spark plugs that are set to the correct gap are ready for installation. Use your fingers, a spark plug socket, or a short piece of vacuum hose to start the plugs in their holes. Study **Figure 35-14**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 35-11. Read the spark plugs by observing the condition of their insulators and electrodes. A—A properly burning plug has minimal deposits and is grayish-tan color. B—This carbon-fouled plug is the result of a prolonged rich air-fuel mixture. C—This high-mileage plug shows erosion at the gap. D—An oil-fouled plug is shiny and dark gray or black in color. E—An ash-fouled plug can result from burning low-quality gasoline. F—The physical damage on this spark plug indicates an internal engine failure. The piston, a broken valve, or foreign matter struck the tip of the plug.

Copyright Goodheart-Willcox Co., Inc.

Snap-on Tool Corp.

Figure 35-12. Use a wire feeler gauge to measure gap. Both electrodes should just touch gauge.

Goodheart-Willcox Publisher

Figure 35-13. If needed, bend the side electrode with a gapping tool to achieve correct electrode spacing. Then recheck the spark plug gap.

Caution

Do not use the ratchet to start the plug in its hole because the plug and cylinder head threads can be cross-threaded and damaged. This is particularly critical when starting plugs in aluminum cylinder heads.

Goodheart-Willcox Publisher

Figure 35-14. Always start spark plugs with your fingers so you can feel the threads go into the cylinder head without binding. Never use a ratchet or impact wrench to initially thread in spark plugs because they can easily cross-thread in the aluminum cylinder head. If this happens, you might have to remove and replace the damaged cylinder head for free!

After threading the spark plugs into the head a few turns by hand, turn them in the rest of the way with your ratchet. Tighten the spark plugs to specifications. Some manufacturers specify a spark plug torque. Others recommend bottoming the plugs on the seat and then turning them an additional one-quarter to one-half turn. Refer to the appropriate service information for exact procedures.

Secondary Wire Service

A faulty secondary wire can have a burned or broken conductor or deteriorated insulation. Most secondary wires have a resistance conductor that is easily damaged. If the conductor is broken, voltage and current cannot reach the spark plug.

If the secondary wire insulation is faulty, current may leak (or arc) through the insulation to ground or to another wire instead of reaching the spark plugs.

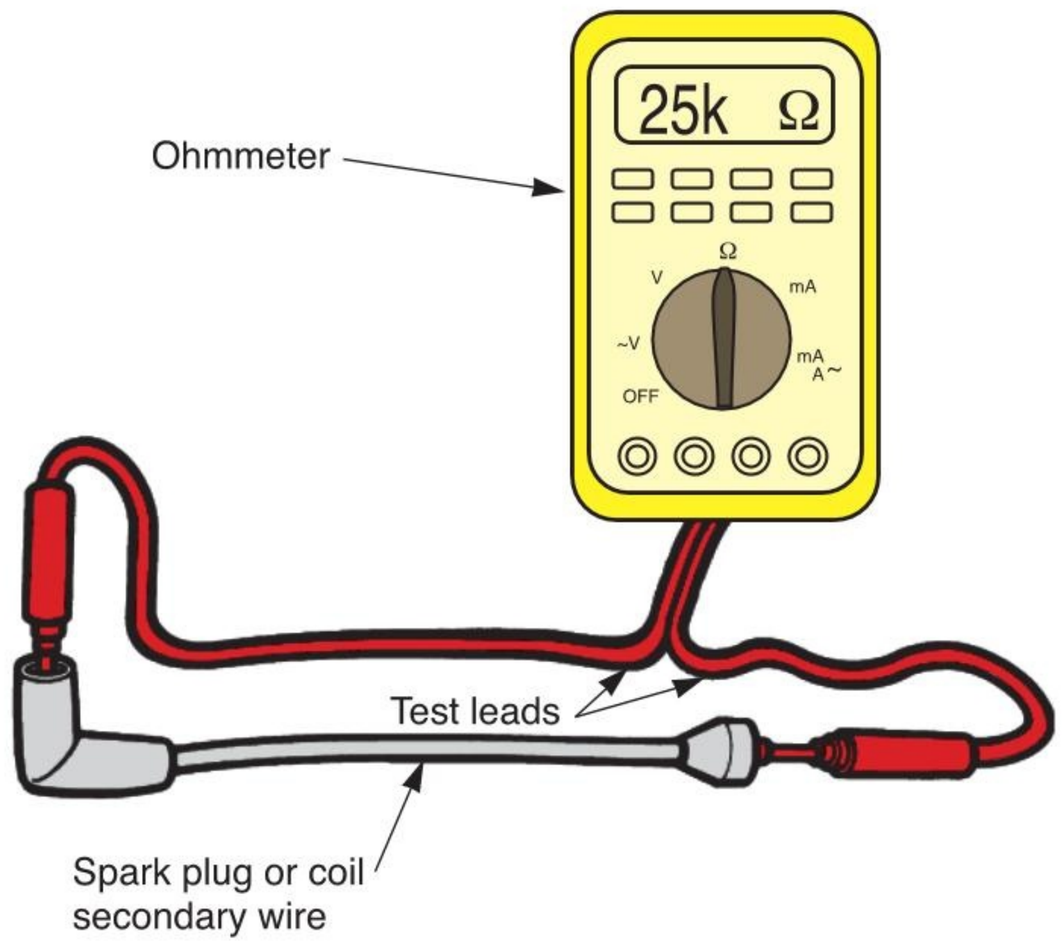
A ***secondary wire insulation test*** is used to check for sparks arcing through the insulation to ground. An ohmmeter test will not detect bad insulation.

Copyright Goodheart-Willcox Co., Inc.

Service Procedure

To check secondary wire insulation:

1. Darken the shop or place fender covers over the sides of the vehicle's hood to block out light.
2. Start the engine and visually inspect each wire for sparks of electric arcing leakage. Large ignition secondary leakage can make a popping or clicking sound as the electricity flows through the air faster than the speed of sound.
3. If arcing is not evident during the visual inspection, move a high-impedance test light or a grounded screwdriver along the length of each wire. Hold the tip of the tool about 1″ from the wire insulation.
4. If an arc jumps through the insulation and onto the test light probe or the screwdriver, the wire is bad and must be replaced.



Chrysler

Figure 35-15. To check the conductor in a secondary wire, measure the wire's resistance with an ohmmeter. If the resistance is too high, the conductor or terminal is broken and the wire must be replaced.

Tech Tip

Secondary wire insulation leakage will usually show up when it rains or in damp weather. The moisture will cause excessive leakage, and the engine may miss or not start.

Secondary Wire Resistance Test

A ***secondary wire resistance test*** can be used to check the condition of a secondary wire conductor. This test is commonly used to check for a bad wire when an oscilloscope is not available or handy.

Typically, secondary wire resistance should not be over approximately 12,000 ohms per foot or about 50,000 ohms for long wires. Since specifications vary, always check an appropriate service manual for the exact value. A bad spark plug wire will often have almost infinite (maximum) resistance.

Replacing Secondary Wires

Installing new secondary wires is simple, especially if one wire is replaced at a time. Compare the length of the old wire with the length of the new wire. Replace each wire with one of equal length. Make sure the new wire is fully attached on the plug and in the coil module. See **Figure 35-16**.

Service Procedure

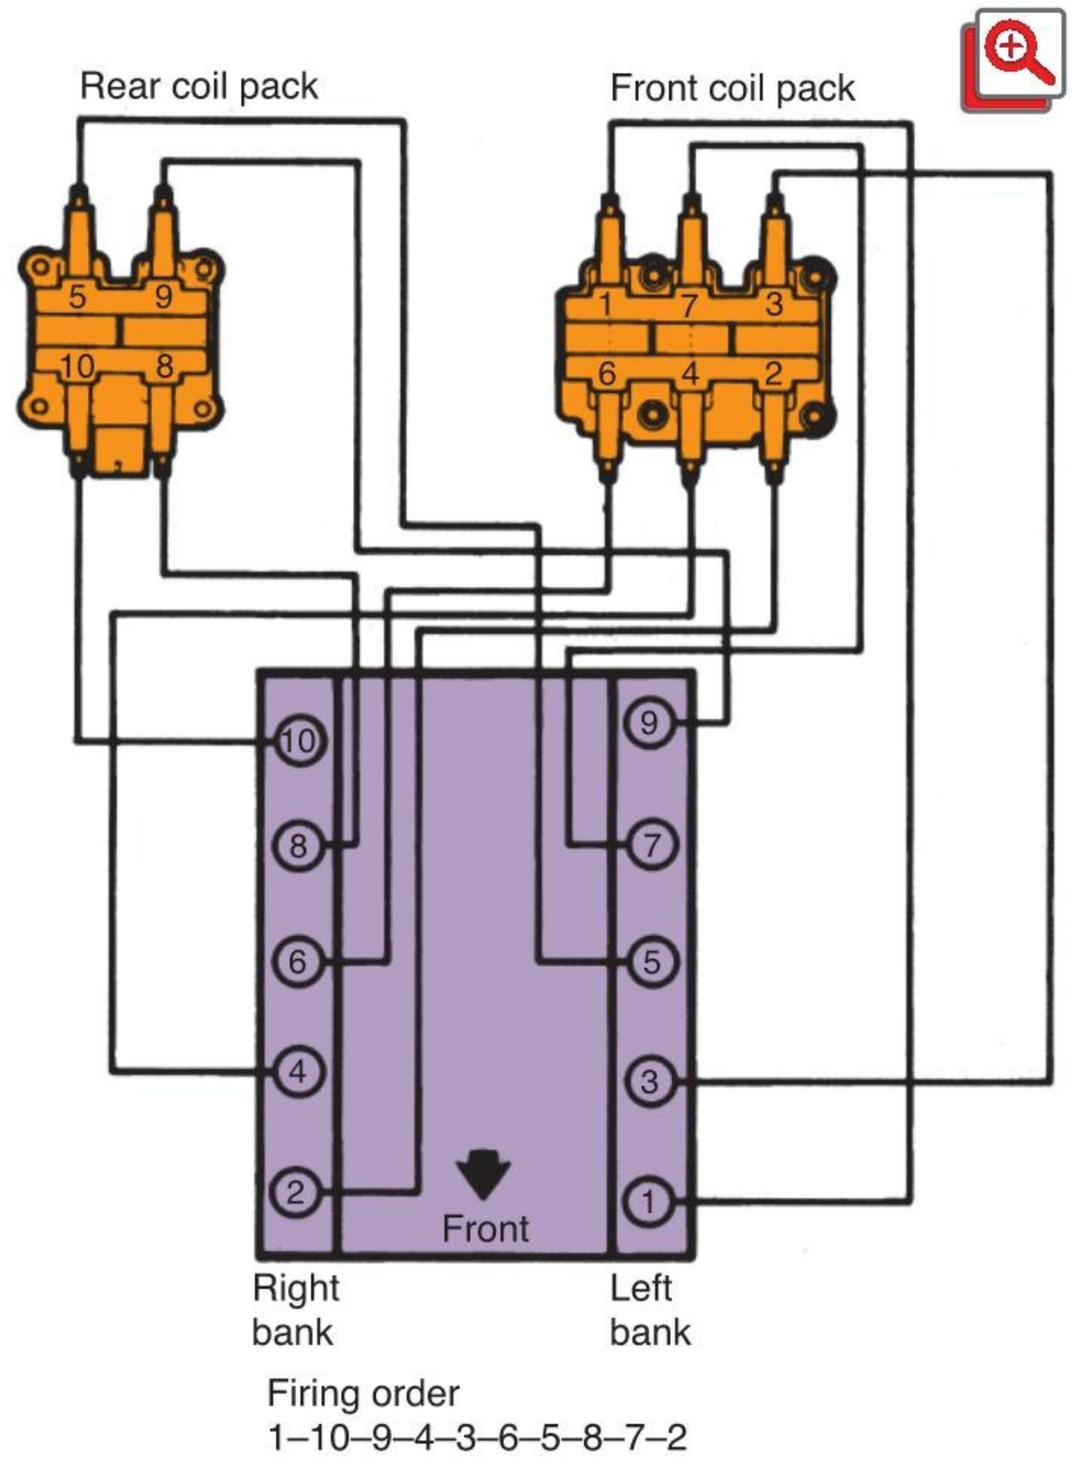
To perform a wire resistance test:

1. Remove each wire from its spark plug and from the coil pack.
2. Connect an ohmmeter to each end of the secondary wire. The meter will measure the wire's internal resistance in ohms. Look at **Figure 35-15**.
3. Compare your reading to specifications.

Tech Tip

Some sensor circuits use lower-than-normal reference voltages (1.5 volts dc). This can make them more susceptible to interference from outside magnetic fields. To prevent induced voltage from entering these sensor wires, always keep secondary wires in their clips.

Copyright Goodheart-Willcox Co., Inc.



Chrysler

Figure 35-16. If all the spark plug wires have been removed, locate a service manual illustration (like this one) for your engine. Then, trace and install the wires from the correct ignition coil tower to the proper spark plug.

Ignition Timing Service

Proper ignition timing is critical to the performance of an engine. If ignition timing is incorrect, the engine is not firing the spark plugs at the right time in relation to engine crankshaft position. If the ignition timing is off by even 1° of crankshaft rotation, fuel economy and power can drop considerably.

With ***over-advanced ignition timing***, the engine will suffer from spark knock or ping, caused by abnormal combustion. A light metallic-like pinging sound may result when the engine is accelerating or is under a high-torque load. The ping will sound like a small hammer tapping on the engine. Causes for spark knock include carbon on piston heads, low octane fuel for piston compression ratio, an overheated engine, a bad engine knock sensor, a turbocharger over-boost problem, or a partial failure of ignition control module or engine control module.

With ***retarded ignition timing***, the engine will have poor fuel economy and lack power, especially during acceleration. If timing is extremely retarded, combustion flames blowing out of the open exhaust valves can overheat and crack the exhaust manifolds. A worn or stretched timing chain or belt is a common cause of retarded spark timing on high-mileage engines.

Measuring Ignition Timing

Ignition timing should be checked if the engine is experiencing poor fuel economy or performance problems, spark knock, or exhaust manifold and catalytic converter overheating. Always obtain the exact timing specifications from the engine emission control sticker or a service manual.

After a technician connects it to the vehicle diagnostic connector, a scan tool will display ignition timing as live data so it can be compared to specifications. Scan tool live data of spark timing shows when high voltage is being sent to the spark plugs in relation to piston position and camshaft position (with variable valve timing).

Check ignition timing at idle and at various engine speeds to verify that the computer advance is operating properly. Generally, the timing reading should go up as engine speed increases. Compare your scan tool timing readings at specific engine speeds to determine if there is a computer or programming problem.

In late-model vehicles, ignition timing cannot be adjusted mechanically. If timing is incorrect, the ECM or another component affecting timing must be replaced or updated (reprogrammed). Today's engines rely on the camshaft position sensor, crankshaft position sensor, and MAP sensor to provide data for electronically adjusting ignition timing. As a result, a worn engine timing chain or stretched timing belt can cause trouble codes and symptoms related to ignition timing and these sensors.

With difficult-to-locate problems, compare the signals from the camshaft and crankshaft position sensors with scan tool live timing data to get more information that will help you find ignition timing-related problems.

Reprogramming ECM and Ignition Timing

The engine control module (ECM) must be reprogrammed to change the ignition timing of late-model

Copyright Goodheart-Willcox Co., Inc.

vehicles. Make and model specific software on a personal computer or laptop must be downloaded into the engine ECM. This can be done to change the ignition timing curve with speed, load, engine temperature, air temperature, and other variables. Sometimes software fixes are provided by the manufacturer for vehicles that experience ignition timing problems, such as spark knock or ping.

Ignition Coil (Coil Pack) Service

A faulty ignition coil may result in a weak spark, an intermittent spark, or no spark at all. The engine may miss or stall. In some cases, the engine will not start at all. The windings inside the coil can break, producing high resistance or an open in the coil circuit. In some cases, heat from the engine can make the coil windings expand and open, with a resulting loss of high-voltage output. The engine will stop running when the coil heats up.

A bad coil pack may only affect two cylinders. The other coils in the assembly may continue working normally. If you find misfiring or dead cylinders that correspond to one coil in a coil pack, suspect the coil pack.

Testing Ignition Coil

A coil test may be needed when the ignition system fails the spark test, but proper supply voltage is found. Since coil designs are different, testing procedures vary.

Generally, an ohmmeter is used to measure the internal resistance of the coil windings. Follow the manufacturer's instructions to check the resistance of both the primary and secondary windings. A reading that is out of specifications indicates a faulty ignition coil.

With a coil pack, test the windings of the coil having the spark problem. If, for example, the number two cylinder is not firing, the coil for that cylinder should be checked first. Normally, a bad coil pack winding will show infinite resistance, or open.

Direct ignition coils mount directly over the top of the spark plug. A short conductor inside a rubber insulator boot carries high voltage to the spark plug center electrode. A direct ignition coil is tested like other ignition coils. Measure both primary and secondary winding resistance. Also, make sure primary voltage is getting to the coil.

After years of service, the rubber boot on the direct ignition coil can harden and crack. This can allow moisture to enter the spark plug hole and short high voltage to engine ground, preventing the spark plug from firing. Keep this in mind when one or more cylinders misfire and trip a misfire code.

Replacing Ignition Coils

When an ignition coil or coil pack is mounted on the engine, coil replacement involves disconnecting the wires, removing the bolts securing the old coil, and lifting the coil from the engine. To install a new coil, simply bolt the coil in place and reconnect all the wires. Make sure the direct ignition coil fully snaps over the spark plug.

Ignition Switch Service

A bad ignition switch can cause several problems: the engine may not crank or start, the engine may not shut off when the ignition key is turned off, or the starter may not disengage when the ignition key is returned to run. When these types of problems occur, a faulty ignition switch may be the cause.

Testing Ignition Switch

A test light can be used to check the action of an ignition switch. When a test light is touched to the start terminal on the back of the switch, the light should glow only when the key is turned to *Start*. The test light should not glow when the key is released to the *Run* position.

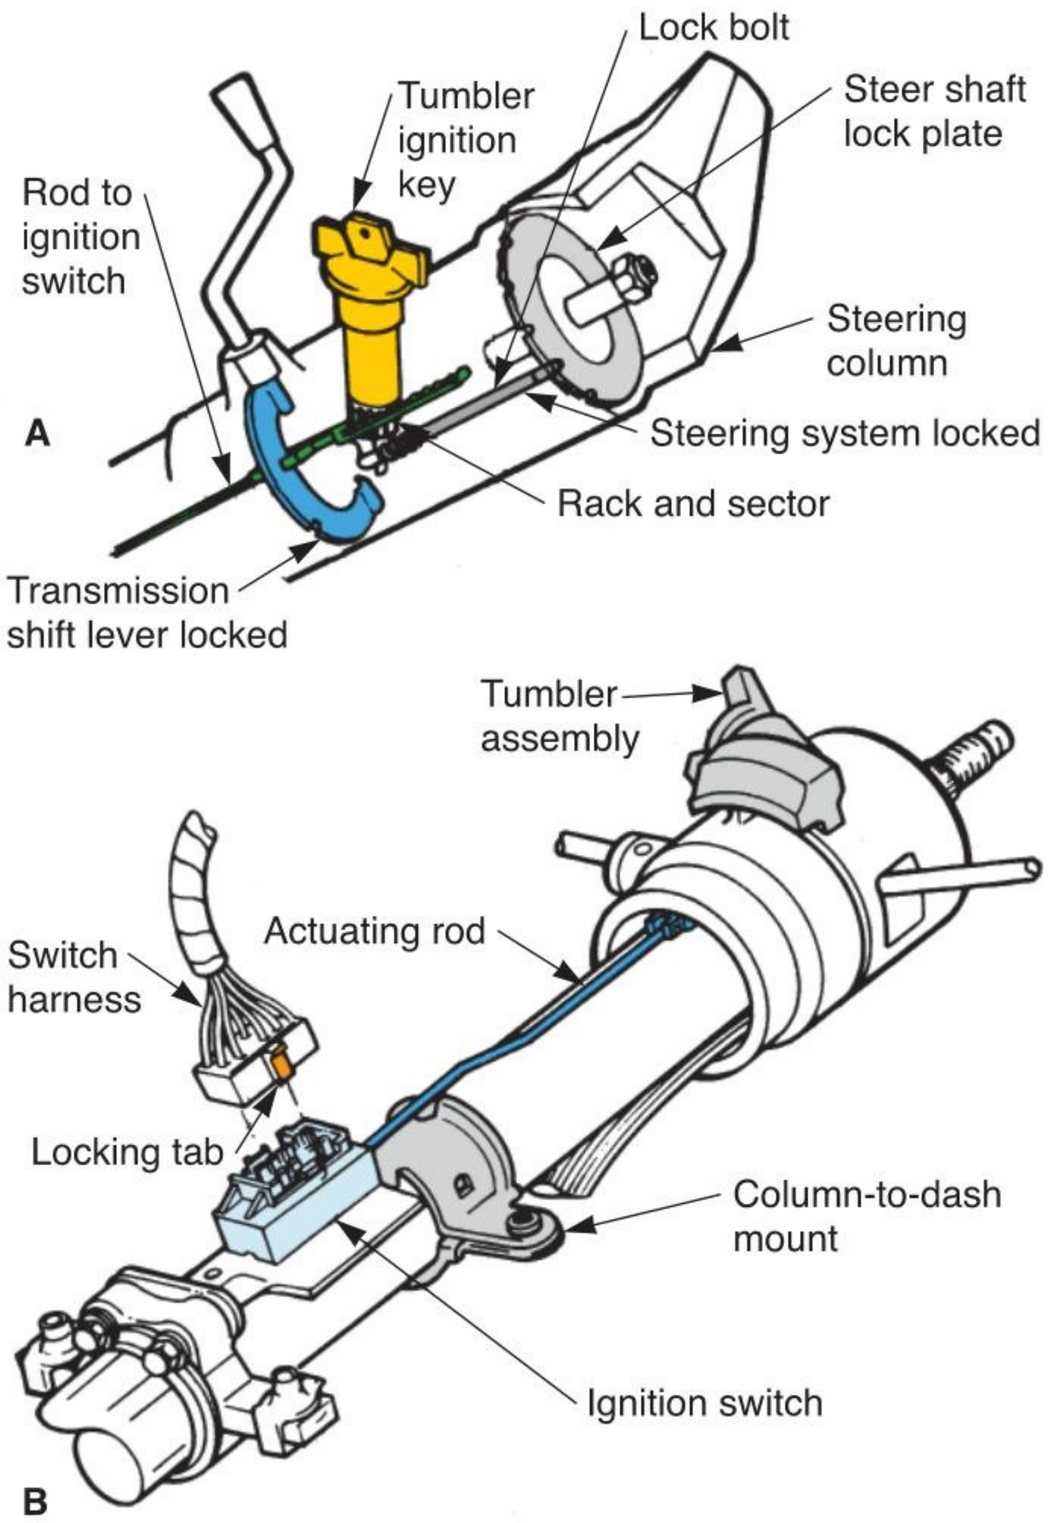
In the *Run* position, the test light should glow when touched on the *Run* terminal of the switch. With the ignition key in the *Off* position, neither terminal (*Start* or *Run*) should make the test light glow.

Replacing Ignition Switch

If the ignition switch is defective, it must be replaced. Before removing a dashboard-mounted switch, the ***tumbler*** (lock mechanism) must be removed from the switch. For most vehicles, plastic covers and the wiring harness fasteners must be removed to install a new ignition switch.

A steering column-mounted ignition switch is separate from the tumbler, **Figure 35-17**. It is normally about halfway down and on top of the steering column. To remove this type of switch, remove the fasteners holding the steering column to the dash.

Copyright Goodheart-Willcox Co., Inc.



Florida Dept. of Voc. Ed. and Ford

Figure 35-17. Most cars have the ignition switch and key tumbler in the steering column. A—Construction of a typical steering lock mechanism. B—A small rod runs down the column to the ignition switch. To remove the switch, remove the column-to-dash fasteners to drop the column. Then, remove the small nuts holding the switch to the top of the column.

This lets the steering column drop down so you can replace the ignition switch.

Ignition Control Module Service

A faulty ignition control module can produce a wide range of problems: engine stalls when hot, engine cranks but fails to start, engine misses at high or low speeds, etc. Quite often, an ignition control module problem will show up after a period of engine operation because engine heat soaks into the module and raises its temperature. The heat upsets the operation of electronic components in the unit.

Fixed and Variable Dwell

With modern computer-controlled ignition systems, the dwell time (number of degrees of crankshaft rotation that the circuit conducts current to the ignition coil) is controlled by the ignition control module and varies with vehicle make and model. Modern systems electronically vary the dwell and ignition timing with changes in engine speed and load.

Fixed dwell means that the dwell time should remain the same at all engine speeds. Some vehicles can be set to a fixed dwell for testing purposes.

Variable dwell means the ignition control module alters ignition coil dwell time with engine speed. If a system fails to alter dwell when it should, the ignition control module has a problem and should be replaced.

Current-limiting dwell means the ignition control module sends high current through the ignition coil windings until a strong magnetic field is developed around the windings. Once the module senses a ***saturated ignition coil*** (coil's magnetic field is fully formed), it reduces the amount of current sent through the coil windings. Reducing the current avoids overheating and possibly prevents burning the small conductors in the primary coil windings.

Testing Ignition Control Module

Many shop manuals list the ignition control module as one of the last components to test when troubleshooting an ignition system. If all the other components are in good working order, then the problem might be in the ignition control module.

If a specialized tester is available, it may be used to quickly determine the condition of the ignition control module. Unplug the wires going to the module and connect the tester to the module. The tester will indicate whether an ignition control module fault exists.

Heating Ignition Control Module

The microscopic components (transistors, diodes, capacitors, resistors) inside the ignition control module are very sensitive to high temperatures and vibration.

When testing the control module, many technicians use a heat gun or heat lamp bulb to warm the unit. This simulates the temperature in the engine compartment after the engine has been running. The heat may make the ignition control module act up and allow you to find an intermittent problem.

Do not apply too much heat to an ignition control module or it may be ruined. Only heat the unit to a temperature equal to its normal operating temperature.

Copyright Goodheart-Willcox Co., Inc.

Replacing Ignition Control Module

Replacing an ignition control module is a simple task.

Service Procedure

If the control module is mounted in the engine compartment or under the dash:

1. Carefully unplug the wiring harness without damaging the small terminal pins and plastic connectors.
2. Unbolt and remove the old ignition or engine control module.
3. Install the new unit.
4. Reconnect the wiring harness.

In many cases, the bottom of the ignition control module must be coated with a special grease (silicone grease, dielectric heat-transfer compound, or heat-sink compound) before installation. This grease helps heat transfer away from the circuits, protecting the module from overheating and damage. See **Figure 35-18**.

Make sure you have the correct ignition control module. The new control module may look identical to the old one, but it may have internal circuit differences. Even cars of the same year and make can require different ignition control modules.

Goodheart-Willcox Publisher

Figure 35-18. Some manufacturers recommend that a heat-sink compound be applied to the bottom of the ignition control module before installation. This will allow the module to dissipate heat properly.

Ignition System Sensor Service

Testing procedures for many of the parts in a computerized ignition system (spark plugs, secondary wires, ignition coils, etc.) have been covered earlier in this chapter. However, the computerized ignition system also contains engine sensors that must be tested and serviced when troubleshooting these systems.

Replacing Crankshaft Position Sensor

The crankshaft position sensor, which is used to monitor engine speed in many modern ignition systems, can be mounted on the front, side, or rear of the engine.

Most crankshaft position sensors simply lock into place and are not adjustable. However, a few require adjustment. Crankshaft position sensor air gap is the distance from the tip of the sensor to an unnotched area on the trigger wheel. This gap must be correct for proper sensor signal output.

Service Procedure

To adjust crankshaft position sensor air gap:

1. Loosen the mounting screws that hold the sensor in place.
2. Fit a flat feeler gauge between one of the teeth on the crank trigger wheel and the sensor tip.
3. Adjust the sensor position so there is a slight drag on the feeler gauge.
4. Tighten the crank sensor mounting screws so that they remain the correct distance from the trigger wheel on the crankshaft.

Knock Sensor Service

A knock sensor is used to detect abnormal combustion, or ping. When it "hears" pinging or knocking, the sensor retards ignition timing or lowers turbo boost with the turbo waste gate. A bad knock sensor can upset ignition timing and affect turbocharger boost pressure. Many computers store a trouble code if there is a potential problem with the knock sensor.

To check knock sensor operation, start the engine and allow it to reach operating temperature. Lightly tap on the engine block or on a bracket with a wrench or small

Copyright Goodheart-Willcox Co., Inc.

hammer. This simulates pinging or knocking, and should make the computer retard the ignition timing. Light taps should make the engine speed drop slightly. You might need to prop open the throttle to increase engine speed slightly so timing is advanced and will retard.

If tapping on the engine has no effect on timing and engine speed, check the sensor with a VOM or scope. Refer to the manual for recommendations. Remember to check the wiring that leads to the knock sensor before removing or replacing the sensor.

Camshaft Position Sensor Indexing

Camshaft position sensor indexing involves installing the sensor with the number one piston at TDC on the compression stroke. Use a breaker bar to rotate the crankshaft snout until air is pushed out of the number one cylinder (hold thumb or finger over the spark plug hole). Then continue rotating the crankshaft until the dampener or flywheel timing marks line up at zero. If no timing marks are provided, use a dial indicator with a long extension rod and rotate the crankshaft back and forth until the number one piston is at TDC.

The camshaft position sensor is normally mounted on the cylinder head or front timing cover. Make sure the rubber O-ring is fully in its groove on the sensor and that any spacer is placed under the sensor before installation.

A special plastic alignment tool may be required to hold the sensor in correct orientation as you slide the sensor into place before securing it. The tool may have an arrow that must face toward the front of the vehicle or engine. Since procedures vary, always refer to your service information for the year, make, and model car being repaired if in doubt. Also check for any software updates or reprogramming that may be required when replacing the camshaft position sensor.

An incorrectly indexed camshaft position (CMP) sensor may be difficult to diagnose since it can slightly affect fuel injection timing and ignition timing. The engine might have poor fuel economy or drivability problems, and the MIL may illuminate. Surging, hesitation, missing upon acceleration, or a lack of engine power may result.

Tech Tip

Most modern camshaft position sensors do not require indexing. They will only go into the engine one way. Only early model camshaft position sensors require indexing.

Diagnostic Case Study

Concern: Mrs. Kim drives her 2011 Honda Accord with 100,000 miles on the odometer into the shop complaining of low engine power and a rough idle. She says an engine warning light in the dash is glowing.

Cause: Duff questions Mrs. Kim about the exact nature of the problem. She explains that the problem occurs more at initial engine startup with the engine cold. She admits that she has never changed the spark plugs.

Correction: The technician connects a scan tool to the vehicle and notes a misfire code for cylinder number three. He removes cylinder three's direct ignition coil and the spark plug. Inspecting the spark plug, he finds that the air gap is three times greater than specifications. The spark plug has been run so long that the air gap has opened enough to prevent an arc from jumping the gap. New spark plugs are installed in the engine to correct the poor engine performance problem. After checking engine power and idle smoothness on a test drive, the technician releases the vehicle back to the customer.

Summary

- Problems caused by spark plugs, secondary wires, ignition coils, ECMs, and related wiring manifest themselves in a variety of ways.
- To start diagnosis, visually inspect the ignition system with and without the engine running.
- Connect a scan tool to the diagnostic connector under the dash to find many ignition-related problems.
- A spark intensity test (spark test) checks the strength of the electric arc (spark) produced by the ignition system.
- A dead cylinder is an engine combustion chamber that is not igniting and burning its fuel-air mixture on that cylinder's power stroke.
- Bad spark plugs can cause a wide range of problems, including misfiring, lack of engine power, poor fuel economy, exhaust odor, rough idle, and hard starting.
- To read a spark plug, closely inspect and analyze the condition of its tip and insulator.

Copyright Goodheart-Willcox Co., Inc.

- Set the spark plug gap by spacing the side electrode the correct distance from the center electrode.
- A faulty secondary wire or spark plug wire can have a burned or broken conductor or deteriorated insulation.
- Proper ignition timing is critical to the performance of an engine. If the ignition timing is off by even 1° of crankshaft rotation, fuel economy and power can drop considerably.
- A faulty ignition coil may result in a weak spark, an intermittent spark, or no spark at all. The engine may miss or stall. In some cases, the engine will not start at all.
- A bad ignition switch can cause several problems: the engine may not crank or start, the engine may not shut off when the ignition key is turned off, or the starter may not disengage when the ignition key is returned to run.
- An ignition control module problem often shows up after a period of engine operation because engine heat soaks into the module and raises its temperature.
- When a knock sensor "hears" pinging or knocking, it retards ignition timing or lowers turbo boost with the turbo waste gate.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

current-limiting dwell
dead cylinder
fixed dwell
ignition primary voltage test
misfire code
over-advanced ignition timing
retarded ignition timing
saturated ignition coil
secondary wire insulation test
secondary wire resistance test
spark intensity test
spark test
spark tester
tumbler
variable dwell

Activities

1. Demonstrate the use of a wire feeler gauge to measure the gap of a spark plug. Then, demonstrate the method used to set the gap to specifications.
2. Use a scan tool to check the timing at idle on two or three engines. Compare your findings with the appropriate service manual specifications to determine if timing is "within specs" for each engine.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Explain how to use a scan tool to detect problems in an ignition system. What problems can a scan tool typically detect?
2. A(n) _____ test checks the strength of the electric arc produced by the ignition system.
3. Which of the following is commonly used to check ignition system output voltage?
   (A) Voltmeter.
   (B) Ohmmeter.
   (C) Spark tester.
   (D) Ammeter.
4. Define the term *dead cylinder*.
5. Burned secondary connections inside direct and indirect ignition coils can indicate high voltage leakage. True or False?
6. What does an oscilloscope measure?
7. A(n) _____ spark plug is shiny and dark gray or black in color.
8. Which of the following pertains to setting spark plug gap?
   (A) Wire feeler gauge.
   (B) Bend side electrode.
   (C) Space between center and side electrode.
   (D) All of the above.
9. When screwing a spark plug into the cylinder head, a socket, an extension, and a ratchet should be used to start the plug threads. True or False?
10. With _____ ignition timing, the engine will suffer from spark knock or ping, caused by abnormal combustion.
11. Normally, a bad ignition coil pack will measure infinite resistance on an ohmmeter. True or False?

Copyright Goodheart-Willcox Co., Inc.

12. If the engine does not shut off when the ignition key is turned off, a technician should suspect a(n) _____ as the probable cause.
    (A) parasitic battery load
    (B) bad knock sensor
    (C) faulty ignition switch
    (D) All of the above.
13. In an ignition system, the crankshaft position sensor fits all of these descriptions *except:*
    (A) monitors spark plug voltage.
    (B) can be replaced if faulty.
    (C) measures engine speed.
    (D) mounts on the front, side, or rear of the engine.
14. Why do ignition control module problems often show up after a period of engine operation?

ASE-Type Questions

1. In an engine with a dead cylinder, the problem could be a bad:
   (A) ignition system.
   (B) fuel system.
   (C) starting system.
   (D) All of the above.
2. Which device will properly measure ignition system operating voltages over time?
   (A) Oscilloscope.
   (B) Dynamometer.
   (C) Spark tester.
   (D) All of the above.
3. Which of the following is *not* a problem that can be caused by bad spark plugs?
   (A) Misfiring.
   (B) High idle speed.
   (C) Hard starting.
   (D) Lack of power.
4. A properly burning spark plug should be:
   (A) grayish-tan.
   (B) black.
   (C) white.
   (D) yellow.
5. Each of the following can be used to start spark plugs in their holes *except:*
   (A) a ratchet.
   (B) your fingers.
   (C) a spark plug socket.
   (D) a short piece of vacuum hose.
6. While conducting a secondary wire resistance test, Technician A states that wire resistance should be approximately 12,000 ohms per foot. Technician B says that a direct ignition coil boot can deteriorate over time. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Ignition modules are being discussed. Technician A says that the module may be adversely affected by excessive heat and vibration. Technician B says that a specific car company's ignition modules will be identical across all the vehicle makes and models they manufacture. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Direct ignitions systems are being discussed. Technician A says that service procedures for these systems are very similar to procedures used on contact point distributor ignition systems. Technician B says that when replacing this type of coil, the new coil requires a 1″ air gap with the spark plug. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Which of the following is the ignition switch locking mechanism?
   (A) Tumbler.
   (B) Steering column.
   (C) Actuating rod.
   (D) Suppressor shield.
10. A car equipped with a coil pack ignition enters the shop with two dead cylinders. Technician A says to check to see if the dead cylinders are operated by the same ignition coil pack. Technician B says there is no need for this step as one coil pack fires all engine cylinders in this system design. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Ignition System Diagnosis

Condition	Possible Causes	Correction
No spark.	1. Breaker points defective or misadjusted (point ignition). 2. Distributor pickup defective or misadjusted (electronic ignition). 3. Defective condenser. 4. Discharged battery. 5. Faulty coil or primary circuit resistor. 6. No primary current to points. 7. Defective coil high tension lead. 8. Defective rotor and/or distributor cap. 9. Defective plug wires. 10. Moisture in distributor cap and on points. 11. Breaker plate not grounded. 12. Defective ignition control module. 13. Loose, corroded, or open electronic control module ground lead. 14. Loose, corroded, or disconnected primary connections. 15. Defective distributor electronic pickup. 16. Trigger wheel positioned too high. 17. Incorrect trigger wheel-to-pickup air gap. 18. Defective cam or crankshaft sensor.	1. Install new points. 2. Replace or adjust as needed. 3. Replace condenser. 4. Charge battery. 5. Replace coil or resistor. 6. Check ignition switch, coil, resistor, wiring. 7. Replace lead. 8. Replace cap and rotor. 9. Replace plug wires. 10. Dry cap and points. 11. Replace or tighten ground wire. 12. Replace ignition module. 13. Tighten, clean, or connect as needed. 14. Clean, cover with special, protective grease and shove firmly into distributor. 15. Replace pickup unit. 16. Reposition correctly. 17. Set correctly. Use nonmagnetic feeler gauge. 18. Replace defective sensor.
Weak or intermittent spark.	1. Breaker points defective (where used). 2. Defective condenser (where used). 3. Point dwell set incorrectly. 4. Discharged battery. 5. Loose or dirty primary wiring connections. 6. Weak coil. 7. Defective primary circuit resistor. 8. Burned rotor and cap contacts. 9. Defective resistance spark plug wires. 10. Insufficient system voltage. 11. Weak breaker spring pressure (point ignition only). 12. Worn distributor bushings or bent shaft. 13. Worn distributor cam (point ignition only). 14. Breaker arm sticking (point ignition only). 15. Loose spark plug wires. 16. Defective distributor electronic pickup. 17. Trigger wheel pin sheared. 18. Shorted primary wiring. 19. Loose wiring harness connectors.	1. Install new points. 2. Install new condenser. 3. Set dwell correctly. 4. Charge or replace battery. 5. Clean and tighten connections. 6. Replace coil. 7. Replace resistor. 8. Replace cap and rotor. 9. Replace resistance wires. 10. Adjust regulator. 11. Increase spring pressure. 12. Replace bushings or shaft. 13. Replace cam. 14. Free and lubricate bushing. 15. Clean and tighten connections. 16. Replace pickup. 17. Replace pin. 18. Replace wire and relocate. 19. Tighten connections.

Continued

Condition	Possible Causes	Correction
Missing at idle or low speed.	1. Weak or intermittent spark at plugs. 2. Fouled spark plugs. 3. Spark plug gaps too narrow. 4. Improper plug heat range. 5. Damaged plugs. 6. Defective distributor electronic pickup. 7. Loose harness connections. 8. Discharged battery. 9. Coil polarity incorrect.	1. See *Weak or intermittent spark.* 2. Clean or replace plugs. 3. Adjust gaps to specifications. 4. Install proper heat range. 5. Replace plug or plugs. 6. Replace pickup unit. 7. Clean and tighten connections. 8. Charge or replace battery. 9. Reverse coil primary leads.
Missing during acceleration.	1. Weak spark. 2. Plugs damp. 3. Fouled plugs. 4. Plug gap too wide. 5. Damaged plug. 6. Incorrect trigger wheel-to-pickup air gap. 7. Defective vacuum advance. 8. Incorrect coil polarity. 9. Crossfiring. 10. Weak ignition coil.	1. See *Weak or intermittent spark.* 2. Dry plugs. 3. Clean or replace plugs. 4. Gap as specified. 5. Replace plug. 6. Set gap to specifications. 7. Repair or replace vacuum advance. 8. Reverse coil primary leads. 9. Rearrange ignition secondary wires. 10. Replace ignition coil.
Missing during cruising and high-speed operation.	1. Weak spark. 2. Improper heat range plug (too hot). 3. Crossfiring. 4. Fouled plugs. 5. Plug gap incorrect. 6. Damaged plug. 7. Ignition timing incorrect. 8. Defective distributor. 9. Loose or corroded wire connections. 10. Defective spark plug wires. 11. Weak ignition coil.	1. See *Weak or intermittent spark.* 2. Install proper heat range plug. 3. Arrange wires properly. If needed, install new wires. 4. Clean or replace plugs. 5. Gap to specifications. 6. Replace plug. 7. Reset timing. 8. Repair or replace distributor. 9. Clean and tighten connections. 10. Replace wires. 11. Replace ignition coil.
Missing at all speeds.	1. Weak spark. 2. Fouled spark plugs. 3. Damaged plug. 4. Crossfiring. 5. Plug gap too wide or too narrow. 6. Plugs and/or distributor damp. 7. Improper plug heat range. 8. Defective distributor. 9. Defective spark plug wires. 10. Distributor trigger wheel pin sheared or missing. 11. Burned or corroded breaker points. 12. Defective condenser.	1. See *Weak or intermittent spark.* 2. Clean or replace plugs. 3. Replace plug. 4. Arrange wiring correctly and if needed, install new wires. 5. Adjust gap as needed. 6. Dry distributor and plugs. 7. Change to correct heat range. 8. Repair or replace distributor. 9. Replace plug wires. 10. Install new pin. 11. Replace and gap points. 12. Replace condenser.

Continued

Condition	Possible Causes	Correction
Coil failure.	1. Carbon tracking on tower. 2. Excessive system voltage. 3. Oil leak in coil. 4. Engine heat damage. 5. Physical damage.	1. Replace coil and wire nipple. 2. Adjust voltage regulator. 3. Replace coil. 4. Replace coil. Relocate or baffle against heat. 5. Replace coil.
Short spark plug life.	1. Incorrect plug heat range (too hot—burns). 2. Incorrect plug heat range (too cold—fouls). 3. Mechanical damage during installation. 4. Loose spark plug (overheats and burns). 5. Incorrect plug reach (too short—fouls). 6. Incorrect plug reach (too long—strikes piston). 7. Worn engine—oil fouling. 8. Bending center electrode. 9. Detonation. 10. Preignition. 11. Lean mixture.	1. Install correct (cooler) spark plug. 2. Install correct (hotter) spark plug. 3. Install correctly. 4. Tighten plugs to proper torque. 5. Install plugs with correct reach. 6. Install plugs with correct reach. 7. Switch to hotter plugs or overhaul engine. 8. Bend side electrode only. 9. Adjust timing. Change to higher octane gas and/or remove carbon buildup. 10. Remove carbon buildup, install valves with full margin, install cooler plugs. 11. Adjust air-fuel ratio.
Preignition.	1. Overheated engine. 2. Glowing pieces of carbon. 3. Spark plugs overheating. 4. Sharp valve edges. 5. Glowing exhaust valve.	1. Check cooling system. 2. Remove carbon. 3. Change to cooler plugs. 4. Install valves with full margin. 5. Check for proper tappet clearance, for sticking, and air leaks.
Detonation.	1. Ignition timing advanced. 2. Engine temperature too high. 3. Carbon buildup is raising compression ratio. 4. Low octane fuel. 5. Exhaust heat control valve stuck. 6. Excessive block or head metal removed to increase compression.	1. Retard timing. 2. Check cooling system. 3. Remove carbon. 4. Switch to high octane fuel. 5. Free valve. 6. Use thicker gasket, change head, or true warped head or block surface.

Chapter 36
Lights, Instrumentation, Wipers, and Horns—Operation and Service

After studying this chapter, you will be able to:

- Explain the operating principles of automotive light, wiper, and horn systems.
- Diagnose problems in light, wiper, and horn systems.
- Summarize automatic light and wiper systems.
- Replace burned-out bulbs.
- Explain how to aim headlights.
- Describe the safety practices to follow when working with light, wiper, and horn systems.
- Explain both analog and digital instrumentation.
- Summarize how to remove and service an instrument cluster.
- Correctly answer ASE certification test questions on light, instrumentation, wiper, and horn systems.

The lighting and instrumentation circuits on today's cars can be very complex. The dash instrument clusters can have their own ECM and power supply to operate the dash cluster and display screen in the center of the dash. The number of wires and electronic devices in and under the dash can be mind-boggling if you are not familiar with each individual circuit.

This chapter summarizes the typical lighting and instrumentation systems found on late-model vehicles, including exterior lighting, interior lighting, instrument cluster, and dash monitor displays. It will give you the background for using factory service manuals for specific makes and models of vehicles. See **Figure 36-1**.

Light

Light is energy from electromagnetic radiation within the frequency or spectrum of the human eye. Life would not exist on earth without light, and it would be dangerous to drive at night without some form of artificial light.

The speed of light is exactly 299,792,458 meters per second (186,282 miles per second). There are two scientific theories for light:

- Light is the movement of electromagnetic waves through space.
- Light is the movement of atomic particles (photons) through space.

Light energy can be used to illuminate objects or to send computer data or information in a digital circuit. In the automobile, lights are used to illuminate the road ahead of the vehicle, illuminate the dash displays, provide interior lights when you open the doors, and illuminate the rear of the vehicle. With the use of photonic devices, light energy can also represent data when transferring information in a digital circuit.

Honda

Figure 36-1. Light, wiper, and other major electrical systems are simple when studied separately. Note the location of the major components.

Lightbulbs

A lightbulb, **Figure 36-2**, is a resistance element surrounded by a vacuum or inert gas enclosed in a sealed glass housing. The resistance element, or ***filament***, is a hard metal that can withstand extreme heat. The bulb's glass housing is either air-free or filled with an inert gas to keep the filament from burning up.

Incandescent lightbulbs send current through a filament (usually tungsten resistance wire) inside a partial vacuum in an airtight glass enclosure, producing heat and the emission of light energy. The current makes the filament glow white-hot. Incandescent bulbs produce a white light, unless the glass is tinted.

Since the element of an incandescent bulb is not exposed to oxygen, it does not burn in half. A burned-out incandescent bulb has slowly vaporized its filament or resistance wire over an extended service time, or its airtight seal has been broken, causing the filament to burn in half.

Thumb-sized incandescent bulbs are used for running lights, turn lights, and backup lights. Turn signal lights, brake lights, and marker lights use one- or two-filament, low-current incandescent bulbs. Bulbs for turn signal lights and brake lights often have two separate filaments. Backup lights and marker lights normally have only one filament.

Halogen lightbulbs use tungsten and halogen gas to produce white light. This type of bulb is brighter than a conventional incandescent bulb because the halogen gas surrounding the filament glows more brightly. Halogen bulbs are commonly used for headlights, fog lights, and sometimes marker and signaling lights.

High-intensity discharge bulbs (HIDs) emit light energy by producing a small electric arc between two metal halide electrodes. HID bulbs are encased in glass and usually contain xenon gas that glows when exposed to an electric arc. Sometimes called a "burner lightbulb," an HID bulb can produce a light output three times brighter than a conventional filament bulb.

A ***ballast*** (transformer) and control circuit is needed to step up battery voltage and send high-voltage pulses to the HID electrodes to produce tiny, but blindingly bright, welding-type arcs. The high frequency of the voltage going to the bulb electrodes makes the flashing electric arc appear to glow constantly. HID bulbs are normally used for headlights and fog lights. They emit bluish light rather than white light.

Neon (Ne) lightbulbs use a ballast to send current though an inert or noble gas that glows when excited by electrical energy. Neon bulbs are seldom used as OEM equipment but are available in the aftermarket as add-on lighting.

Light-emitting diodes (LEDs) emit light energy when a tiny amount of current is sent through a semiconductor material. LEDs are very small and only draw a small amount of electrical energy. They are often used as tiny indicator lights in vehicle dashboards because of their long service life and small packaging. LEDs are also used in taillights, turn signals, and brake lights.

Lighting Systems

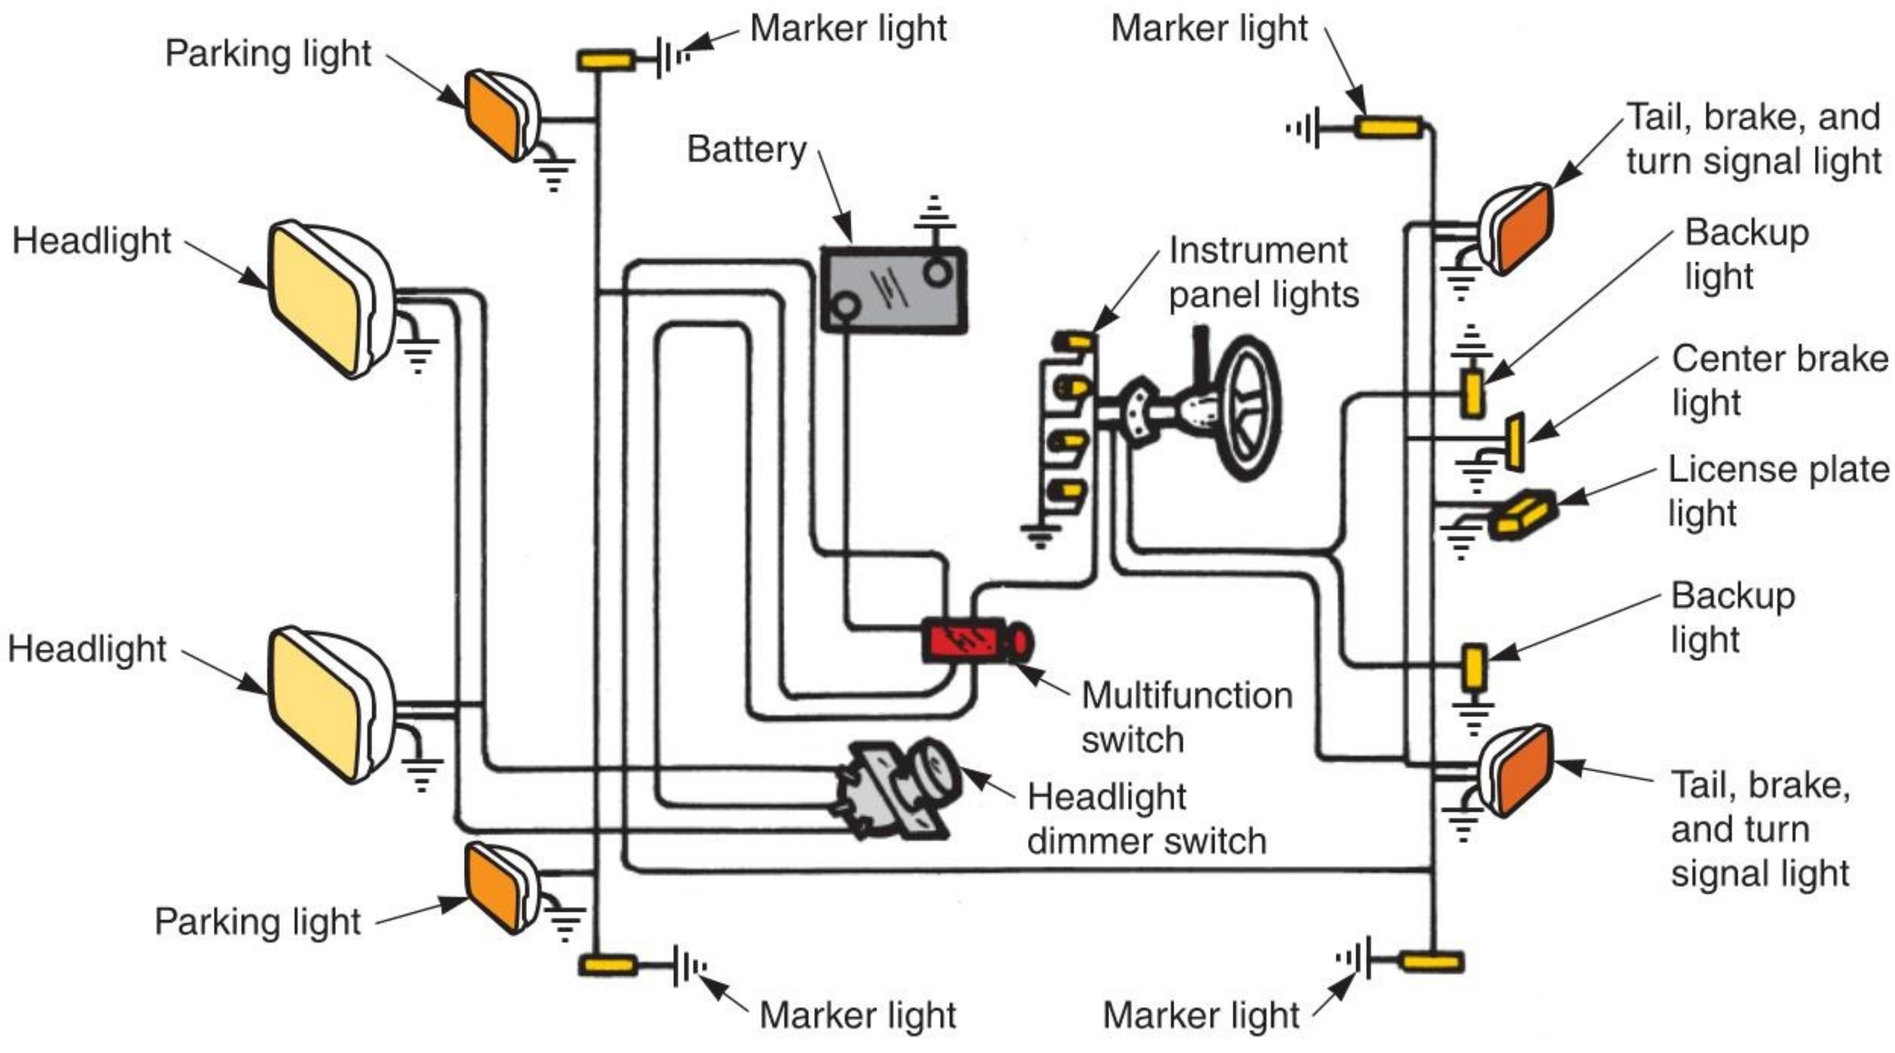
The lighting system consists of the components (fuses, wires, switches, and relays) that operate the interior and exterior lights on a vehicle. The exact circuit and part configurations vary with each make and model of vehicle. However, the systems operate similarly.

The exterior lights typically include the headlights, turn signal lights, stoplights, parking lights, backup lights, and side marker lights.

The interior lights normally include the dome light, instrument lights in the dash, trunk light, and other courtesy lights.

Headlamp System

The ***headlamp system*** includes the battery, headlamp wiring, fuse panel, light switch, dimmer switch, headlamps (headlights), taillights, marker lights, and instrument lights. See **Figure 36-3**. If the headlamps are concealed, the system also has either a vacuum



Florida Dept. of Voc. Ed.

Figure 36-3. The light switch is the heart of the lighting system. It feeds current to circuits.

Copyright Goodheart-Willcox Co., Inc.

or electric motor mechanism to operate the doors (flaps) over the headlamps.

The headlamp switch is an on/off switch in the dash panel or on the steering column. It controls current flow to the bulbs in the headlamp system. It may also contain a ***rheostat*** (variable resistor) for adjusting the brightness of the instrument panel lights. The rheostat can also be mounted in the dash. A vacuum switch may be added to the headlamp switch or in the circuit when vacuum doors are used over the headlamps.

A ***multifunction switch*** is capable of controlling several circuits simultaneously—headlights (bright and dim circuits) and turn lights, for example. Most late-model vehicles use multifunction switches. Look at **Figure 36-4**.

Most multifunction switches have a ***flash-to-pass feature***, which energizes the high beams when the switch arm is pulled back. This lets the driver quickly warn traffic that he or she is going to increase speed and pass. As soon as the multifunction switch arm is released, the headlamps return to low beams.

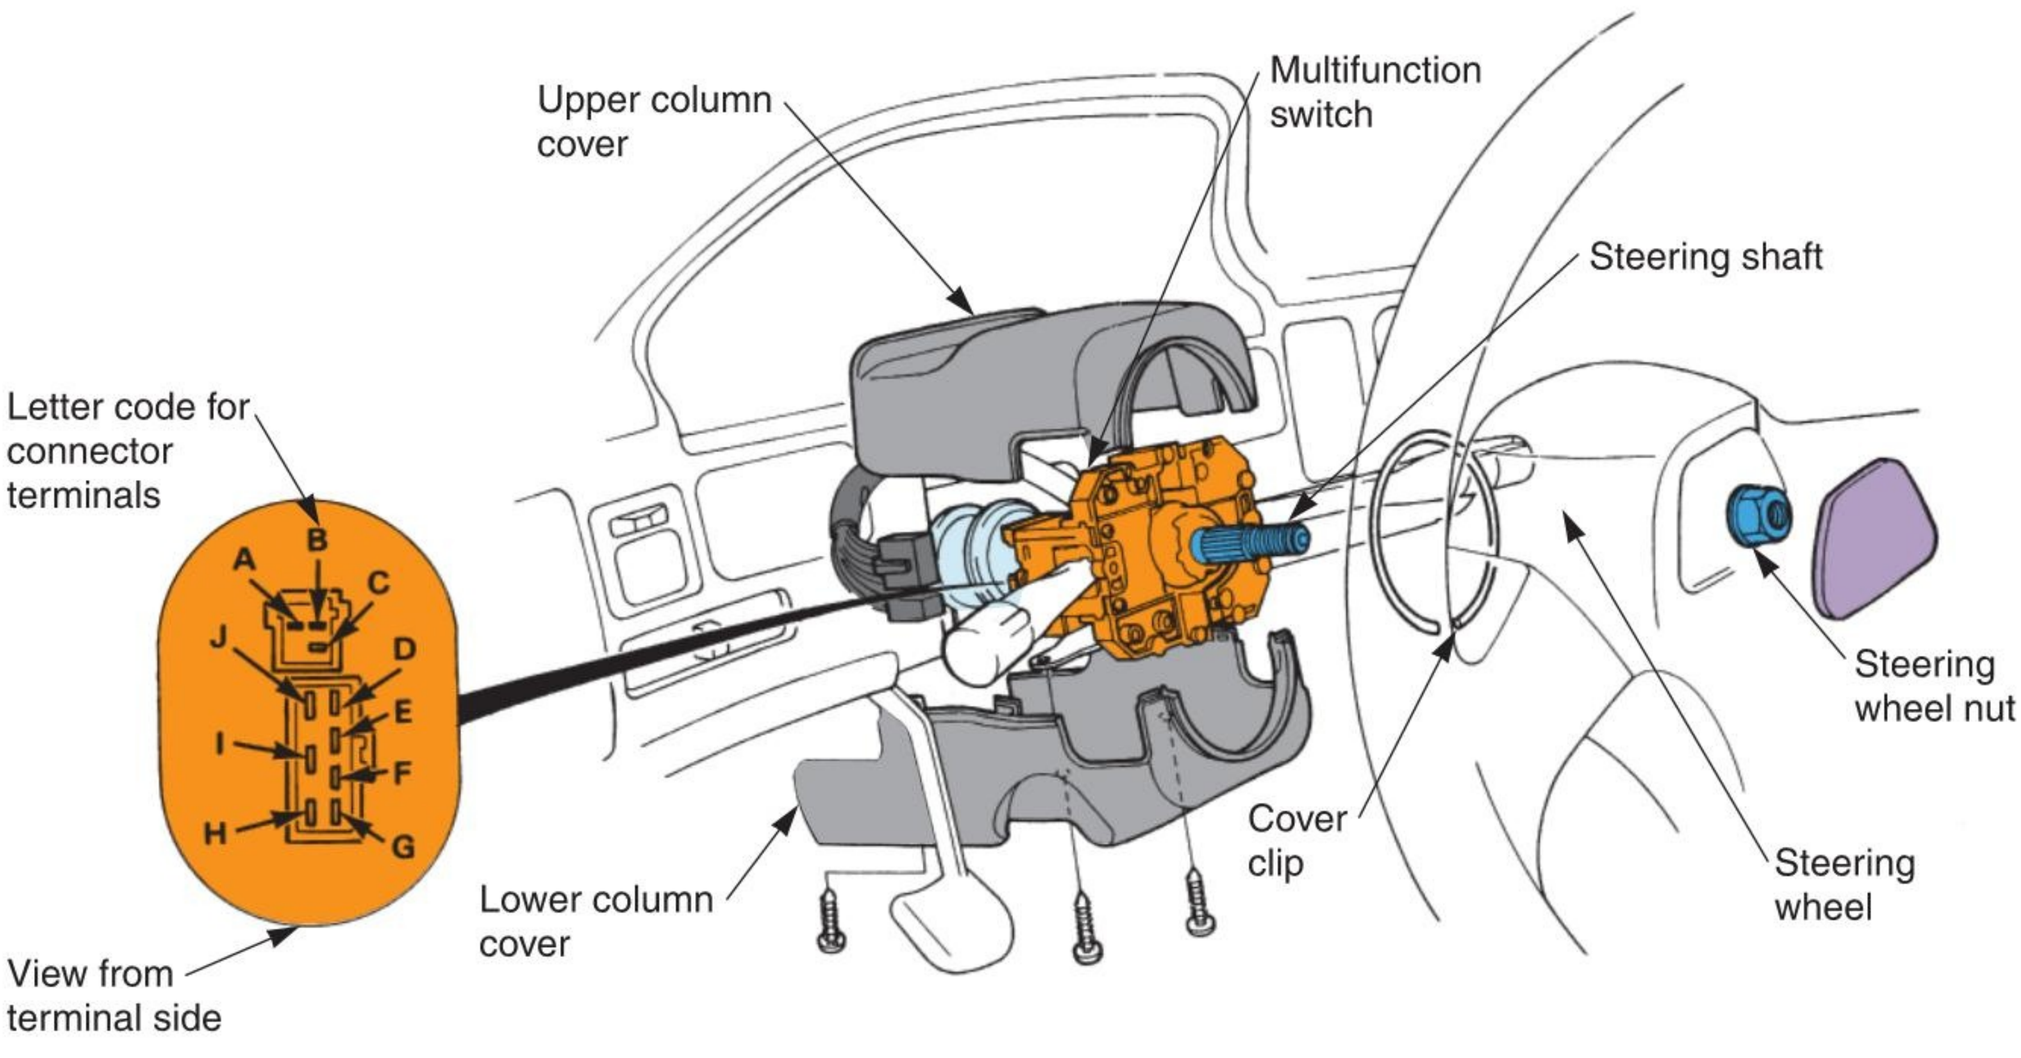
The headlamp bulbs illuminate the road during night driving or bad weather conditions. Headlight bulbs can have one or two elements. Two elements are needed to provide low and high beams. Low beams are used for driving in traffic and high beams for greater visibility when there is no oncoming traffic. When current flows through the bulb element or filament, it gets white-hot and glows to produce light energy.

Most late-model cars use halogen headlamp bulb inserts, which are small bulbs that fit into a larger plastic housing. A headlight lens disperses the light beam in front of the vehicle and protects the bulb. This lens can be made of glass or plastic. The bulb is made of heat-resistant quartz that is filled with halogen gas to protect the filament from damage. See **Figures 36-5** and **36-6**.

Halogen bulbs are rated in watts. A typical low-beam bulb is 45 watts, and a typical high-beam bulb is 65 watts. Federal regulations limit how bright low-beam headlamps can be on public roads. The maximum brightness for low beams is 20,000 candlepower. Brighter bulbs are available, but should not be installed for use on public roads.

Some late-model vehicles are equipped with high-intensity discharge bulbs (HIDs). This type of lamp does not use a filament. Instead, a high-voltage electric arc flows between two electrodes in the bulb. This arc excites the xenon vapor contained in the bulb, producing a bright blue-white light.

An external ballast is used to convert battery voltage into high-voltage ac to create and maintain the



Honda

Figure 36-4. A multifunction switch on the steering column is common. It can be tested after removing the covers around the steering column. Letters on the connector can be compared to service manual charts and diagrams for probing voltage in different switch positions.

Honda

Figure 36-5. Late-model vehicles commonly have halogen headlamp bulb inserts. The bulb insert installs in a plastic housing behind the lens. The lens and housing are not vacuum sealed. Note how the retaining ring nut locks the insert bulb into the housing.

Fiat

Figure 36-6. An insert-type headlight bulb is shown. In the inset, you can see that the bulb has filaments for low and high headlight beams.

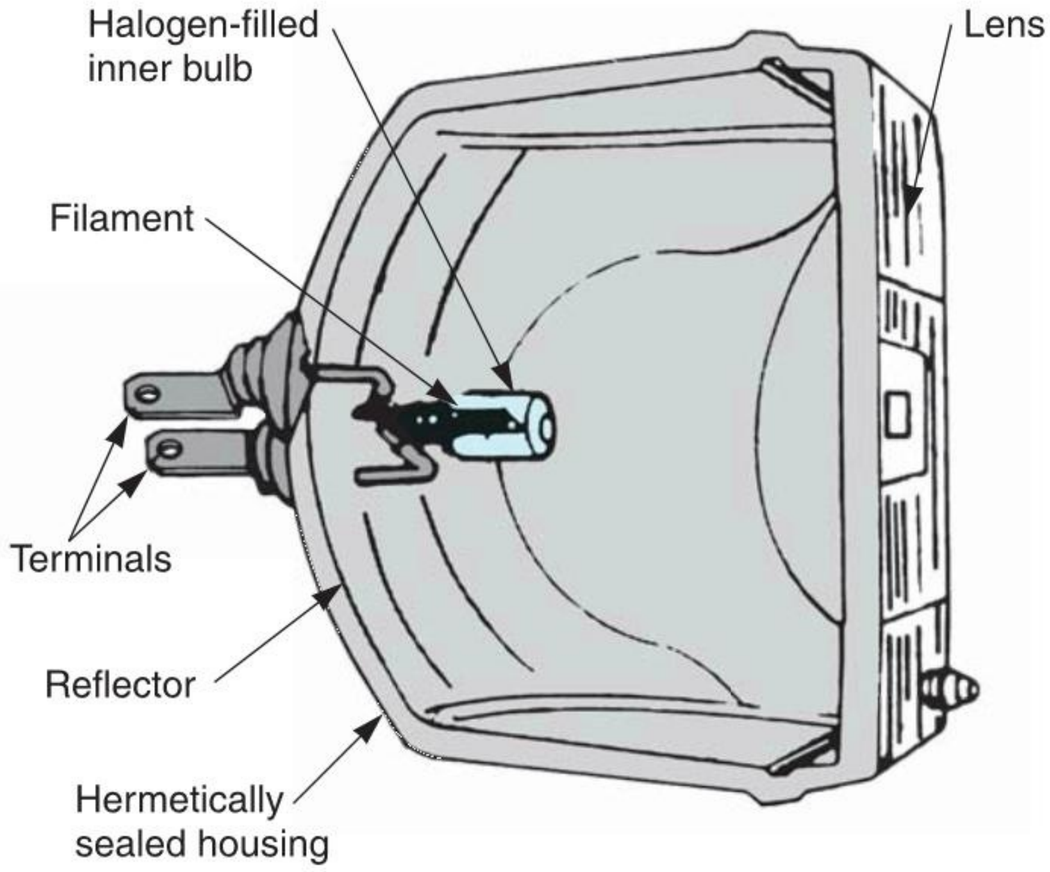
Older vehicles were equipped with ***sealed-beam headlamps***. These lamps have their filament(s) enclosed in a vacuum-sealed glass housing that has an integral headlight lens. See **Figure 36-7**. Sealed-beam headlamps have been phased out for smaller halogen headlamp bulb inserts.

arc. When an HID is first turned on, an igniter works with the ballast to provide several thousand volts to establish the arc. The ballast then provides as many as 450 volts to maintain the arc. As the bulb warms, the amount of voltage needed to maintain the arc drops to as little as 50 volts.

High-intensity discharge bulbs produce more light than standard halogen bulbs while consuming less power. Another advantage to HID lights is that they last longer than conventional bulbs.

Warning

Be aware of the startup voltage of HIDs and use basic safety measures to prevent electric shock. Also, HID bulbs are under high pressure when hot, creating an explosion hazard. Never operate an HID bulb that has been removed from the headlight assembly.



Chrysler

Figure 36-7. A sealed-beam lamp has an airtight glass housing around the filaments. This sealed-beam lamp has a small halogen inner bulb inside a glass lens.

Copyright Goodheart-Willcox Co., Inc.

Tech Tip

Always make sure you have the correct replacement lamp. Normally, a lamp number is stamped on the housing. If needed, take the old lamp to the parts house so it can be matched up.

Headlamp Dimmer Switch

A ***dimmer switch*** controls the high and low headlamp beam function. This switch is commonly mounted on the steering column. It simply controls which bulb filaments receive power. Refer to **Figure 36-8**.

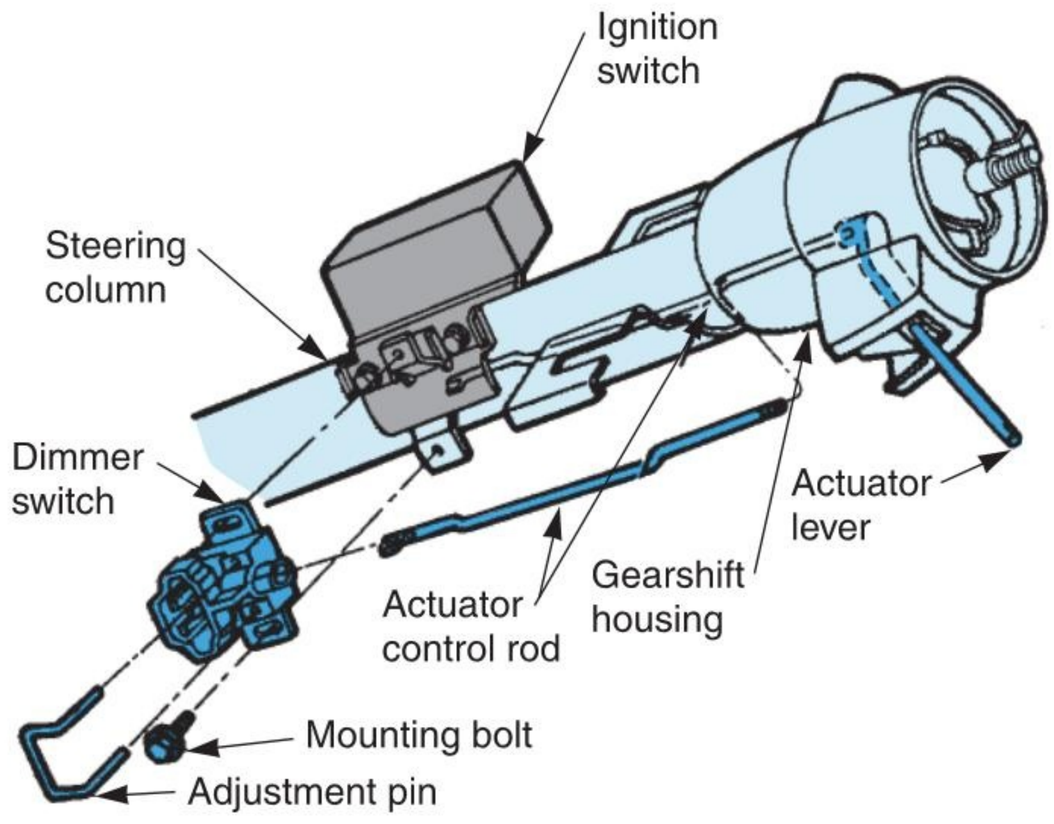
When the driver activates the dimmer switch, the electrical connection to the headlamps is changed. In one position, the headlamp high beams, or brights, are turned on. In the other position, the dimmer switch changes to low beam filaments for driving in traffic.

Automatic Headlamp Systems

An ***automatic headlight dimmer system*** uses a light sensor, amplifier, and relay to control the high and low beams. The system automatically dims the lights when detecting light from oncoming traffic. It switches to high beams when no oncoming light is detected.

The light sensor, or photosensor, may be mounted in the grille area or on the dash. The sensor produces a small amount of electric current when exposed to light. The amplifier uses this current to operate a dimmer relay. The relay changes the electrical connection from high beam to low beam automatically to keep the bright lights from blinding the occupants of oncoming vehicles.

Other variations of automatic control of the lighting system are available. Some turn the headlamps on when dark. Others (***auto-off headlamp system*** or delayed exit system) automatically turn the headlamps off after a short delay period. By remaining lit, the headlamps increase visibility and security when walking away from the vehicle.



Chrysler

Figure 36-8. The dimmer switch is mounted on the steering column in late-model vehicles.

Daylight Running Lights

With ***daylight running lights*** (DRL), the headlamps are lit anytime the engine is running. This is a safety feature that makes the vehicle more visible. **Figure 36-9** shows a lighting system circuit diagram that includes DRL.

Turn Signal, Emergency, and Brake Light Systems

The turn signal, emergency, and brake light systems are normally considered separate circuits. However, they commonly use some of the same wiring, electrical connections, and lightbulbs. This is illustrated in **Figure 36-10**.

The lights in these systems are small incandescent bulbs. They can contain either one or two filaments. **Figure 36-11** shows two common types of bulbs for turn, emergency, stop, and backup lights.

Flashers

A ***flasher*** is used to operate the turn signals and emergency flasher lights on a vehicle. It is the component that makes and breaks the circuit to make the lightbulbs flash on and off. Usually, one flasher is used for the turn signals and another is used for the emergency flasher lights.

Flashers are similar to circuit breakers, but are designed to open and close the circuit at a constant rate. Flashers use a bimetal strip and a small heating element. Current flows through the heating element, warming and warping the bimetal strip. This turns off the lights. Then the strip cools and reconnects the circuit to flash the lights back on. This cycle is repeated to operate the turn signals or emergency flasher lights. A clicking sound can be heard from a flasher as its contact points open and close. See **Figure 36-12**.

Goodheart-Willcox Publisher

Figure 36-10. Study the basic circuit for turn signals and marker lights.

Flashers can be located on the fuse panel or wired in-line somewhere under the dash. Service manual diagrams show flasher locations.

Turn Signal System

The ***turn signal system*** consists of a fuse, turn signal switch, flasher unit, turn signal bulbs, indicator bulbs, and related wiring. When the steering column-mounted switch is activated, it causes the right or left side turn lamps to flash. Turn indicator lights in the instrument panel or on the fenders also flash.

The turn signal switch may be mounted in the center of the steering column, behind the steering wheel. A multifunction switch can also be used to control turn lights, horn, and dimmer switch. Look at **Figure 36-13**.

The turn signal flasher automatically opens and closes the turn signal circuit, causing the bulbs to flash. A bimetal strip is connected to a set of contact points and to the fuse panel. When current flows through the turn signal flasher, the bimetal strip is heated and

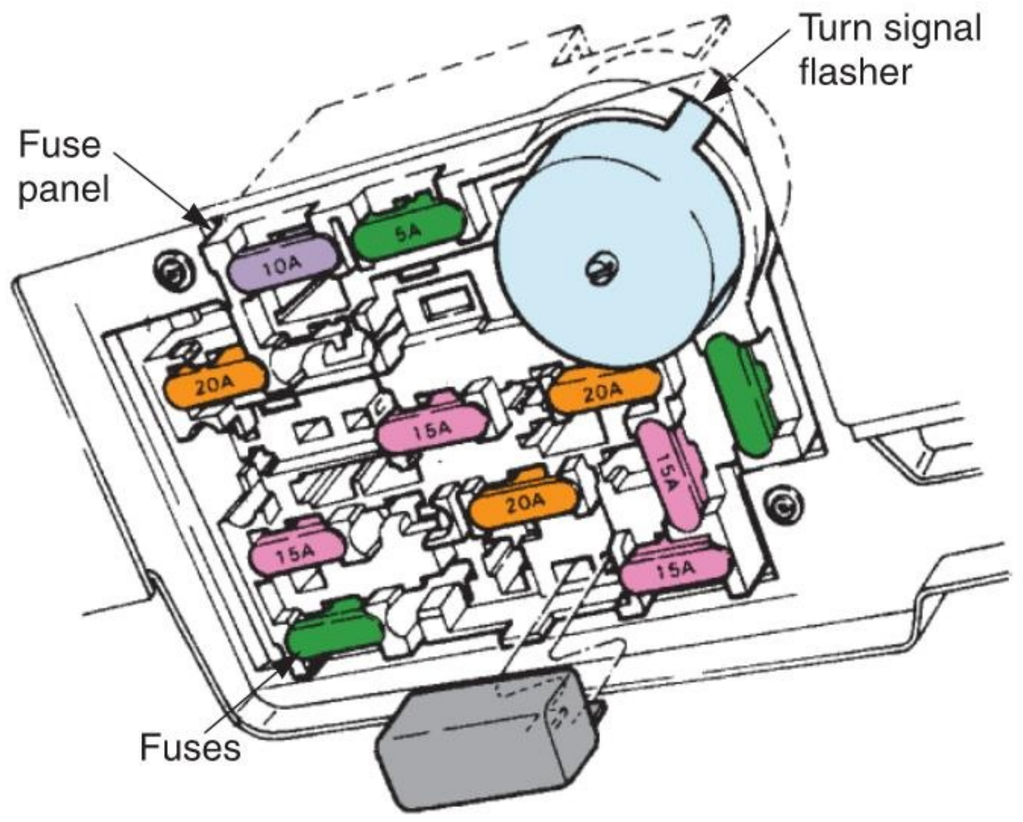
Chrysler and Ford

Figure 36-13. The turn signal switch can be mounted around the steering shaft or on the side of the steering column.

bends. This opens the contact points and breaks the circuit. As the bimetal strip rapidly cools, it closes the points and again completes the circuit. This heating and cooling cycle takes place in about a second. The turn lights flash as the points open and close.

The turn signal flasher is frequently mounted on the fuse panel, **Figure 36-14**. However, it may be



Ford

Figure 36-14. The turn signal flasher is often located on the fuse panel or under the dash.

located somewhere else, such as under the dash. A shop manual will give the flasher location.

Tech Tip

A turn signal flasher is designed to operate with a specific current draw. Altering the load (adding trailer lights, for instance), can affect the operation of the flasher. Generally, if you increase current draw through the circuit, the flasher will blink more quickly. If you decrease current draw (one bulb burns out), it will slow or even stop the blinking action of the flasher.

Emergency Light System

The ***emergency light system***, also termed hazard warning system, consists of a switch, a flasher unit, turn signal lamps, and related wiring. The emergency light switch is normally mounted on the dashboard or the steering column. It is either a push-button switch or a push-pull switch.

When the switch is closed, current flows through the emergency flasher. Like a turn signal flasher, the emergency flasher opens and closes the circuit to the lights, causing the turn signals to flash. Oncoming traffic is warned of a possible emergency or hazard.

Brake Light System

The ***brake light system*** is commonly made up of a fuse, brake light switch, rear lamps, and related wiring.

Copyright Goodheart-Willcox Co., Inc.

The brake light switch is normally mounted on the brake pedal, as in **Figure 36-15**. Battery power is fed to the brake light switch from the ignition switch. When the brake pedal is pressed, it closes the switch, and current flows through the wiring to the brake lights. This turns on the rear brake lights to warn traffic of the stop.

The brake light switch can also be located on the master cylinder. In these switches, hydraulic pressure from the brake system closes the switch to turn on the brake lights.

Backup Light System

A backup light system typically has a fuse, gear shift- or transmission-mounted switch, two backup lamps, and wiring to connect these components.

The backup lamp switch closes the light circuit when the transmission is shifted into reverse. This illuminates the area behind the car. See **Figure 36-16**.

Illuminated Entry System

The ***illuminated entry system*** turns on the interior lights when you move the door handle or open the door. It allows you to see the key cylinders and the interior of the passenger compartment at night. Illuminated entry systems vary from simple to complex. Look at **Figure 36-17**.

A simple illuminated entry system uses door-jam switches to turn on the interior lights. When a door is opened, it closes that switch to energize the lights.

More complex illuminated entry systems use an electronic control module, various switches, and several interior lights. Both door switches and a driver's door handle switch energize the system. When one of the switches is closed, it signals the ECM. The ECM can then turn on the lights and time when they go off. Note that this circuit also illuminates the key cylinders and footwell in the passenger compartment.

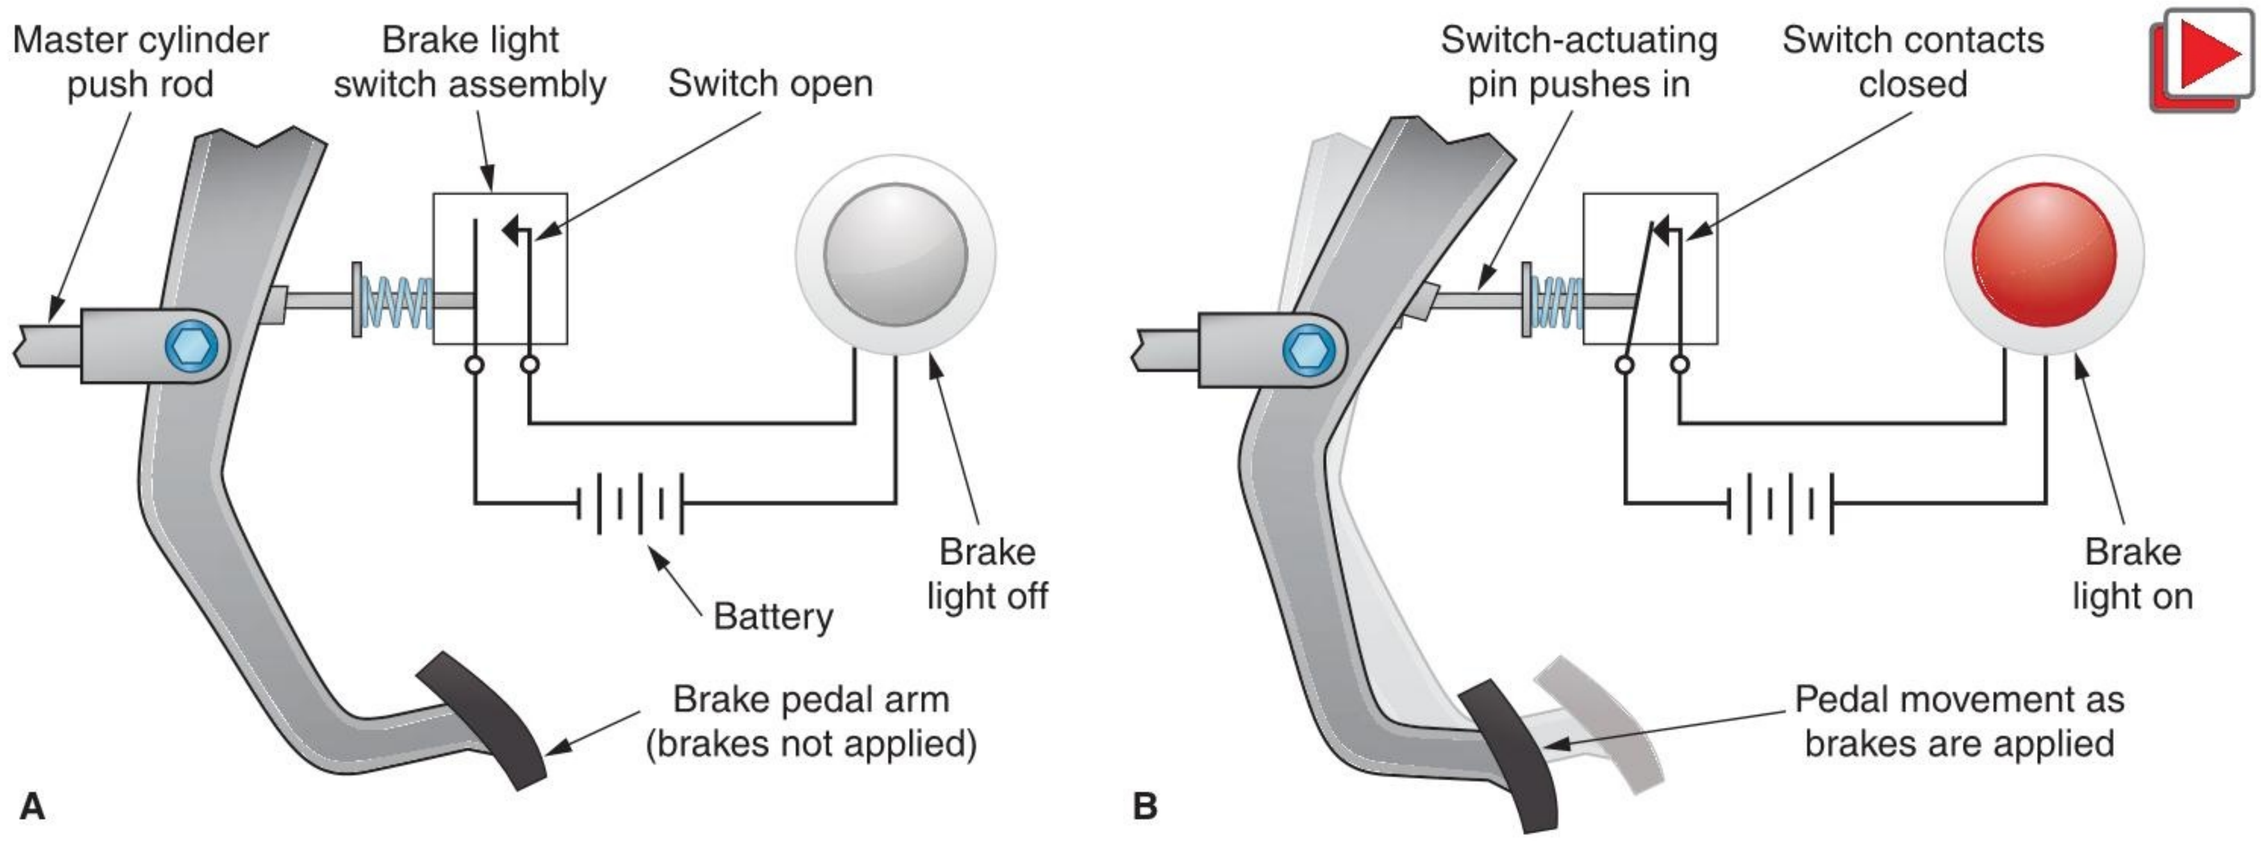
Light-Monitoring Systems

A ***light-monitoring system*** turns on a warning light in the instrument panel when a headlight, brake light, or other light burns out. This is a safety feature to help ensure that all the vehicle's lights are working properly.

In most systems, a control module monitors the amount of current flowing through each of the lighting circuits. If a bulb burns out, less current will flow through the related circuit. The control module detects this change in current flow and illuminates the warning light, alerting the vehicle's driver to the problem.

Light System Service

Light system service involves changing burned-out bulbs, testing bulb sockets, checking fuses, finding shorted and open circuits, aiming headlights, and similar tasks. This section of the chapter will summarize the most important types of electrical tests and repairs performed on a car's lighting system.



Goodheart-Willcox Publisher

Lexus

Figure 36-17. This illuminated entry system uses several switches (left) to signal the ECM (center), which operates the lights (right). When you pull up on the driver's door handle, it energizes the system. The lights fade in about ten seconds if no other switch is closed.

Lamp Replacement

A burned-out bulb has the filament melted in half. Sealed-beam headlamps are usually held in place with small screws and a retaining ring. Halogen insert bulbs normally fit into the rear of the bulb housing. You must push and twist to install some headlamp bulb inserts. Sometimes a small ring screws over and secures the halogen insert. Spring clips can secure halogen fog lamp bulbs.

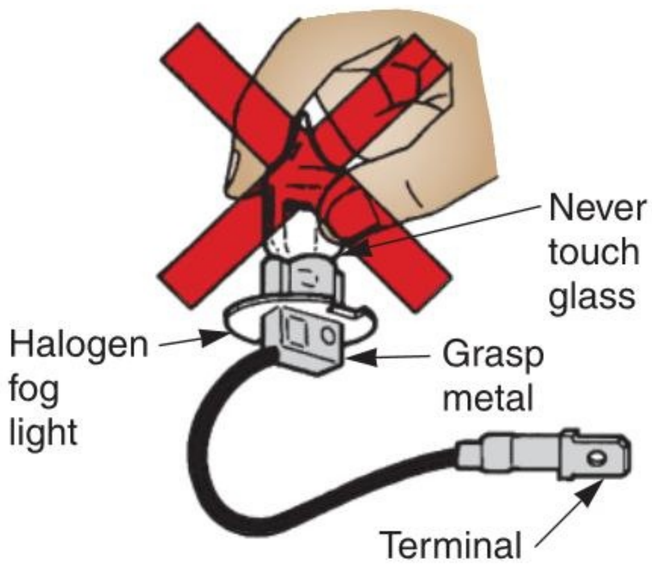
Copyright Goodheart-Willcox Co., Inc.

Most incandescent bulbs are housed in a lens. They are normally held in the socket by a spring and small dowels or a press fit. You may have to remove the lens or reach behind the housing to access the bulb. This is illustrated in **Figure 36-18**.

Always make sure you have the correct replacement bulb.

Caution

Never touch the glass surface of a halogen or high-intensity discharge bulb. The oil from your skin and the high operating temperature can make the glass shatter or shorten the bulb's service life. See **Figure 36-19**.



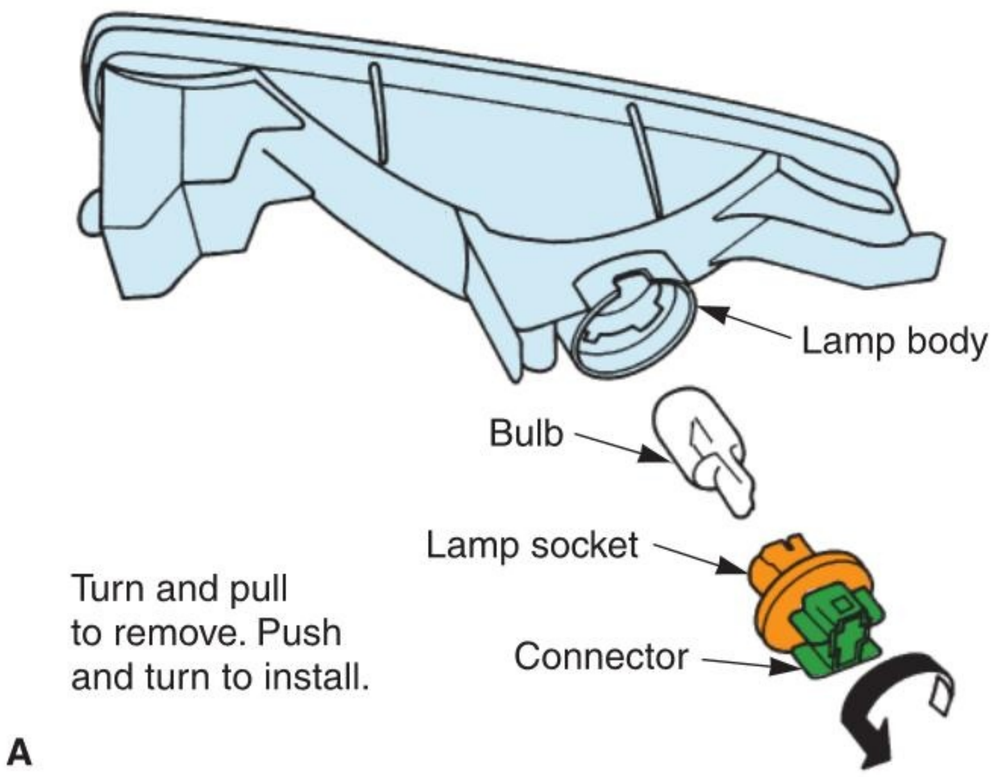
Mazda

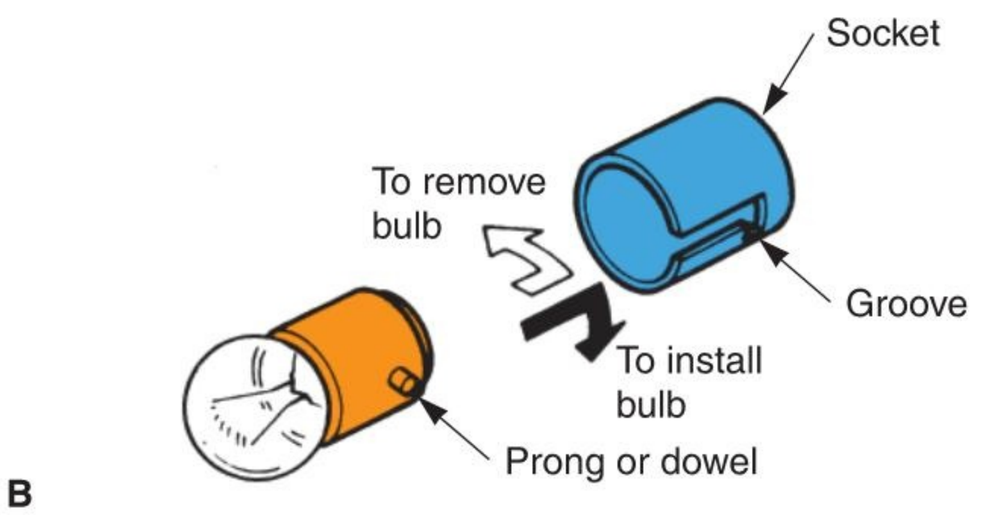
Figure 36-19. Never touch the glass on a high-intensity halogen headlamp or fog lamp bulb. Oil from your skin can make the glass shatter and ruin the new bulb.

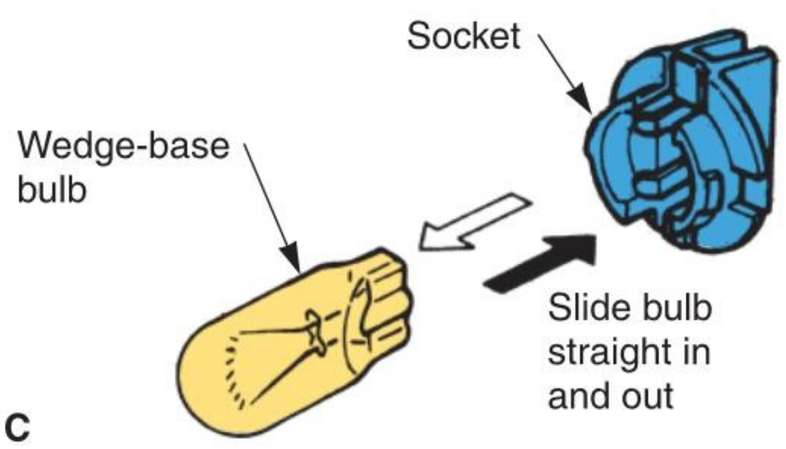
No-Light Problems

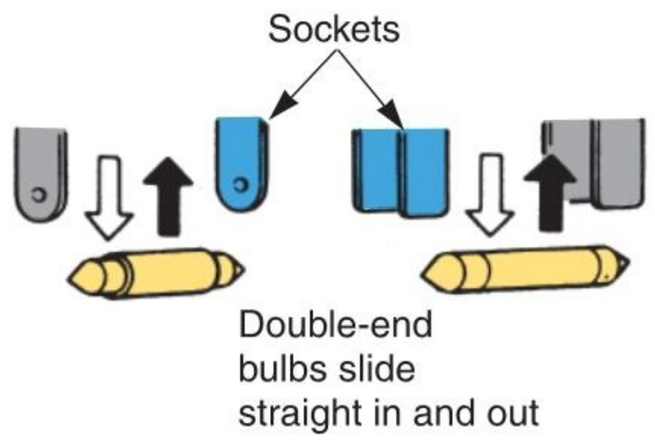
A no-light problem is a total failure of the light circuit or bulb. First, check to see if the bulb is burned out. Close inspection of the filament will show whether it has burned. If the bulb is good, check for power to the bulb socket.

Figure 36-20 shows how to check for voltage in a bulb socket. With the light turned on, there is a socket or circuit problem if the test light does not glow. If you









Honda and Nissan

Figure 36-20. If the new bulb does not work, check for voltage to the socket with a test light. You may need to clean rust and corrosion out of the socket.

do not have power to the socket, trace back through the circuit to find the open preventing current flow.

Flickering Light Problems

Flickering lights (lights go on and off) point to a loose electrical connection or a circuit breaker that is kicking out because of a short.

If all or several of the lights flicker, the problem is in a section of the circuit common to those lights. Check to see if the lights flicker only with the light switch in one position. For example, if the lights flicker only when the headlights are on high beam, you should check the components and wiring in the high beam section of the circuit.

If only one light flickers, the problem is in that section of the circuit. Check the bulb socket for corrosion. Clean the socket. Also, make sure the bulb terminals are not worn. Worn bulb terminals can upset the electrical connection. If needed, replace the bulb socket and bulb.

Light Switch Problems

Light switch problems occur when a switch shorts closed or becomes open all the time. If shorted closed, the lights will always glow. If always open, the lights will not come on.

Figure 36-21 shows several types of switches used to operate lights and instrumentation systems.

To test a switch, use a test light or voltmeter to check for power going to and from the switch in the closed, or on, position. You can also disconnect the switch and test it with an ohmmeter, **Figure 36-22**.

Turn Signal Problems

If the turn signals do not flash, check for a burned-out bulb. Even one burned bulb will reduce current and prevent the flasher unit from functioning. A burned-out bulb is the most common cause of turn signal problems.

If both right and left turn signals do not work, check the fuse and flasher unit. The problem may also be in the turn signal, or multifunction, switch. This switch is prone to wear and failure after prolonged service. Something common to both sides of the circuit may be at fault if no bulb is coming on.

The basic steps for removing a multifunction switch are demonstrated in **Figure 36-23**.

Brake Light Problem

If none of the brake lights are working, something common to all the bulbs is at fault, such as the brake light switch or feed circuit. If only one bulb is not working, check the bulb and its section of the circuit.

Other Light Circuit Problems

With other light circuit problems, you may want to refer to the wiring diagram for the specific make and model of vehicle. It will give wire color codes, connector locations, and other useful troubleshooting information.

Aiming Headlights

Aiming headlights involves adjusting the beams so they are directed to light the area in front of the vehicle. Headlights can be aimed using headlight aimers, a wall screen, or leveling bubbles on the headlight housings. These methods ensure that the headlight beams point in the direction specified by the vehicle manufacturer.

Headlights aimed too high could blind occupants in oncoming vehicles. Headlights aimed too low or to one side could reduce visibility for the driver.

Before attempting to aim a vehicle's headlights, make sure the vehicle has about a half tank of gas and the correct tire inflation pressure. Remove extra cargo that could lower rear curb height and upset your headlamp adjustments. Only the spare tire and jack

should be in the trunk. Some manufacturers recommend that someone sit in the driver and passenger seats while the lights are being aimed.

Headlight aimers are devices for pointing the car's headlamps in a specified position. To use aimers, follow the instructions for the specific type of equipment. Some require a level floor. Others have internal leveling mechanisms to allow for an uneven shop floor. A headlight aiming screen is a series of measured lines marked on a shop wall for aiming a car's headlamps. One is shown in **Figure 36-24**. Note that lines are drawn on the wall at specific horizontal and vertical locations depending upon vehicle dimensions.

The car is normally located 25″ (7.6 meters) from the screen on a level floor. When the headlights are turned on, the highest points of light intensity (brightness) should align with the marks on the wall or screen. Aiming the low beams also aims the high beams. Refer to a service manual for added details.

Headlight adjusting screws are provided to alter the direction of the headlamp beams. One screw provides vertical adjustment. Another screw provides horizontal adjustment. Turn the screws until the aimer or screen shows correct beam alignment. See **Figure 36-25**.

Headlight leveling bubbles are built into many late-model headlight assemblies to simplify headlight aiming, **Figure 36-26**. You simply adjust the housing screws until the leveling bubble is centered in its indicator.

Honda

Figure 36-22. Switches, because of their moving parts, are a common source of trouble. They can short closed or become broken and remain opened. A—To test a switch, remove the wiring connector. This is a door switch that must be squeezed lightly for removal from the door pillar. B—Connect an ohmmeter across the switch terminals. Activate the switch and the meter reading should go from almost zero to infinity.

Figure 36-23. To service a bad multifunction switch, follow these basic steps and detailed instructions in service manual. A—Remove electrical connections or test the switch using service manual diagrams and instructions. B—If bad, replace the multifunction switch. The switch shown can be replaced without steering wheel removal. Others may require steering wheel removal.

Dash Instrumentation

Instrumentation is used to inform the driver of various operating conditions—oil pressure, engine temperature, computer trouble codes, air bag system status, etc. Today's vehicles use a wide range of instruments, some simple and others complex. It is important that you understand the basics of instrumentation because it must be serviced in the field when problems develop.

Analog instruments use rotating needles or dials to indicate operating conditions. See **Figure 36-27A**. An analog speedometer, for example, uses a large needle that rotates around to show vehicle speed. An analog tachometer gives the same type of display for engine speed.

Digital instruments use various lights and electronic displays to show operating conditions. They do not have the mechanical parts, as with analog instruments. Digital displays are more complex than analog displays because an electronic control module is needed to act as an interface between the sensor

Copyright Goodheart-Willcox Co., Inc.

and the digital readout panel. Digital instruments can use vacuum fluorescent or liquid crystal displays. Look at **Figure 36-27B**.

Vacuum fluorescent displays are small glass tubes filled with neon or argon gas. They glow when electrically energized, making them very visible and easy to read.

Liquid crystal displays (LCDs) are semiconductor panels that pass light when electrically energized and block light when not energized. An LCD display is often backlighted to make it easier to read.

Instrument Cluster

The instrument panel is the general area of the dash behind the steering wheel that holds most displays. It is usually a removable assembly that includes the dash pad and the plastic covers over the front of the instrument cluster. The ***instrument cluster*** is the housing and clear plastic cover that holds the gauges, indicator lights, speedometer head, and bulbs.

To service an instrument cluster, remove the small screws around the outside of instrument panel. Often, you must remove a cover before accessing the screws that hold the instrument cluster in place. See **Figure 36-28A**.

Before completely removing the instrument cluster, disconnect the wires and speedometer cable (if used). If you try to force the cluster out without disconnecting everything on the rear of the housing, the wiring and cluster could be damaged. Look at **Figure 36-28B**.

With the cluster out, it is easy to replace burned-out bulbs and inoperative gauges. Refer to **Figure 36-29**.

To replace gauges, you must open up the instrument cluster. Small screws hold the front lens to the housing. Remove these screws and remove the lens. The gauges may also be held in place by small screws through the rear of the cluster, **Figure 36-30**.

Tech Tip

The instrument cluster warning lights should glow when the ignition key is turned to the *On* position and go out when the engine is started. If a light does not glow, the bulb may be burned out or there may be a problem in the warning light circuit. If a light remains on after the engine is started, there is a problem in the corresponding system.

Dash Gauges

There are basically two types of gauges—balancing coil gauges and bimetal gauges. Both are commonly used. The two types are illustrated in **Figure 36-31**.

A ***balancing coil gauge***, **Figure 36-31A**, uses two electric coils to cause needle deflection. The sending unit changes the current flow through the coils to deflect the gauge needle right or left using the magnetic field generated by each coil.

A ***bimetal gauge***, **Figure 36-31B**, uses two dissimilar metals bonded together to cause gauge needle deflection. Generally, as current flow from the sending

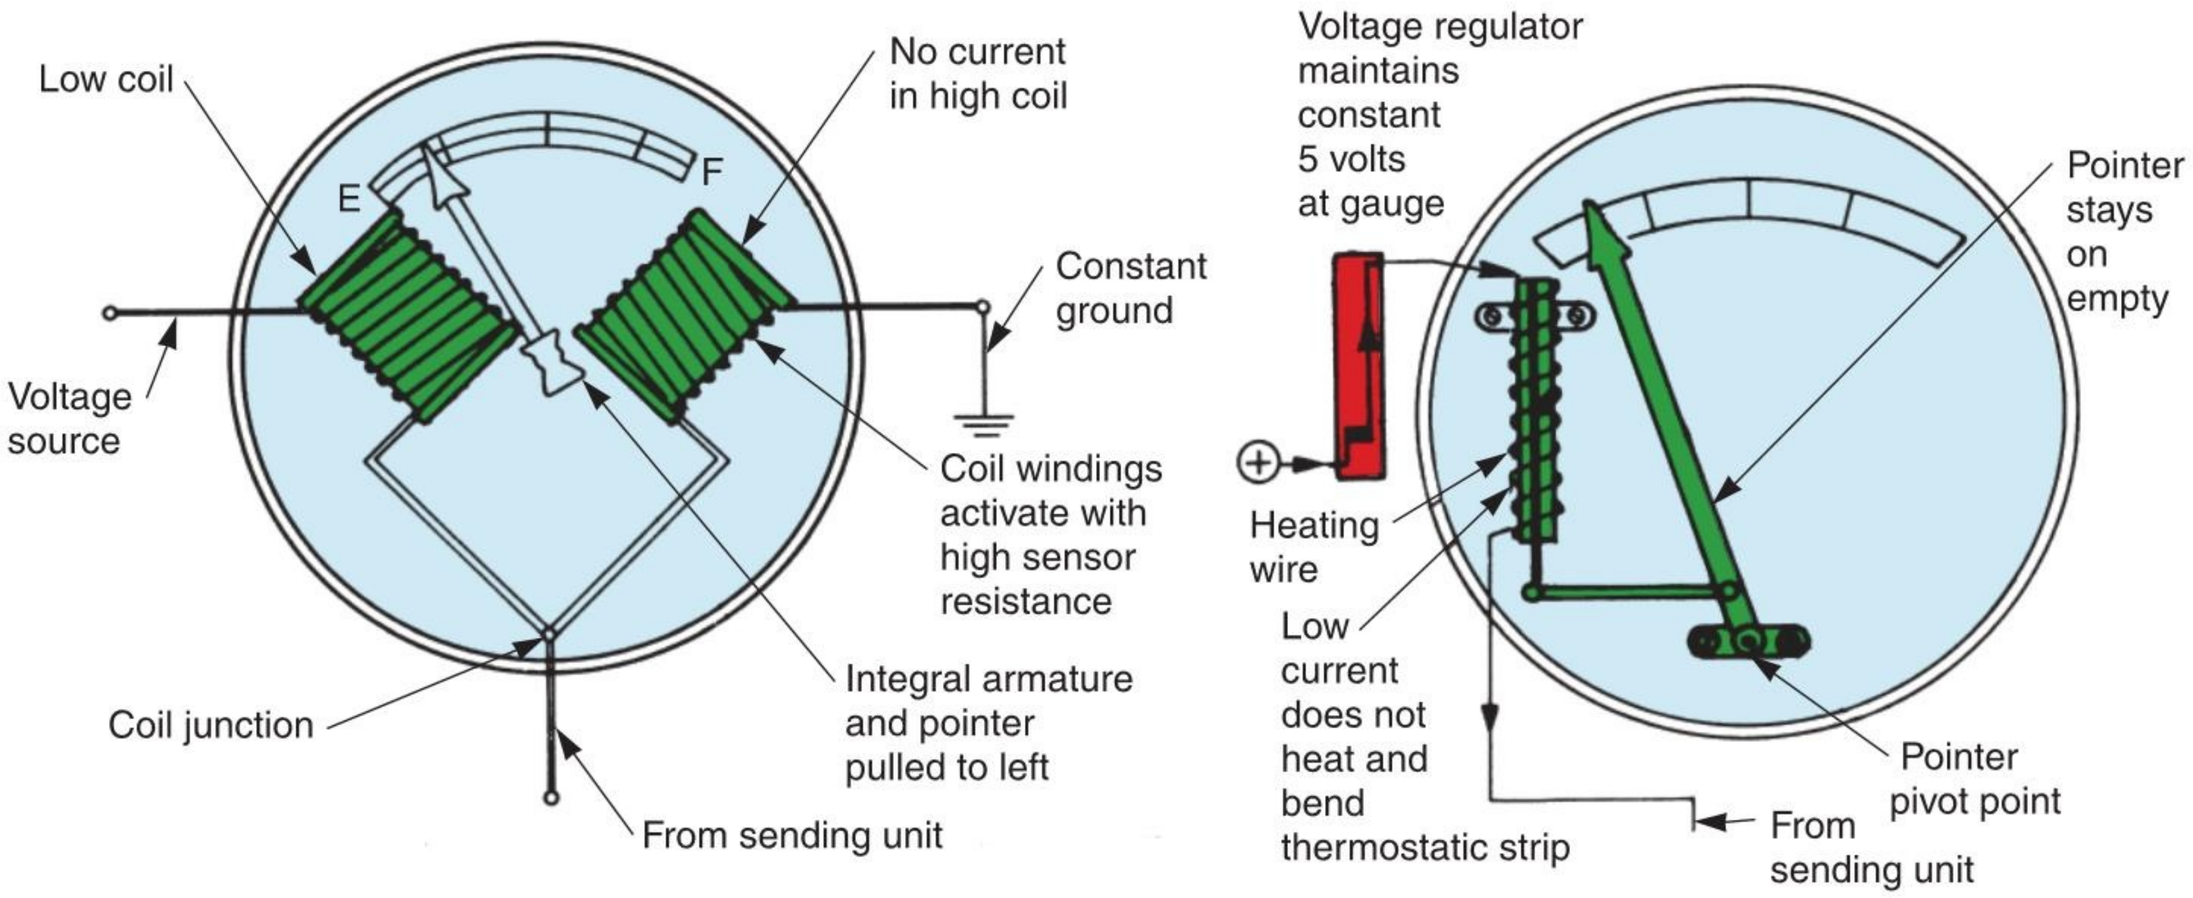
unit increases, the bimetal strip heats and deflects more. Less current flow causes less bimetal arm bending and less needle deflection.

Sending units are used to control current flow to gauges. Many sending units are simply variable resistors. For example, with an oil pressure gauge, the sending unit is mounted on the engine to sense oil pressure. If oil pressure is low, the sending unit's resistance may be high to limit current flow to the oil pressure gauge. The gauge does not deflect to the right and the driver knows there is low oil pressure. This same principle also applies to other gauges.

If a gauge is not working, check the sending unit first. The sending unit may not be working and may be preventing gauge operation. Special testers are available for checking the sending unit current going to the

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 36-31. Compare the two types of gauges. Note the gauge voltage regulator in the circuit on the right. It maintains constant supply voltage to the gauge so it reads accurately. A—A coil gauge uses two coil windings to magnetically attract the indicating needle. With high current flow through the sending unit (low sending unit resistance), the left coil produces a stronger magnetic field, which moves the needle to the left. With low current through the sending unit (high sending unit resistance), more current flows through the coil on the right and the needle moves to the right. B—A bimetal gauge uses a thermostatic strip to move the indicator needle. With low current flow through the sending unit, the strip stays cool and does not bend, so the needle stays to the left. With higher current flow through the sending unit (low sending unit resistance), high current heats the bimetal strip and bends it. This bending action acts on the indicator needle to move it to the right.

gauge. For example, the sending unit wire may need to be grounded. This should make the gauge deflect completely to the right or left. If not, something other than the sending unit is at fault (wiring, fuse, gauge, connector).

Caution

Do not ground a sending unit wire unless told to do so in a service manual. Some digital display circuits can be damaged by grounding the sending unit wire.

Speedometers

There are two basic types of speedometers—mechanical and electronic. The electronic speedometer is becoming more common on late-model vehicles. **Figure 36-32** compares simplified mechanical and electronic speedometers.

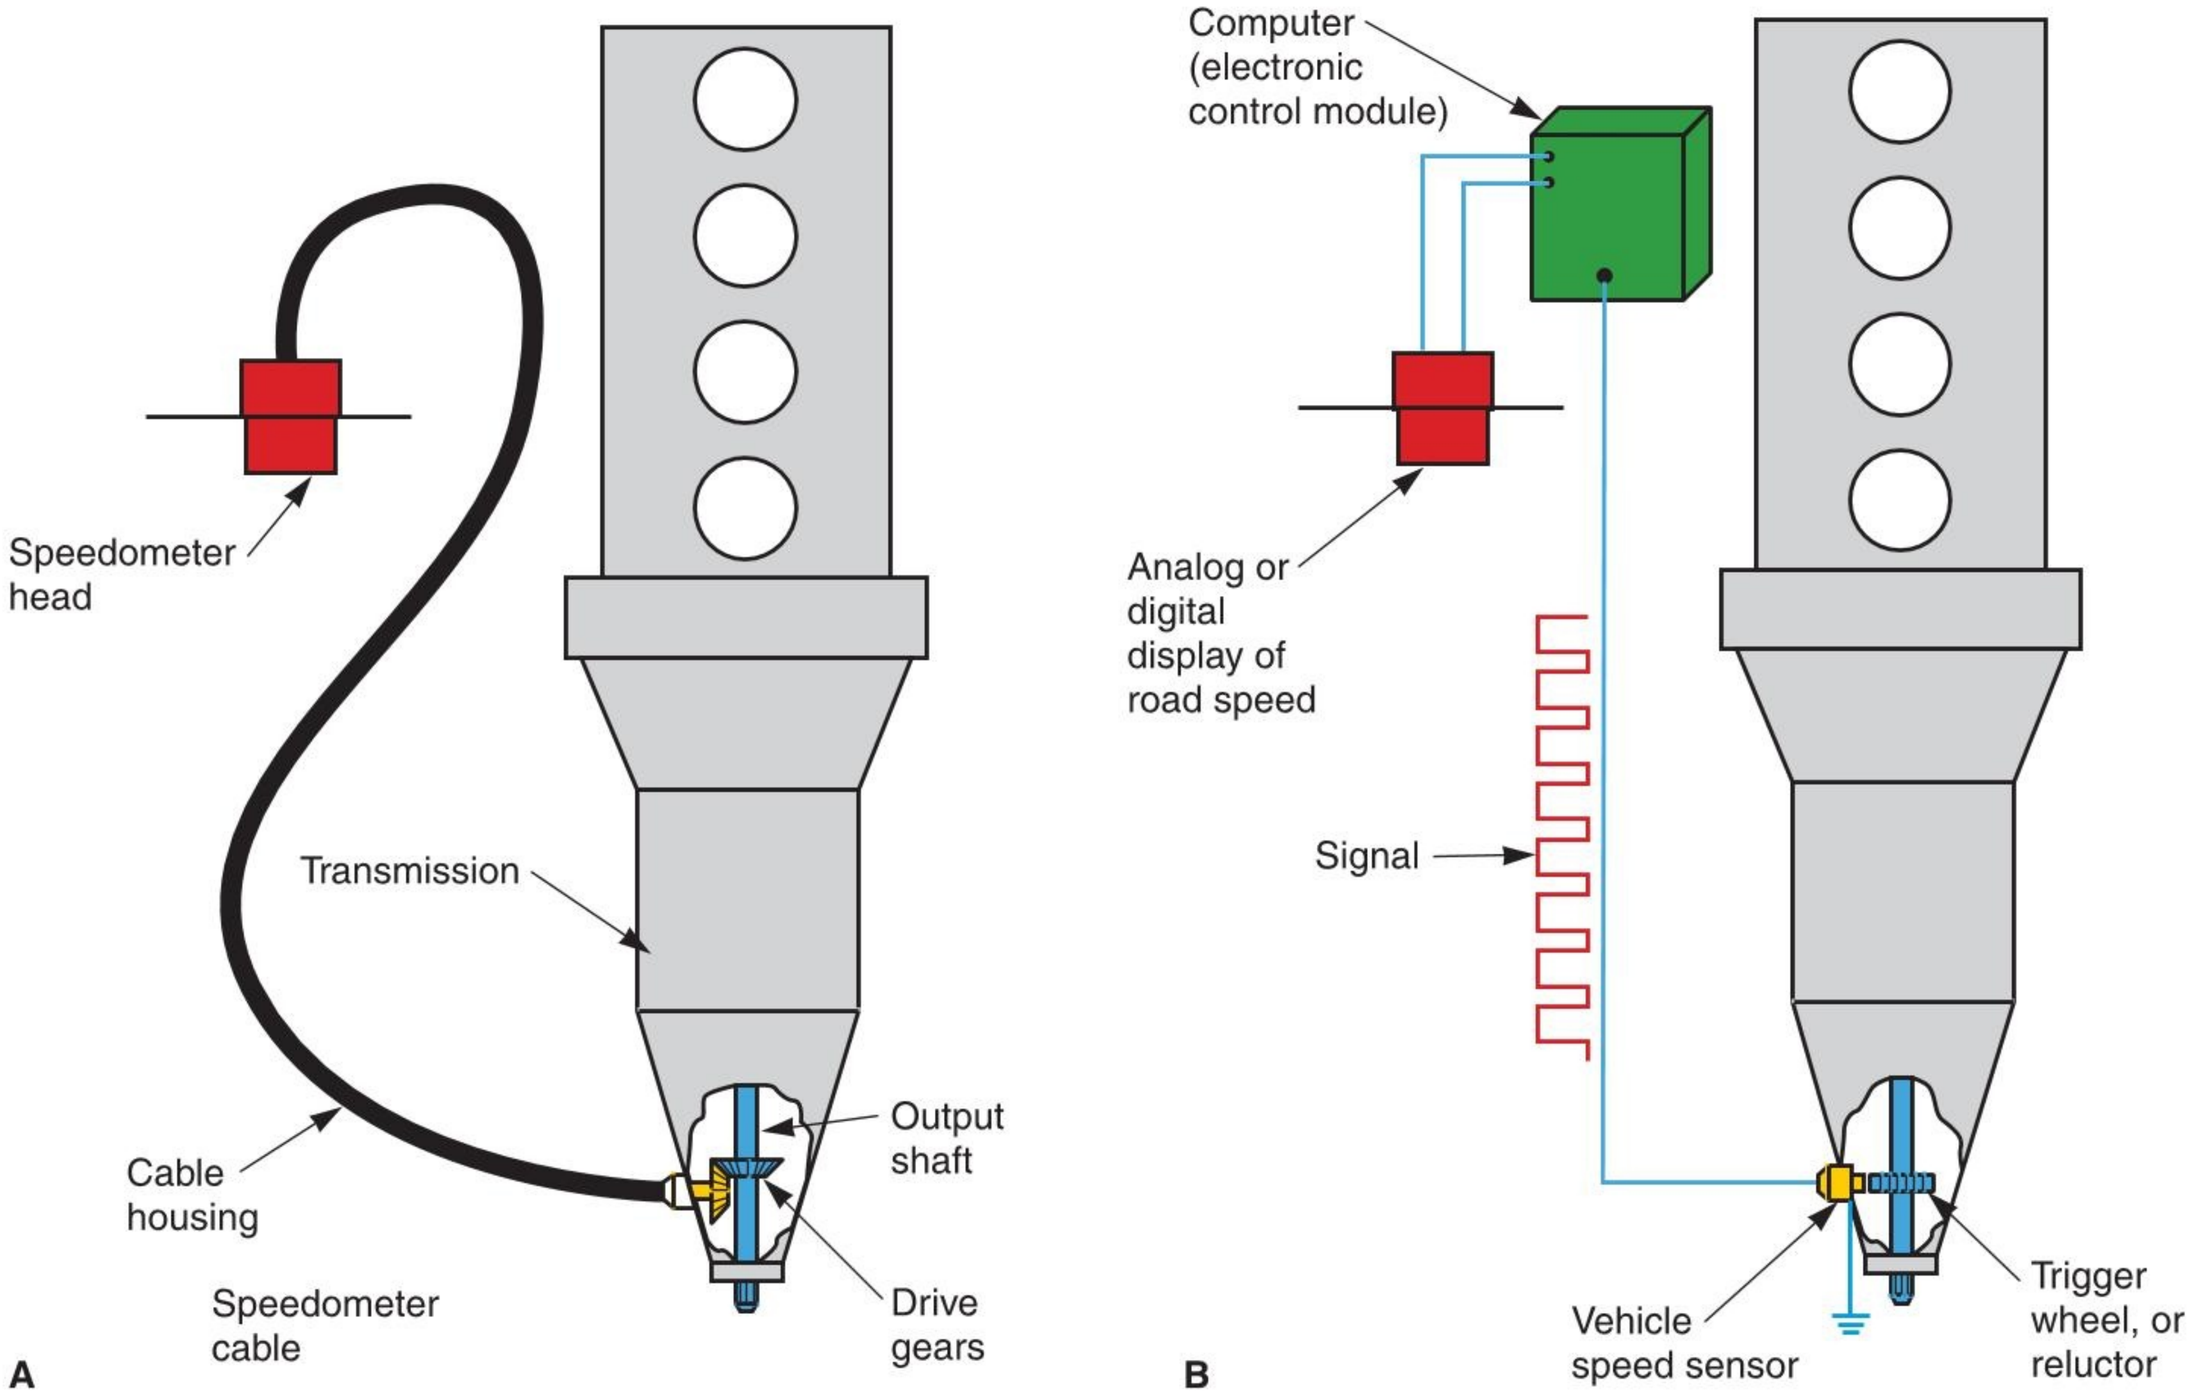
Mechanical Speedometers

Older vehicles are equipped with a ***mechanical speedometer*** that uses plastic transmission/transaxle drive gears, a metal speedometer cable, a cable housing, and a mechanical speedometer head. When the vehicle is moving, a drive gear on the transmission or transaxle output shaft turns a speedometer cable gear. This gear spins the metal speedometer cable in its housing. This rotating motion is transferred up to the dash to the speedometer head. Depending on rotating speed, the needle on the speedometer head is deflected to the right to indicate vehicle speed.

A dry speedometer cable will stick in its housing and cause the indicator needle to jump back and forth. The speedometer cable can also break, preventing speedometer operation. These are common problems with high-mileage vehicles.

To service a mechanical speedometer cable, disconnect the cable housing at the instrument cluster. You must normally depress a plastic latch that holds the cable housing to the cluster. Then, you can slide the speedometer cable out of the rear of the cluster.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 36-32. Compare mechanical and electronic speedometers. A—A mechanical speedometer is driven by small gears inside the transmission or transaxle. A gear on the output shaft spins another gear on the end of the speedometer cable. The cable spins inside the housing to transfer motion to the speedometer head to deflect the needle. B—An electronic speedometer commonly uses a vehicle speed sensor on the side of the transmission or transaxle. A trigger wheel or reluctor on the transmission output shaft sends a frequency signal into a sensor. The sensor signal is then used by the electronic control module to power the speedometer display.

To remove the speedometer cable, grasp and slide it out of its housing using a pair of pliers. If it is dry, wipe grease on the cable and slide it back into its housing. If it is broken, disconnect the cable housing at the transmission. You may need to use needle nose pliers to remove the small broken end from the transmission. Install a new speedometer cable of the original length.

If the speedometer needle does not return to zero when the vehicle is stopped, the speedometer head is usually bad. It should be replaced.

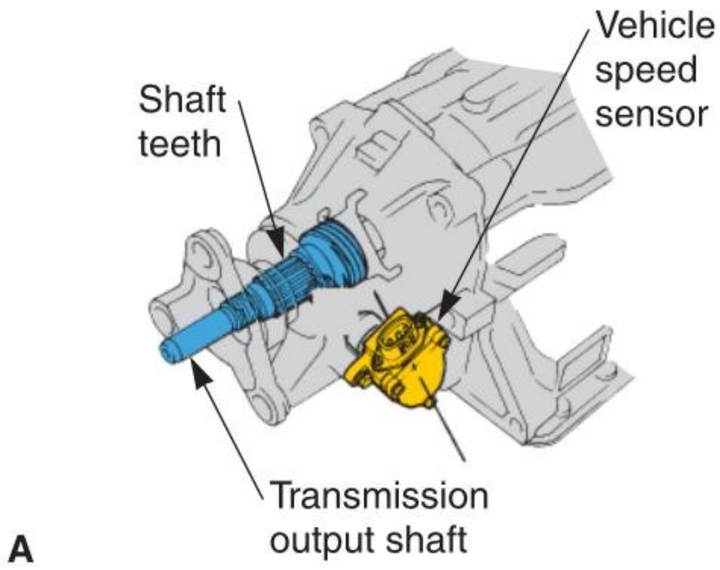
Electronic Speedometers

A modern ***electronic speedometer*** uses the vehicle speed sensor, an electronic control module, and an electronic or electric speedometer head or display. The vehicle speed sensor on the transmission or transaxle sends a signal representing road speed to the control module. The module can then produce an output signal to drive the digital display or servo motor in the speedometer head.

Electronic speedometers are now more common than mechanical speedometers. They are more dependable and consume less energy. Instead of spinning a heavy steel cable, the speed sensor electrical signal is used to drive the electronic speedometer more efficiently. Look at **Figure 36-33**.

Many electronic speedometers will only read up to a certain speed (85 mph or 145 km/h). Even though the vehicle can be driven faster, the ECM will not display a higher speed. This is normal on most vehicles.

Copyright Goodheart-Willcox Co., Inc.



Lexus

Figure 36-33. Study the parts of an electronic speedometer-odometer system. A—The speed sensor is mounted on the side of the automatic transmission. It feeds signals to the ECM. Note the teeth on the output shaft. B—A pulse motor is used to drive a mechanical odometer, which shows vehicle mileage. The pulse motor is also driven by the ECM.

Tech Tip

When servicing an electronic speedometer, never change the odometer (mileage) reading. You must often reuse the old ***odometer chip*** (miniaturized circuit that stores mileage of the vehicle). If it is not reprogrammable, the chip must be removed from the old cluster and installed in the new one. For more information on odometer chip replacement and reprogramming, refer to the text index.

If an electronic speedometer fails to work properly, first check for stored trouble codes. Then, check for a good signal from the vehicle speed sensor. If the signal is reaching the ECM, check for a control signal going to the digital display. If only part of the display is working, you probably have a bad segment (part of display number or letter), and the display should be replaced.

Driver Information Center

The driver information center is a dash-mounted keyboard-display for inputting and reading data about the vehicle. It allows you to send data to the instrumentation computer to find miles-to-empty, average fuel consumption, estimated time of arrival, and other information. The information center uses signals from many sensors to calculate this information. **Figure 36-34** shows how a digital display operates for several types of vehicle conditions.

Driver information centers are very complex and vary with make and model. Always refer to the service manual for testing and repair directions.

Digital Instrument Clusters

A digital instrument cluster does not use analog or needle gauges; it uses computer-driven numbers or graphic displays. The trend is to use digital displays in new cars. They are easy to read, lightweight, and dependable.

Instrumentation ECM

The ***instrumentation electronic control module*** reacts to signals from vehicle sensors, dash switches, and other ECMs to operate the digital or digital-analog displays in the dash. Its construction and design is similar to the computers or ECMs discussed in previous chapters.

An instrumentation ECM has integrated circuits and a powerful processor that can handle a large quantity of input data and then rapidly send out control

Goodheart-Willcox Publisher

Figure 36-34. This simplified illustration shows how different types of sensors can be used to indicate different conditions. The ECM converts sensor signals into output signals for displays. A—The engine is cold and sending unit internal resistance is high. The ECM shows a cold temperature readout. B—The engine is warmer and the sending unit resistance drops. The ECM uses a different amount of current flow to show the warmer engine temperature.

signals for the instrument displays and, sometimes, other devices.

A ***multiplex integrated control (MIC) system*** allows several ECMs to communicate with each other by exchanging digital signals over a single wire or conductor. New vehicles have MIC systems that electronically connect or integrate all or most of the ECMs or computers in the vehicle. This allows for more precise control of every computer-controlled system. An MIC allows different ECMs to communicate with each other digitally.

A ***body control area network (B-CAN)*** operates relay modules, such as:

- Entry lights.
- Exterior lights.
- Horns.
- Interlocking system.
- Key-in reminders.
- Keyless entry.
- Power door locks.
- Seat belt reminders.
- Security alarm.
- Turn and hazard signals.
- Wiper-washer system.

A B-CAN communicates at a data rate of about 33 kbps (kilobits per second).

A ***fast control area network (F-CAN)*** is a computer interface used to control the engine, transmission, air bags, and other more critical systems. F-CAN communicates at 500 kbps. To allow both computer data rate systems to communicate, the gauge control module can convert from F-CAN to B-CAN and B-CAN to F-CAN.

Instrumentation Power Supply

An instrumentation power supply can be used to provide a constant voltage for the digital displays, ICs, and other related devices. An instrumentation power supply can provide up to 60 volts of power needed to drive and illuminate the displays.

Copyright Goodheart-Willcox Co., Inc.

Instrumentation Switches

Instrumentation switches trigger the ECM to output another signal. For example, dash switches normally use dropping resistors to send a unique current level back to the ECM. Each switch is fed a constant reference voltage. However, each switch has a different ohms value-dropping resistor. As a result, each switch produces its own voltage output signal for the ECU. The ECU will know which switch has been activated and output a correct response, such as changing a radio station or turning on a blower.

Dash Monitors

A ***monitor***, or display screen, provides graphic information for the driver and passengers. It can give the driver information from the global positioning or mapping system, in-car telephone, climate control system, sound system, and other systems. The monitor is usually mounted in the center of the dash, although it is sometimes placed in the instrument cluster.

A liquid crystal display (LCD) polarizes light into an image when energized by an electrical signal. LCDs can be very thin and light. They consume very little electrical energy and are commonly used in passenger vehicle dashboards.

An LCD is often used as an information screen for voice command, a navigation map, roadside assistance, a stereo, a calendar, and other display functions.

A plasma screen contains a layer of hundreds of thousands of phosphor cells between two panels of glass. The phosphor cells emit visible light (red, green, and blue) when excited. Plasma screens are sometimes used as aftermarket, rear-seat-mounted video displays for DVD players in four-door trucks, SUVs, and vans.

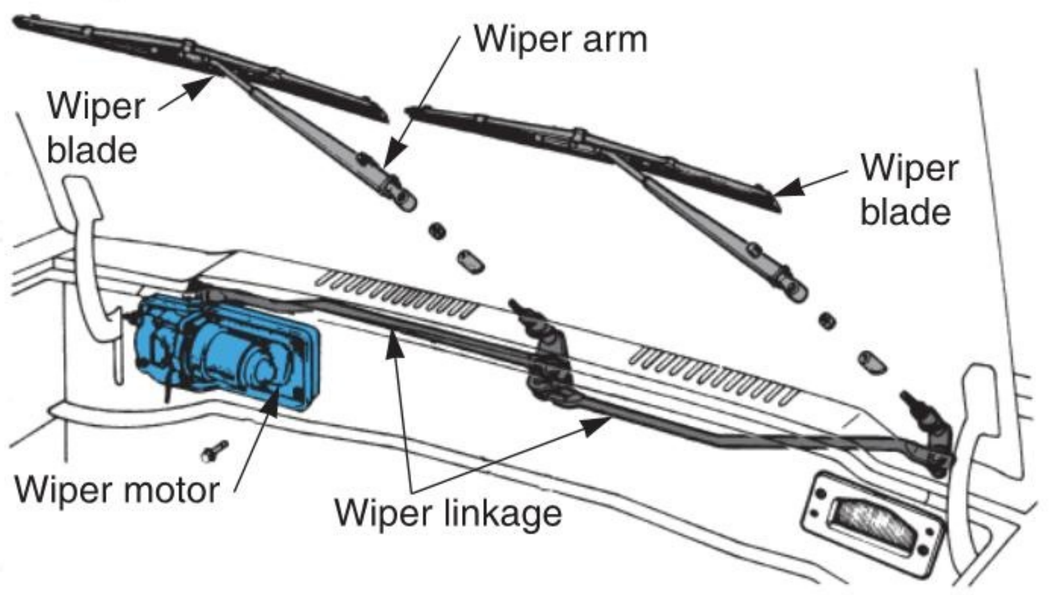
A monitor ECM is used as an interface between the main body ECM and the LCD display. It processes the data from the body computer, other ECMs, and control switches to drive the LCD screen. The monitor controller mounts under the dash. It is similar in construction to other electronic control circuits.

Heads-Up Display

A ***heads-up display (HUD)*** reflects display information onto the windshield or a plastic dash panel for easier viewing. It complements the conventional displays in the instrument cluster. The driver does not have to take his or her eyes off the road to view the HUD, **Figure 36-35**.

Siemens

Figure 36-35. This heads-up display reflects images onto the windshield so readings are easy to see while driving.



Toyota

Figure 36-36. Study the basic parts of a typical windshield wiper system.

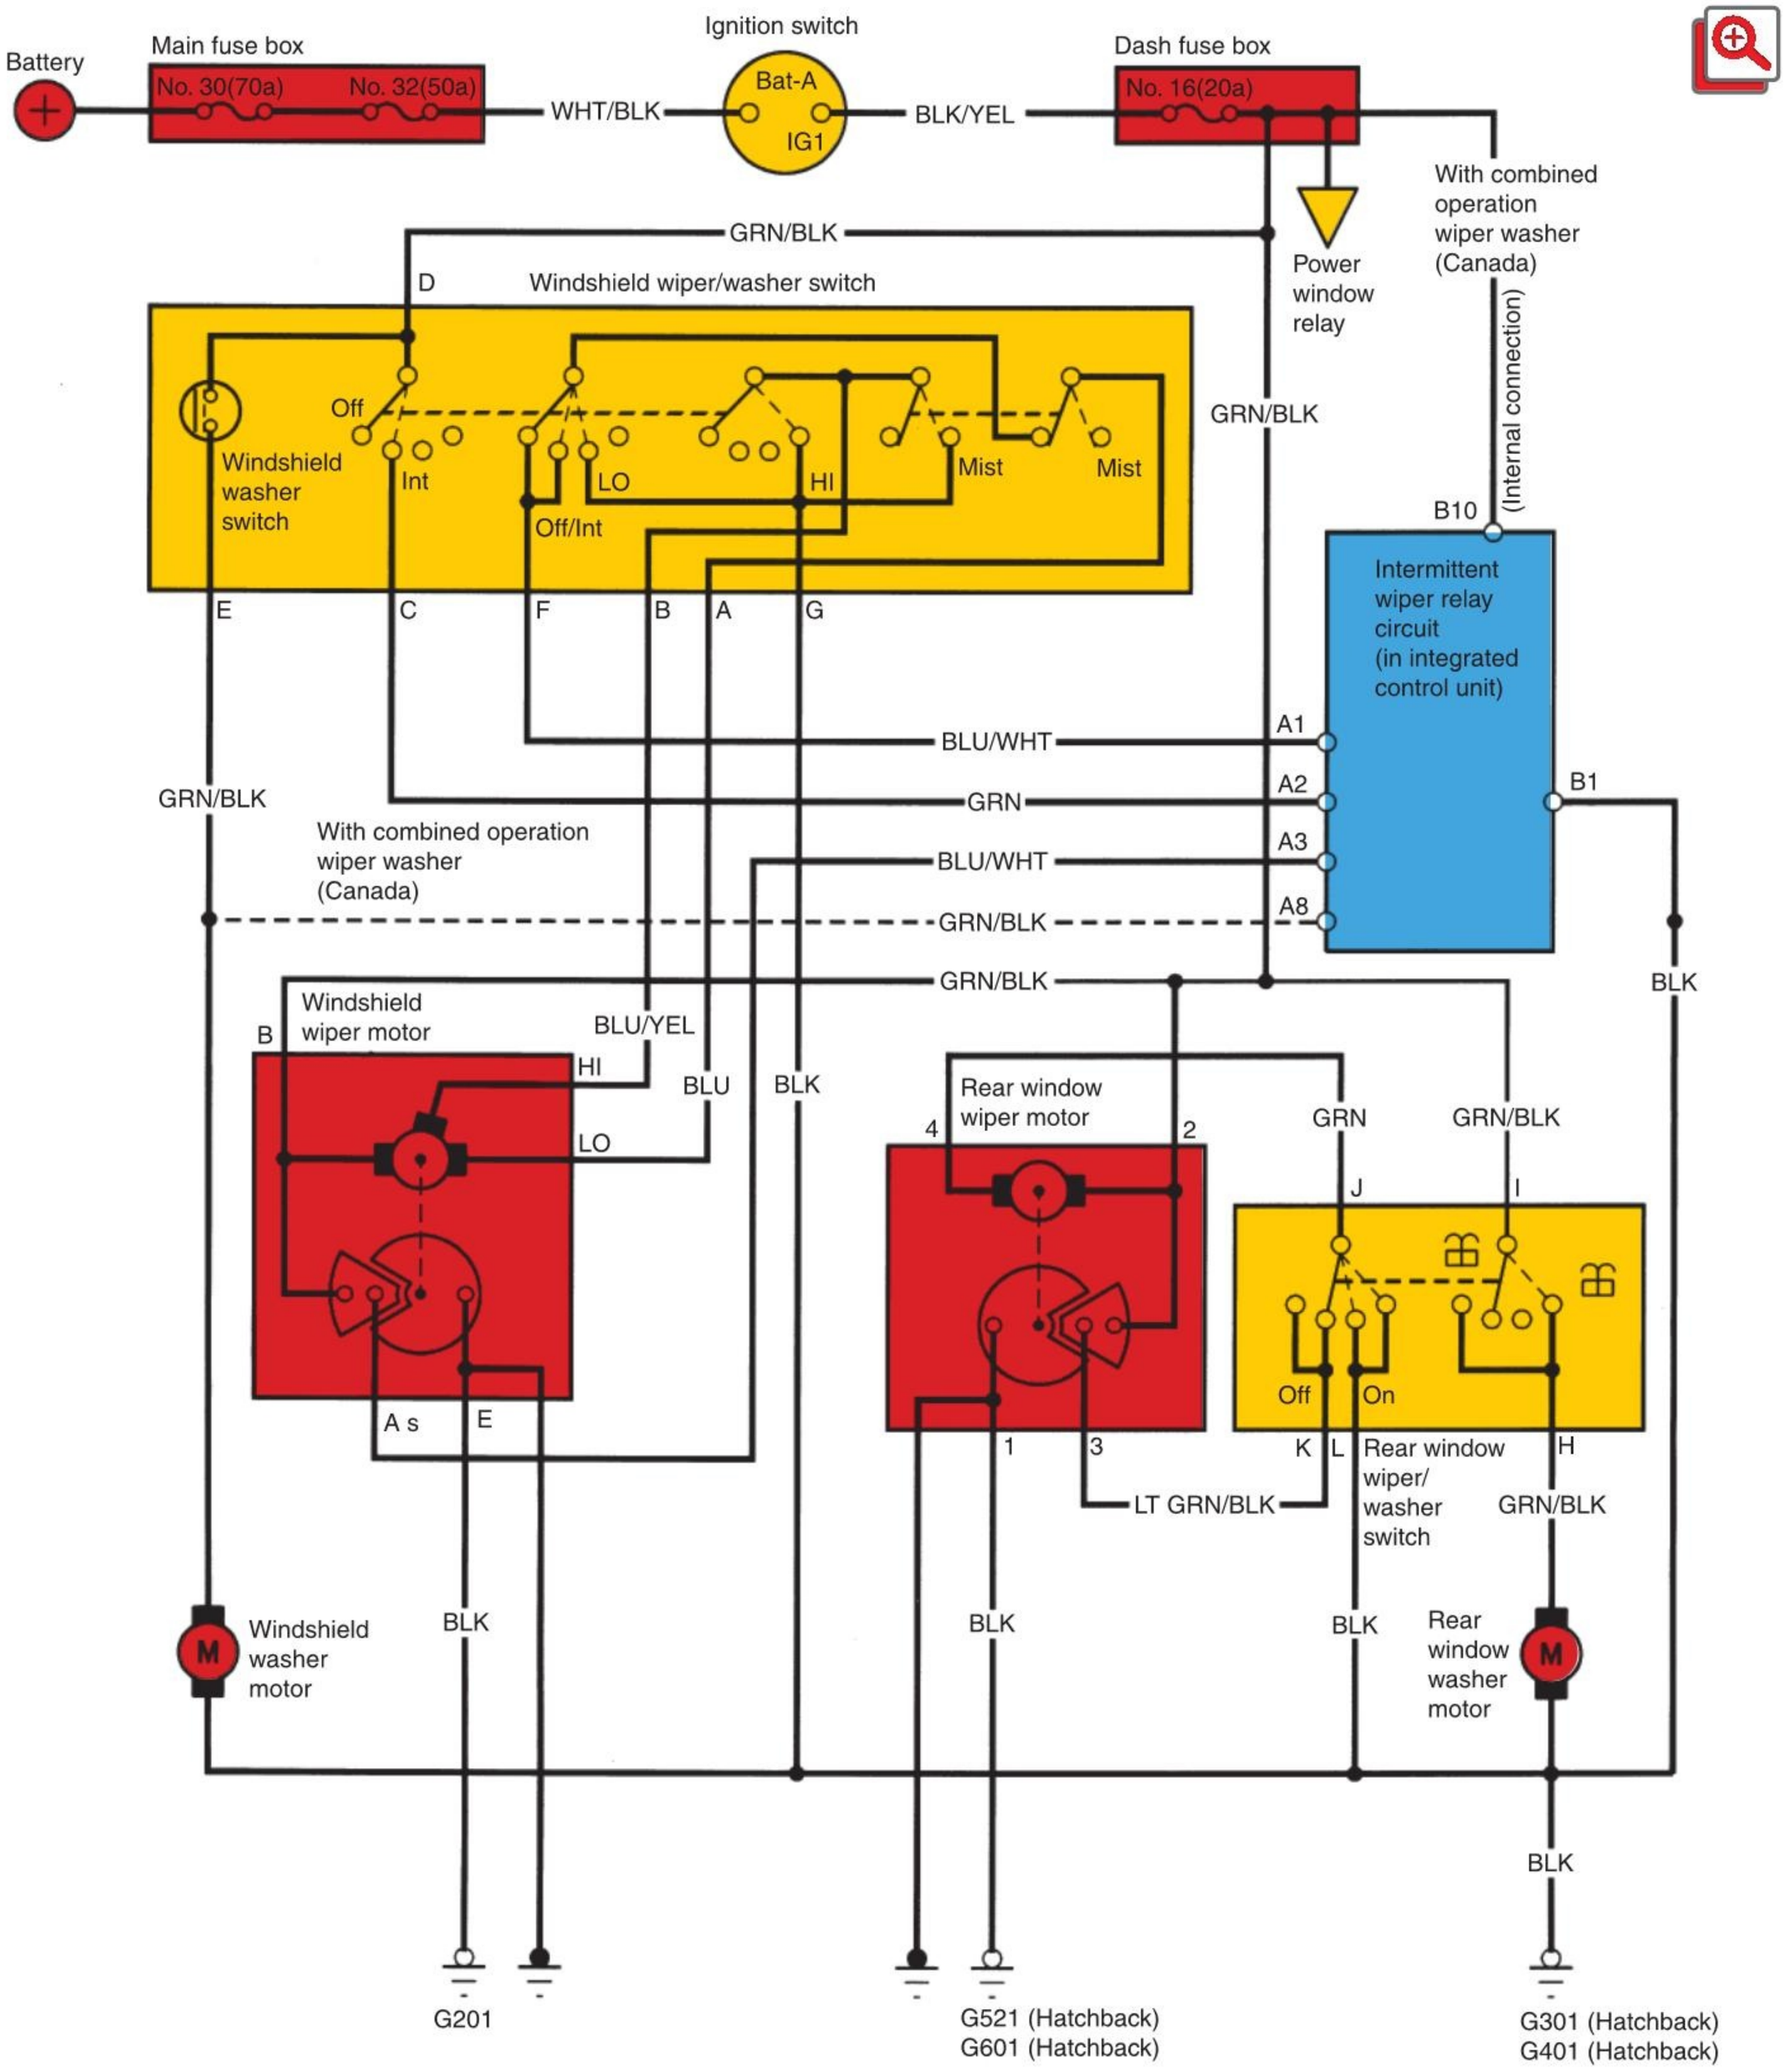
Windshield Wipers

A typical ***windshield wiper system*** is made up of a switch, wiper motor assembly, wiper linkage, wiper arms, wiper blades, and usually a windshield washer system. Either a fuse or circuit breaker protects the system. See **Figure 36-36**.

The windshield wiper switch is a multiposition switch that sometimes contains a rheostat. Each switch position provides a different wiping speed. The rheostat operates the delay mode for slow wiping action. A relay is frequently used to complete the circuit between the battery and the wiper motor. A typical windshield wiper-washer circuit diagram is shown in **Figure 36-37**.

The wiper motor assembly consists of a permanent-magnet motor and a transmission. See

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 36-37. Study the wiring diagram of a wiper-washer system. Trace through and find all major parts.

Copyright Goodheart-Willcox Co., Inc.

Figure 36-38. The wiper motor transmission changes rotary motion into a back-and-forth wiping motion. The transmission is normally a set of plastic gears, an end housing, and a crank.

The ***wiper linkage*** is a set of arms that transfers motion from the wiper motor transmission to the wiper arms. The rubber wiper blades fit on the wiper arms.

Tech Tip

If a vehicle's windshield wipers fail to return to the park position at the bottom, check for a bad ground in the wiper motor circuit. A separate ground circuit may be opened and ungrounded if the wiper arms stop in the middle of the windshield. Fixing the wiper motor ground will often repair this common windshield wiper problem.

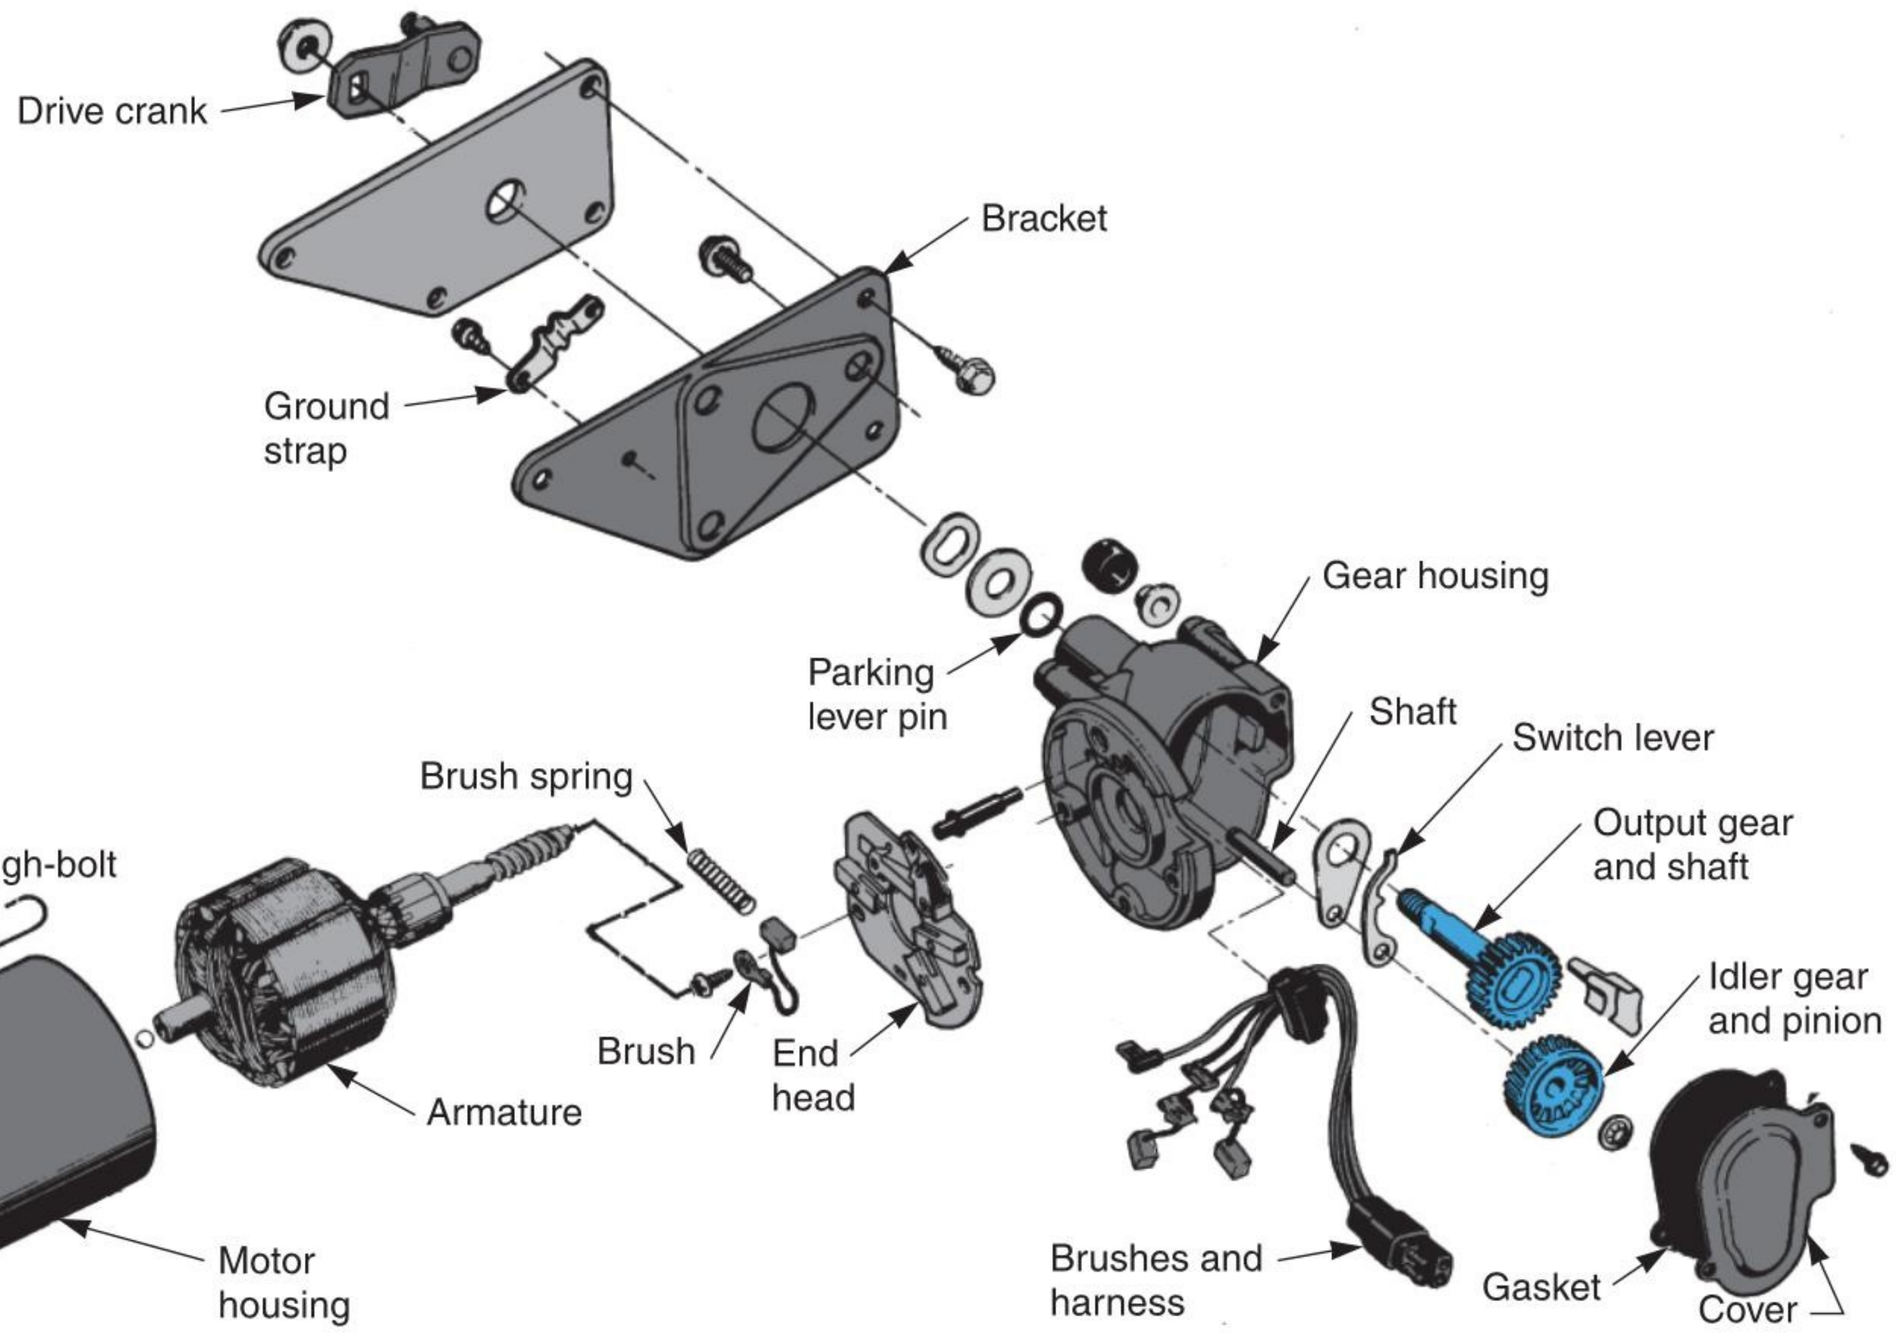
Windshield Washers

A ***windshield washer*** consists of a reservoir, pump, rubber hoses, connections, and washer nozzles. See **Figure 36-39**. The reservoir is located in the engine compartment and holds a supply of windshield washer solution. When the washer switch or button is activated, the wiper motor and the washer pump turn on. The washer solution is forced out of the reservoir and onto the windshield.

There are two types of pumps used with windshield washer systems: a rotary pump and a bellows (diaphragm) pump. Most new cars use a rotary pump mounted in the solvent reservoir. A tiny electric motor spins an impeller, which forces the washer solution onto the windshield. A bellows pump is normally mounted on and powered by the wiper motor.

Rain-Sensing Wiper System

A ***rain-sensing wiper system*** automatically turns the windshield wipers on when water is detected on the windshield. The system uses light-emitting diodes



Goodheart-Willcox Publisher

Figure 36-38. An exploded view of a wiper motor assembly is shown. The two plastic gears are the most common problem. They are replaced when stripped or broken.

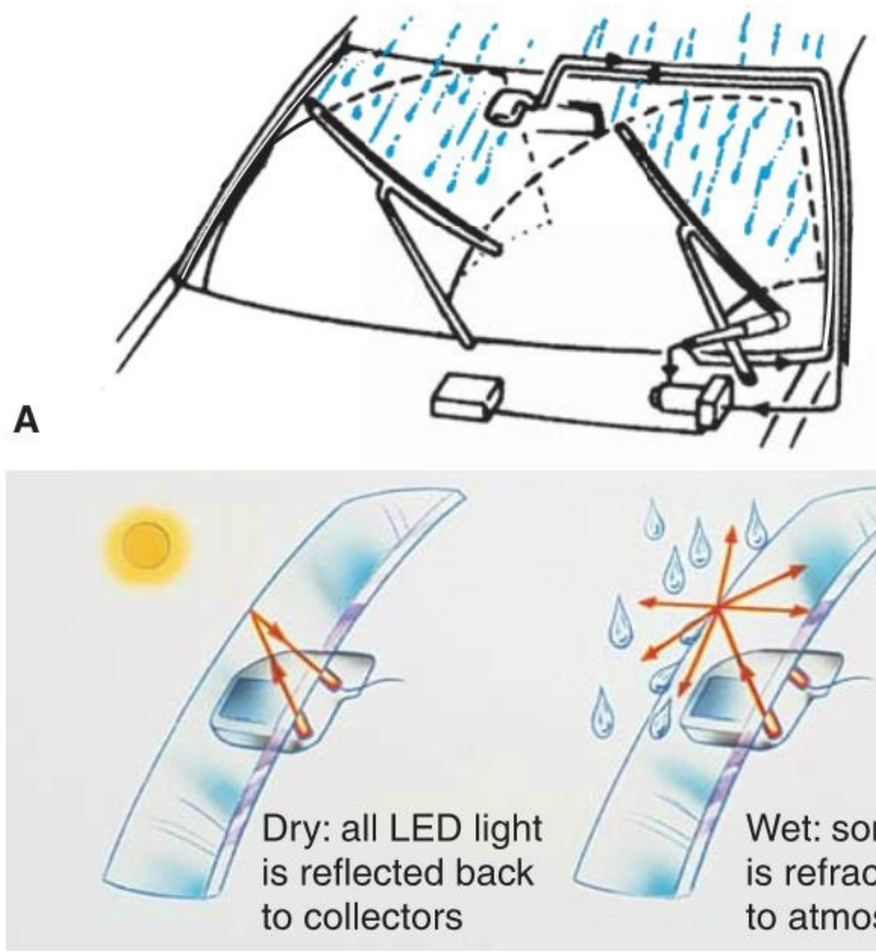
and a light sensor or an infrared system to detect water. When water is on the windshield, less light is refracted back from the windshield to the light sensor. This allows an electronic control module to turn the wipers on to remove rain or snow. In heavy rain, the wipers wipe across the windshield more quickly. Manual override is also possible. **Figure 36-40** shows the basic operation of a rain-sensing wiper system.

Windshield Wiper Service

Windshield wiper blades should be inspected periodically. If they are hardened, cut, or split, replace them. **Figure 36-41** shows common wiper blade service methods.

For electrical problems in a wiper system, use a service manual and its wiring diagram of the circuit. First, check the fuses and electrical connections. If they are good, use a test light to check for power to the wiper motor.

If power is being fed to the wiper motor, either the motor or transmission may be at fault. Before replacing the motor or transmission gears, make sure the motor is properly grounded. If power is not reaching



Goodheart-Willcox Publisher

Figure 36-40. Basic operation of a rain-sensing wiper system is shown here. A—A sensor on the back of the windshield and the ECM operate the wiper motor. B—When the windshield is clear, LED light is reflected back to a photo sensor and the wipers stay off. When the windshield has water or snow on it, some light is reflected away from the sensor. The sensor signal tells the ECM to turn on the wipers.

Figure 36-41. Study basic wiper service. A—A new rubber wiper refill is slid into place. B—To replace the complete wiper blade assembly, free it from the wiper arm. C—The arm can sometimes be removed by prying up as shown. D—Typical pattern for positioning arms on output shafts. Refer to a service manual for exact procedures.

the wiper motor, check the wiper switch and circuit connections for openings.

If the windshield washer does not work, check the fuse and connections. Use a test light to check for power going to the motor. If the test light does not glow (washer on), the wiper switch may be bad.

When working on a windshield wiper or washer system, always follow the exact recommendations given by the manufacturer. Systems and procedures vary from car to car.

Normally, the wiper motor must be replaced as a unit. The transmission gears are usually the only serviceable part in the assembly. An electric washer motor is also replaced when defective. It cannot be disassembled and repaired.

Horns

Today's ***horn systems*** typically include a fuse, horn button switch, relay, horn assembly, and related wiring. When the driver presses the horn button, it closes the horn switch and activates the horn relay. This completes the circuit. Current then flows through the relay circuit and to the horn.

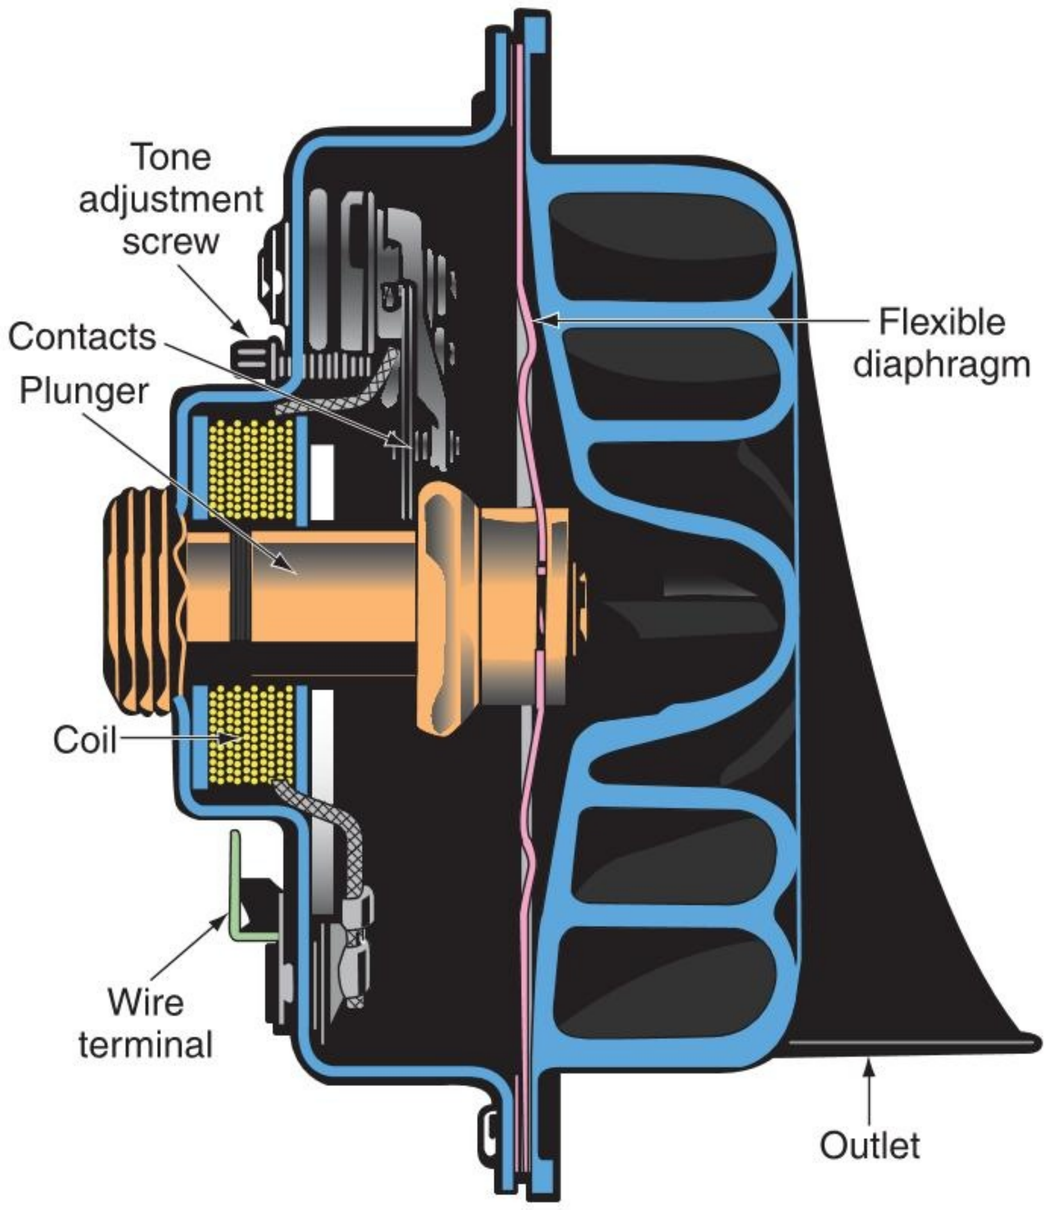
Most horns have a diaphragm that vibrates by means of an electromagnet. When energized, the electromagnet pulls on the horn diaphragm. This movement opens a set of contact points inside the horn. This allows the diaphragm to flex back toward its normal position. Again, the points close and the diaphragm is pulled into the electromagnet. As a result, a rapid vibrating action is produced. A honking sound is transmitted out of the horn, **Figure 36-42**.

Horn Service

When a horn will not sound, check the fuse and connections, and test for voltage at the horn terminal. If a horn blows continuously, the horn switch may be bad. A relay is another cause of horn problems. The contacts in the relay could be burned, or they may stick together.

Refer to a shop manual when diagnosing and repairing a horn system. Use your knowledge of the system and basic testing methods to locate troubles.

Copyright Goodheart-Willcox Co., Inc.



Deere & Co.

Figure 36-42. A horn contains a coil, points, and a flexible diaphragm. Coil and point action makes the plunger slide in and out of the coil. The plunger moves the diaphragm to produce horn sound.

The technician uses the test light to check for power at the low-beam terminal of the light switch. Power is going to the switch, but it is not flowing through the switch to the low-beam circuit.

Correction: The technician replaces the multifunction switch on the steering column. He then checks to make sure all the vehicle's lights are working properly. He describes the problem and explains the repair to Mrs. Jones. He also shows her the old part.

Diagnostic Case Study

Concern: Mrs. Jones walks into the office and says, "My headlights don't work. They work on high beams, but when I switch to low beams they go dead."

Cause: Duff verifies the problem and turns the repair over to the shop's electrical technician. The technician removes the halogen bulbs and inspects the elements. Both bulbs are in good condition. He then uses a test light to check for voltage at the wire terminals in the bulb sockets. With the light switch in the high-beam position, voltage is present at the high-beam terminals of the sockets. However, when the switch is moved to the low-beam position, there is no voltage at the low-beam terminals. This narrows down the possible problem sources to the headlight switch or the wiring harness.

Summary

- The lighting system consists of the components (fuses, wires, switches, and relays) that operate the interior and exterior lights on a vehicle.
- The headlamp system generally includes the battery, headlamp-related wiring, fuse panel, light switch, dimmer switch, headlamps, taillights, marker lights, and instrument lights.
- A multifunction switch is capable of controlling several circuits—headlights (bright and dim circuits) and turn lights, for example—simultaneously.
- Most late-model cars use halogen headlamp bulb inserts, which are small bulbs that fit into a larger plastic housing.
- A dimmer switch controls the high and low headlamp beam function.
- An automatic headlight dimmer system uses a light sensor, amplifier, and relay to control the high and low beams.
- The turn signal system consists of a fuse, turn light switch, flasher unit, turn lightbulbs, indicator bulbs, and related wiring.
- Light system service involves changing burned-out bulbs, testing bulb sockets, checking fuses, finding shorted and open circuits, aiming headlights, and other similar types of tasks.
- Aiming headlights involves adjusting the beams so they shine in the proper direction.
- Instrumentation is used to inform the driver of various operating conditions—oil pressure, engine temperature, computer trouble codes, air bag system armed, etc.
- Analog instruments use rotating needles on dials to indicate operating conditions.

Copyright Goodheart-Willcox Co., Inc.

- Digital instruments use various types of lights or electronic displays to show operating conditions.
- The instrument cluster is the housing and clear plastic cover that holds the gauges, indicator lights, speedometer head, and bulbs.
- A balancing coil gauge uses two electric coils to cause needle deflection.
- A bimetal gauge uses two dissimilar metals bonded together to cause gauge needle deflection.
- A sending unit or sensor is used to control current flow to the gauge.
- A mechanical speedometer uses plastic transmission/transaxle drive gears, a metal speedometer cable, a cable housing, and a mechanical speedometer head.
- An electronic speedometer uses the vehicle speed sensor, an electronic control module, and an electronic or electric speedometer head or display.
- A typical windshield wiper system comprises a switch, wiper motor assembly, wiper linkage, wiper arms, wiper blades, and usually a windshield washer system.
- Horn systems typically include a fuse, horn button switch, relay, horn assembly, and related wiring.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

analog instruments
automatic headlight dimmer system
auto-off headlamp system
balancing coil gauge
ballast
bimetal gauge
body control area network (B-CAN)
brake light system
daylight running lights
digital instruments
dimmer switch
electronic speedometer
emergency light system
fast control area network (F-CAN)
filament
flasher
flash-to-pass feature
halogen lightbulbs
headlamp system
headlight aimers
heads-up display (HUD)
high-intensity discharge bulbs (HIDs)
horn systems
illuminated entry system
incandescent lightbulbs
instrument cluster
instrumentation electronic control module
light
light-monitoring system
mechanical speedometer
monitor
multifunction switch
multiplex integrated control (MIC) system
odometer chip
rain-sensing wiper system
rheostat
sealed-beam headlamps
sending units
turn signal system
windshield washer
windshield wiper system
wiper linkage

Activities

1. Select a specific vehicle make and model that is at least two years old. Go to the automotive department of a discount or department store. Find the store's replacement lamp identifier system, which may be a book, large card, or computer screen. Use it to identify the proper replacements for headlights, taillights, turn signals, brake lights, backup lights, and side marker lights (if used). List all the part numbers.
2. Demonstrate the proper procedure for checking headlight aiming using marks on a wall. Show how to correct the aim of the lights, if necessary.
3. Find a wiring diagram for a car or truck, and make a photocopy. Use a brightly colored pencil or marker to trace the wiring that makes up the windshield wiper and washer circuit.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Incandescent lightbulbs send current through a _____ located inside a partial vacuum in an airtight glass enclosure.
2. List three advantages of high-intensity discharge bulbs.
3. An automatic headlight dimmer system consists of a(n) _____ sensor, _____, and _____ to control the high and low beams.
4. Explain the construction and operation of a flasher unit.

Copyright Goodheart-Willcox Co., Inc.

5. A vehicle has a problem causing the left headlight to flicker on and off. The right headlight works properly. The light seems to flicker when the car strikes bumps in the road. Technician A says that the light system relay may be bad. Vibration could be opening the points in the relay. The relay should be tested and replaced if needed. Technician B says that the problem involves just the left headlight section of the circuit. This technician suggests checking the headlamp socket and electrical connections to that bulb. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. One burned-out bulb cannot keep the turn signals from flashing on and off. True or False?
7. Describe the operation of both mechanical and electronic speedometers.
8. List and explain the major parts of a windshield wiper system.
9. How does a rain-sensing wiper system work?
10. Explain the operation of a horn circuit.

ASE-Type Questions

1. Headlight systems are being discussed. Technician A says that most late-model cars use halogen headlamp bulb inserts. Technician B says HID bulbs produce more light than standard halogen bulbs while consuming less energy. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Which of the following is often used by automatic headlight dimmers to control beams?
   (A) Relay.
   (B) Amplifier.
   (C) Light sensor.
   (D) All of the above.
3. Each of the following is part of the brake light system *except:*
   (A) brake light switch.
   (B) fuse.
   (C) rear lamps.
   (D) flasher unit.
4. A halogen headlight bulb must be replaced. Technician A says these bulbs are generally held in place with a retaining ring secured with small screws. Technician B says you should never touch the glass surface of the bulb. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. The right turn signals work but the left ones do not. Technician A says to check the flasher unit. Technician B says the turn signal switch could be bad. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Each of these conditions should exist during a headlight aiming test *except:*
   (A) panel lights dimmed.
   (B) tires inflated correctly.
   (C) car has half a tank of gas.
   (D) spare tire and jack in trunk.
7. A headlight aiming screen is a:
   (A) veil covering headlights.
   (B) series of lines on shop wall.
   (C) transparent paper partition.
   (D) None of the above.
8. Which of the following is *not* a type of pump used with windshield washer systems?
   (A) Rotary.
   (B) Bellows.
   (C) Rheostat.
   (D) Diaphragm.
9. Generally, the *only* serviceable part of a windshield wiper motor assembly is the:
   (A) wiper motor.
   (B) wiper blades.
   (C) wiper switch.
   (D) transmission gears.
10. When correcting a horn system problem, Technician A says horns are not serviceable and can only be adjusted. Technician B says horns are serviceable but cannot be adjusted. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Headlamp Diagnosis		
Condition	**Possible Causes**	**Correction**
Headlamps are dim with the engine off or idling.	1. Loose or corroded battery cables. 2. Loose or worn alternator drive belt. 3. Charging system output too low. 4. Battery has insufficient charge. 5. Battery is sulfated or shorted. 6. Faulty lighting circuit. 7. Both headlamp bulbs defective.	1. Clean and tighten battery cable clamps and posts. 2. Adjust or replace alternator drive belt. 3. Test and repair charging system. 4. Test battery state-of-charge. Recharge or replace battery. 5. Perform load test. Recharge or replace battery. 6. Test and repair circuit. 7. Replace both bulbs.
Headlamp bulbs burn out frequently.	1. Charging system output too high. 2. Loose or corroded terminals or splices in circuit.	1. Test and repair charging system. 2. Inspect and repair all connectors and splices.
Headlamps are dim with engine running above idle.	1. Charging system output too low. 2. Faulty headlamp circuit. 3. High resistance in headlamp circuit. 4. Both headlamp bulbs defective.	1. Test and repair charging system. 2. Test and repair circuit as necessary. 3. Test amperage draw of headlamp circuit. 4. Replace both bulbs.
Headlamps flash randomly.	1. Poor headlamp circuit ground. 2. High resistance in headlamp circuit. 3. Faulty headlamp switch. 4. Loose or corroded terminals or splices in circuit.	1. Repair circuit ground. 2. Test amperage draw of headlamp circuit. 3. Replace headlamp switch. 4. Repair terminals or splices.
Headlamps do not illuminate.	1. No voltage to headlamps. 2. No ground at headlamps. 3. Faulty headlamp switch. 4. Faulty headlamp dimmer switch. 5. Faulty headlamp circuit.	1. Replace fuse. 2. Repair circuit ground. 3. Replace headlamp switch. 4. Replace headlamp dimmer switch. 5. Repair circuit.

Copyright Goodheart-Willcox Co., Inc.

Turn Signal Diagnosis

Condition	Possible Causes	Correction
Turn signal flashes at twice the normal rate.	1. Faulty external lamp. 2. Poor ground at lamp. 3. Open circuit in wiring to external lamp. 4. Faulty contact in turn signal switch.	1. Replace lamp. 2. Check and repair wiring. 3. Repair wiring harness. Check connectors. 4. Replace switch.
Dash indicator lamp illuminated brightly; external lamp glows dimly and flashes at a rapid rate.	1. Loose or corroded external lamp connection. 2. Poor ground circuit at external lamp.	1. Tighten or replace connection. 2. Check and repair wiring.
Hazard warning system does not flash.	1. Faulty fuse. 2. Faulty flasher. 3. Open circuit in wiring to turn signal switch. 4. Faulty contact in turn signal switch. 5. Open or grounded circuit in wiring to external lamps.	1. Replace fuse. 2. Replace flasher. 3. Repair wiring. 4. Replace switch. 5. Repair wiring.
Indicator lamp illuminates brightly, but external lamp does not light.	1. Open circuit in wire to external lamp. 2. Burned out lamp.	1. Repair wiring. 2. Replace lamp.
System does not flash on either side.	1. Faulty fuse. 2. Faulty flasher unit. 3. Loose bulkhead connector. 4. Loose or faulty rear wiring harness or terminals. 5. Open circuit to flasher unit. 6. Open circuit in feed wire to turn signal switch. 7. Faulty switch connection in turn signal switch. 8. Open or grounded circuit in wiring to external lamps.	1. Replace fuse. 2. Replace flasher. 3. Tighten connector. 4. Repair wiring harness. 5. Check repair wiring harness. 6. Check and repair wiring harness. 7. Test and replace switch. 8. Check and repair wiring harness.
System does not cancel after completion of the turn.	1. Broken canceling finger on turn signal switch. 2. Broken or missing canceling cam on clockspring.	1. Replace switch. 2. Replace clockspring.
External lamps operate properly; no indicator lamp operation.	1. Faulty indicator lamp in instrument cluster.	1. Replace lamp.

Chapter 37
Sound Systems and Power Accessories

After studying this chapter, you will be able to:

- Describe the operating principles of a radio.
- Explain the basic difference between AM, FM, digital, and satellite radios.
- Diagnose basic sound system problems.
- Explain the operation and service of power windows.
- Describe and repair a power door lock system.
- Sketch a rear window defogger circuit.
- Summarize the operation and testing of a cruise control system.
- Correctly answer ASE certification test questions on the service of sound systems and power accessories.

Today, cars are often equipped with a wide array of options. These include power seats, power windows, power rearview mirrors, power antennas, memory functions, satellite radio, and exotic sound systems. To be a competent technician, you must be able to understand how these systems are constructed and operate. This chapter covers the principles of these systems. It will prepare you for later chapters that cover diagnosis and repair.

After studying this chapter, you will be well-prepared to diagnose and repair optional power accessories. Remember that power accessory designs and circuits vary. Therefore, you must refer to factory service information to get specific diagrams and specifications for the exact car being repaired.

Radio

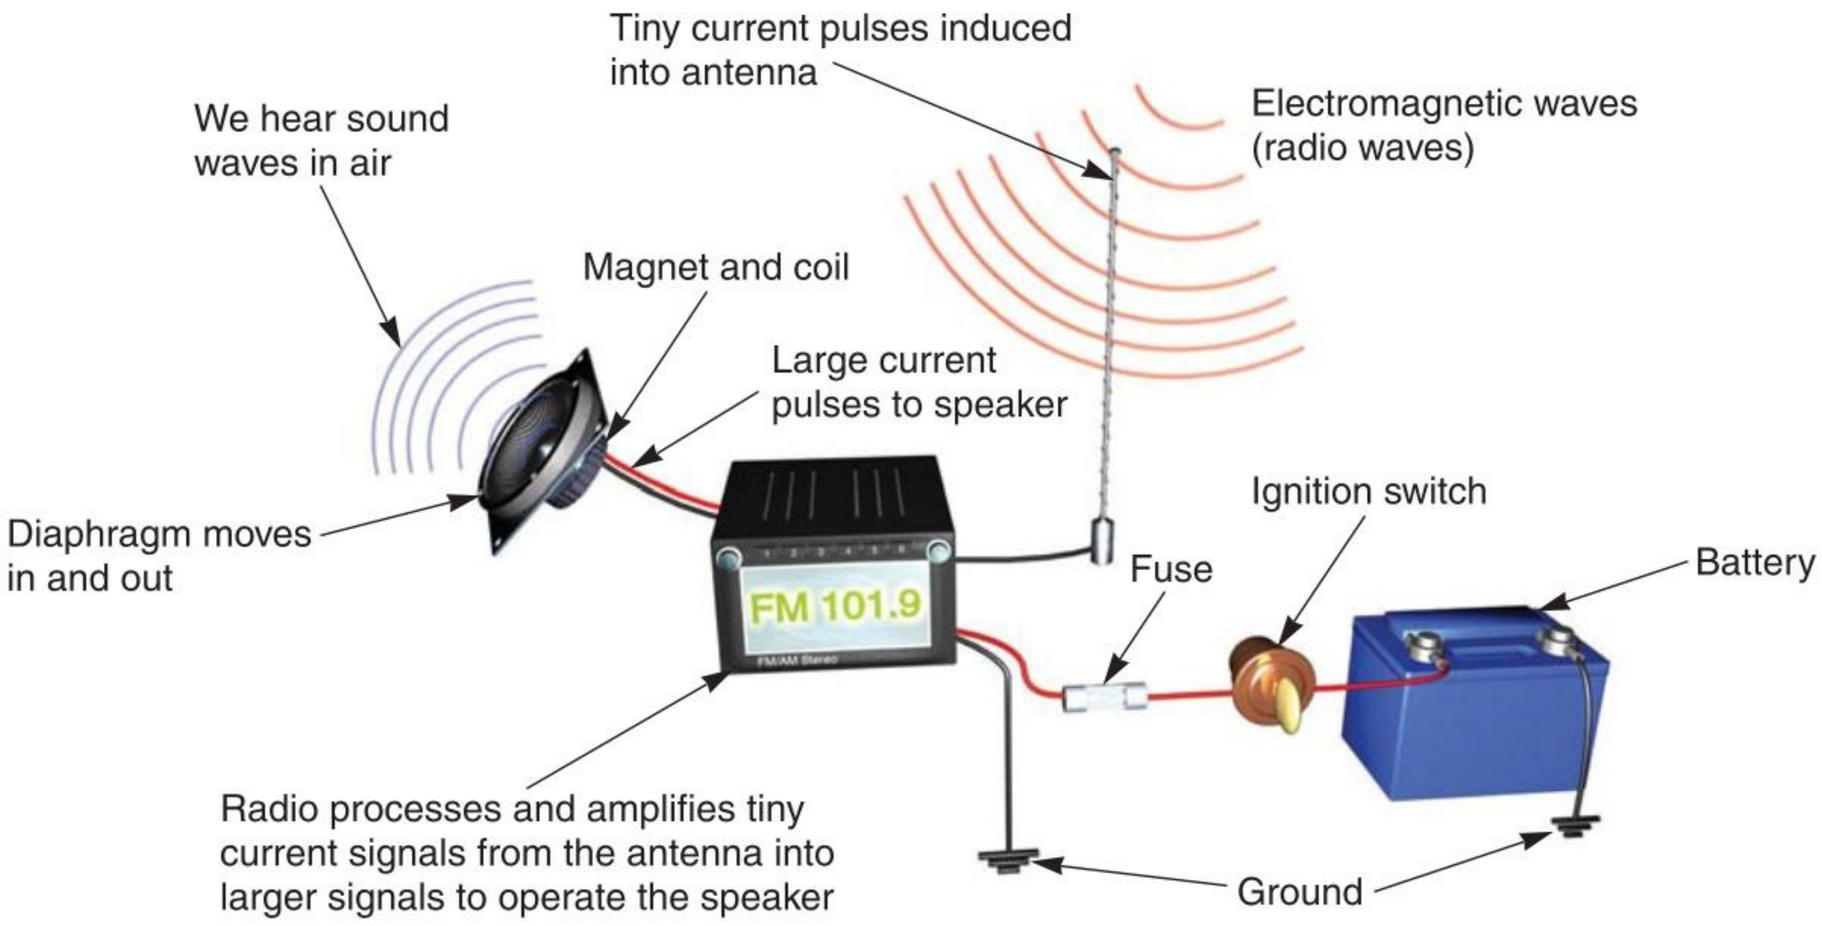
The term ***radio*** refers to the transmission of information through space using electromagnetic waves with frequencies below visible light. By modulating, or changing, the amplitude (voltage), frequency (speed), phase (spacing between separate codes waves), and/or pulse width (digital signal) of the electromagnetic waves, the radio transmitter can send information such as music, speech, and display data (such as channel, song, artist, and track) through space.

A basic ***radio system*** consists of the antenna, radio (receiver-amplifier), power supply circuits, and speakers.

The basic operation of a radio is illustrated in **Figure 37-1**. The ***radio station*** sends out an electromagnetic signal from a large broadcasting tower. When this signal moves past the vehicle's antenna, tiny electrical signals are induced in the antenna.

The radio amplifies and alters these "weak" radio signals into stronger current pulses that operate the

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 37-1. Study the basic principle of a car radio. Radio waves are tiny electromagnetic pulses picked up by the antenna. The radio alters and amplifies these waves into strong current signals for speakers. The physical movement of each speaker diaphragm causes air pressure pulses, which we hear as sound.

speakers. Each speaker diaphragm moves back and forth, producing air pressure waves. We hear these air pressure waves as sounds (voices or music).

A ***sound system*** is more elaborate than the basic radio system just described and often includes an AM/FM digital stereo radio, a CD player, and sometimes a power booster, a subwoofer speaker, and a power antenna. These parts are shown in **Figure 37-2**.

Radio System

The following are fundamental parts of a radio system:

- Antenna—An antenna is a metal shaft or wire in the window glass that picks up electromagnetic waves sent from a radio station.
- Antenna cable—The antenna cable is a coaxial cable that protects weak electrical signals induced into the system by electromagnetic radio waves.
- Radio—The radio contains a receiver-amplifier that strengthens weak radio wave signals and electronically processes them to drive the speakers. It also contains a ***tuner***, which allows the driver to select different ***radio frequencies*** (stations).
- Speaker wires—Speaker wires are small-gauge wires that carry pulsing current signals to the speaker coils.
- Speakers—Speakers are coil-operated diaphragms that move back and forth, causing vibrations in air to produce sound.
- Power supply circuit—The power supply circuit includes the wiring, fuses, and other parts that feed direct current to the radio.

An antenna picks up the broadcast signal and feeds it through the antenna lead to the radio. Some antennas are a very fine piece of wire in the windshield glass. Other antennas are a metal mast (rod) mounted in the car body. A power antenna uses a small electric motor and gear mechanism to raise and lower the antenna mast.

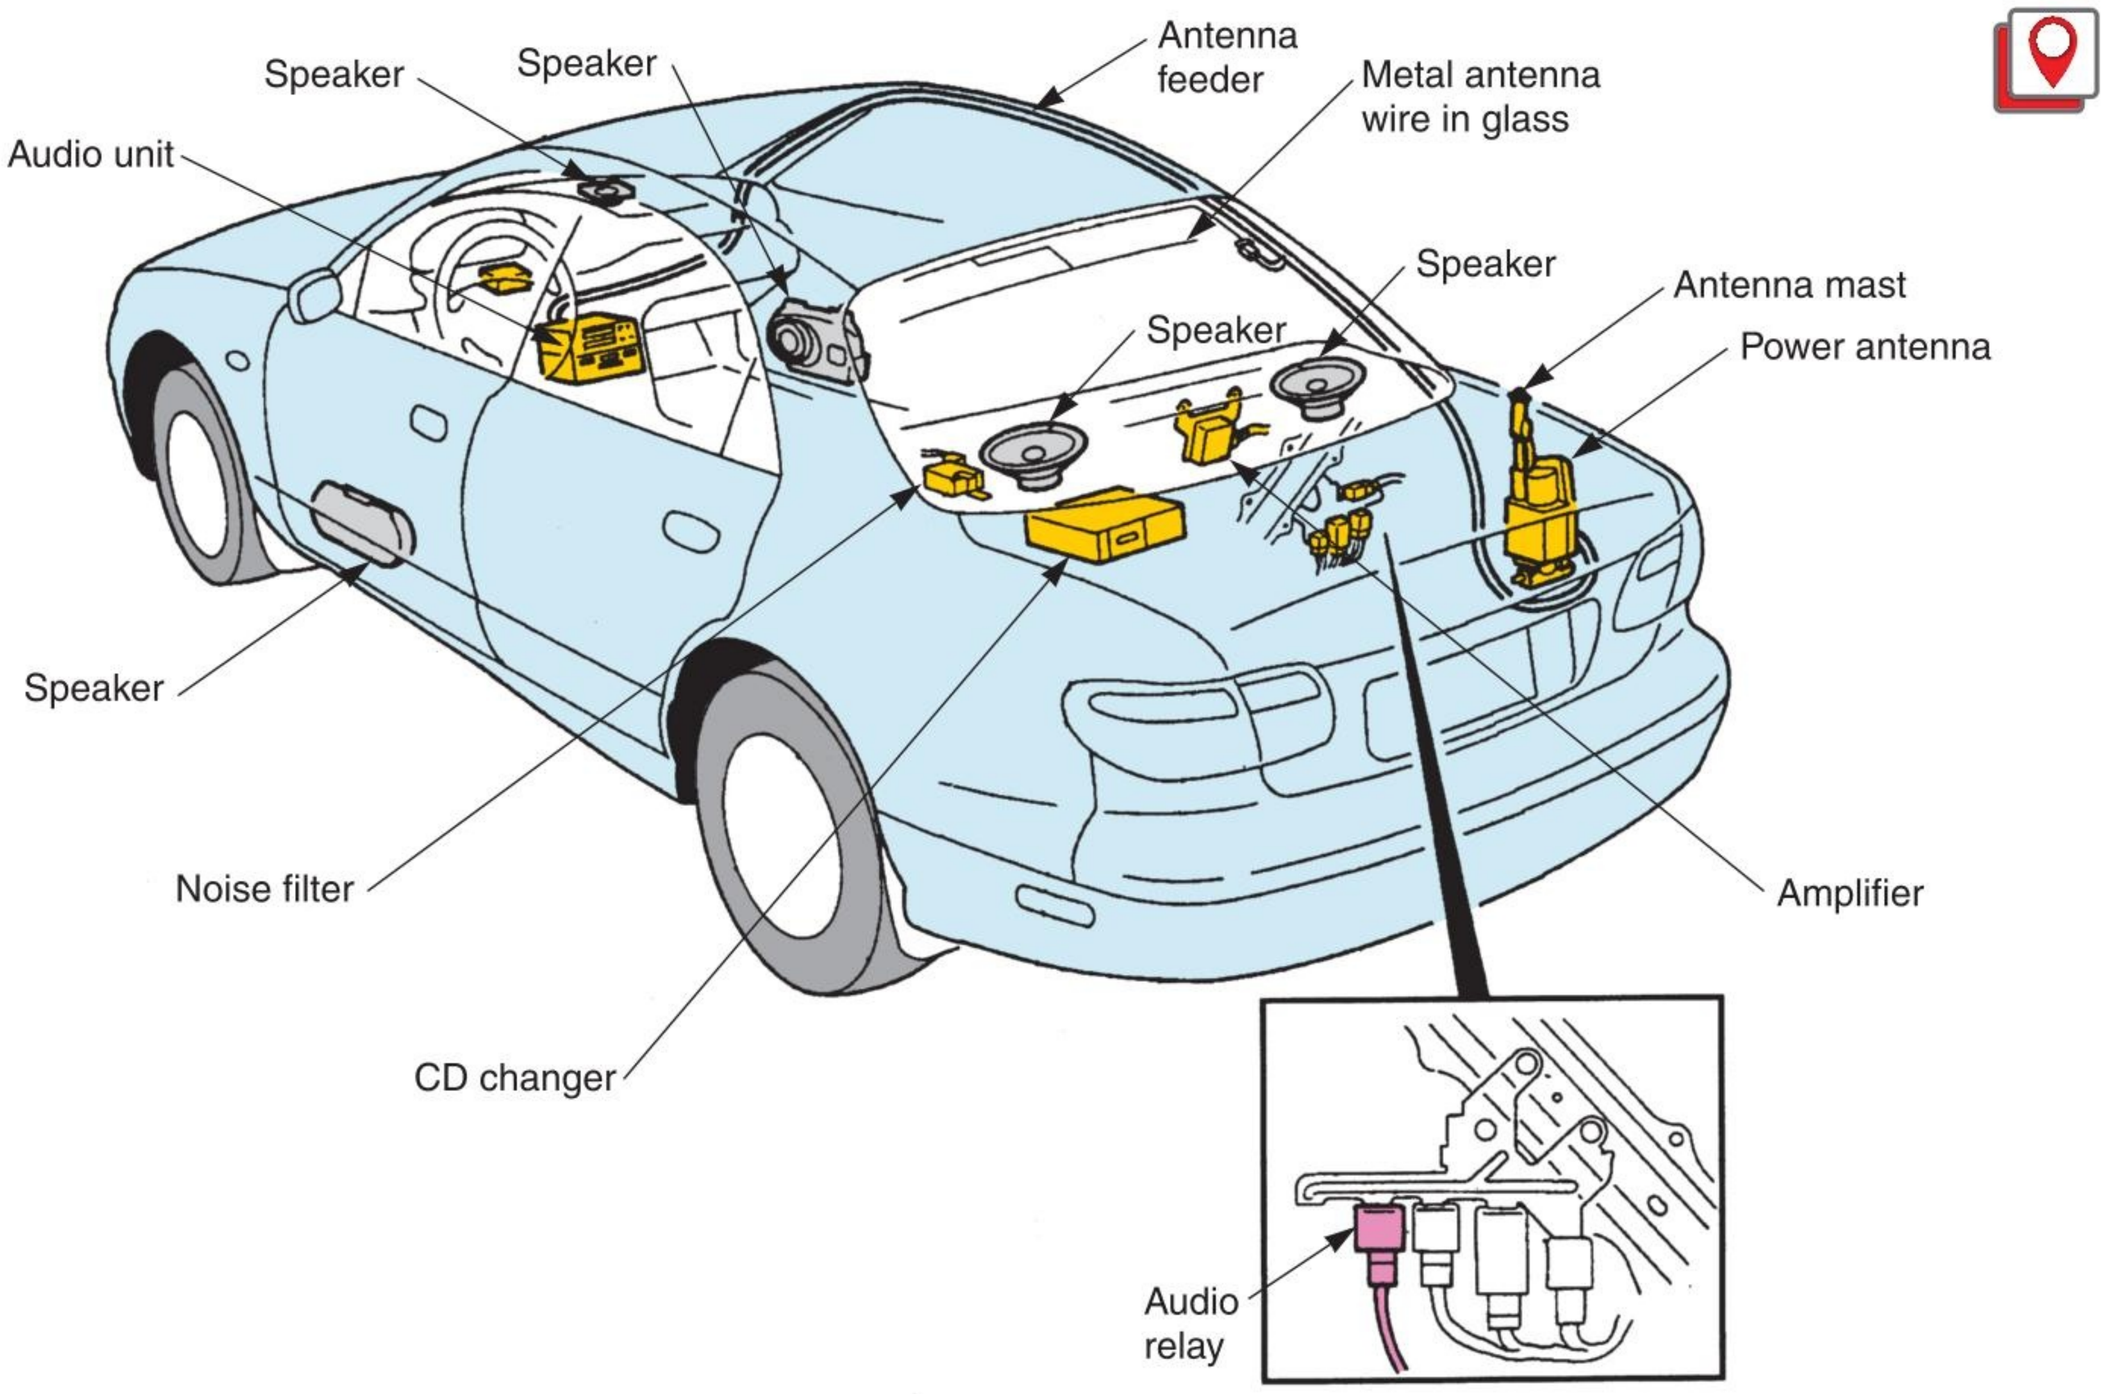
AM, FM, Digital Radio Systems

There are three types of radio signals generated by broadcast towers: AM (amplitude modulating), FM (frequency modulating), and digital, **Figure 37-3**.

An ***AM radio*** is designed to pick up a radio signal that varies in amplitude (strength). It operates on a frequency of 530–1,610 kilohertz (kHz), which gives it a longer broadcasting range than FM.

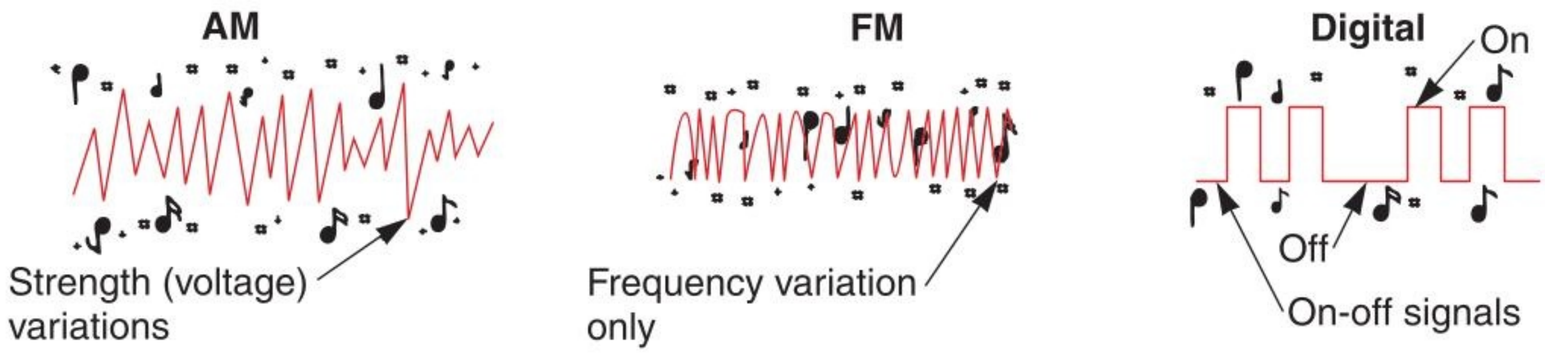
An ***FM radio*** is designed to receive a radio signal that varies in frequency (fluctuating speed). The FM band is a higher frequency, from 88–108 megahertz (MHz). Since the FM radio wave is not reflected off the ionosphere (upper atmosphere), it has a relatively short broadcasting range (approximately 35 miles

Copyright Goodheart-Willcox Co., Inc.



Mazda

Figure 37-2. Late-model vehicles normally come equipped with elaborate sound systems. Multiple speakers, an amplifier or power booster, a CD player, and a power antenna add to service complexity.



Chrysler

Figure 37-3. Note the difference between AM, FM, and digital signals. Radios must have circuitry that can "read" these different radio signals.

or 56 kilometers). FM radio is capable of producing stereo (stereophonic or multidimensional) sound. A stereo uses at least two speakers and has different sounds coming from each speaker.

Digital radio uses analog signals that are compressed and digitized (converted to on-off signals) so more programming can be broadcast in a given spectrum. The digital signal is similar to the one produced by a digital compact disc. HD programming is found between analog FM stations.

Satellite Radio

Satellite radio operates off a radio (electromagnetic) transmitter that orbits about 22,000 miles (35,000 km) above Earth. The satellite broadcasts use an FCC-allocated broadcast frequency in the S-band (2.3 GHz) for sending digital data. One satellite can send out the same radio signal for hundreds of miles. While AM and FM signals are good only within a certain radius, satellite radio systems employ multiple

Copyright Goodheart-Willcox Co., Inc.

satellites so listeners can hear the same stations without losing reception when traveling across the country.

Satellite radio uses a special chip set inside the radio. This chip accepts and translates the digital satellite signals to a lower frequency for operating the amplifier circuits and speakers of the system. Consumers must pay the service provider a fee for their radios to translate and play a satellite radio signal.

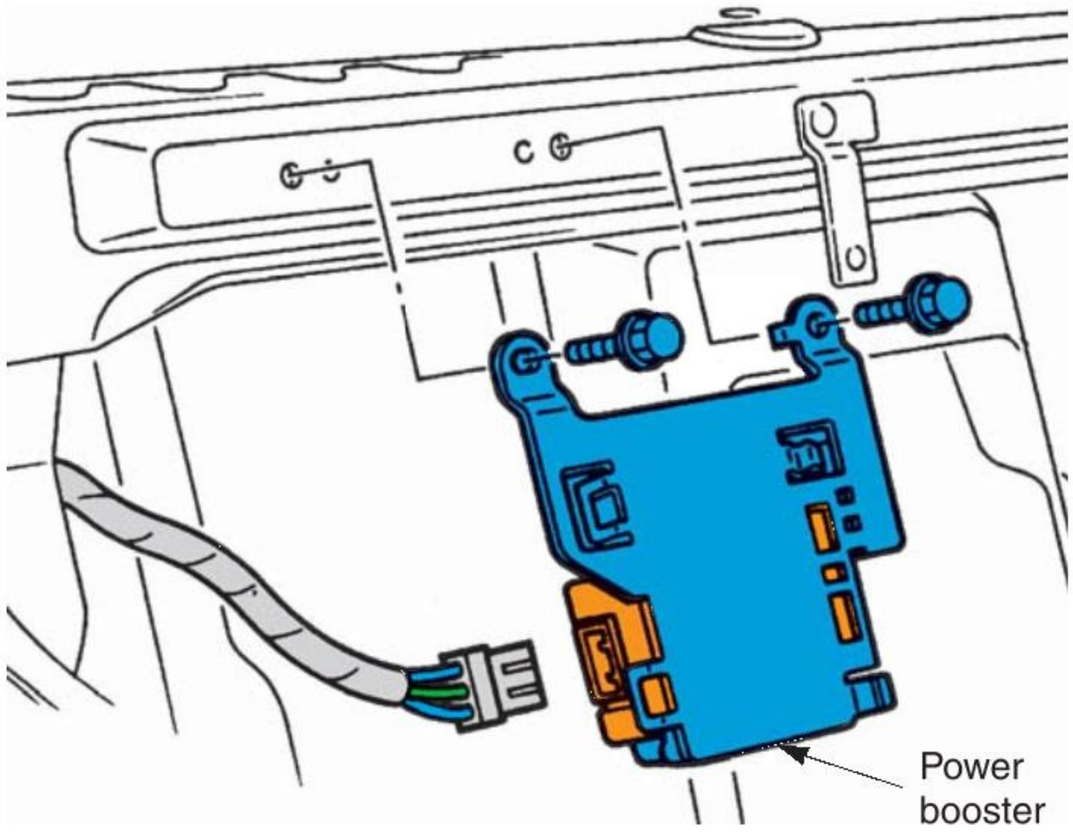
Auxiliary Audio Input

Many new vehicles have a built-in ***auxiliary audio input*** that allows a digital audio player to be connected to the vehicle's stereo system. A ***digital audio player***, such as an iPod or an MP3 player, is a compact music player that stores large amounts of digital data on an internal memory chip.

When the player is connected to the auxiliary audio input and selected, the vehicle's stereo often displays the name of the song being played and the artist. Controls on the stereo receiver or the steering wheel can often be used to advance to the next song stored in the player.

Power Booster

A ***power booster***, also known as a ***stereo amplifier***, or "stereo amp," is sometimes added to the sound system to increase volume without sound ***distortion***, **Figure 37-4**. It can be located in the passenger compartment or trunk. It simply increases the electrical power available to drive the speakers. Without a power booster, the stereo power transistors may go into thermal runaway when the stereo is played at high volumes.



Mazda

Figure 37-4. A power booster may be located in the trunk or under a seat.

Thermal runaway occurs when a transistor is driven too hard (too much output current is controlled by the transistor). The output of the transistor will fluctuate as the transistor's thermal capacity is exceeded, and severe distortion will be heard from the speakers. With enough thermal runaway, the transistor will fail.

When troubleshooting a sound system, determine which sections of the system are working and which are not. For example, if the radio and tape player work but the CD player does not, check the part of the circuit related only to the CD player. If tests find something wrong with the CD player, send it to a specialized shop for repairs.

Radio Service

If a radio fails to work, check its fuse. You may have external problems: a blown fuse, an open antenna or power supply lead, or bad speakers. Do not condemn the radio until all other problem sources have been eliminated. If only one speaker is not working, the coil in that speaker coil could be faulty. If two or more speakers are not working, the problem is probably inside the radio circuits.

Tech Tip

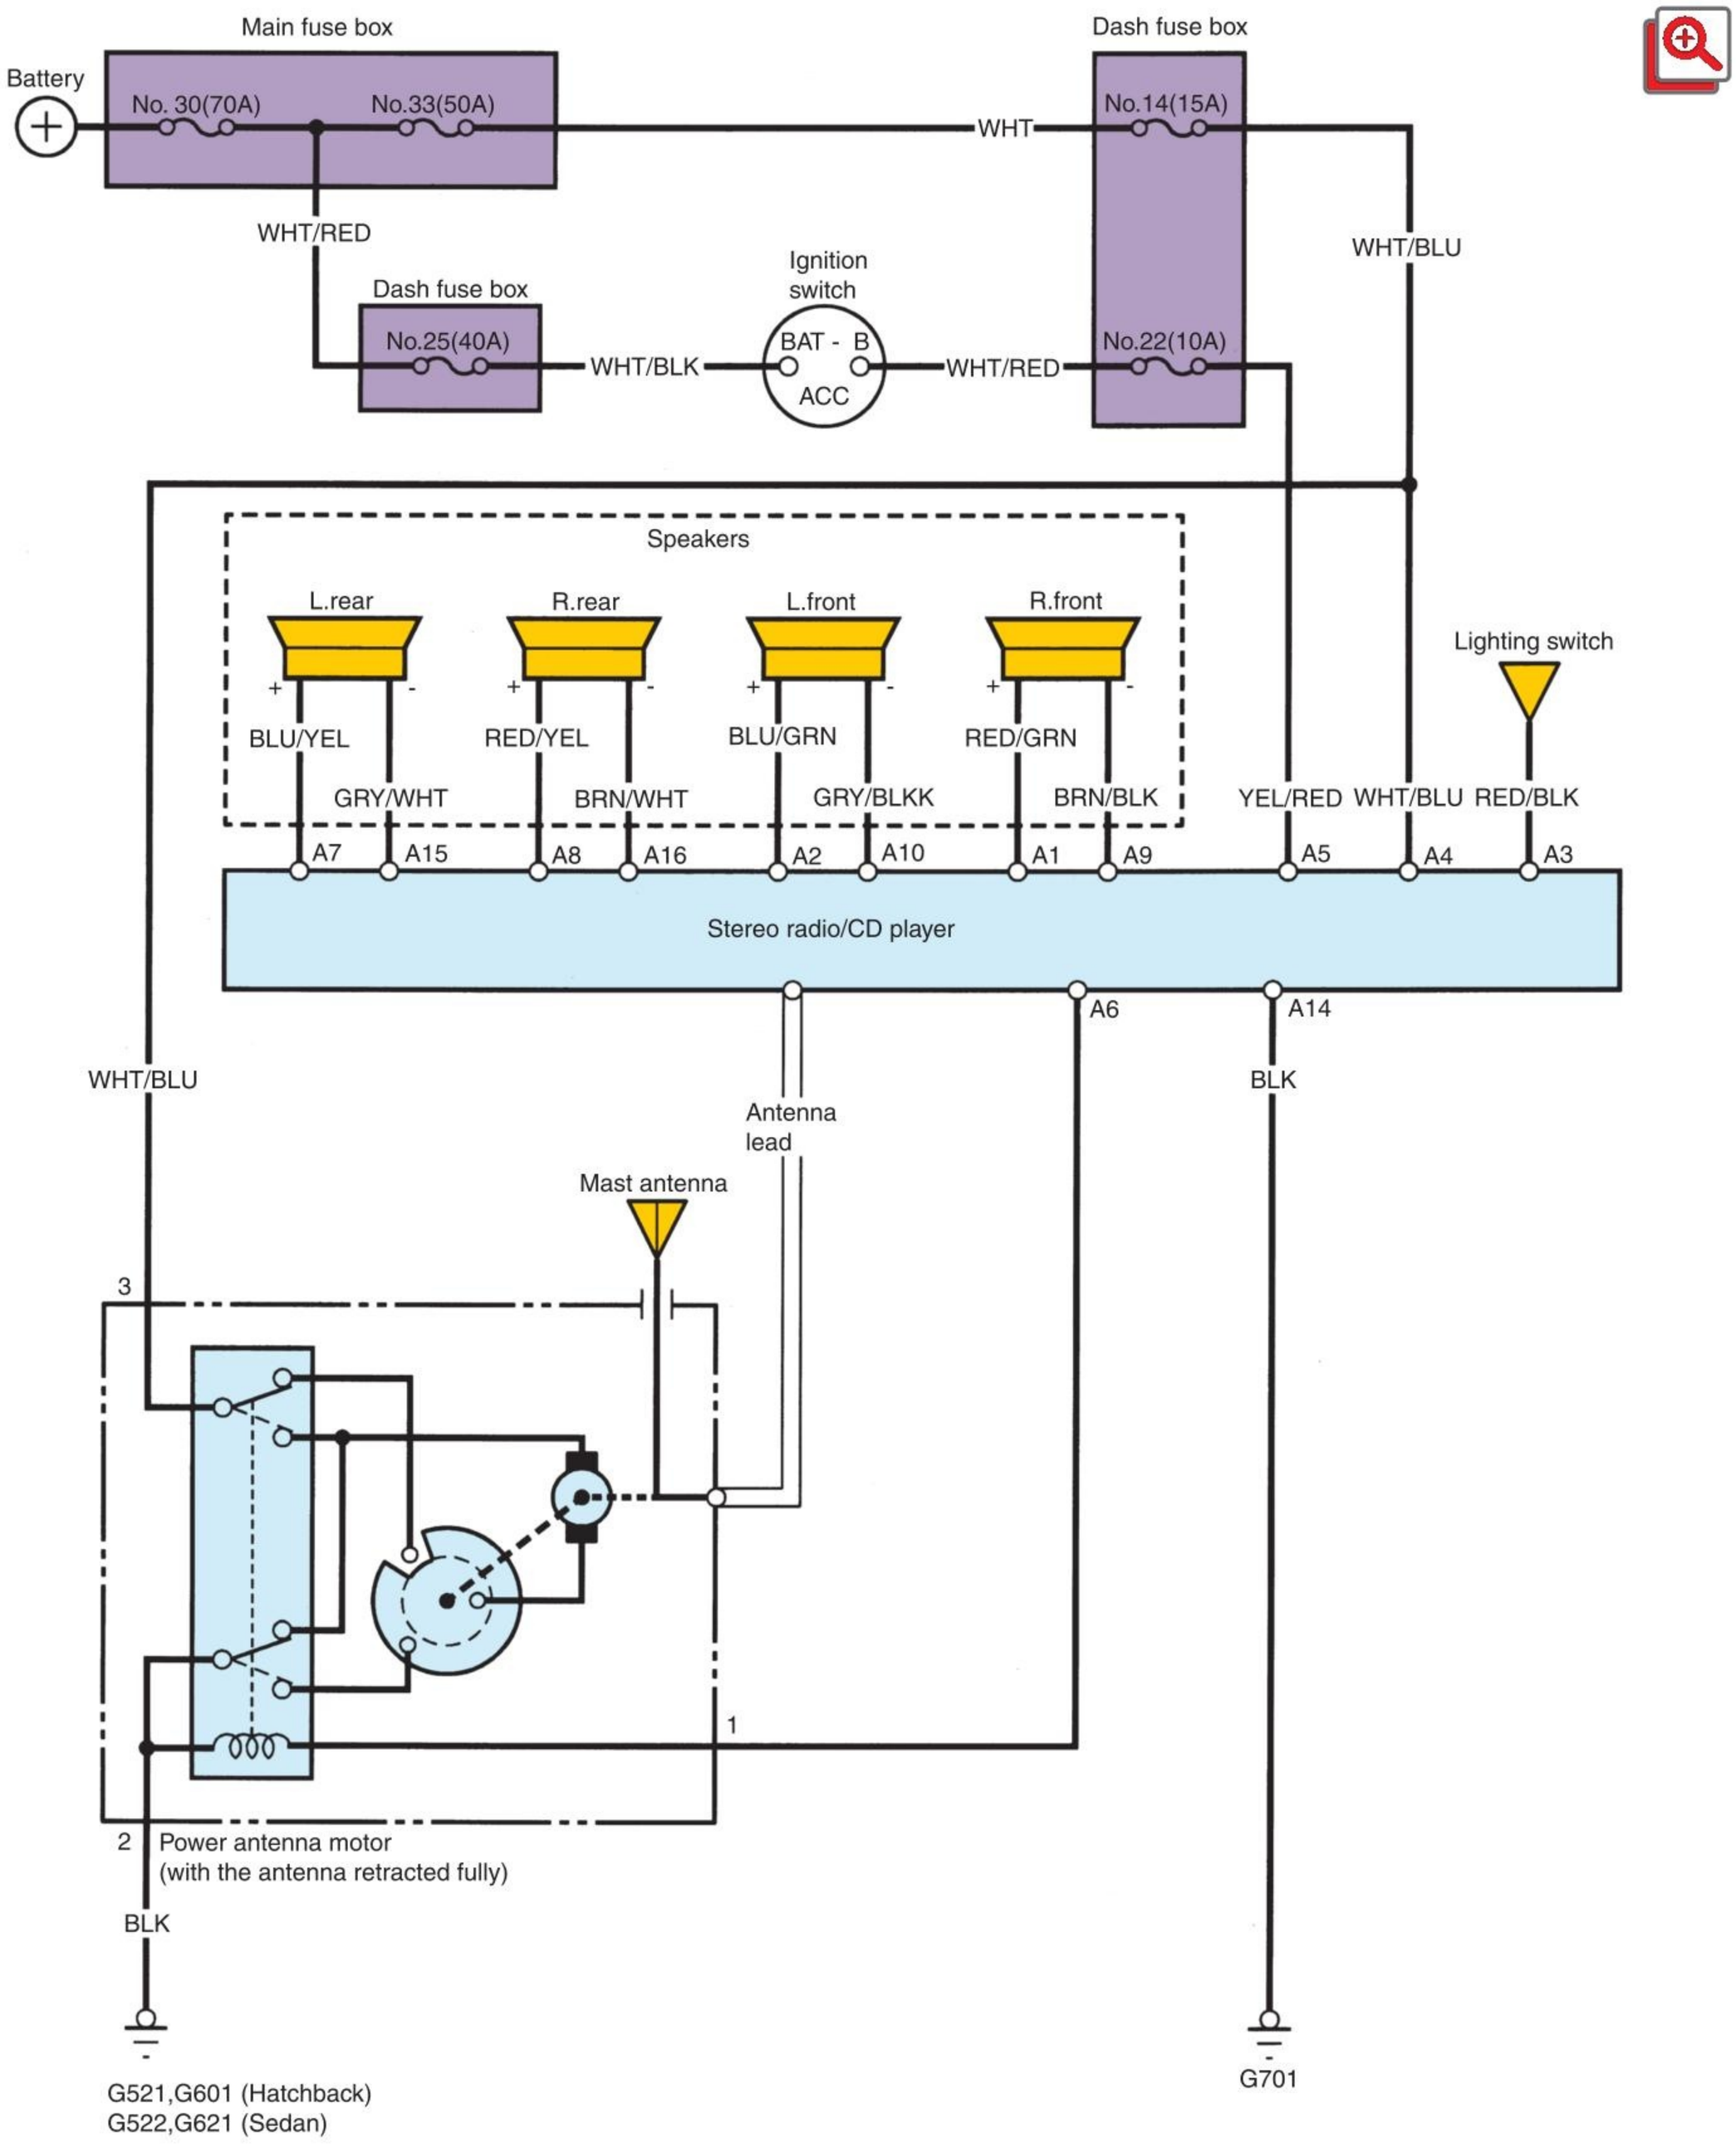
Just because the lights in a radio are working does not mean the radio circuitry is getting power. Quite often, two power leads feed the radio. One lead is for the memory circuitry and the other is for the face lights. Make sure both leads are providing electrical power to the radio, as show in **Figure 37-5**.

When the radio is found to be faulty, it should be removed and sent to an authorized repair technician. Various methods are used to secure radios. Some radios can be removed by simply removing the screws on the faceplate. You can then pull the radio out far enough to disconnect the speaker wires, power connectors, and antenna lead. Others require partial dash disassembly for removal. In some cases, you may need to lie on the floor to remove a rear support bracket and the wiring. Other stereo heads require small metal tools to reach in and release hidden clips securing the unit in the dash. Refer to factory literature if in doubt.

Antennas

An ***antenna*** picks up the broadcast signal and feeds it through the antenna lead to the radio. A very fine piece of wire mounted in the windshield glass can

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 37-5. Study connections and components in this stereo system wiring diagram.

Copyright Goodheart-Willcox Co., Inc.

serve as the antenna. Other antennas are a metal ***mast*** (rod) mounted on the body. Look at **Figure 37-6**.

A ***power antenna*** is a telescoping antenna that is extended and retracted by an electric motor. The electric motor turns a gear. The gear then operates a cable or slide mechanism on the antenna mast. Most power antennas go up and down automatically when the stereo is turned on or off. In some cases, however, a dash-mounted switch actuates the electric motor to move the antenna up or down.

Antenna Service

If you suspect a bad antenna (no signal coming from antenna lead), connect a known good antenna to the radio. If the new antenna causes the stereo to work, replace the old antenna.

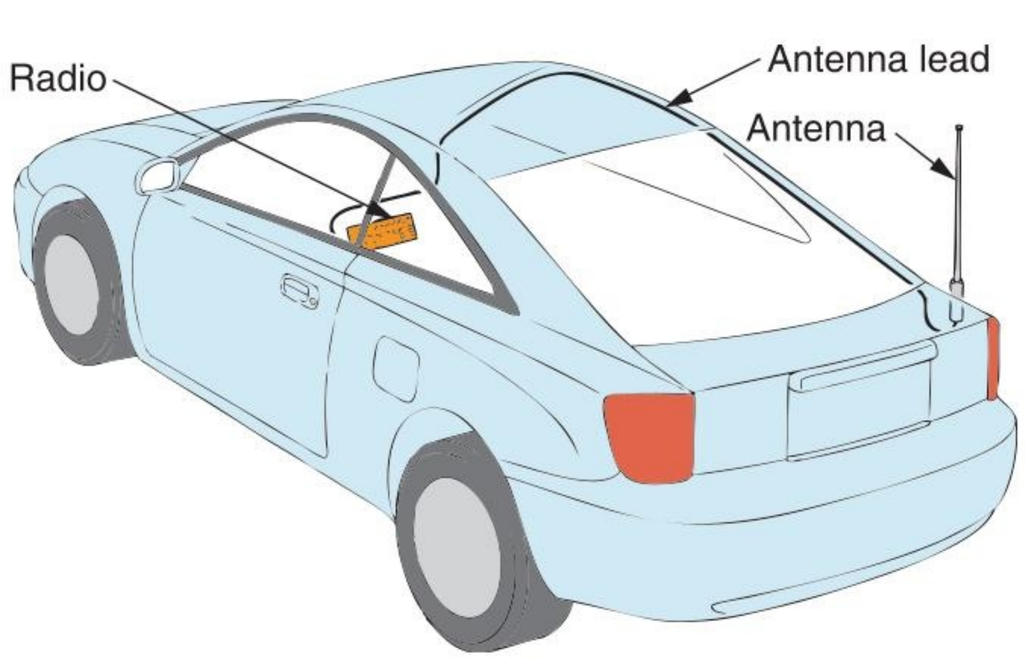
If a power antenna does not go up or down, check for power going to the motor. Use a test light or voltmeter. If power is reaching the antenna motor, the motor is probably bad. If you are not getting power, trace back through the circuit to find the problem.

Speakers

A ***speaker*** uses a permanent magnet and a coil of wire mounted on a flexible diaphragm to convert electricity into motion and sound. When current passes through the coil of wire, the resulting magnetic field pulls the coil and diaphragm toward the permanent magnet. Rapid movement of the speaker diaphragm causes pressure waves in the air. We hear these pressure waves as sound.

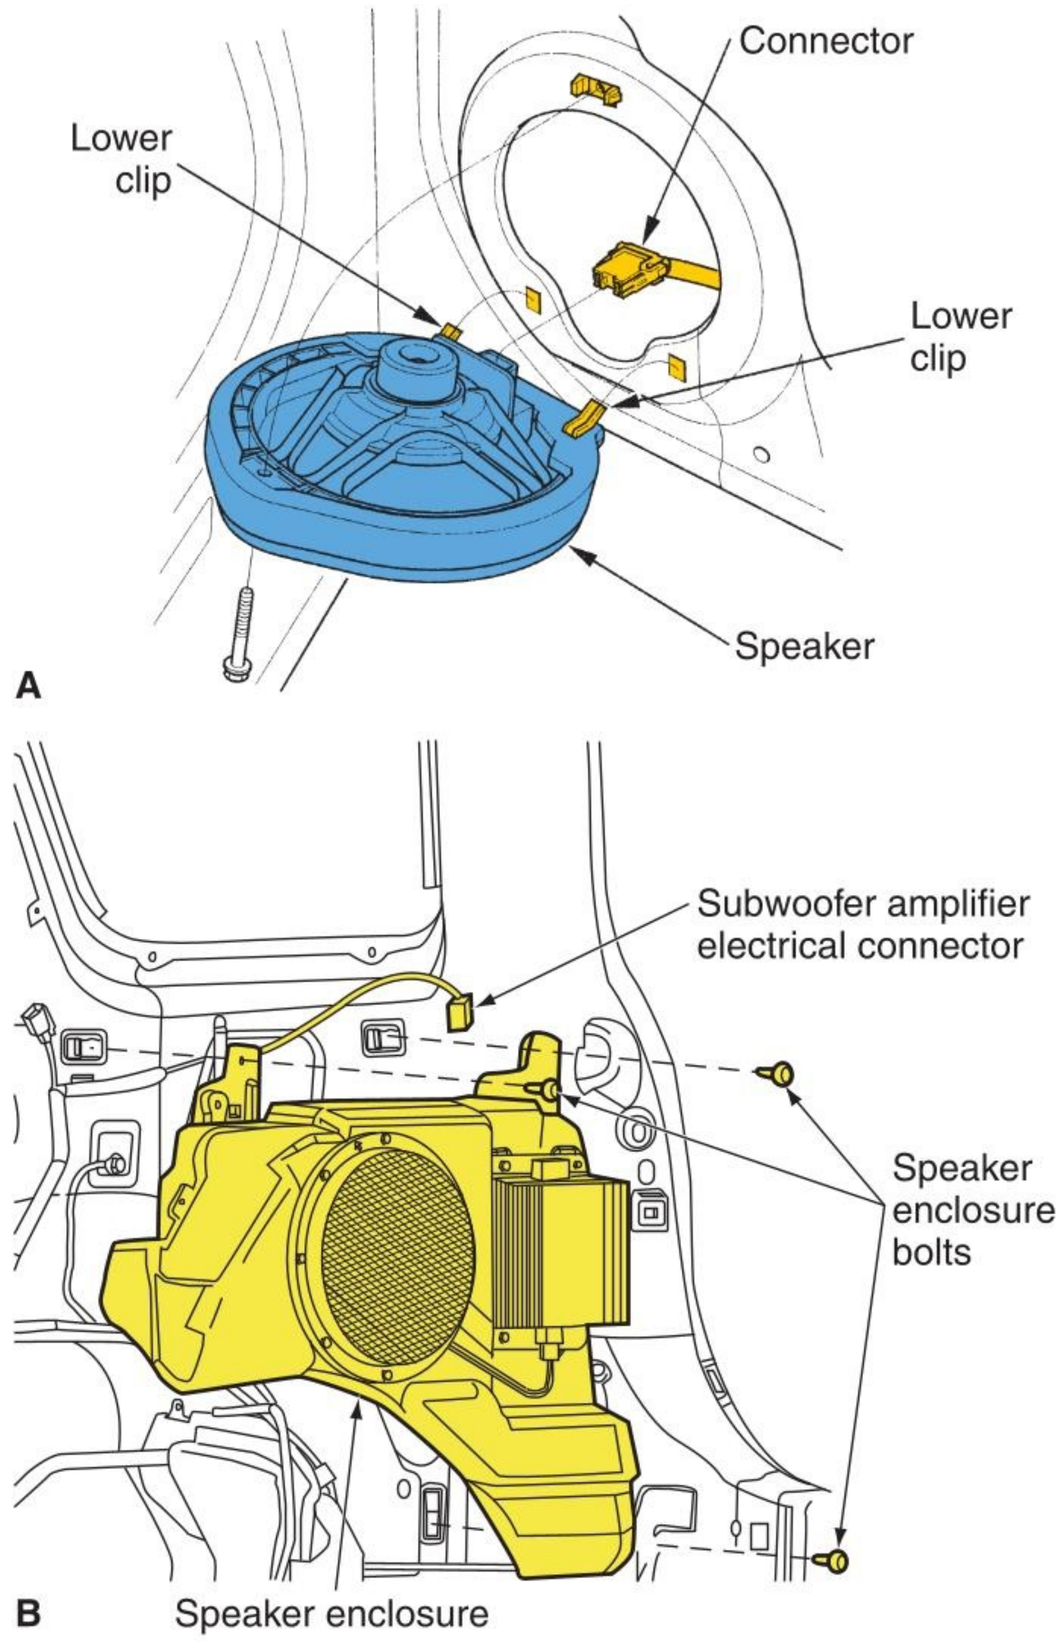
Different types of speakers are used to reproduce different sound frequencies. A tweeter is a small-diameter speaker cone that is able to reproduce the highest frequencies detectable by the human ear. A midrange speaker is a medium-size speaker that is ideal for reproducing sounds in the middle of the ear's frequency range. A subwoofer is a medium-size speaker mounted in a large enclosure to reproduce low and midrange sound waves.

The speakers may be mounted in the doors, dash, or behind the rear seat. Look at **Figure 37-7**. FM and digital stereo radios have two or four speakers.



Toyota

Figure 37-6. This vehicle has a mast-type antenna. The antenna picks up the broadcast signal. The signal then travels through the antenna lead to the radio.



Honda

Figure 37-7. Speakers can be mounted in doors, in the upper dash, in interior side panels, or behind the rear seat. A—This speaker has a conventional mount in the door frame. Remove the screws after carefully popping of the grille. You may have to remove the inner door trim panel. The rattle of loose mounting screws will sound like a blown speaker diaphragm or separated coil windings, which require speaker replacement. B—Many of today's automotive speakers are mounted in an acoustic chamber that benefits sound quality. This one has a small amplifier mount on it next to the speaker. Always test the amplifier with a scope if the speaker looks and tests good as described earlier.

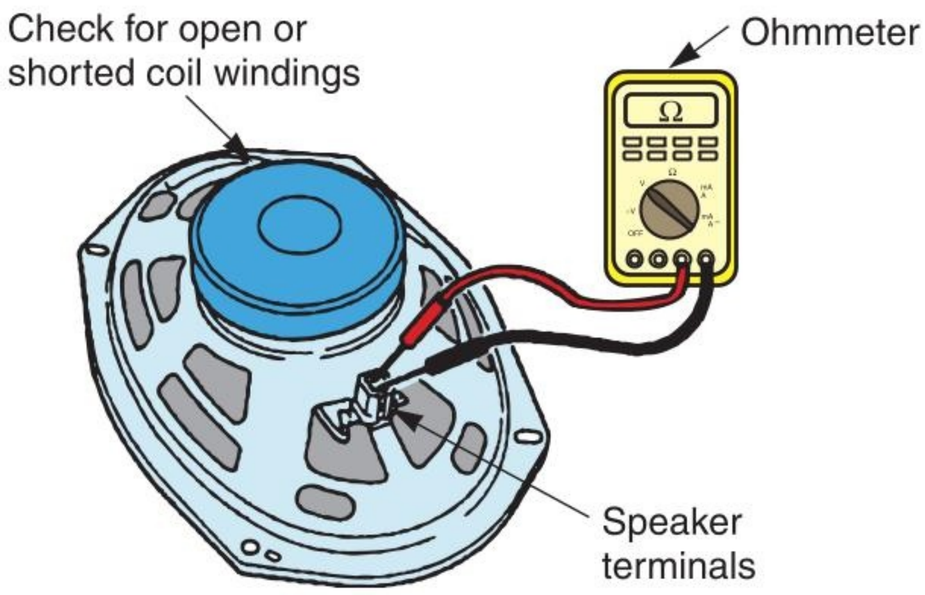
Copyright Goodheart-Willcox Co., Inc.

Speaker Service

A faulty speaker will usually distort the sound of the radio. The speaker may rattle, especially when the volume is adjusted to a higher output level. A broken coil winding or terminal-to-coil wire can render the speaker inoperable.

Speakers are not usually repairable and should be replaced when defective. However, terminal-to-coil wires can sometimes be soldered when broken. The speaker mounting screws can also vibrate loose, creating a sound similar to a blown speaker. Tighten the speaker mounting screws and recheck audio quality.

Figure 37-8 shows how to check for shorted or open speaker coil windings. Most auto speakers should have an impedance of either 4 or 8 ohms.



Mazda

Figure 37-8. To verify an internal problem with a speaker coil, check it with an ohmmeter. If shorted, resistance will be almost zero. If the windings are open, the ohmmeter reading will be very high.

CD Players

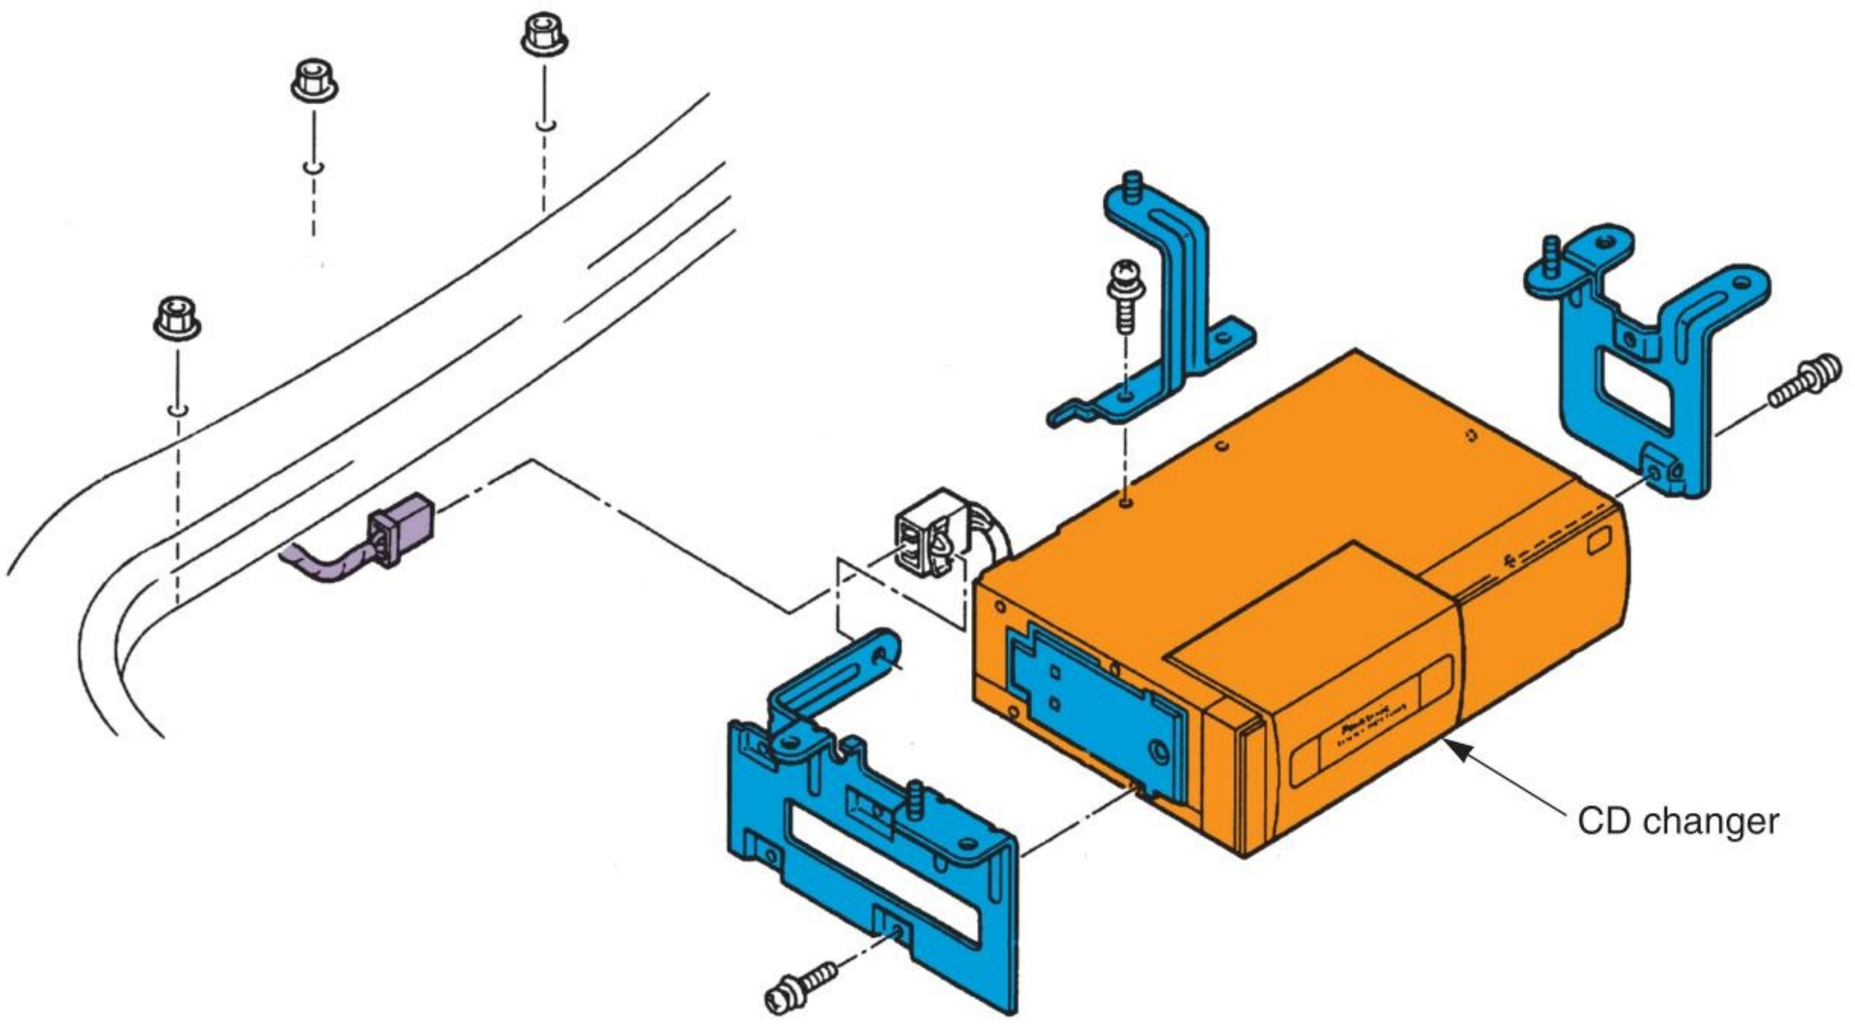
CD players, also termed ***compact disc players***, play music that is stored digitally on a plastic disc. They are common on today's vehicles. The CD player can be made as part of the stereo in the dash, or a remote unit located in the trunk, **Figure 37-9**.

DVD Player

An automotive ***digital video disc (DVD) player*** with a display screen is usually mounted in the rear seatbacks. This allows backseat passengers to watch a DVD while the vehicle is in operation.

Tech Tip

Steering wheel touch controls (switches mounted on steering wheel) are sometimes provided for the stereo, air conditioning, speed control, and other systems. Keep the steering wheel controls in mind when troubleshooting problems with these systems.



Mazda

Figure 37-9. A CD changer normally mounts in the trunk. Check for stuck CDs, dirty heads, and power feed problems caused by bad wiring before sending the unit out for repairs.

Copyright Goodheart-Willcox Co., Inc.

Radio Noise

Radio noise is undesired interference or static (popping, clicking, or crackling) obstructing the normal sound of the radio station. Radio noise is commonly caused by a bad antenna, an open or shorted noise suppressor (capacitor), a bad secondary wire, a faulty radio, or other problems. If the stations are too far away, noise will also interfere with the signal.

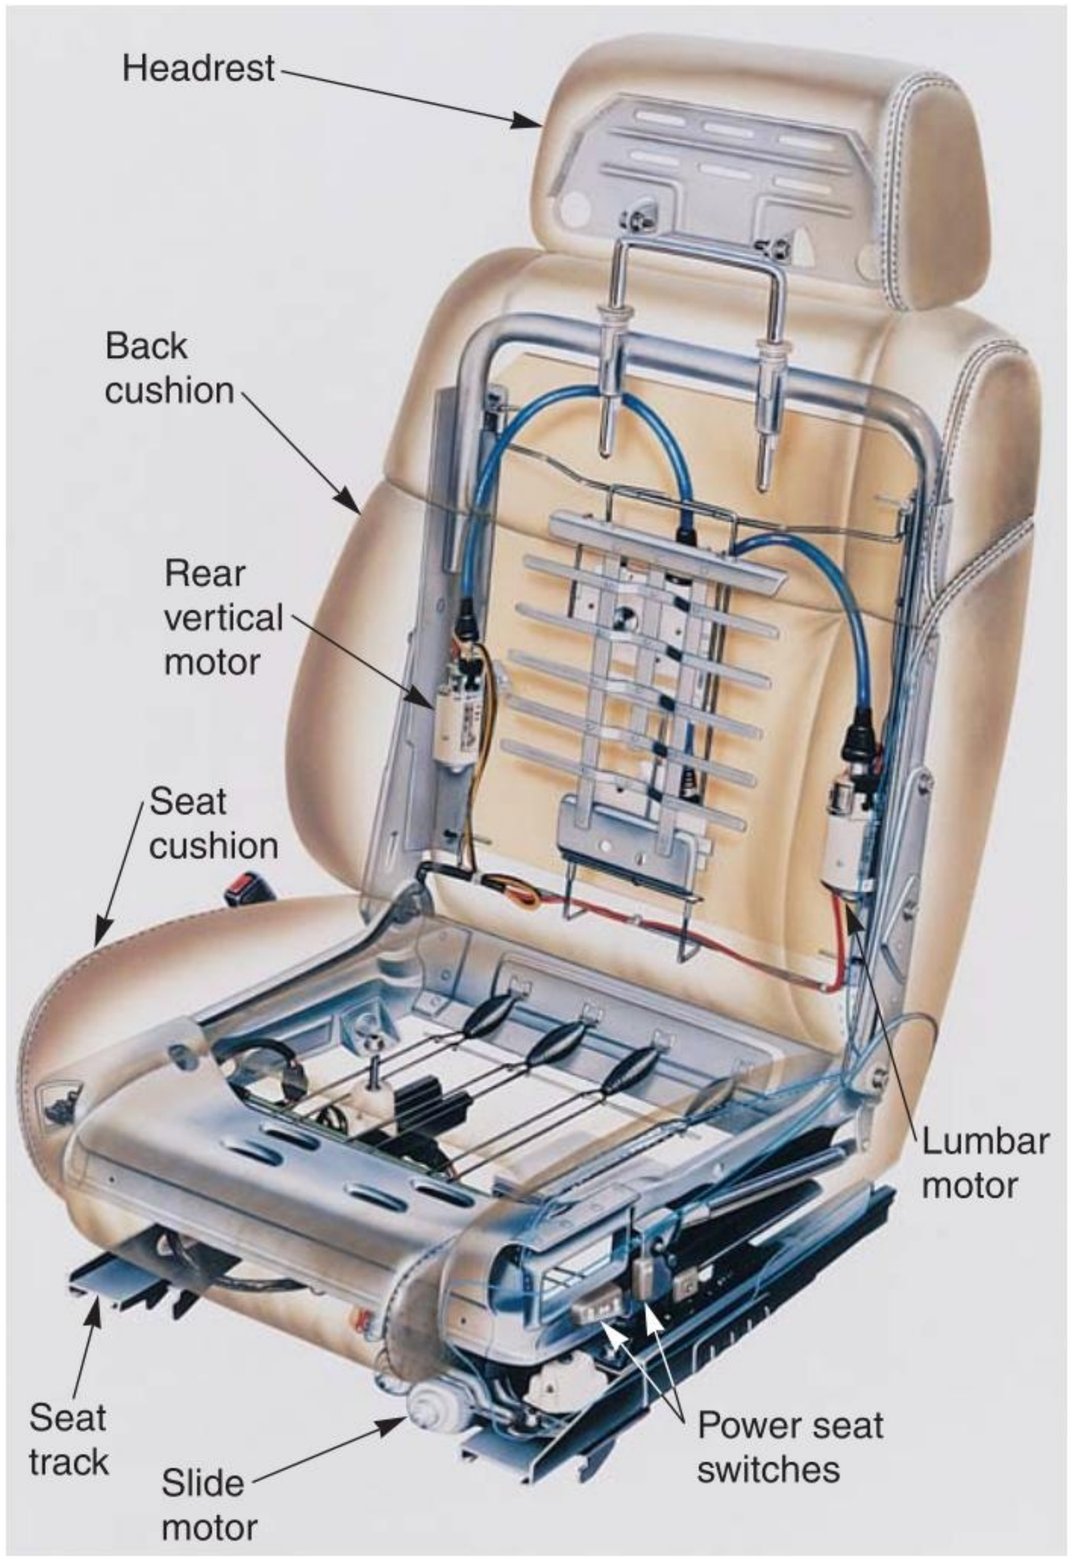
Study the sound of the radio noise to determine its source. For example, a low-pitched clicking that changes with engine speed may be caused by the ignition system (open secondary wire). A high-pitched whirring sound that also changes with engine speed could be from the electrical system (bad capacitor or alternator diode).

One of the first parts to check when radio noise is present is the antenna. Plug a known good antenna into the radio. Ground the antenna base and note any changes in radio output. If the noise is eliminated, the old antenna is faulty. If the noise remains the same, check the noise suppressors.

Noise suppressors are capacitors that absorb voltage fluctuations in the car's electrical system. They result in smoother dc current entering the radio, which reduces radio noise.

Noise suppressors can be located at the alternator, ignition coil, heater blower motors, servo motors, and ac hybrid drive motors. All these components can produce voltage fluctuations and noise. Refer to a service manual for exact suppressor locations.

A clip-on test capacitor can be used to check noise suppressors. Connect the test capacitor across or in place of the suppressor. If the radio static is reduced, the old noise suppressor may be bad.



General Motors

Figure 37-10. Cutaway view of a power seat shows the seat motors, transmission cables, tracks, and other parts. Seat removal may be needed to service seat motors.

Power Seats

Power seats use several switches, electric motors, and drive assemblies to change the seat positions. The power seat switches can be on the inner door panels or on the sides of the seats. The power seat motors and drive assemblies can be under or in the seats, **Figure 37-10**.

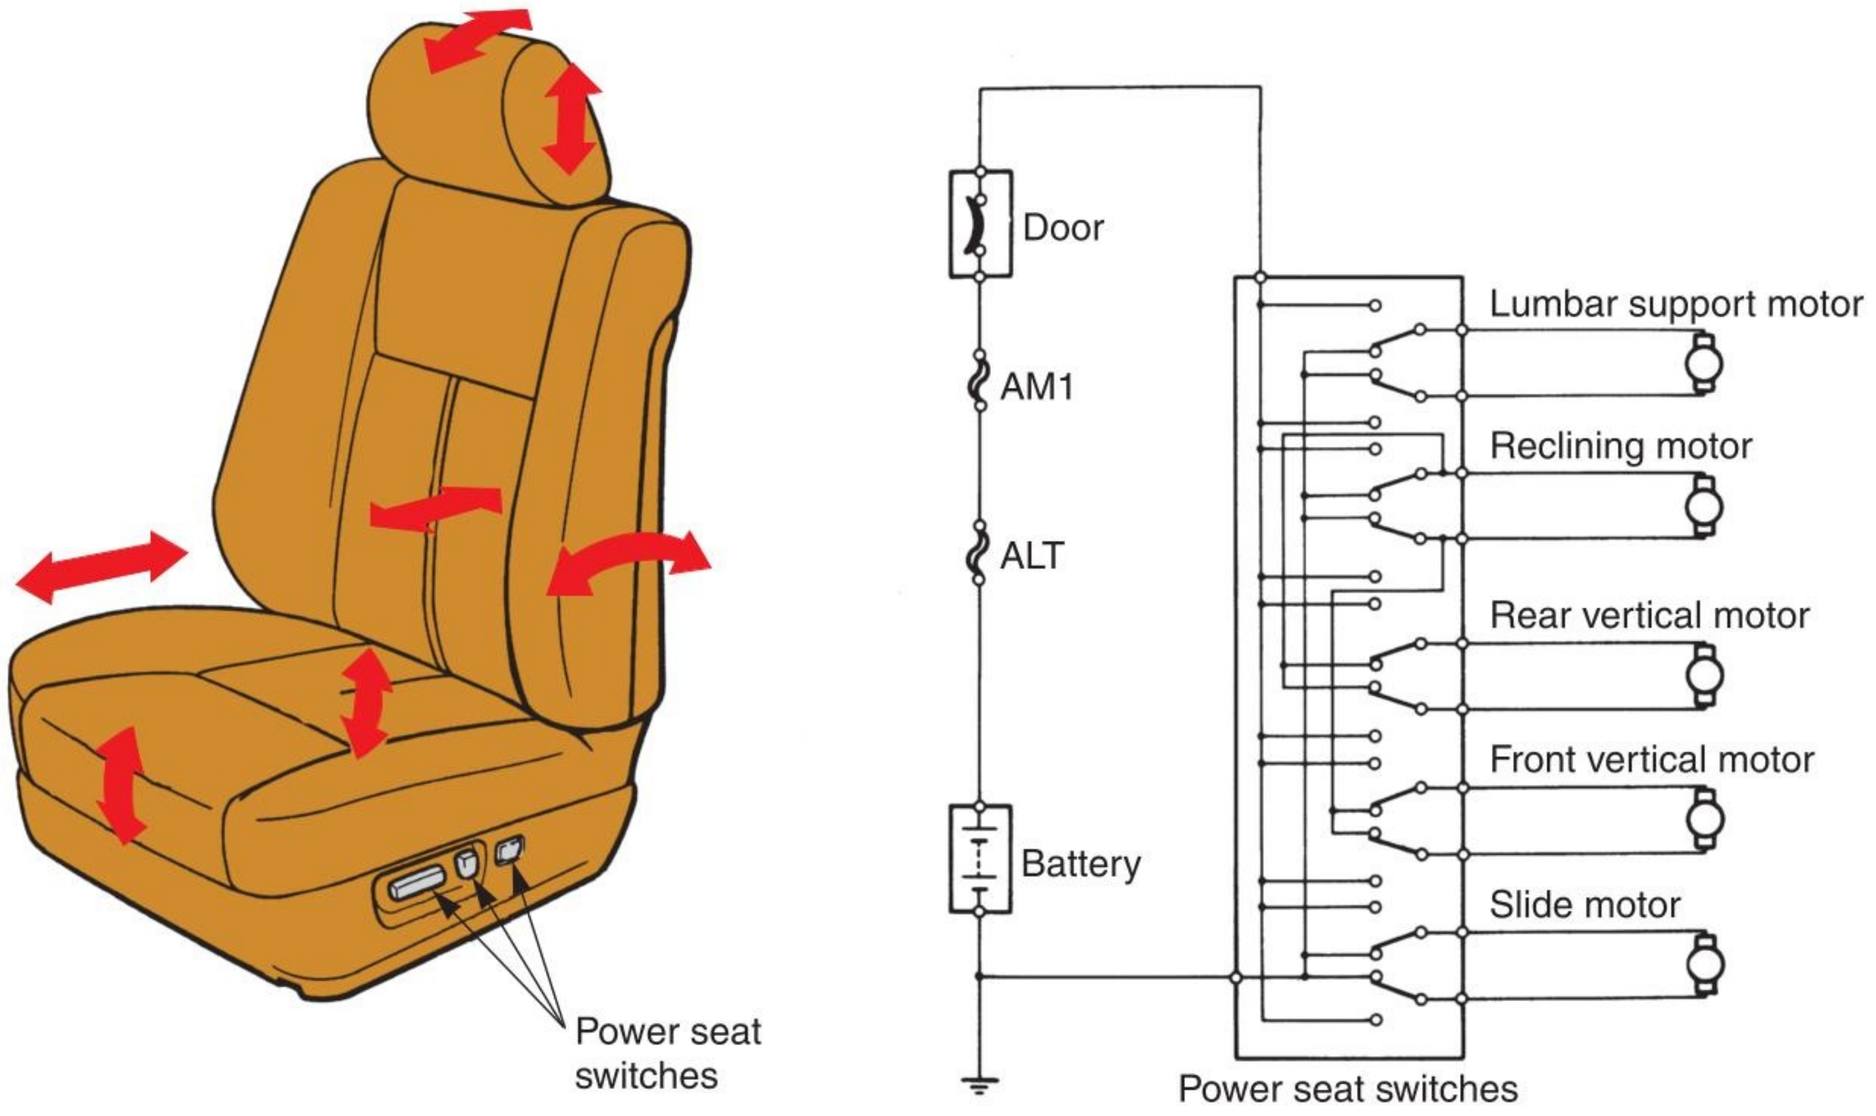
When activated by a switch, the reversible dc motors operate a gear mechanism. The gear mechanism changes the rotating motion of the motor armature into a linear motion that positions the seat. Most power seats have more than one seat motor. Power is sometimes transmitted from the power seat motors to the tracks or adjustment mechanisms by steel cables inside metal housings. **Figure 37-11** shows how a simple power seat circuit can create several seat positions.

Memory seats use a small computer, or module, to "remember" seat positions for several people. Some computer memory systems are networked and will remember not only seat positions but also steering wheel tilt positions, rearview mirror settings, and even electronic suspension settings for each driver.

Tech Tip

As a safety feature, many power seat memory systems will only work with the transmission shift lever in park or neutral. They are wired to the neutral safety switch or the electronic control module. Make sure the transmission is in park (automatic transmission or transaxle) when checking memory seat operation.

Copyright Goodheart-Willcox Co., Inc.



Driver's Seat

Electrical Circuit (driver's seat-standard type)

Lexus

Figure 37-11. Note that the wiring diagram shows which switches and motors operate the various seat adjustments.

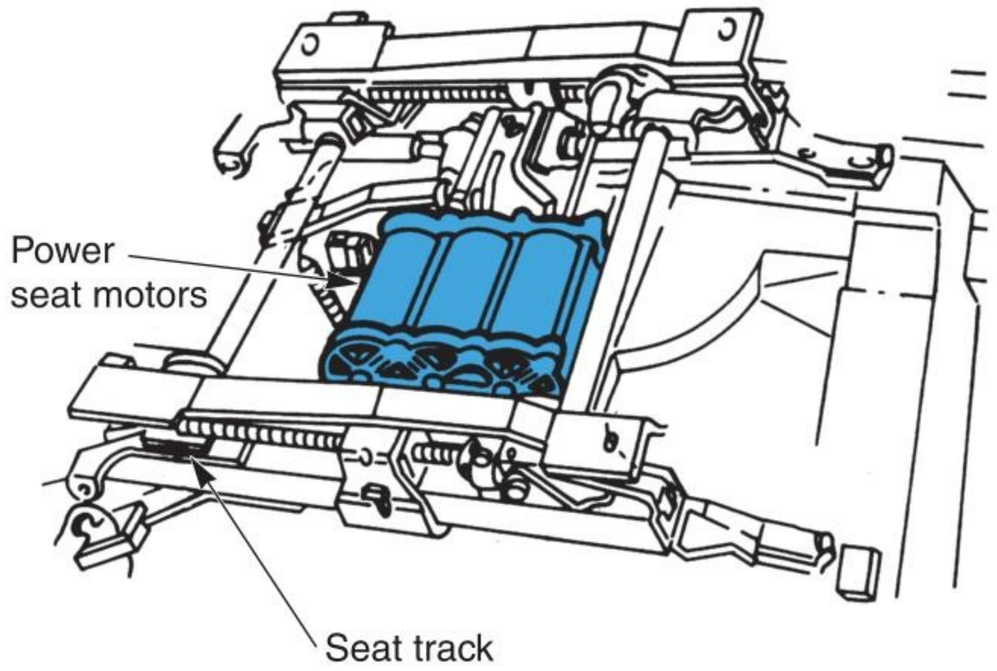
A ***power seat module*** can be programmed to return the seat to a desired position for different drivers. The seat is placed in the desired position and then one of two memory buttons is held down so the module can "remember" the seat location. The next time the memory button is pushed, the module can use the seat sensors and power motors to return the seat to the same location.

Power Seat Service

When diagnosing power seat problems, try to isolate the problem source to a specific area of the circuit. If only one seat fails to work, check parts that affect only that seat. Test its control switch and the wiring between the switch and motors. When the seat only fails in one mode (up and down, for example), check the motor and transmission (gear-cable mechanism) providing that action.

If both front power seats fail to function, check the common section of the circuit. Inspect the fuse, circuit breakers, wire connections, and any other components affecting both seats.

The most common reasons for power seat problems are the switches and drive motors. Remove and replace any switch or motor that does not work properly. See **Figure 37-12**. If you have difficulty repairing a power seat, read the information in a service manual. It will give directions for servicing the particular unit.



Ford

Figure 37-12. This seat has been removed to service a power seat motor. If the seat works in all but one position, only service the motor that operates that seat adjustment.

Copyright Goodheart-Willcox Co., Inc.

Heated Seats

Heated seats use a heating element (or multiple heating elements), switch, relay, and related wiring to warm the seat cushions in cold weather. Most systems have two large-resistance wires or heating elements routed through the seat cushions. See **Figure 37-13**.

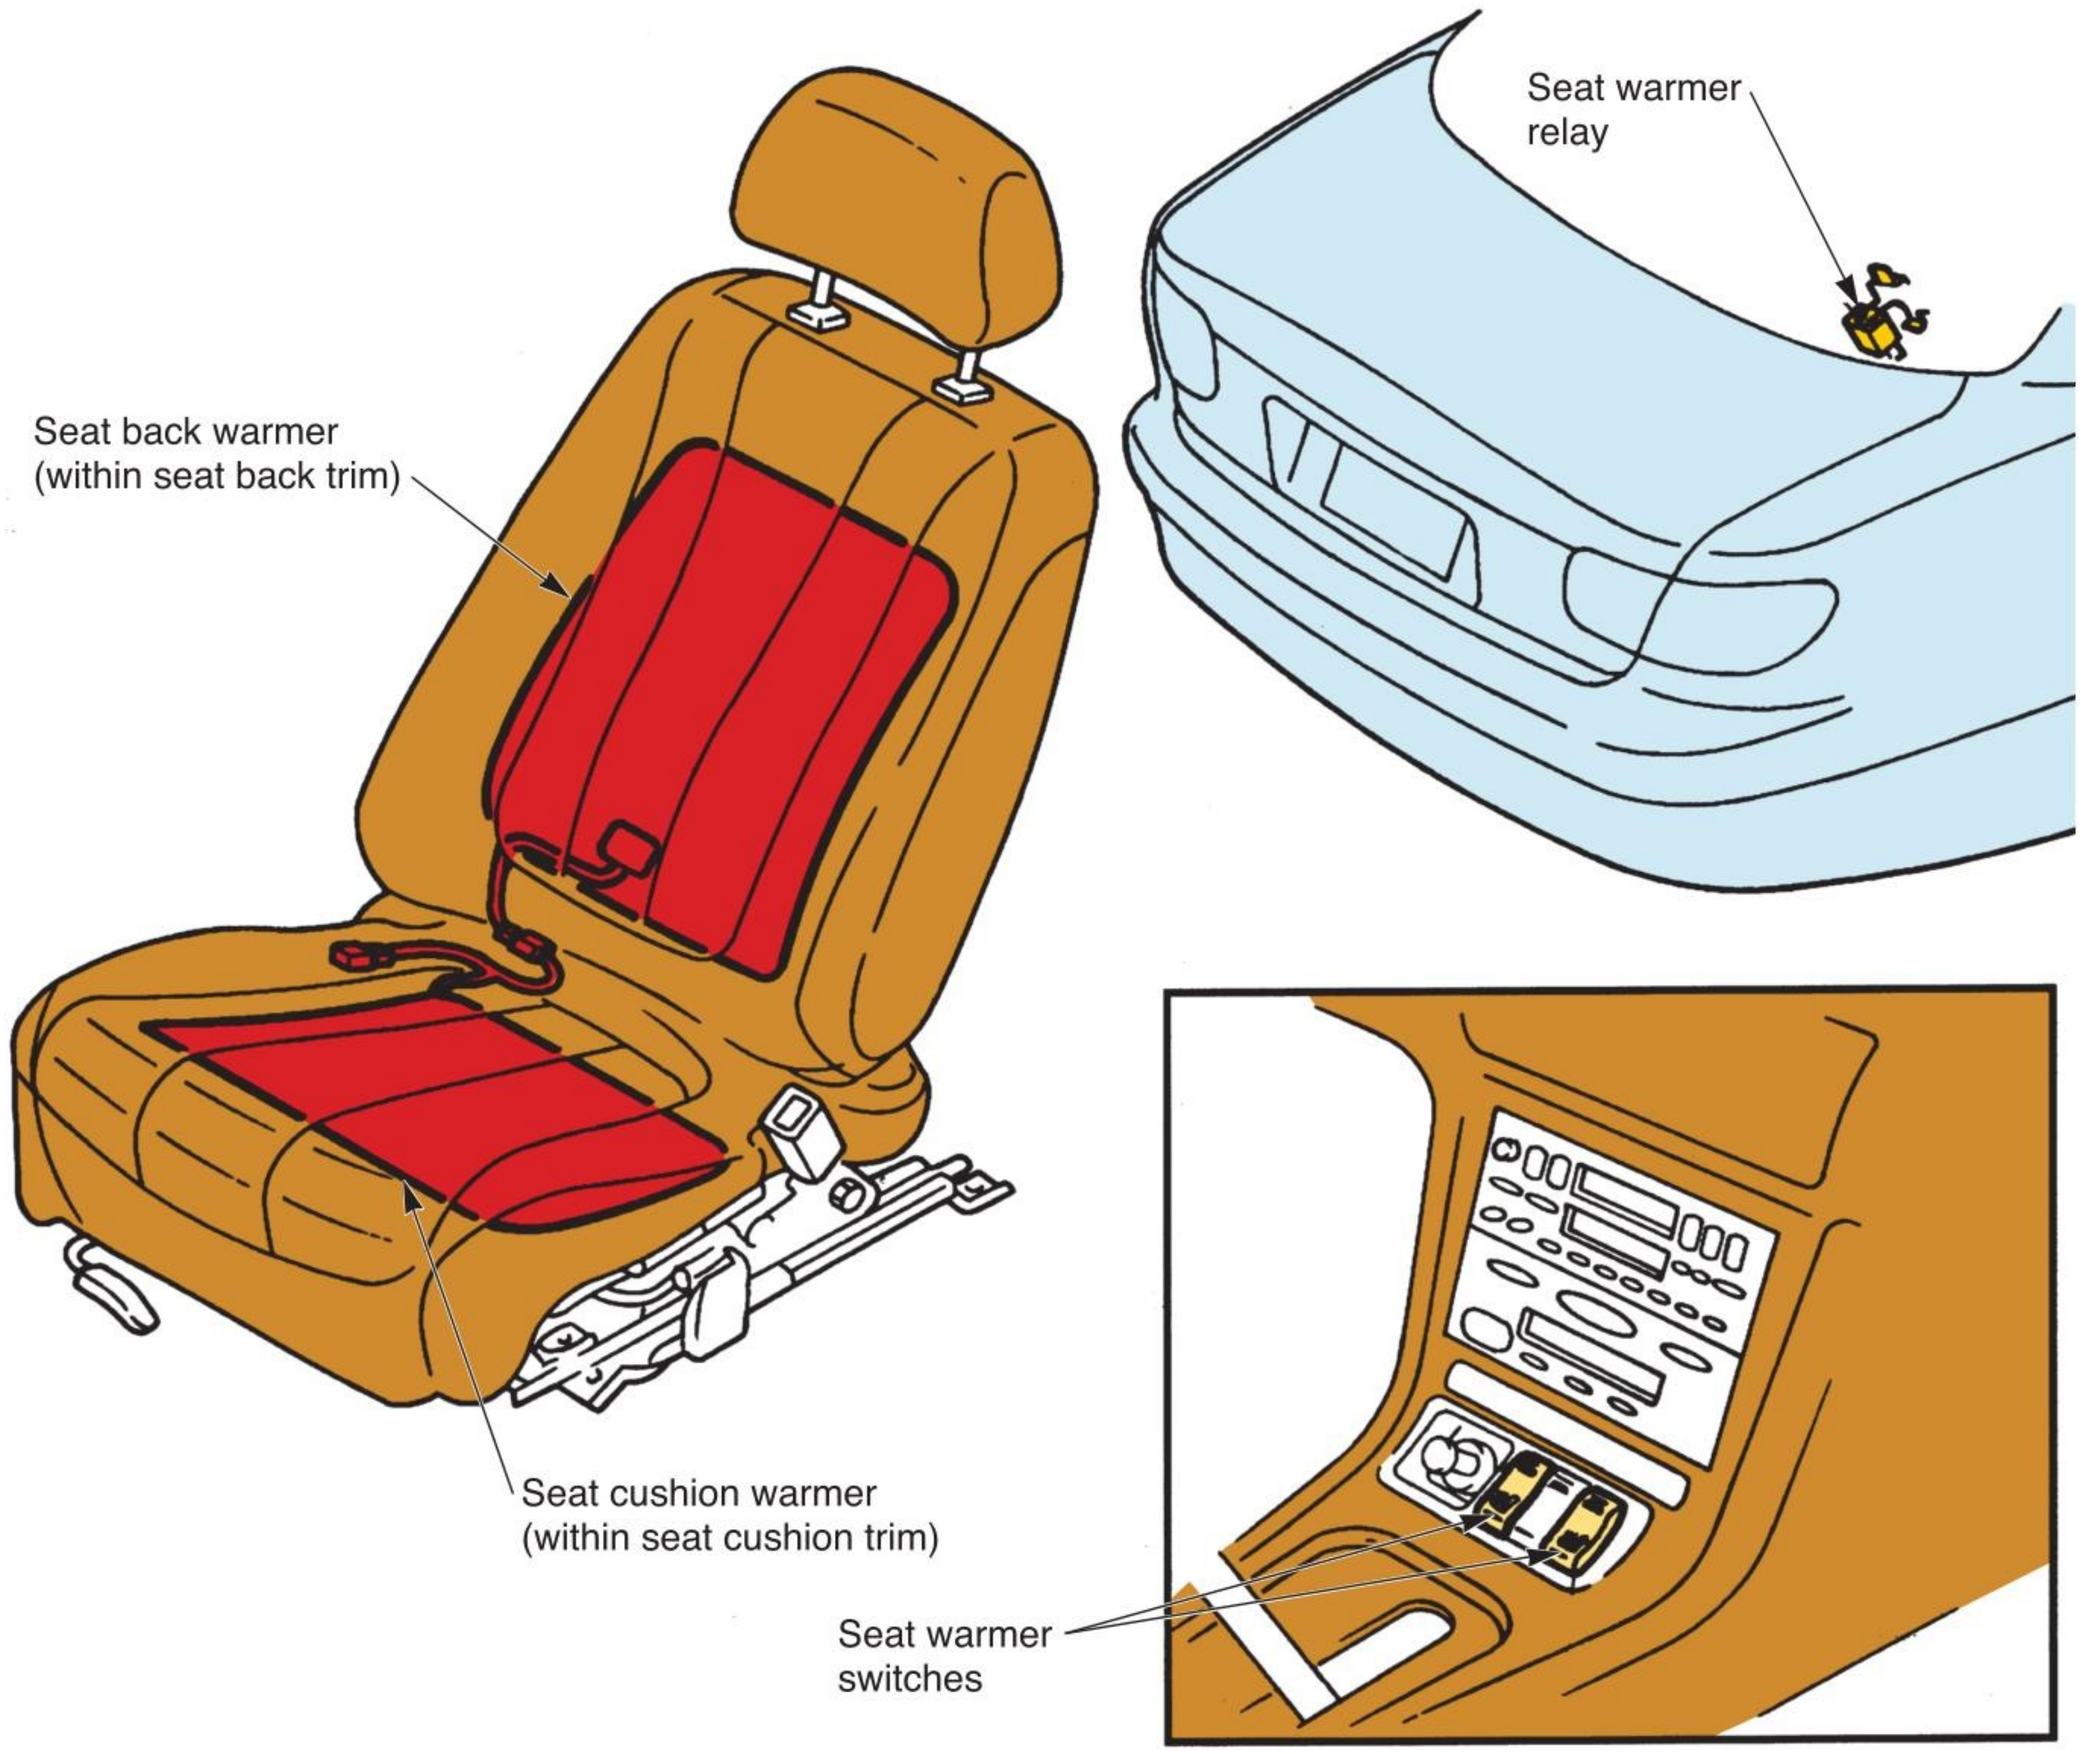
When you press the seat warmer button or switch, it energizes the warmer relay. The relay is a holding relay that stays on once energized. The relay then sends high current through the heating elements, which makes them get warm. The seat warmers stay on until you press an off button or until you shut the ignition switch off.

To service heated seats, check the fuse first. Next, test the warmer switch and then the relay. If you are getting power to the heating element but it does not get hot, the element is probably open and must be replaced.

Power Windows

A ***power window*** uses a control switch, reversible electric motor, circuit breaker, fuse, and related wiring to operate the door windows, **Figure 37-14**.

A small electric ***power window motor*** is located inside each door to operate the ***window regulator*** (up-down mechanism for the glass). The motors have a ***gearbox***, or ***transmission*** (usually worm and



Mazda

Figure 37-13. A heated seat simply uses two wires threaded inside seat cushions. First check for power to the resistance wires from the switch and relay. Then verify problem with resistance wire by testing it with ohmmeter.

Subaru

Figure 37-14. Study the basic layout of a complete power window system. Switches operate electric motors inside each door. With inoperative power windows, check fuses and switches first. Then, remove door panels to test and service window motors.

ring gear), that changes the rotating motion of the motor armature into a partial rotation of a larger gear. This action pushes the window open or closed. See **Figure 37-15**.

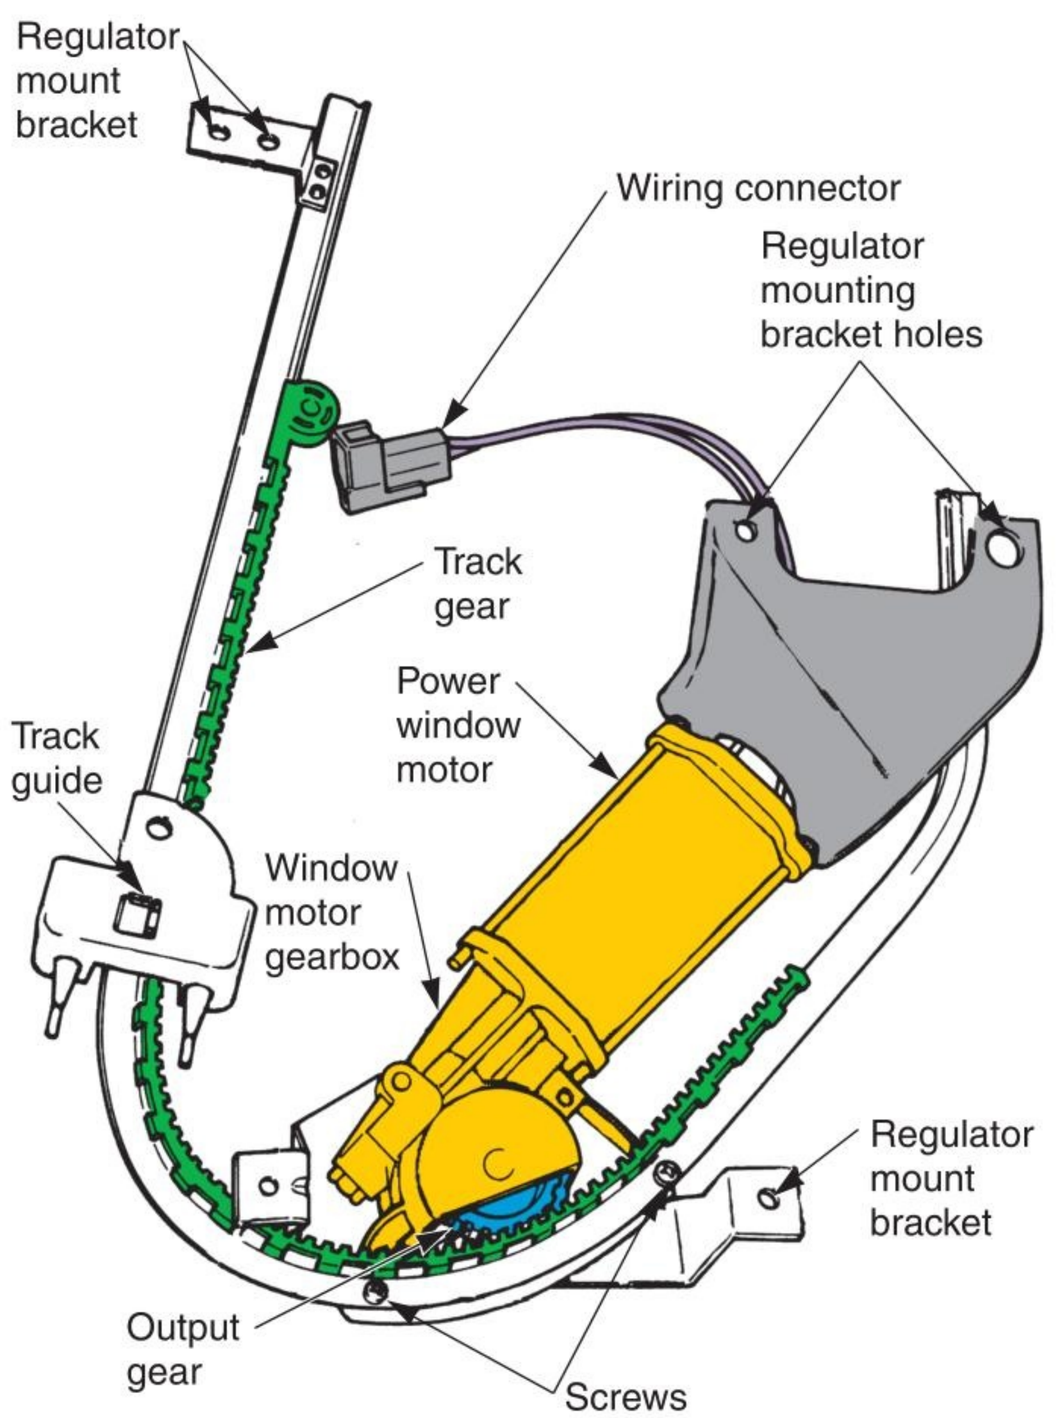
A circuit breaker protects the window motor from overheating damage. The breaker can open if the switch is held in one position too long. The circuit breaker can be located inside the motor or elsewhere in the circuit. A basic power window circuit is shown in **Figure 37-16**.

Some power windows will stop or reverse direction if an obstruction resists window closing. In some of these systems, a magnetic trigger wheel is mounted on the motor's armature shaft. As the trigger wheel turns, it creates a signal in a magnetic or Hall-effect sensor in the motor assembly. If the sensor outputs a slower-than-normal signal, the power window ECM will cut voltage or reverse the polarity of the voltage going to the window motor. This stops the window or lowers it to prevent damage to objects or injury to people who accidentally put parts of their bodies (hands, head, and arms) into the path of the window as it closes.

Power Window Service

When none of the power windows work, first check the fuse or circuit breaker for the whole system. If only one of the windows is inoperative, use a test light to check for power to its switches and motor.

If you hear a humming sound when a window switch is pressed, the motor gearbox may have



Chrysler

Figure 37-15. Check for a good electrical connection at the power window motor first. Also check for worn drive gear, track damage, and bad motor. Loose mounting bolts will cause a clunking sound when window changes direction.

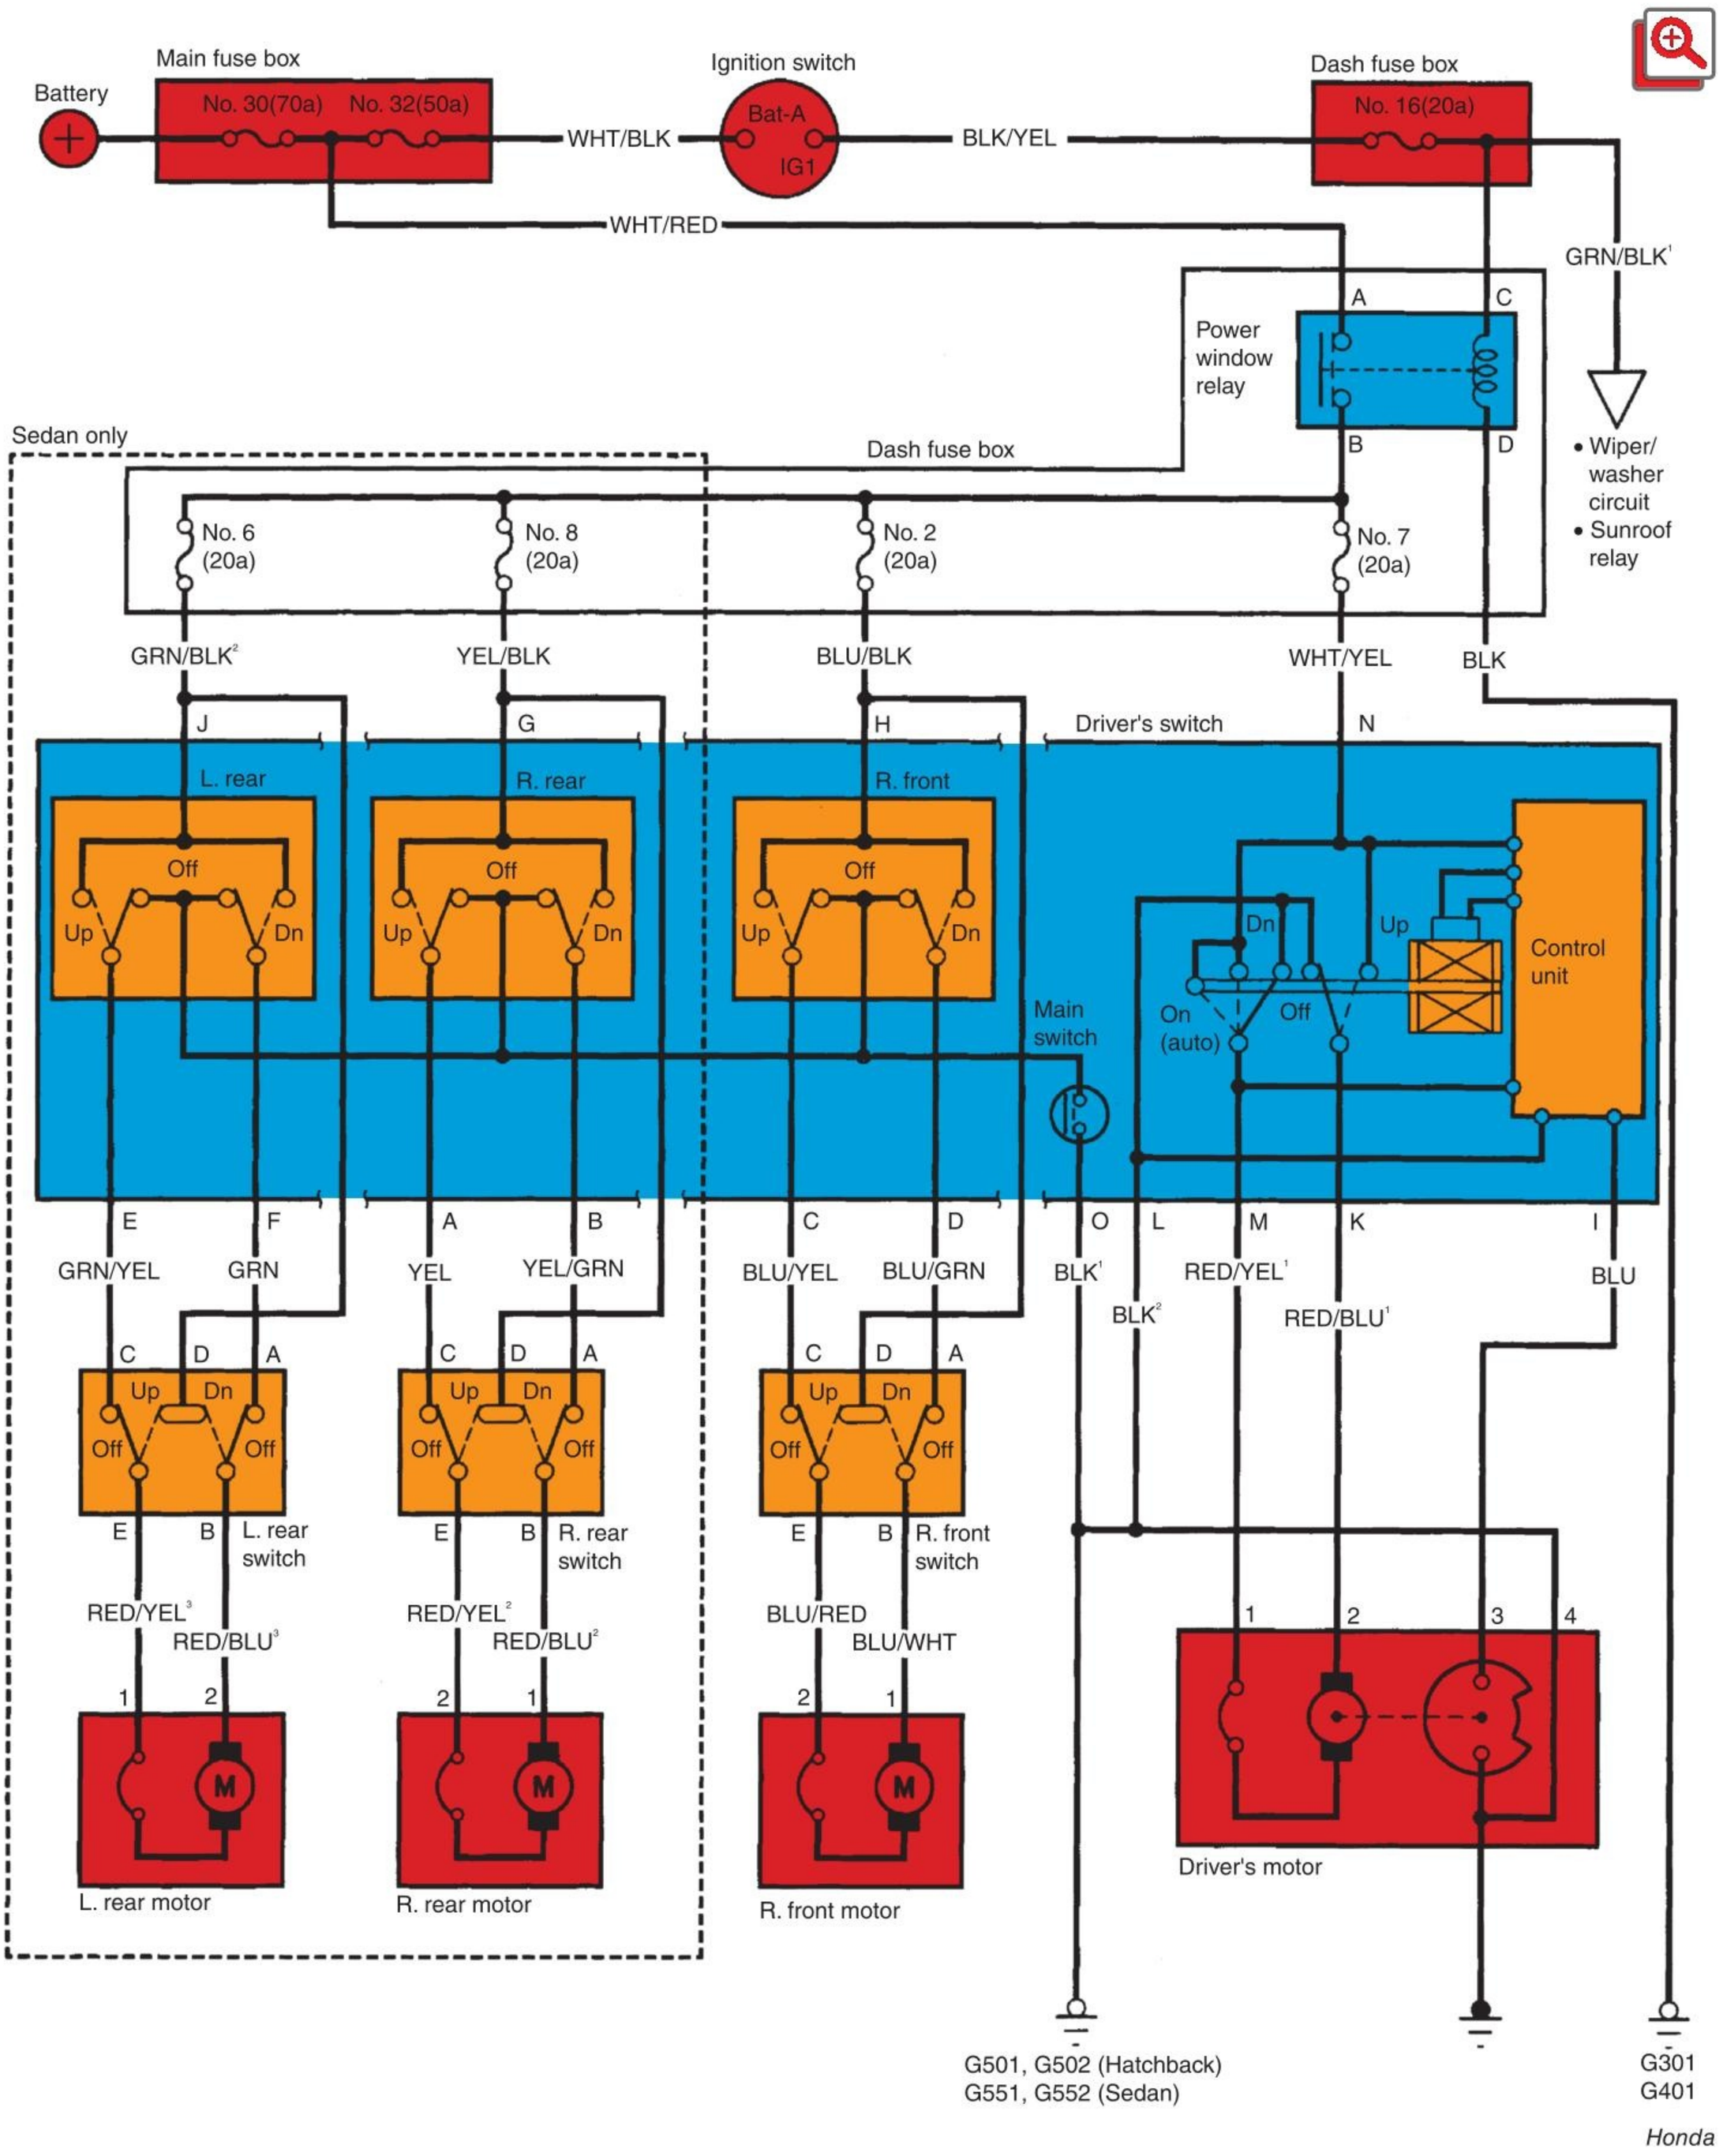

Figure 37-16. Study this wiring diagram for a typical power window circuit. Note how the electronic control unit operates the driver's window. It causes the window to go all the way down when the button is briefly pushed. The driver can release the switch right away to again grasp the steering wheel. This feature is handy at tollbooths.

Copyright Goodheart-Willcox Co., Inc.

stripped gear teeth. The plastic gears in the window motor gearbox can strip after prolonged service. The motor will spin, but movement will not be transferred to the window. If the motor or the switches are found to be bad, they should be replaced.

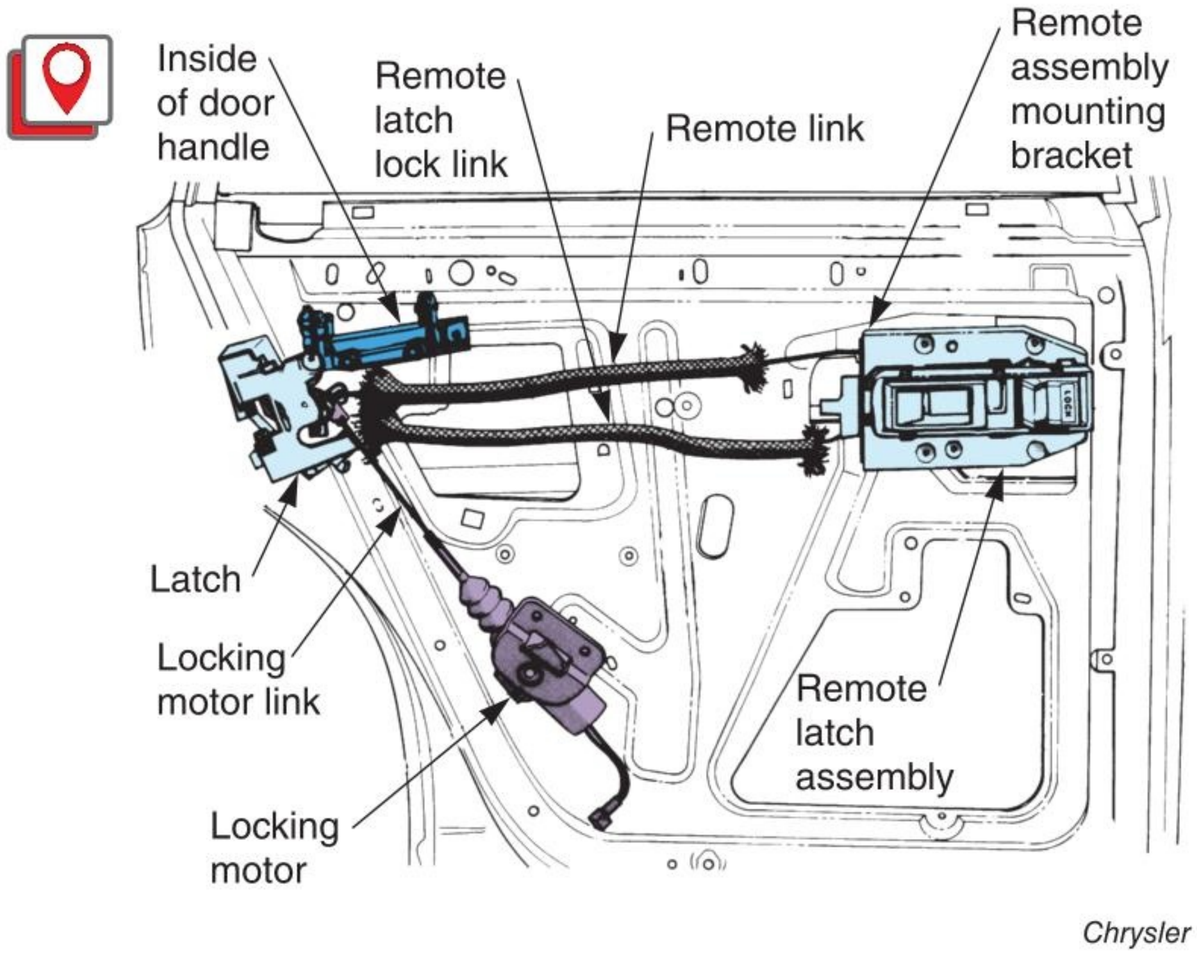
With hard-to-find problems, refer to the service manual wiring diagram for the power windows. The diagram will show all the components that could affect power window operation and help with troubleshooting.

Warning

Be careful because the sheet metal edges on and in doors can cause serious cuts or lacerations. Also, never wear a wristwatch or rings when servicing inside a door. The metal could short across wires or get caught, causing injury or part damage.

Power Door Locks

Power door locks typically use electric switches and solenoids or motors to operate the door lock mechanisms, **Figure 37-17**. When the door key is turned, it closes a switch. A motor or solenoid then moves an arm on the door latch to lock or unlock the door. An additional switch is normally provided on the driver's door panel.



Chrysler

Figure 37-17. Most power door lock systems use a large solenoid to activate the latch. Study construction of this system.

If all the power door locks fail to function, check the main fuse, electrical connections, and other components common to the whole circuit. If only one door lock is bad, check its switch and solenoid or motor. The door lock switches and solenoids are the most common causes of trouble.

Figure 37-18 is a typical power door lock circuit. Study its connections and components.

Door Panel Removal

Door panel removal may be needed to service power windows, seat control switches, door latches, or radio speakers.

Service Procedure

The basic procedure for removing a door panel is as follows:

1. Remove all screws that hold the door panel to the door frame. Some are visible; others may be covered with small plastic buttons or covers.
2. Unscrew and remove the door lock button.
3. Remove the inner door handle and window crank, if used.
4. Once all major parts have been removed, you often have to pop out spring clips around the outside of the door panel. Be careful not to bend or tear the panel. Refer to a manual if you have difficulty.

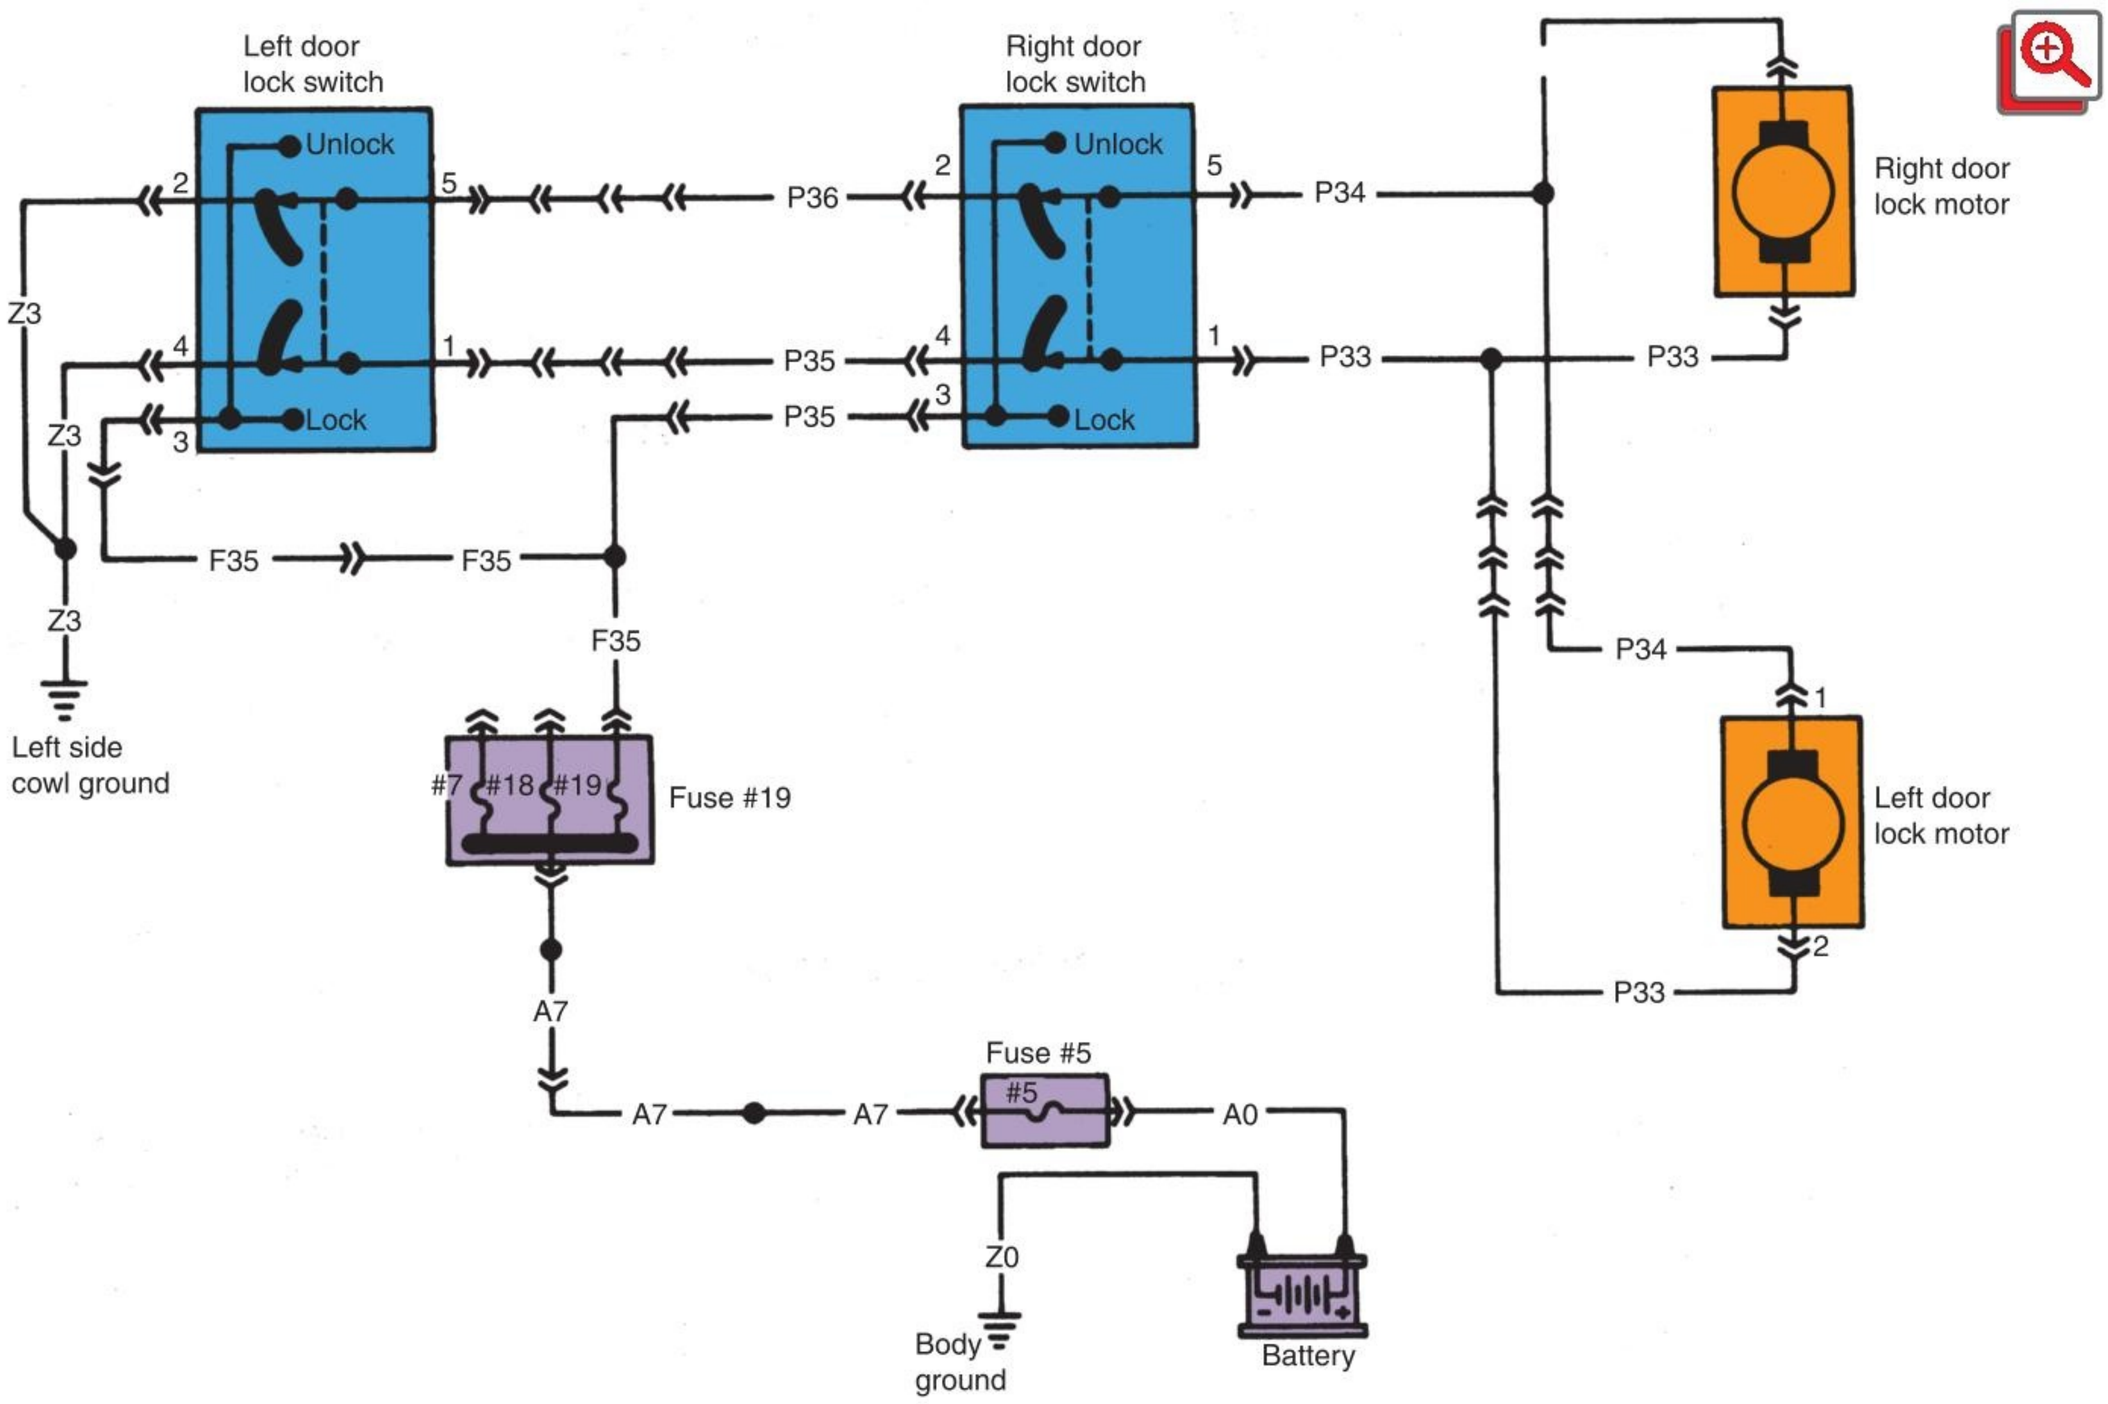
Tech Tip

The wiring going through the body and into the door can break internally after the door has been opened and closed thousands of times. Keep this in mind when troubleshooting any power device inside or on the door.

Power Trunk Release

A ***power trunk release*** is comprised of a solenoid mounted on the trunk latch, a fuse, a switch, and related wiring. When you close the trunk release switch, it sends power to the solenoid. The solenoid plunger then acts on the trunk latch and the trunk pops open.

Copyright Goodheart-Willcox Co., Inc.



Chrysler

Figure 37-18. Basic door lock circuit connections and components.

Service of this circuit is fairly simple. Most problems are in the switch or solenoid. Use basic testing methods to isolate the problem.

Power Steering Wheel

A ***power steering wheel*** uses a computer and various switches, sensors, and motors to automatically tilt and telescope (extend or retract) the steering wheel. Like memory seats, most systems can be programmed to position themselves automatically. Some are tied to the memory seat circuit and use the same computer.

Figure 37-19 shows a power steering wheel circuit. Study its parts and electrical connections.

Rear Window Defogger

A ***rear window defogger***, also called a ***rear window defroster***, commonly uses a switch, a relay, an indicating light, and a window heating grid. See **Figure 37-20**.

When the switch is turned on, it allows current to flow to the indicator light and to the heating grid. The heating grid is resistance wire, usually mounted on or in the window glass. Current flowing through the grid causes the wire to heat up and defog or deice the vehicle's window.

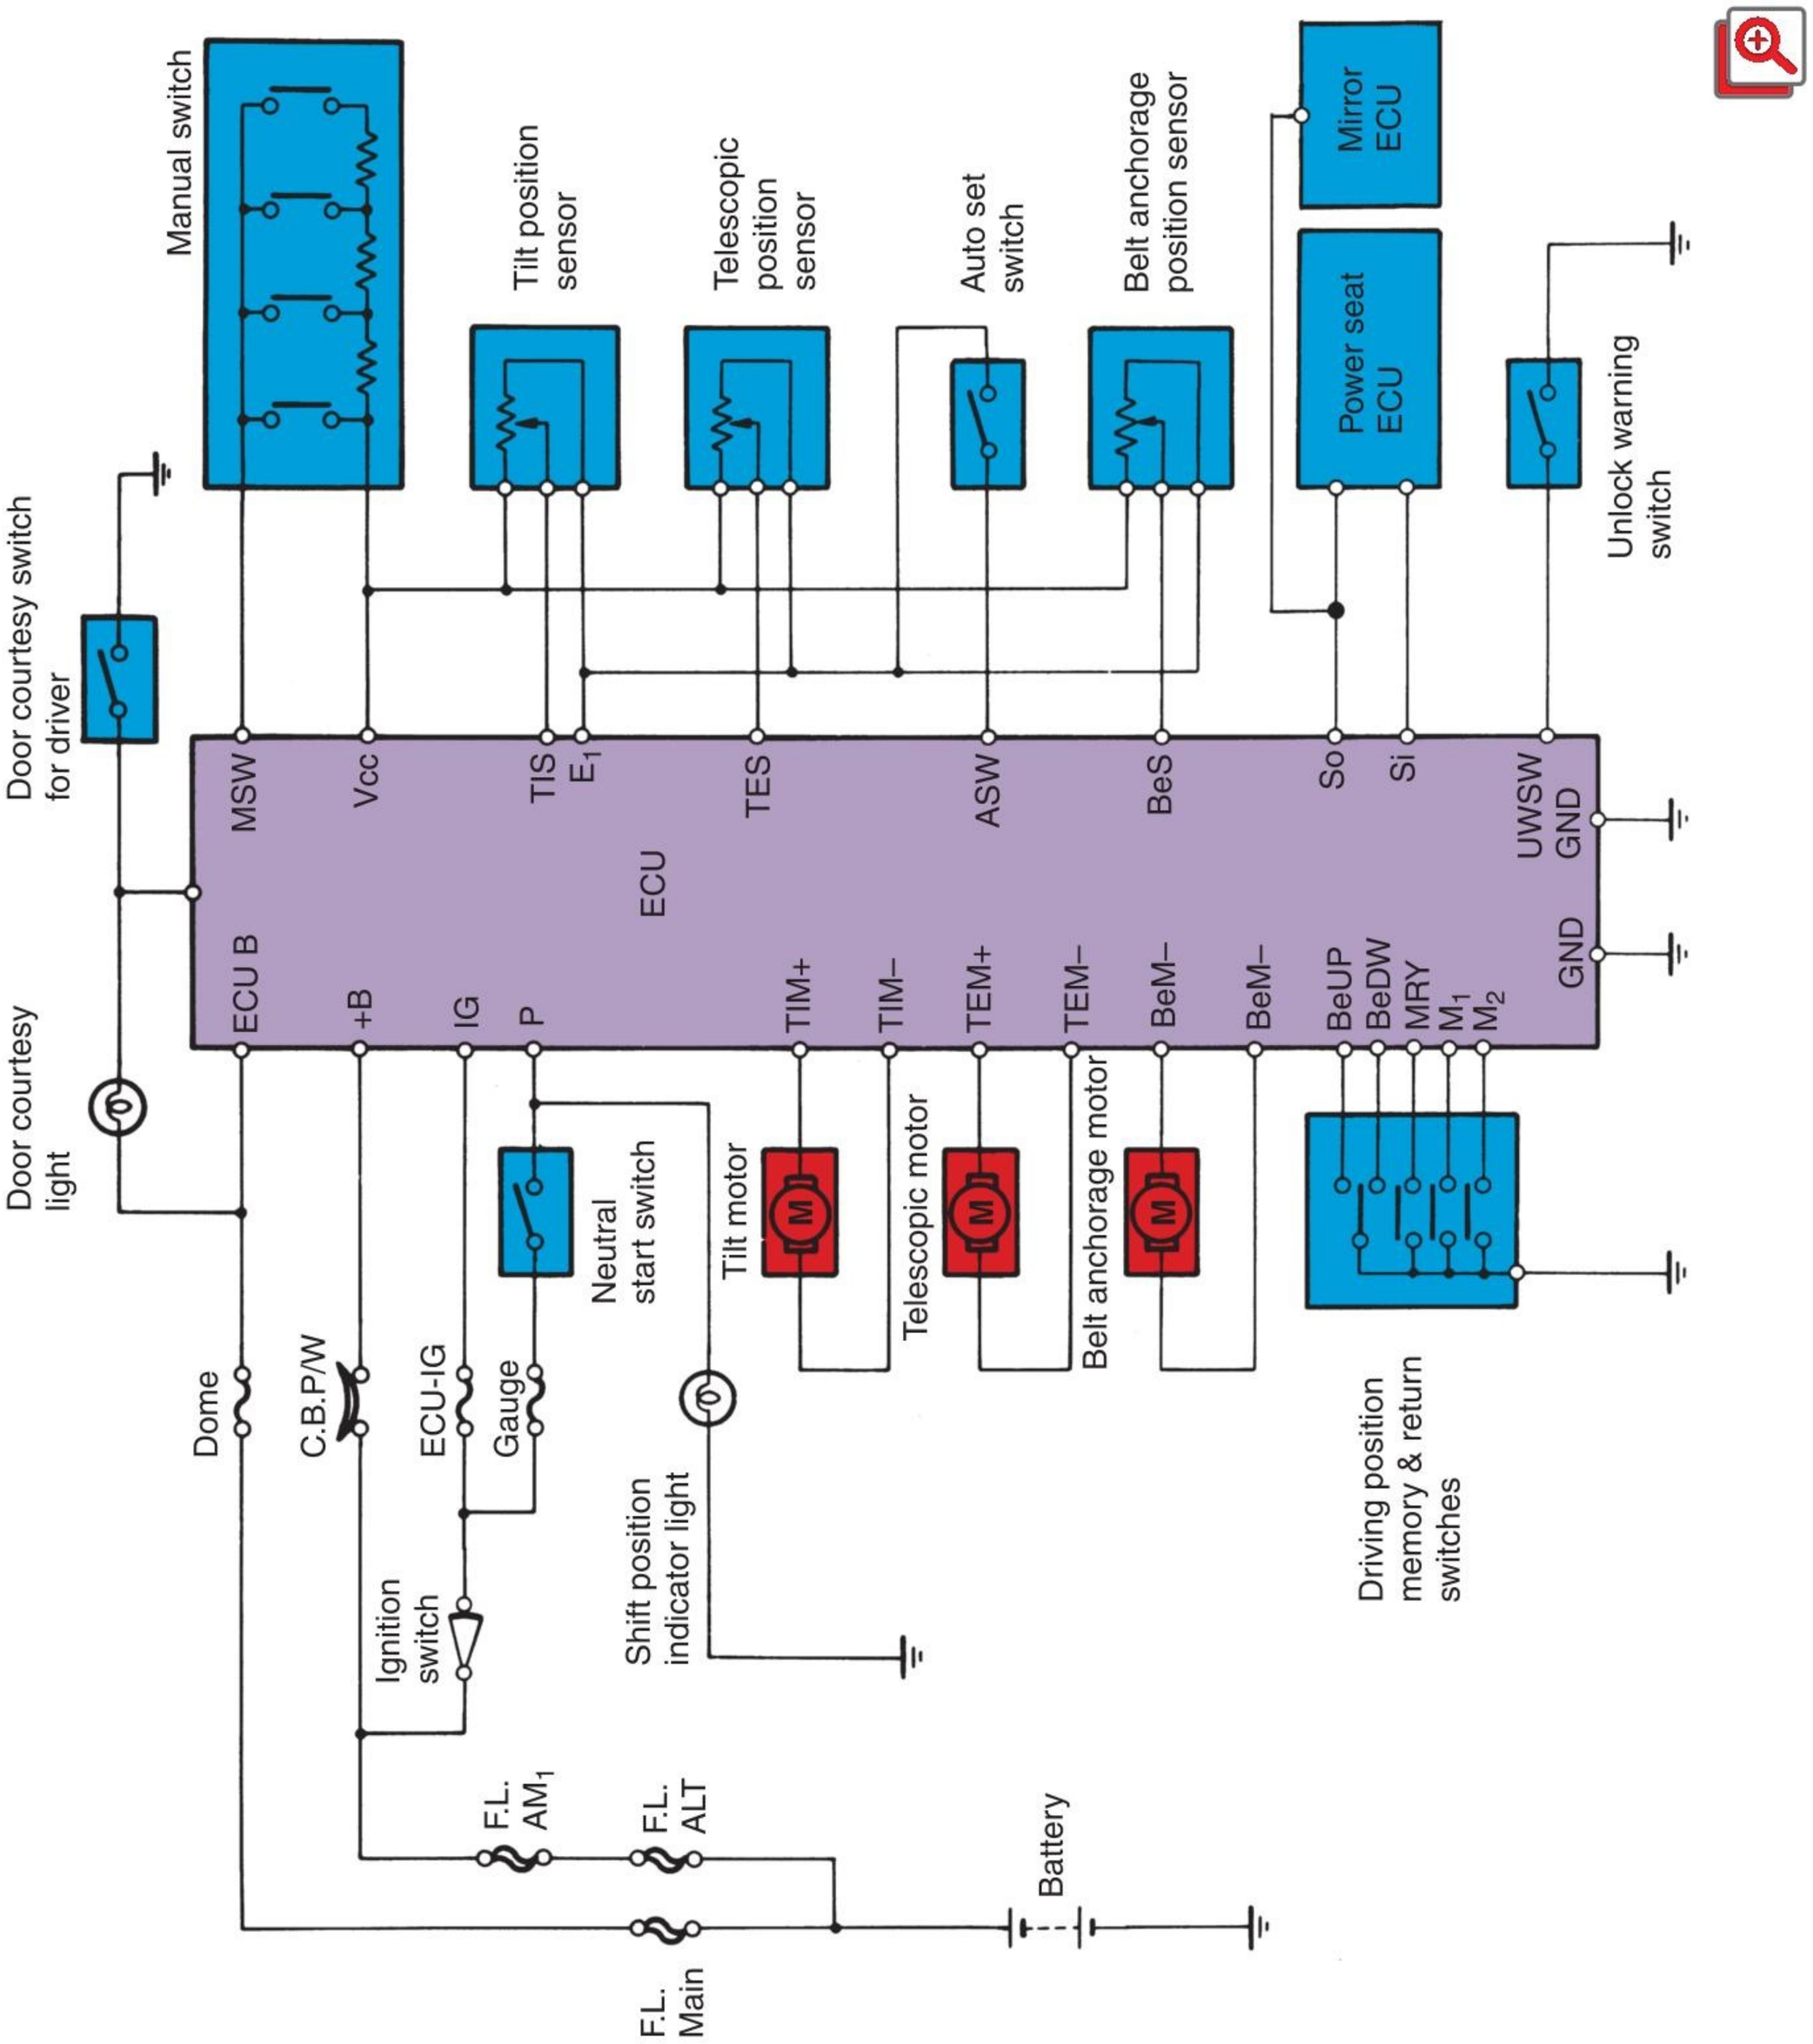
Some rear windows have ***zone clearing defoggers***, which heat and clear one area before another. Most have higher-resistance wire in the middle to heat and clear the center area of the glass first. They provide for more rapid rearview mirror use. Then, the rest of the window heats and clears.

A few vehicles use a blower or fan to defog and deice the rear window. Its operation is similar to a heater blower.

Window Defogger Service

When the grid-type rear window defogger does not work, check the fuse first. Then, check for adequate voltage going to the grid with the power switch closed.

Copyright Goodheart-Willcox Co., Inc.

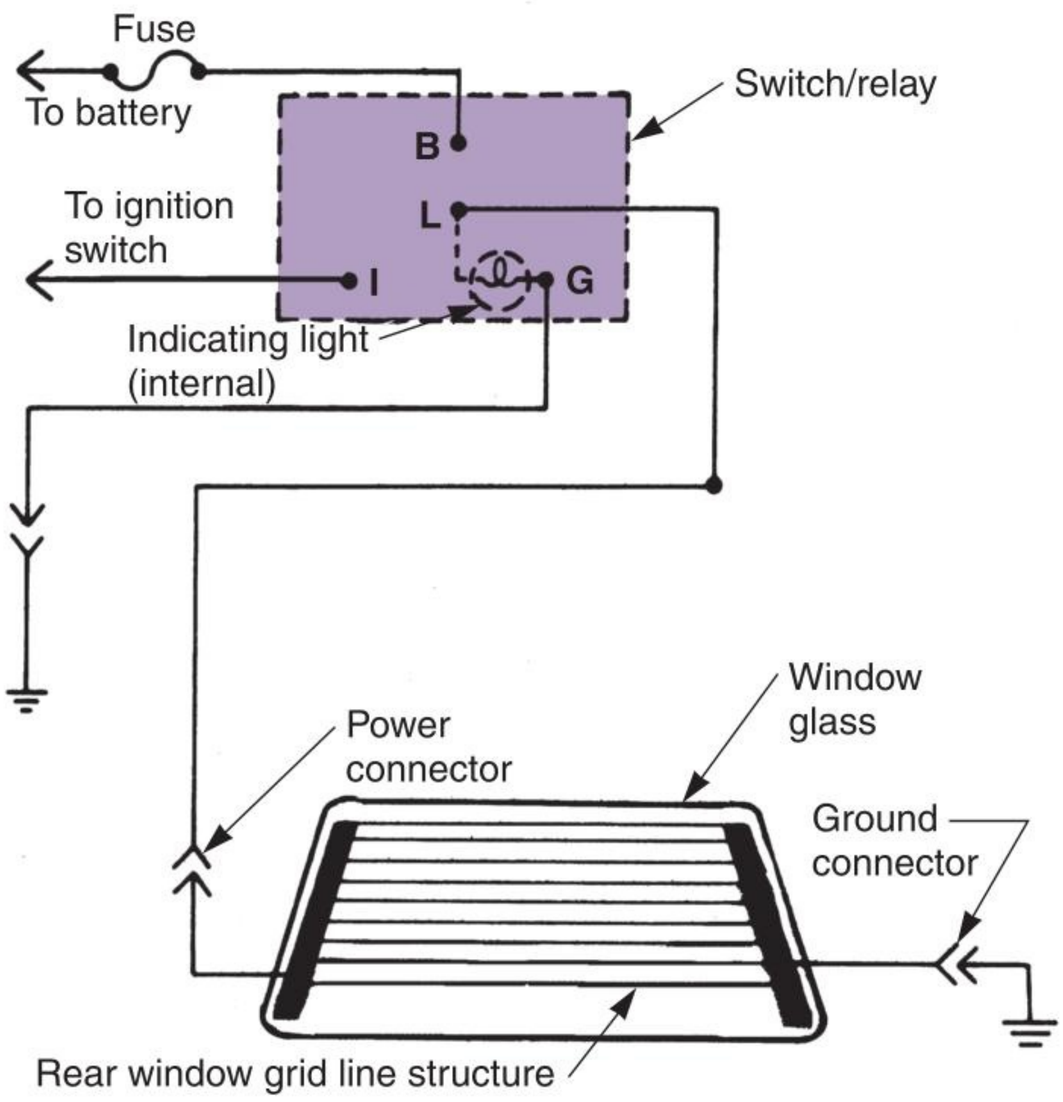


Subaru
Lexus

Figure 37-19. This wiring diagram shows how the ECU can control steering wheel tilt, telescoping action, and the seat belt anchoring motor. Note sensors and switches that feed data to the ECU. Also note the power seat ECU is also networked to this ECU.

If voltage is low at the grid input, test the circuit for opens. If power is being fed to the grid, the grid may be bad. Test the grid as described by the manufacturer. Some allow the repair of a broken heating grid using a special ***grid repair agent***, which conducts electricity.

Copyright Goodheart-Willcox Co., Inc.



Chrysler

Figure 37-20. This is a circuit for a rear window defogger. When fed current through a switch and relay, the resistance wire on the glass heats up.

Heated Windshield

A ***heated windshield system*** uses a special conductive film sandwiched inside the windshield glass. The transparent film in the windshield glass is usually a zinc and tin oxide material. When high voltage (typically 70–90 volts) is passed through this clear conductive film, the glass heats up and melts ice or snow.

Most systems use a control module to full-field the alternator and bypass the rest of the electrical system so that enough energy is available to rapidly warm the windshield glass. The other electrical systems operate off of battery voltage when the windshield deicing system is turned on. If the system senses a low battery charge (below 11 volts), the system automatically shuts off to prevent excessive battery discharge.

Warning

Use caution when working on heated windshield systems. When turned on, there is enough voltage and current to cause a serious electrical shock. Electrocution could result from being shocked by this system's high power output!

Reminder System

A ***reminder system*** (warning system or chime system) makes an audible signal (buzz, chime, or audible warning) if:

- Seat belts are not fastened when the engine is started.
- Keys are left in the ignition with the engine off.
- The headlamps are left on with the engine off and a door is open.

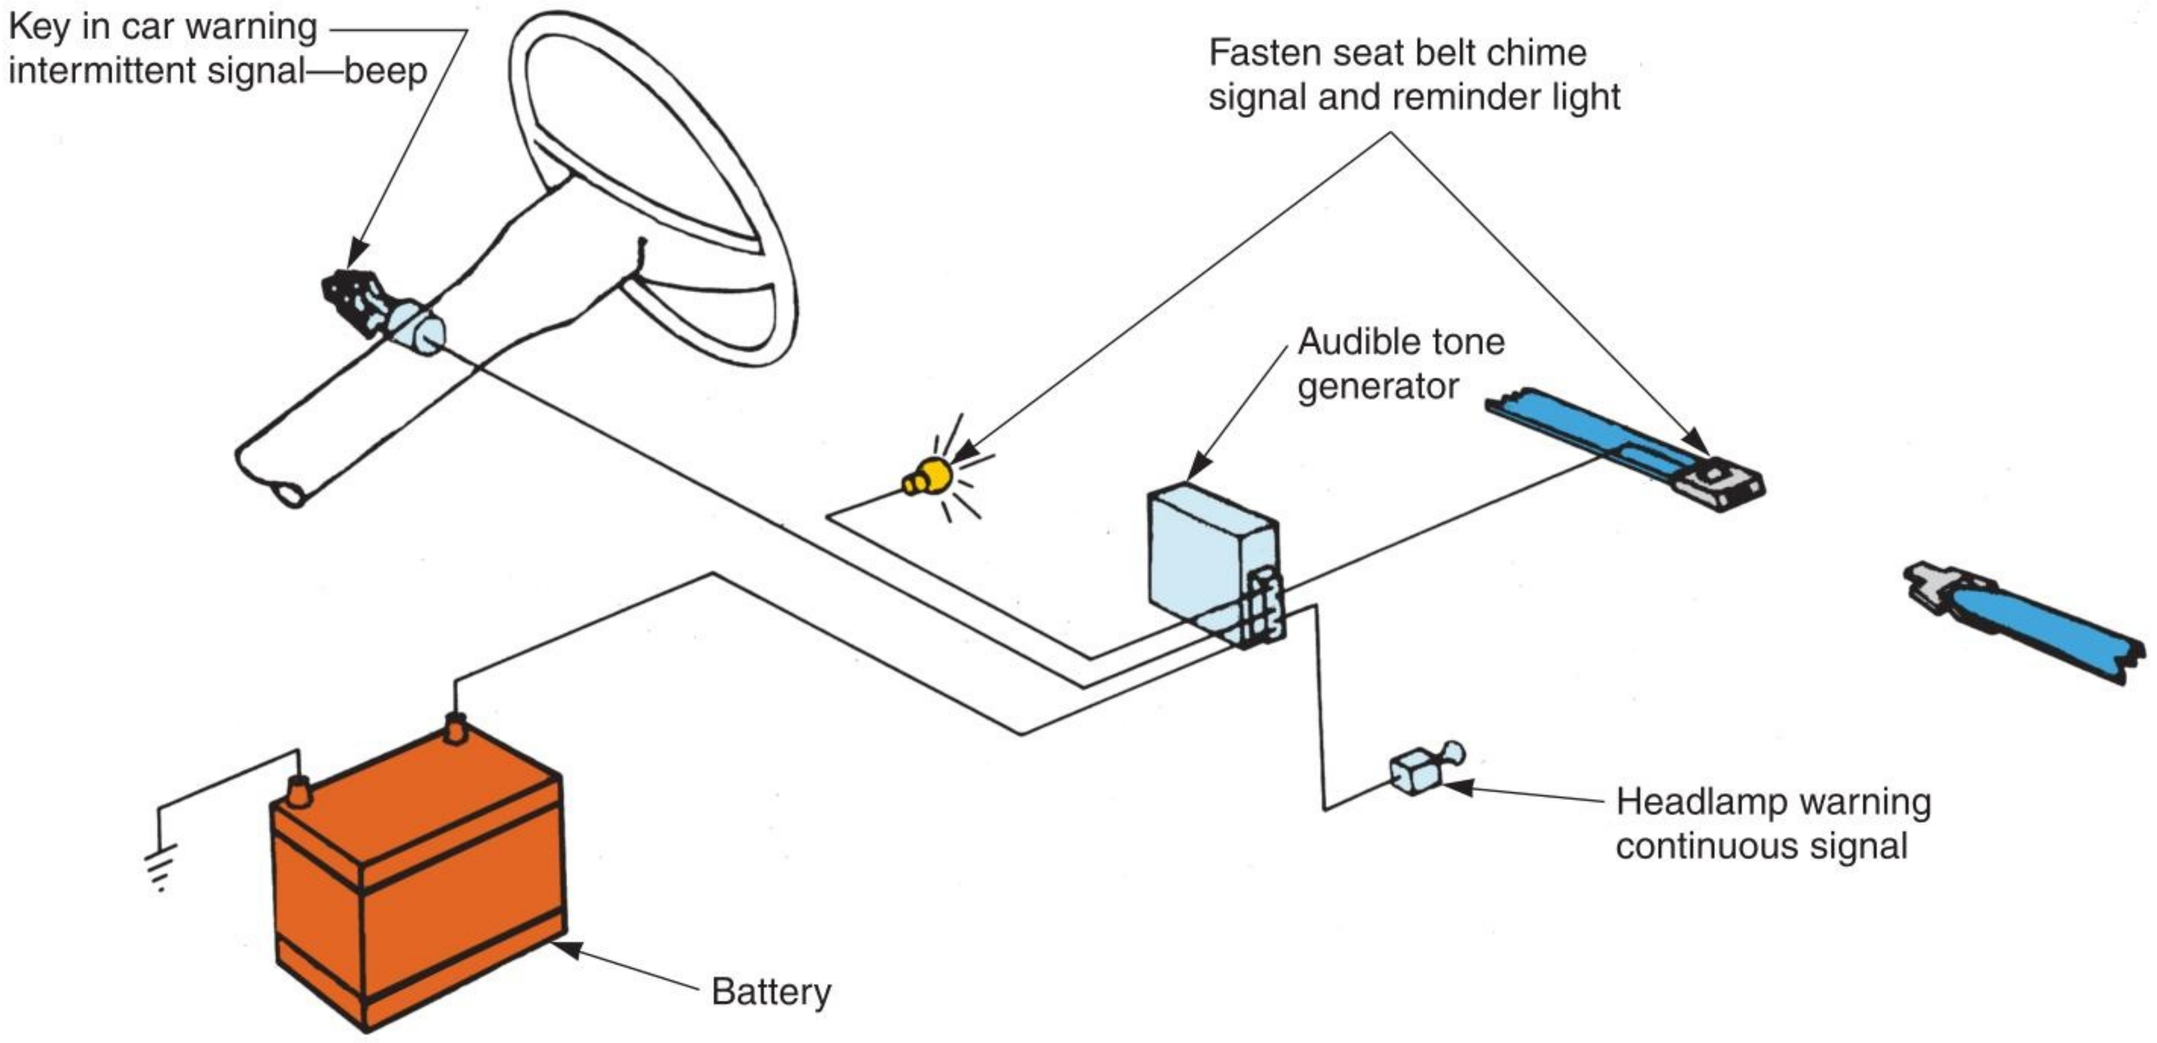
Refer to a service manual when troubleshooting and repairing a reminder system. Numerous design variations are used by different vehicle makers. An illustration of a basic reminder system is shown in **Figure 37-21**.

Cruise Control Systems

An electronic ***cruise control system*** uses a computer, sensors, and a throttle actuator to maintain vehicle speed for highway driving. See **Figure 37-22**.The major parts of a modern cruise control system include:

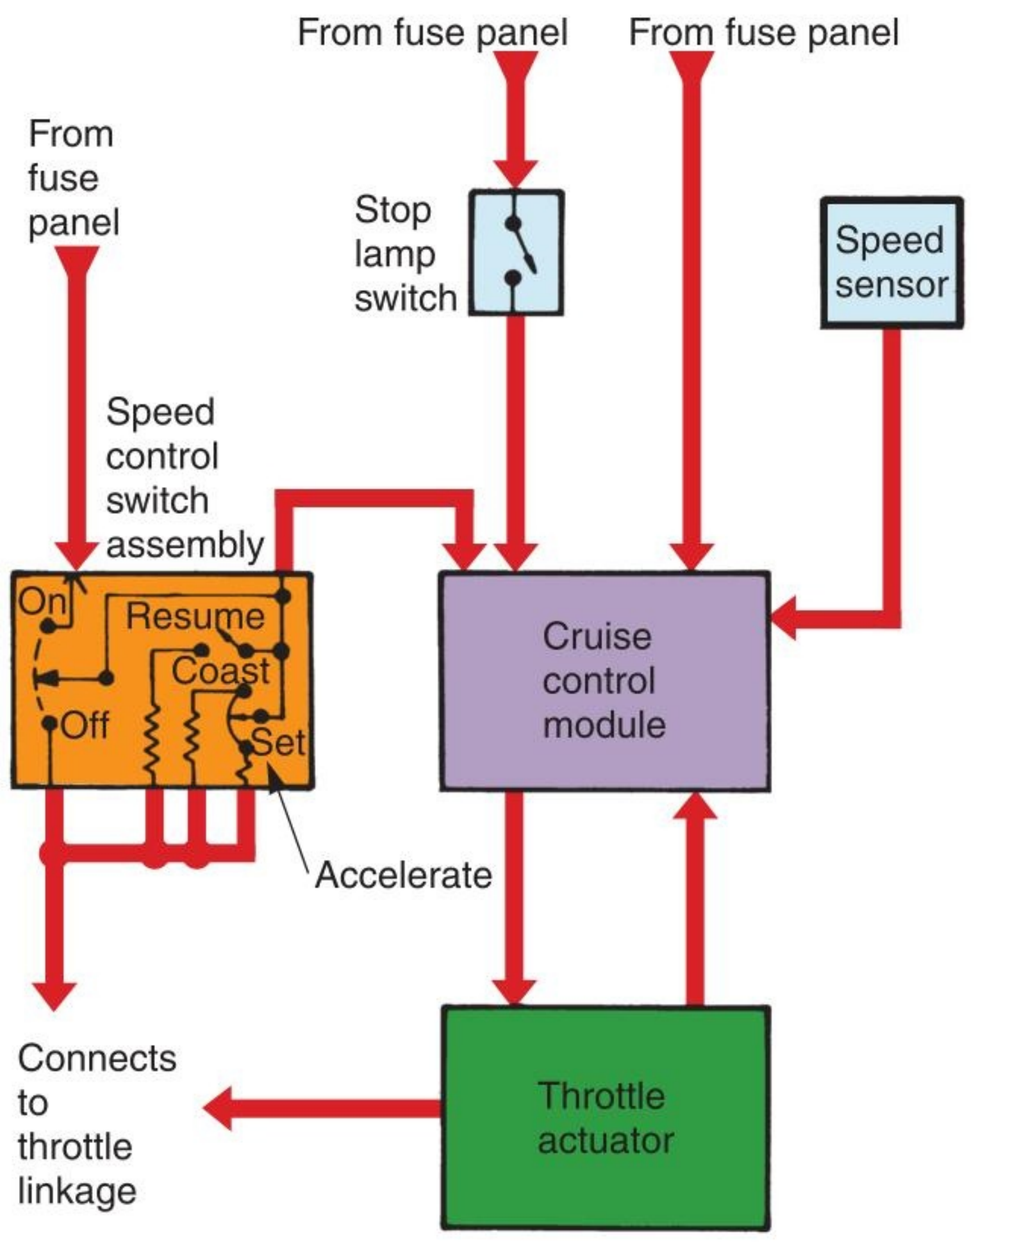
- ***Power switches***—Power switches feed current to computer to activate and ready the system for operation.
- ***Control switch***—The control switch signals the computer to maintain present vehicle speed.
- ***Vehicle speed sensor***—The vehicle speed sensor feeds a pulsing signal that represents velocity of the vehicle into the computer.
- ***Cruise control module***—The cruise control module uses input signals to control outputs to throttle actuator.
- ***Throttle actuator***—The throttle actuator physically moves the engine throttle lever to control engine power and resulting vehicle speed.
- ***Brake light switch***—The brake light switch signals the control module to shut off the cruise control when the brakes are applied.
- ***Clutch switch***—The clutch switch signals the control module to deactivate the cruise control when the clutch pedal is depressed.
- ***Neutral safety switch***—The neutral safety switch signals the control module to shut off the cruise when the shift lever is moved out of drive.
- ***Engine control module***—The engine control module analyzes switch and sensor signals to control the operation of the cruise control system.

Copyright Goodheart-Willcox Co., Inc.



Chrysler

Figure 37-21. A warning or reminder system makes a sound when the key is left in the ignition, when seat belts are not fastened, and when lights are left on. Circuit in tone generator is the "heart" and "brain" of the system.



Ford

Figure 37-22. Layout of an electronic cruise control system. Speed sensors send electrical information to control module. The module can then operate the throttle actuator, which connects to the throttle linkage on the engine. Also note the circuit in the speed control switch.

Tech Tip

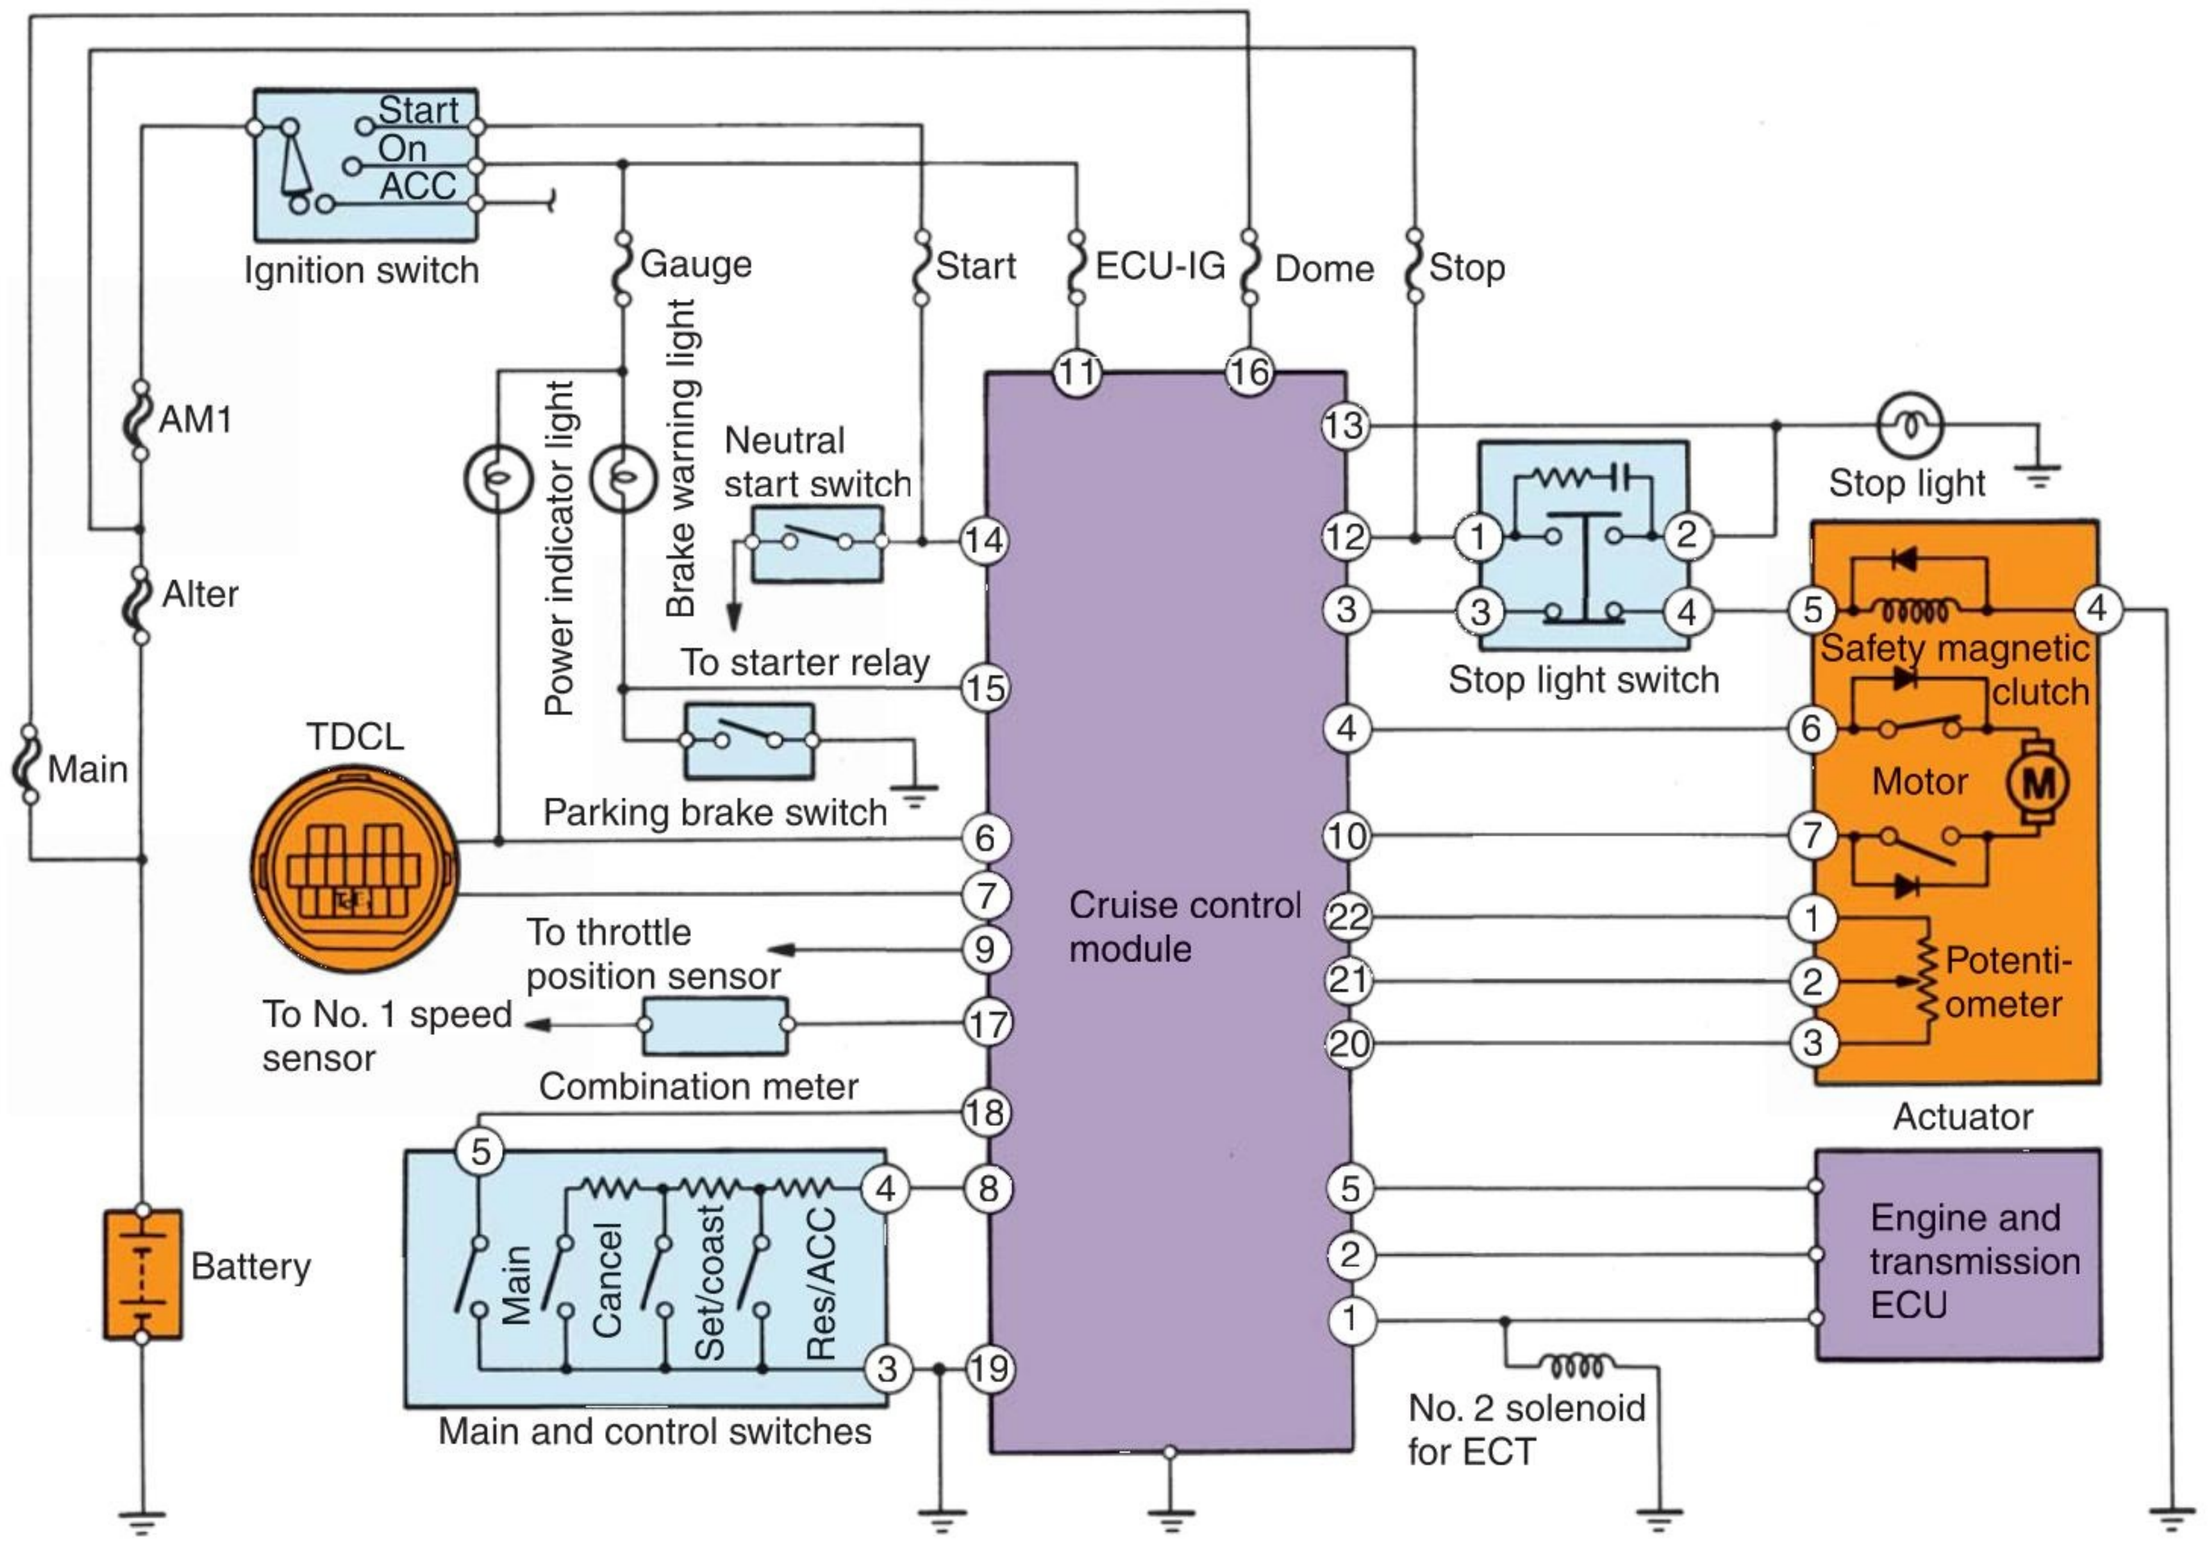
The industry trend is to combine the cruise control module circuitry into the engine control module. This allows the "drive-by-wire" accelerator pedal circuit to work in conjunction with the engine ECM to control engine speed and power output to maintain a preset highway cruising speed.

When cruise control system is activated using the power and control switches, the vehicle speed sensor feeds an ac signal to the cruise control module. The module's circuits use this signal to move the throttle actuator back and forth to maintain the same speed or vehicle sensor frequency, **Figure 37-23**.

The cruise control senses engine speed and controls the throttle valve opening on the engine. In this way, the driver can set the road speed of the vehicle and the cruise control system will maintain that speed.

For example, if the car starts to go up a hill, the vehicle speed will start to drop. The cruise control module will detect a slower frequency signal from the speed sensor. It can then move the throttle actuator for more engine power to keep the car traveling at the preset speed. The opposite occurs if the car starts down a hill.

Copyright Goodheart-Willcox Co., Inc.



Lexus

Figure 37-23. Study the operation of a typical electric cruise control system. Note the various inputs (on left) to the cruise control module and how the module can then operate the actuator (on right), which acts on the engine throttle to control vehicle speed. The vehicle speed sensor signal allows the cruise control module to maintain required road speed.

When the driver presses on the brakes, the ***brake switch*** deactivates the system. The ***resume switch*** allows the driver to reset the same cruising speed when desired.

Cruise Control System Service

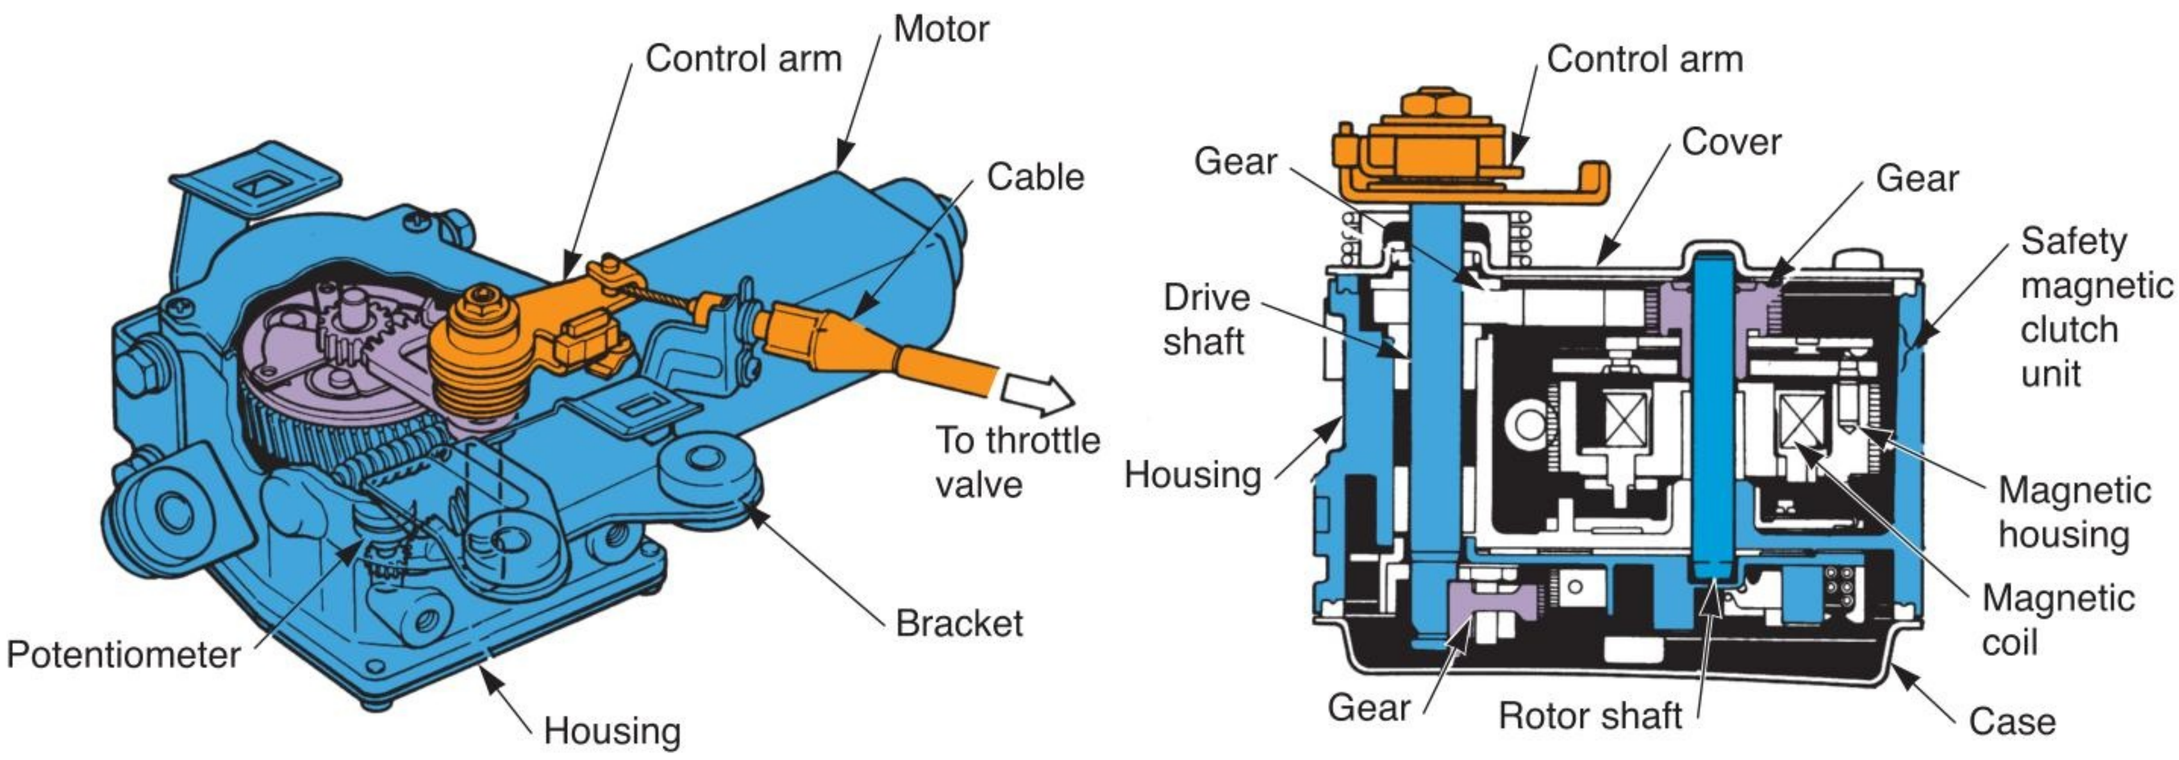
Since cruise control system designs vary so much, only general service methods can be given. Refer to a service manual for details.

If the cruise control will not work at all, check the fuse and power feed wires to the system. Do not forget the simple things. For example, if a brake light switch is shorted on all the time, the cruise control will not engage. The on and resume switches can also wear and fail. Test all simple things before suspecting the control module or actuator.

Figure 37-24 shows a cutaway of a motor-type throttle actuator. It uses a small dc motor and gearbox to move the throttle linkage. Check the motor for normal operation by connecting power to its windings. On older vehicles, the gears may be worn or stripped.

Some systems use a vacuum-type throttle actuator. If the system has a vacuum actuator, check all vacuum lines for leaks. Use a piece of vacuum hose to listen for the "hissing sound" of a vacuum leak. To check actuator operation, use a hand pump to apply vacuum to the actuator diaphragm assembly. The diaphragm may rupture and leak after prolonged use. Any solenoid valves that control vacuum can also be tested using basic methods.

Copyright Goodheart-Willcox Co., Inc.



Lexus

Figure 37-24. Cutaway view shows an electric motor-operated cruise control actuator. A reversible dc motor turns the worm gear. The larger driven gear has a lever that can pull or release a cable going to the engine throttle valve. The ECU can then spin the motor in the needed direction to maintain the desired road speed.

Warning

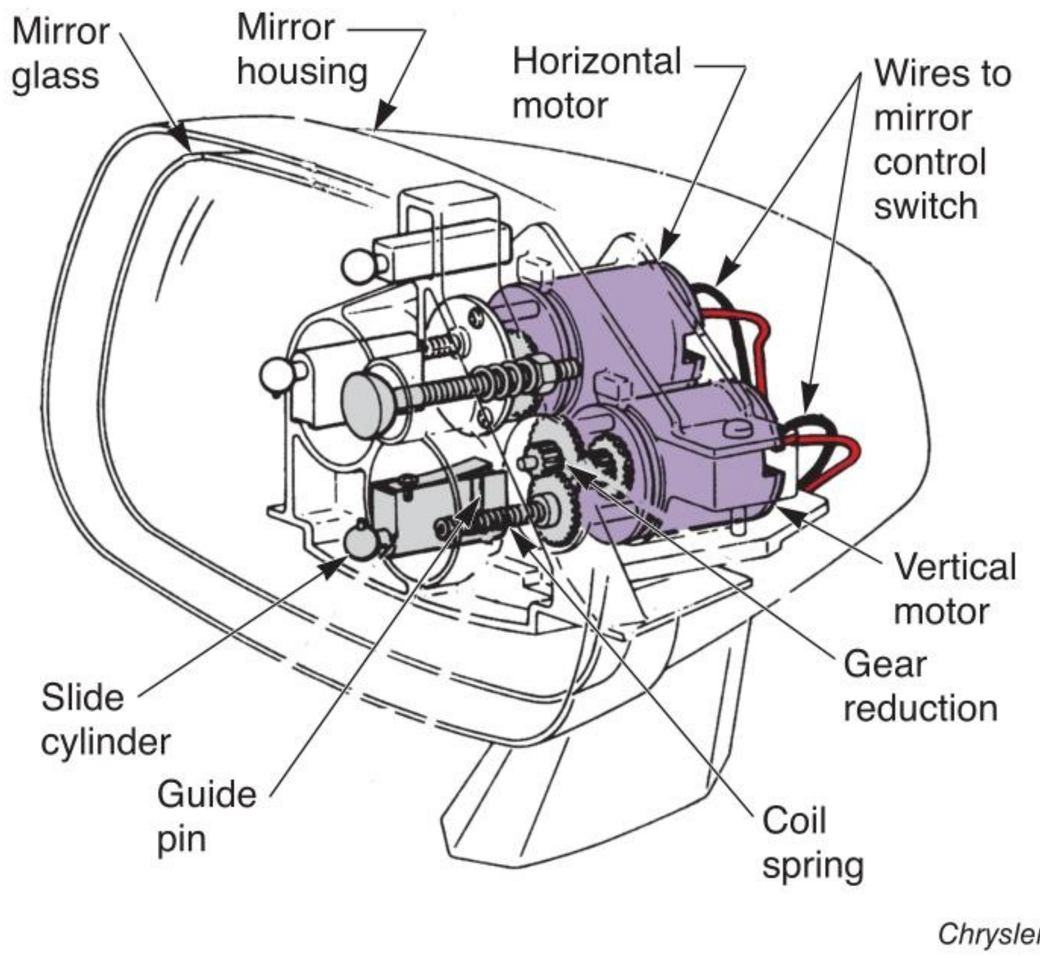
Use only recommended high-impedance testing instruments and factory-recommended procedures when servicing a cruise control system. If you do something wrong and the cruise control will not disengage or not hold the correct speed, it could cause an accident. People could be killed by your mistake!

Power Mirrors

Power mirrors commonly use tiny reversible electric motors to tilt the sideview mirror glass into different positions. A multiposition "joy switch" is normally used to energize each mirror motor. The mirror motors often operate a screw mechanism that can push or pull on the backside of the mirror glass, **Figure 37-25**.

Basic testing methods can be used to troubleshoot a power mirror system. If neither mirror works, check the fuse and power supply circuit. If only one mirror fails to adjust, check its switch and motors. Usually, you will have to remove the door panel to test the switch, wiring, and motors.

A heat gun is often used to warm and remove the rearview mirror glass if cracked or if the motors can be replaced. Many manufacturers recommend replacement of the whole power mirror assembly if anything is wrong with it.



Chrysler

Figure 37-25. This power mirror uses tiny dc motors that drive screw mechanisms to adjust the rearview mirror angle. It is often serviced as a complete assembly and internal repairs are not done.

Driver Information Center

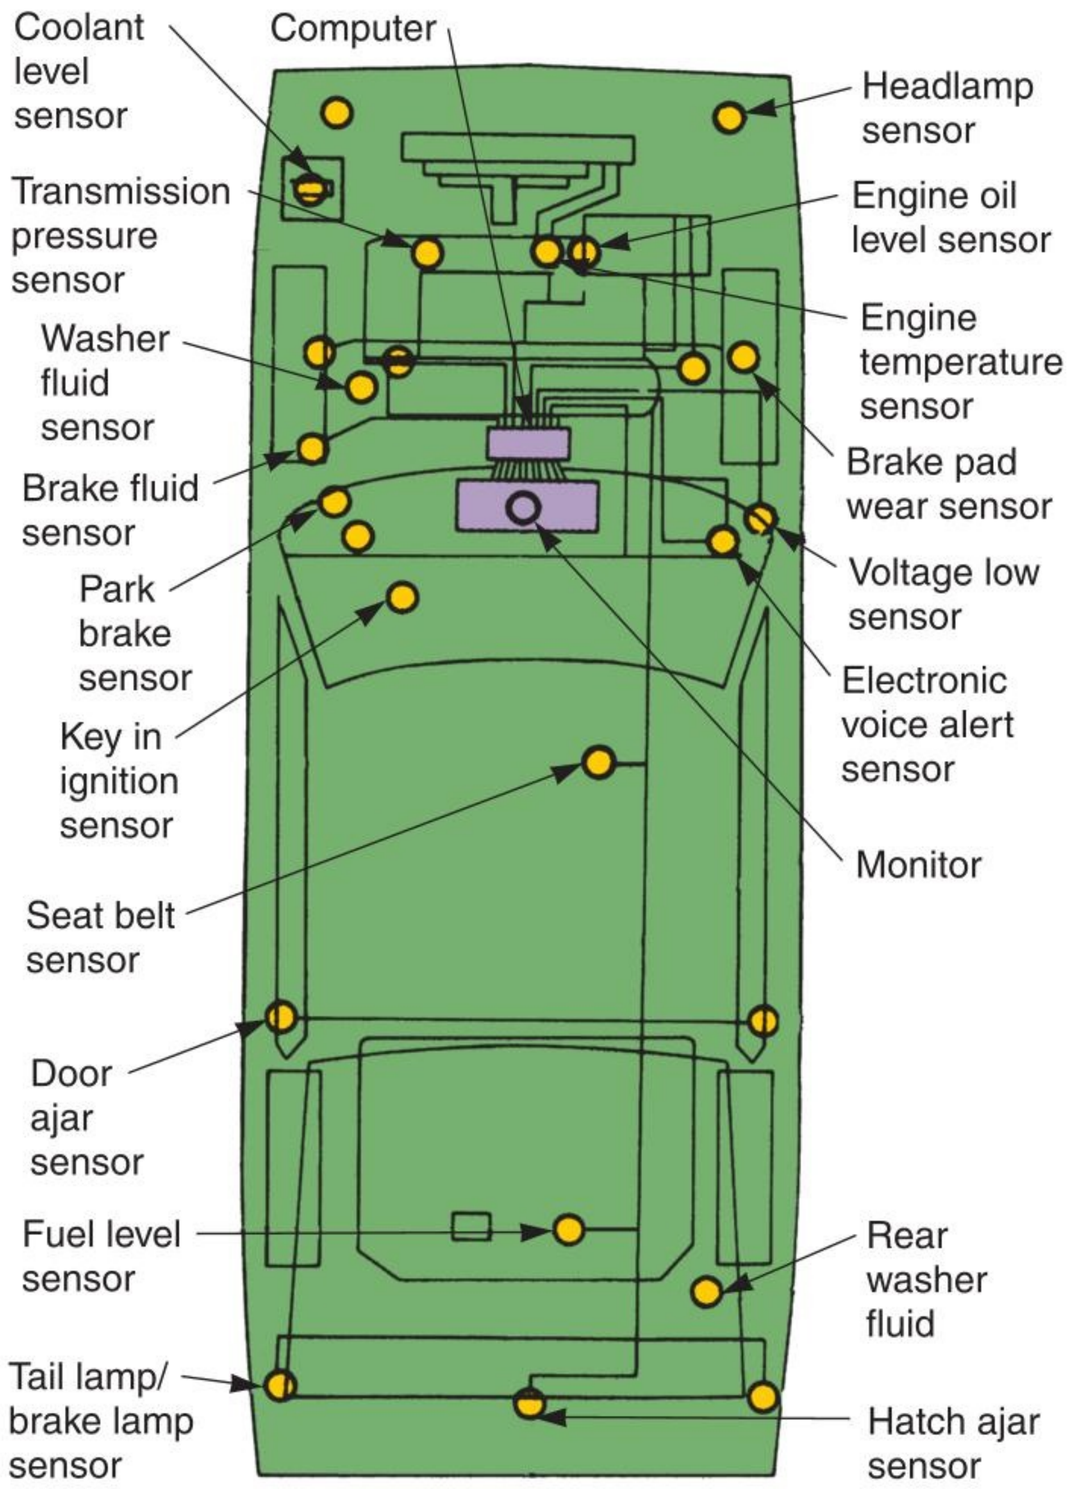
A ***driver information center*** uses a computer, a small speaker or digital display, and numerous sensors and switches to inform the driver of various conditions. The computer is programmed to output a visual display or an audible warning when a specific sensor detects a

Copyright Goodheart-Willcox Co., Inc.

bad condition. This might include displaying—or even saying—your washer fluid is low, check your brake fluid, your door is ajar, and similar messages.

Figure 37-26 shows the major parts of a driver information center. Note the numerous sensors that monitor vehicle conditions so the computer can display information.

Figure 37-27 is a basic wiring diagram for a vehicle monitoring system. It is also capable of relaying audio messages stored in computer memory.



Goodheart-Willcox Publisher

Figure 37-26. Top view of car shows general locations of components in this driver information center. A keyboard is often provided so driver can request information. An on-board computer can then use sensor data to calculate answer to be displayed on the monitor or display window.

Vehicle Degaussing

Magnetic fields sometimes build up around a vehicle's body structure. This can be caused by magnetic antenna mounts, large aftermarket amplifiers, repeatedly driving next to high-voltage power lines, hybrid voltage levels, and parking a car under power lines or large transformers. If the vehicle's steel body becomes highly magnetized, problems can occur with the electronic compass and other devices that are sensitive to magnetic fields.

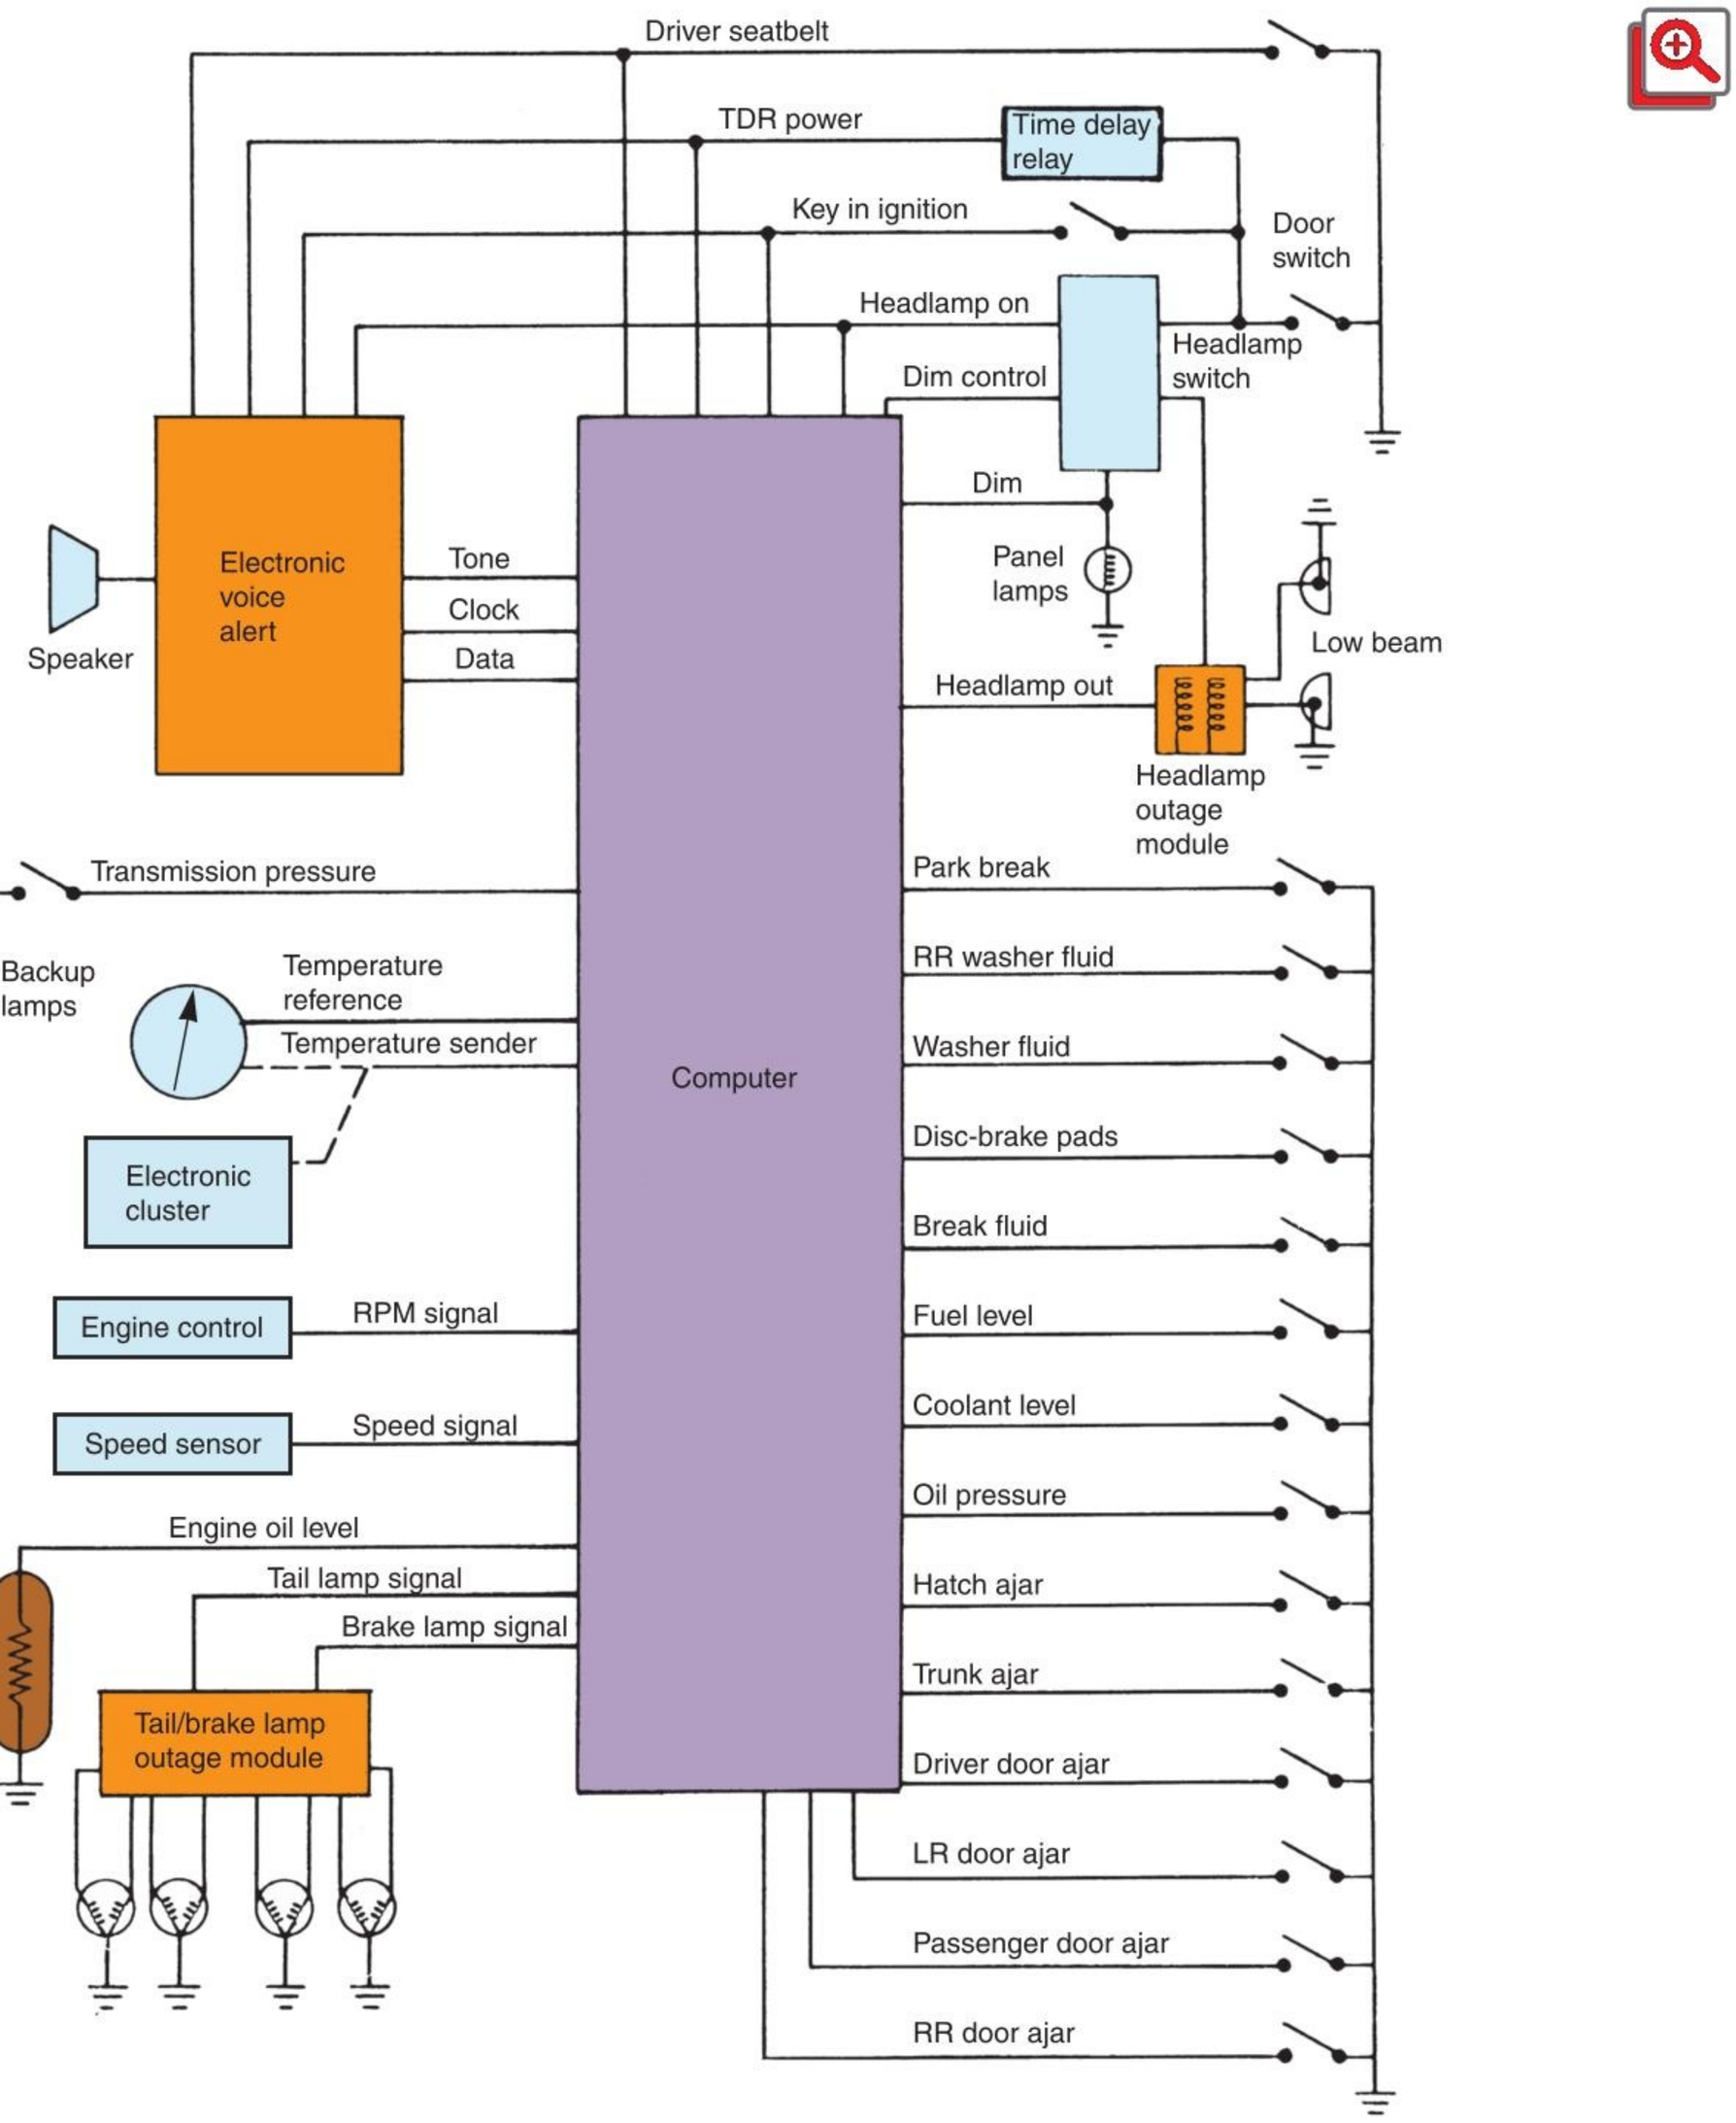
Vehicle degaussing, or ***vehicle demagnetizing***, involves using a demagnetizing tool to remove a magnetic field built up around a vehicle's body. During use, the demagnetizing tool can be pulled toward the steel body with considerable force. If the demagnetizer snaps down against the body, it may scratch the paint or dent the body panel. Before using the demagnetizing tool, place a shop cloth or a large fender cover on the roof or body panels to protect them from damage.

Caution

Never activate a demagnetizing tool near any type of magnetic media, such as computer hard drives, video tapes, audio tapes, digital music devices, or memory chips. A demagnetizing tool will instantly erase all stored information from these devices.

To use the demagnetizing tool, stand several feet from the vehicle and turn on the tool's magnetic coil. Walk toward the vehicle and hold the tool about 1″ (25.4 mm) from the roof panel. Move the demagnetizer in a circular pattern over the roof panel several times. When you have finished, lift the tool straight up from the roof panel and move several feet away from the vehicle before turning off the tool. If needed, the hood and trunk areas can also be demagnetized using the same pattern as the roof panel. After demagnetizing the vehicle, recalibrate the compass if needed and reinstall any devices removed from the vehicle.

Copyright Goodheart-Willcox Co., Inc.



Chrysler

Figure 37-27. This simplified wiring diagram shows how the ECU processes inputs and produces outputs for driver information system. Note the speaker at upper left. With this system, your car will actually talk to you to inform you of many operating conditions or possible problems, such as low fluid levels, fluid change needed, parking brake on, door ajar, and low oil pressure.

Diagnostic Case Study

Concern: Mr. Davis brings in his 2012 Lexus because his passenger-side power window has stopped working.

Cause: Duff asks if the other windows in the vehicle work properly. Mr. Davis says that all the other windows work. Since only one power window does not work, Duff knows that the main fuse is not blown. Duff assigns the task to one of the shop's general repair technicians.

The technician removes the necessary interior trim to expose the switch terminals. He touches a test light to the switch terminals for the passenger-side window. The test light illuminates at both output terminals when the switch is moved to the appropriate position. This indicates that current is flowing through the switch and into the wires going to the window motor.

The technician then removes the door panel and touches the test light on the feed wires at motor. Again, the test light illuminates when the switch is moved to the proper positions. Current is getting to the motor, but the motor is still not working. The technician attaches a jumper wire from the motor's ground wire to another ground. With power applied, the motor still does not work. This is an indication that the motor itself is faulty.

Correction: The technician removes the old power window motor from the door. He obtains a used motor from a salvage yard and bench-tests it. The new motor tests good, and the technician installs it in the car. He makes sure the window is operating properly and then replaces the door panel and interior trim pieces. Finally, he releases the car to the customer.

Summary

- A basic radio system consists of an antenna, radio (receiver-amplifier), speaker(s), and power supply circuit.
- An AM radio is designed to pick up a radio signal that varies in amplitude (strength).
- An FM radio is designed to receive a radio signal that varies in frequency (fluctuating speed).
- A digital radio uses analog signals that are compressed and digitized so more programming can be broadcast in a given spectrum.
- Satellite radio operates off a radio (electromagnetic) transmitter that orbits about 22,000 miles (35,000 km) above Earth.
- Just because the lights in the stereo are working does not mean the radio circuitry is getting power.
- If you suspect a bad antenna (no signal coming from antenna lead), connect a known good antenna to the radio.
- A faulty speaker will usually distort the sound of the radio. Sometimes, a power booster is added to the sound system to increase volume without sound distortion.
- Radio noise is undesired interference or static (popping, clicking, or crackling) obstructing the normal sound of the radio station.
- Power seats use several switches, electric motors, and drive assemblies to change the front seat positions.
- Memory seats use a small computer, or ECU, which can be programmed to remember seat positions for several people.
- A power window basically uses a control switch, reversible electric motor, circuit breaker, fuse, and related wiring to operate the door windows.
- Power door locks typically use an electric switch and a solenoid or motor to operate the door lock mechanisms.
- A power steering wheel uses an ECU, various switches, sensors, and motors to automatically tilt and telescope (extend or retract) the steering wheel.
- A rear window defogger, also called a rear window defroster, commonly uses a switch, relay, indicating light, and window heating grid.
- A heated windshield system uses a special conductive film sandwiched inside the windshield glass.
- An electronic cruise control system uses a computer, sensors, and a throttle actuator to maintain vehicle speed when highway driving.
- Power mirrors commonly use tiny reversible electric motors to tilt the side view mirror glass into different positions.

Copyright Goodheart-Willcox Co., Inc.

- A driver information center uses computer, a small speaker or digital display, and numerous sensors and switches to inform the driver of various conditions.
- Vehicle degaussing, or vehicle demagnetizing, involves using a demagnetizing tool to remove a magnetic field built up around a vehicle's body.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

AM radio
antenna
auxiliary audio input
brake light switch
brake switch
CD players
clutch switch
compact disc players
control switch
cruise control module
cruise control system
digital audio player
digital radio
digital video disc (DVD) player
distortion
driver information center
engine control module
FM radio
gearbox
grid repair agent
heated seats
heated windshield system
mast
memory seats
neutral safety switch
noise suppressors
power antenna
power booster
power door locks
power mirrors
power seat module
power seats
power steering wheel
power switches
power trunk release
power window
power window motor
radio
radio frequencies
radio noise
radio station
radio system
rear window defogger
rear window defroster
reminder system
resume switch
satellite radio
sound system
speaker
steering wheel touch controls
stereo amplifier
thermal runaway
throttle actuator
transmission
tuner
vehicle degaussing
vehicle demagnetizing
vehicle speed sensor
window regulator
zone clearing defoggers

Activities

1. Use a car radio to "hunt" for radio stations broadcasting from other communities, on both the AM and FM bands. Note the call letters and towns, and then mark them on a map. Check the distance the farthest signal traveled. Was it AM or FM?
2. Take a survey among students at your school to determine which vehicle music system options are most popular. Determine how many student cars have just radios, satellite radios, radios with CD changer/players, etc. Make a bar graph to show your results.

Review Questions

Answer the following questions using the information provided in this chapter.

1. What are the parts of a basic radio system?
2. Explain the difference between AM and FM signals.
3. A customer complains that one of the speakers in his vehicle's sound system is not working. Technician A says that the radio is faulty and must be replaced. Technician B says that the inoperative speaker should be checked before condemning the radio. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. A(n) _____ uses a permanent magnet and coil of wire mounted on a flexible diaphragm.
5. What are some of the symptoms of a faulty speaker?
6. Why are noise suppressors used?
7. If one power window fails to go up and down, check the circuit fuse first. True or False?

Copyright Goodheart-Willcox Co., Inc.

8. When a power window switch is pressed, a whirring sound can be heard from inside the door. Technician A says that the motor windings are open and the motor is bad. Technician B states that the power window gearbox might have stripped plastic gear teeth. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. How does a heated windshield system work?
10. Explain the operation of a cruise control system.

ASE-Type Questions

1. Technician A says an AM radio is designed to pick up a radio signal that varies in amplitude. Technician B says an AM radio is designed to pick up a radio signal that varies in frequency. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Technician A says an FM radio has a longer broadcasting range than an AM radio. Technician B says an AM radio has a longer broadcasting range than an FM radio. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Technician A says an AM radio is designed to pick a signal that varies in frequency. Technician B says an FM radio is capable of producing stereophonic sound. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says that the circuits feeding power should be considered when troubleshooting an automotive radio system. Technician B says a receiver-amplifier is a basic circuit inside a radio. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Satellite radio is being discussed. Technician A says that a satellite radio system allows a vehicle's occupants to listen to the same station when traveling across the country without losing reception. Technician B says satellite programming is found between analog FM stations. Technician B says an AM car radio normally has one speaker mounted in the top of the dash. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says a power booster is added to some sound systems to increase volume without sound distortion. Technician B says that systems without a power booster may go into thermal runaway when the stereo is played at high volumes. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. A car's power antenna is inoperative. Technician A checks for vacuum leaks, which may affect the antenna's operation. Technician B checks the antenna's motor and electrical circuit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Which of the following can cause radio noise?
   (A) Bad alternator diodes.
   (B) Open spark plug wire.
   (C) Bad noise suppressor.
   (D) All of the above.
9. An automobile's radio is producing "radio noise." Technician A checks the radio's antenna. Technician B looks for a bad spark plug wire. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Copyright Goodheart-Willcox Co., Inc.

10. Technician A says an automotive "noise suppressor" can be mounted inside the car's alternator. Technician B says an automotive "noise suppressor" can be mounted on the car's ignition coil. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. One of the power seats in an automobile is not operating. Technician A tests the seat's electrical switch. Technician B checks the operation of the seat's electrical motor. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. One of an automobile's power windows is not working. Technician A checks the operation of the window's electric motor. Technician B checks for a blown fuse at the car's fuse box. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
13. All of an automobile's power door locks are inoperative. Technician A looks for a blown fuse at the fuse box. Technician B checks for a faulty solenoid in the left-rear door panel. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. One of a car's door panels must be removed. Technician A removes the window crank handle. Technician B removes the armrest screws. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
15. A car's rear window defogger is malfunctioning. Technician A tests the operation of the defogger's "heating grid." Technician B checks the defogger's electrical switch. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Sound System Diagnosis		
Condition	**Possible Causes**	**Correction**
Nothing works.	1. Blown fuse. 2. Bad switch. 3. Broken feed wire. 4. Broken ground wire. 5. Bad radio.	1. Replace fuse. 2. Replace switch. 3. Repair wire. 4. Repair wire. 5. Send out for service.
Radio powers up, static or no sound.	1. Poor antenna connection. 2. Misadjusted trim screw. 3. Disconnected speakers. 4. Bad radio.	1. Repair antenna. 2. Adjust antenna trim screw. 3. Fix wiring. 4. Send out for service.
Distorted sound from speakers.	1. Blown speakers. 2. Loose speaker mounting. 3. Speaker polarity reversed. 4. Incorrect speaker ohms. 5. Bad radio.	1. Replace speakers. 2. Tighten fasteners. 3. Reverse wires to speaker. 4. Match speaker resistance to radio. 5. Send out for service.
Poor reception.	1. Poor antenna connection. 2. Misadjusted trim screw. 3. Bad radio.	1. Repair antenna. 2. Adjust trim screw. 3. Send out for service.
Popping or clicking noise in speakers.	1. Radio interference. 2. Bad antenna. 3. Bad spark plug wires. 4. Missing ground straps.	1. Replace noise suppressors. 2. Replace antenna. 3. Replace spark plug wires. 4. Install ground straps.

Power Accessory Diagnosis		
Condition	**Possible Causes**	**Correction**
Nothing works.	1. Blown fuse. 2. Open switch. 3. No power to circuit.	1. Replace fuse. 2. Replace switch. 3. Repair feed wire.
Intermittent problem.	1. Loose wires. 2. Bad switch.	1. Repair wiring. 2. Replace switch.

Chapter 38
Security and Navigation Systems

After studying this chapter, you will be able to:

- Explain the operation of vehicle security systems.
- Explain the operation of vehicle navigation systems.
- Compare security system design variations.
- Service vehicle security and navigation systems.

This chapter will introduce the major components and circuits of typical security and navigation systems. Many systems are now networked. They possess video and audio capabilities that display and speak street names and directions on the way to the destination. This allows the driver to better navigate streets and highways. Some will even help the police track and find the exact location of stolen or missing vehicles using global positioning and satellite technology. Refer to **Figure 38-1**.

Security Systems

A ***security system*** is designed to help prevent the theft of a vehicle and its contents. A security system basically uses motion sensors and switches to feed signals to an electronic control module. The control unit can then lock the vehicle and operate a warning siren or horn if someone tampers with the vehicle. Some systems also disable the starting system and engine to prevent the vehicle from being started.

A remote transmitter or a dash-mounted keyboard is used to activate and deactivate the system. Much like a garage door opener, the transmitter produces a radio signal of a specific frequency. A receiver circuit responds to this signal and triggers the control module to perform various tasks, such as turning the system on or off, unlocking the doors, sounding the siren, etc.

Security system designs vary tremendously. This is done so thieves are not able to learn about the operation of any one system too well. For this reason, you should refer to the schematic and technical literature from the manufacturer of the security system. It will give the details for doing competent service and repair work.

thenewsmarket.com

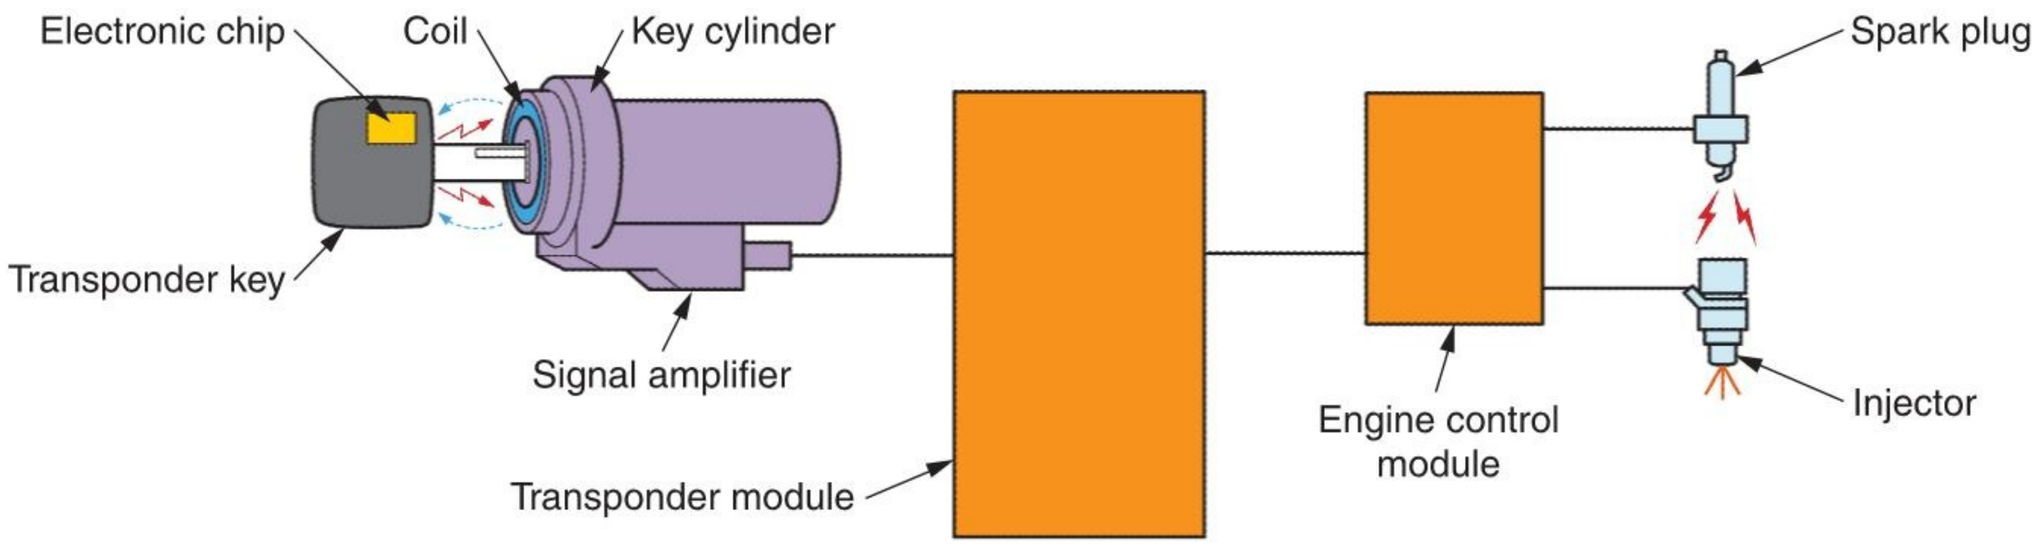
Figure 38-1. Many new cars come equipped with security and navigation systems. To service these systems, you must know how they work.

Transponder Key

Many late-model anti-theft systems use a ***transponder key*** that contains an electronic chip. This type of key is designed to prevent thieves with a knowledge of electronics from overriding the security system. Look at **Figure 38-2**.

Each time the transponder key is inserted into the key cylinder, a coil in the cylinder produces an electromagnetic field that excites the transponder chip. This causes the chip to generate a coded signal, which is amplified and sent to the transponder module.

If the transponder module recognizes the signal produced by the chip, it will allow the engine to be started. If the module does not recognize the chip's signal, it disables the starting and engine support systems so the vehicle cannot be driven.



Toyota

Figure 38-2. A transponder key contains a small electronic chip that produces a coded signal. The signal is amplified and sent to the transponder module. The module then determines if the correct key is being used to start the vehicle.

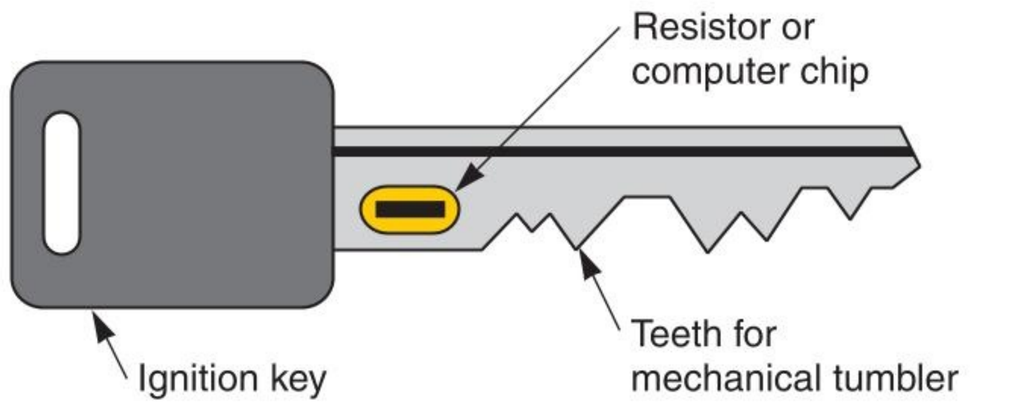
Copyright Goodheart-Willcox Co., Inc.

Resistance Key

Some theft deterrent systems use a ***resistance key***, which is an ignition key with a small electrical resistor mounted on its side. Several key resistance values are available. The resistor has small electrical connections on the sides, **Figure 38-3**. The key's metal teeth and the built-in resistor must match the vehicle to break security.

The ECM reads the resistance of the key to make sure it is not an unauthorized duplicate of only the metal teeth of the key. If the key resistance matches the one programmed into the control module, the vehicle starts normally.

However, if the key's resistance is not correct, the control module opens the starter relay circuit so the engine will not crank. The control module may also disable the engine support systems.



Goodheart-Willcox Publisher

Figure 38-3. A resistance key has a small electrical resistance element built into a hole in the key. It engages contacts in the tumbler when inserted. This allows the vehicle computer to determine whether the correct key has been inserted.

Tech Tip

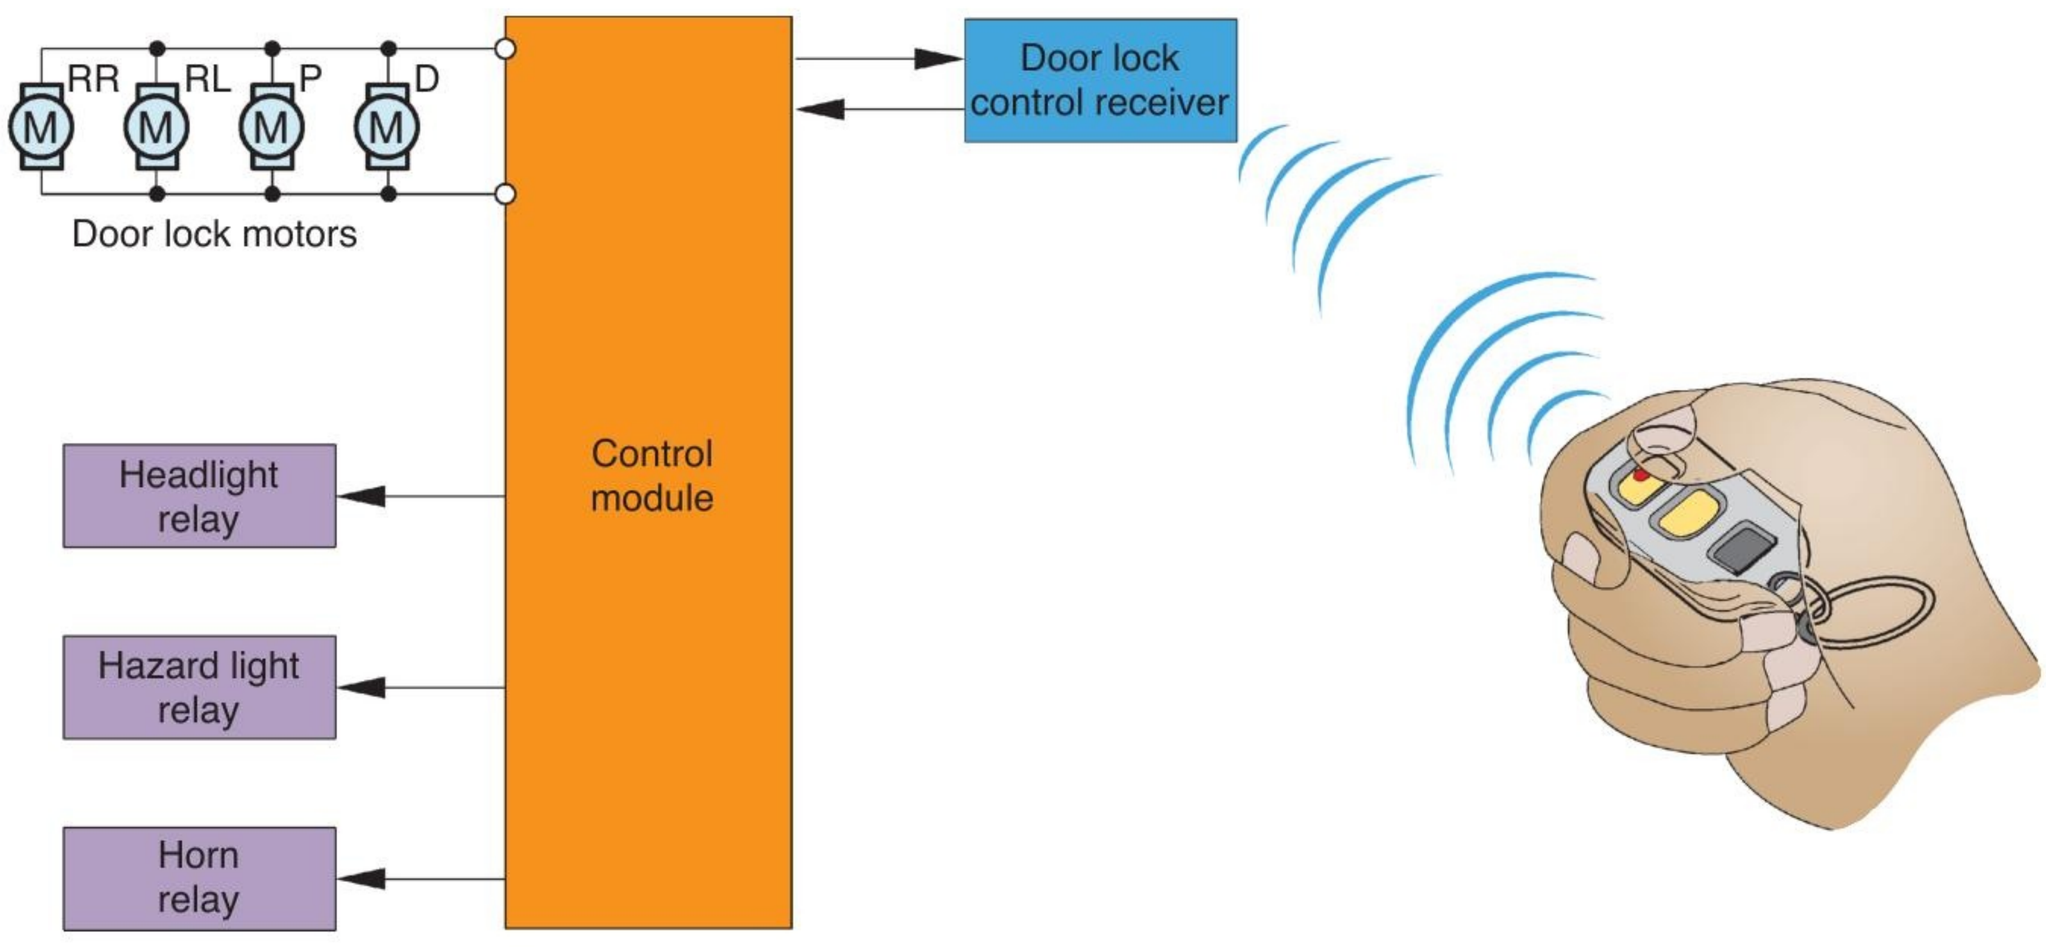
Resistance and transponder keys cannot be duplicated at your average hardware store or locksmith. You must usually contact the manufacturer to get service parts and codes.

Keyless Entry Systems

A ***keyless entry system*** allows the driver to unlock a vehicle's doors without using a key. There are two basic types of keyless entry systems: remote keyless entry systems and keypad-type keyless entry systems.

A remote keyless entry system uses a key fob that contains a small transmitter. When the driver pushes the button on the key fob to lock or unlock the doors, a corresponding signal is sent to a receiver located in the vehicle, **Figure 38-4.** The receiver then signals the lock module to activate the door lock motors, locking or unlocking the doors. Many keyless entry systems can also be used to unlock the trunk or power lift gate.

In keypad-type keyless entry systems, **Figure 38-5**, the keypad is mounted in the door and usually has five numbers. Pressing the numbers in the correct sequence will send a valid code to the module to unlock the doors. If the wrong number sequence is used, the module will ignore the electrical signals from



Toyota

Ford

Figure 38-5. A keyless entry system has a keypad on the outside of the door. When the number buttons are pressed, electrical signals are sent to the processor. If a correct number sequence is pressed, the processor will send current to the door solenoids to unlock the doors. A keypad and processor can also be used to unlock the trunk and other doors.

the keypad and keep the doors locked. The module sends current to the door solenoids only when the keypad is pressed in the right sequence.

Smart Key Systems

Some late-model vehicles are equipped with ***smart key systems***. These systems allow the driver to lock and unlock doors, open the trunk, and start the engine without inserting a key or pushing buttons on a key fob. The smart key system uses proximity sensors that send signals to a control module whenever the key fob is nearby. Some systems automatically unlock the doors when the proximity sensors detect the key fob within a few feet of the vehicle and lock them again when the key fob is moved away from the vehicle. In other systems, the driver must touch one of the front door handles to unlock or lock the doors.

Most smart key systems use a push-button ignition switch rather than a keyed ignition switch. When the proximity sensors determine that the key fob is *inside* the passenger compartment, they prompt the module to allow the vehicle to be started. The driver can then start the vehicle's engine by simply pressing the start button.

Navigation Systems

Navigation systems use our nation's satellite global positioning system to display the geographic location of the vehicle. A dash display shows a road map with the position of the vehicle on it. Advanced systems can give other useful information: traffic information, roadwork, parking lot openings, miles to destination, turnoffs, etc. See **Figure 38-6**.

Basically, the navigation system communicates with the satellite system to determine vehicle direction and speed. The vehicle's on-board computer compares this data with a large database of roads and highways, usually from a compact disc. Look at **Figure 38-7**.

A road map of the area with a representation of the vehicle's location can then be shown on the dash display. This helps the driver navigate highways and roads more efficiently. Besides visually helping the driver navigate, some systems also use verbal output to help the driver. Refer to **Figure 38-8**.

Global Positioning System (GPS)

A ***global positioning system (GPS)*** uses a series of earth-orbiting satellites to communicate through a vehicle's antenna. Also called a ***global navigation satellite system***, or GNSS, it can provide location and time information anywhere near the earth's surface.

Using a GPS, a vehicle receives electromagnetic signals from orbiting satellites through its GPS antenna. This allows the vehicle's navigation systems to pull up maps showing vehicle location (street

map) and direction of movement (compass). See **Figure 38-9**.

Vehicle Tracking Systems

A ***vehicle tracking system*** is a security system that can track the location of a car or truck if it is stolen. One system uses an on-board security control module, a miniature transmitter and receiver, the global positioning satellite (GPS) system, and a 24-hour monitoring/response center, **Figure 38-10**.

If a vehicle with this type of system is stolen, a signal is transmitted by the monitoring center to activate the tracking system. Once activated, the control module uses information received from the GPS system to pinpoint the vehicle's location. The system then transmits the location of the vehicle to the monitoring center.

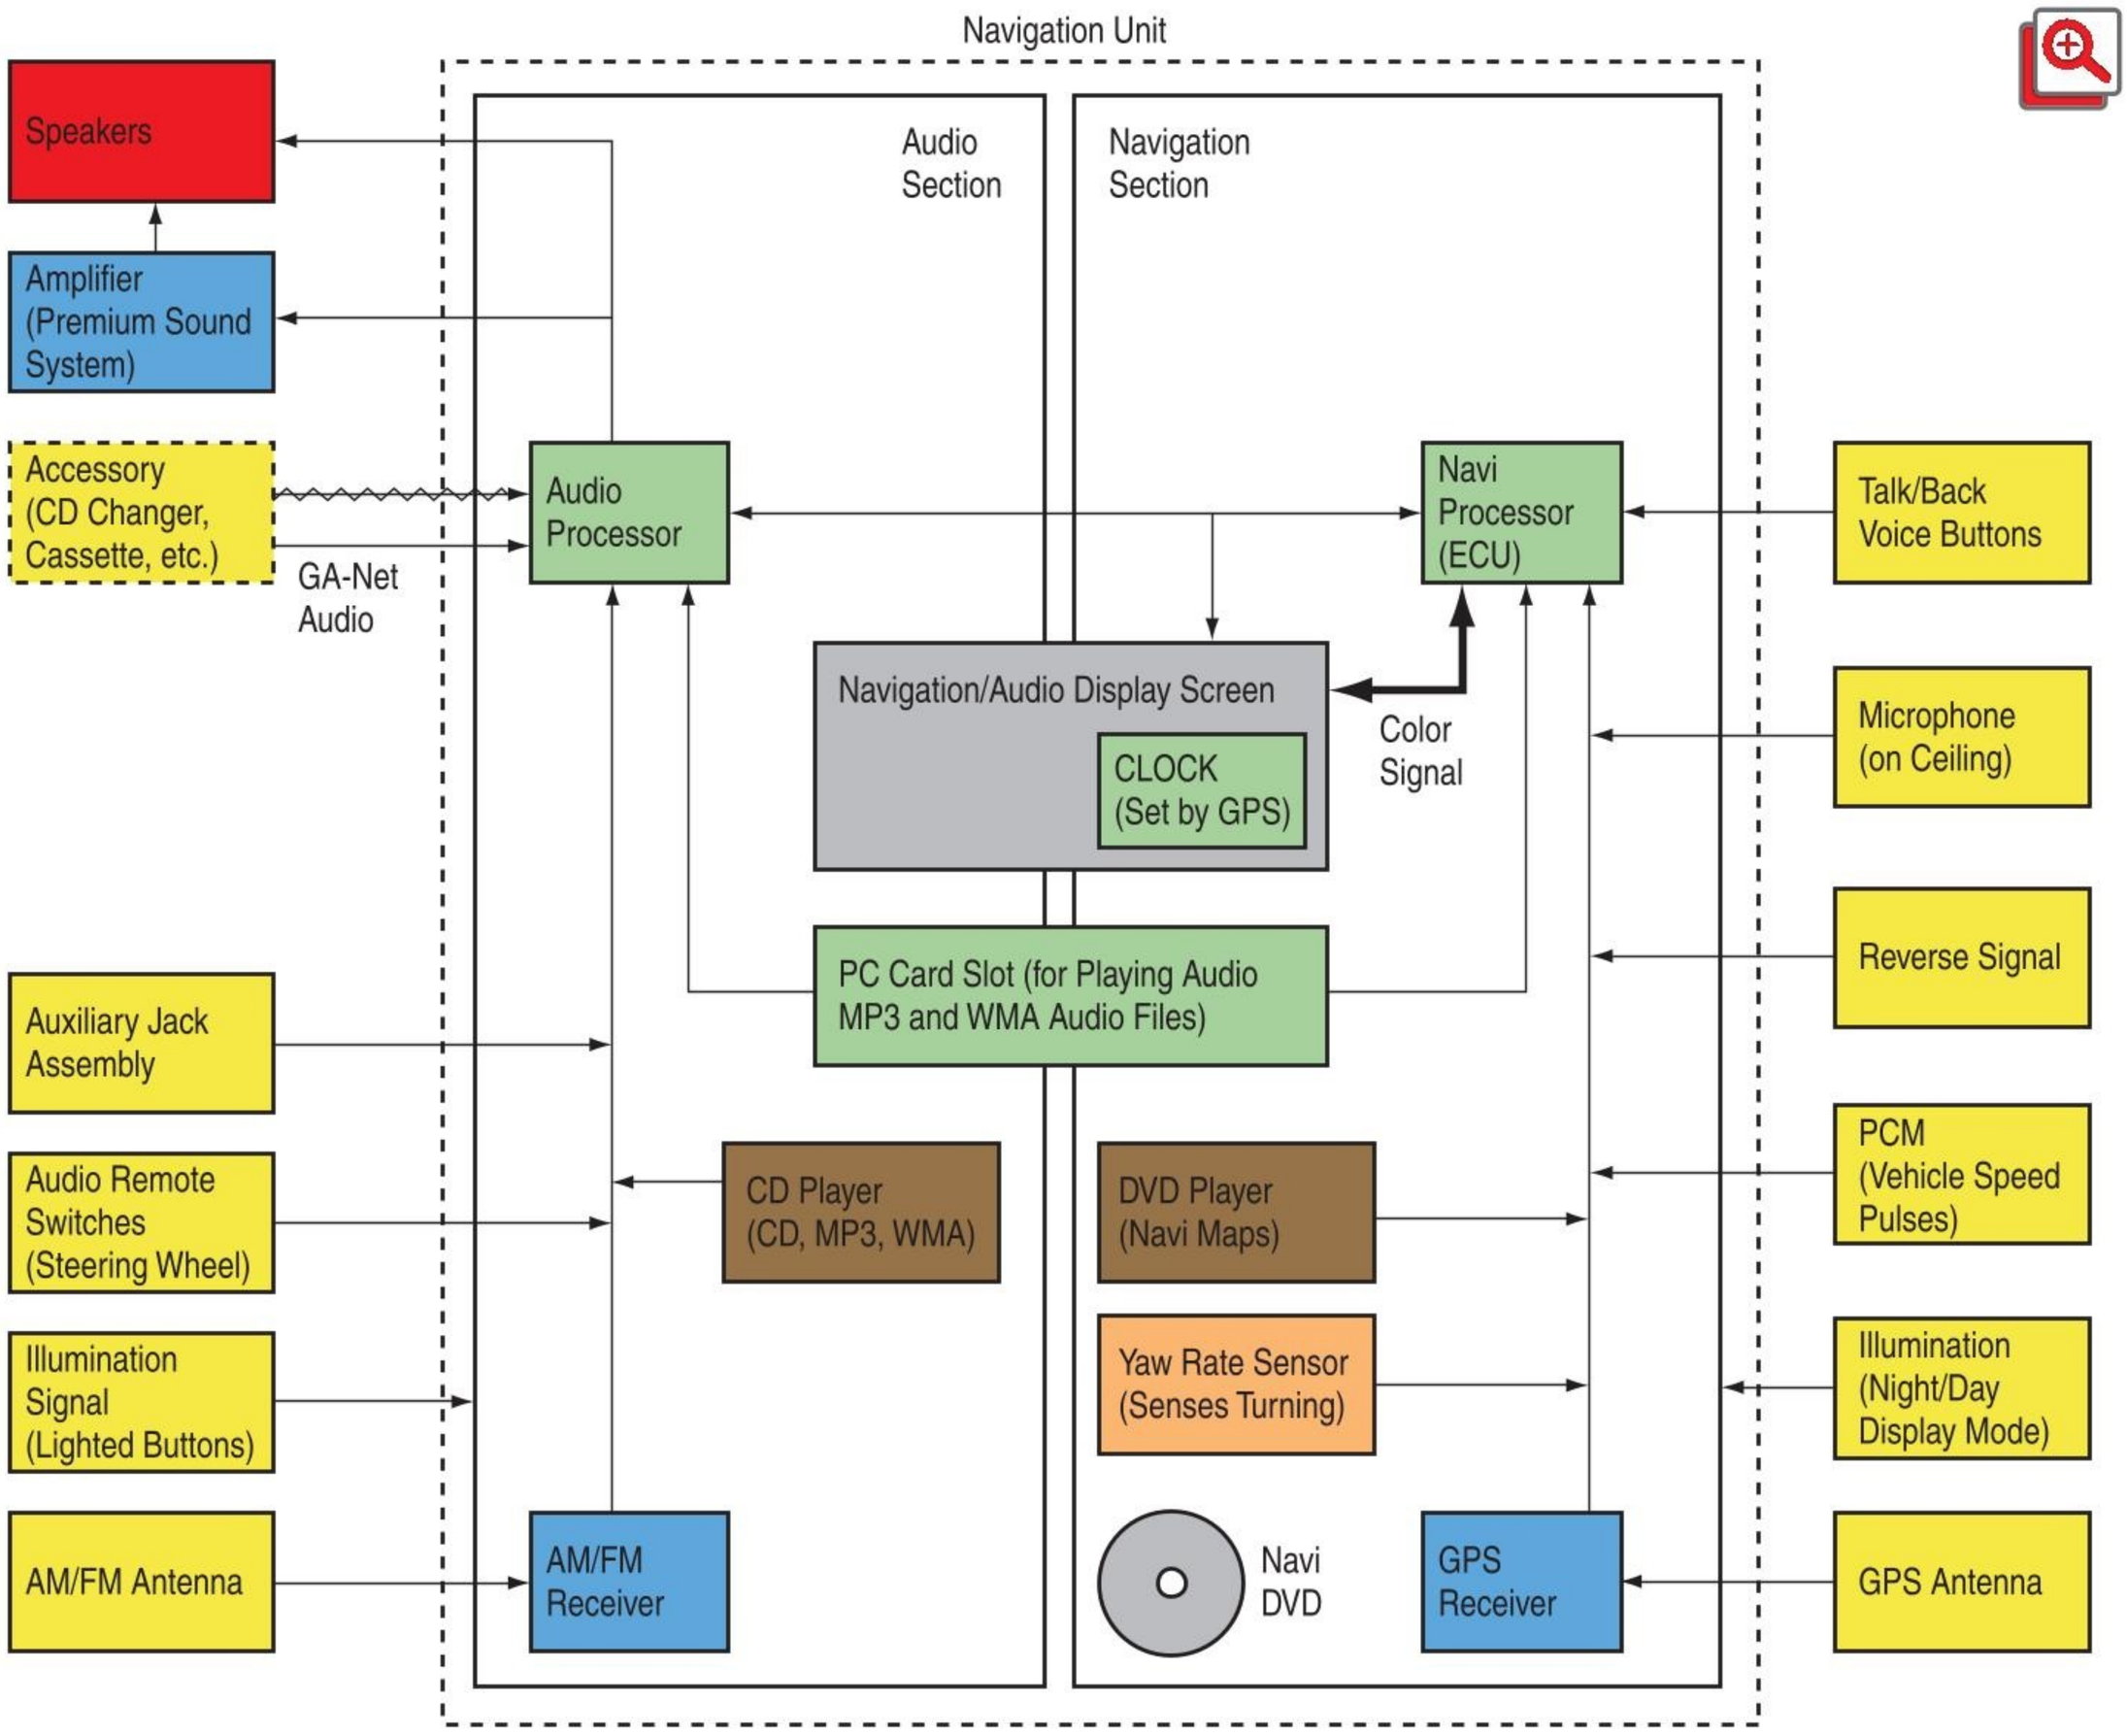
Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 38-8. This block diagram shows how the major components connect in a navigation system.

This type of vehicle tracking system is usually small and self-contained, allowing it to be easily hidden on the vehicle. Such a system usually incorporates a backup battery. This allows the system to continue receiving and transmitting even after the vehicle's battery has been removed.

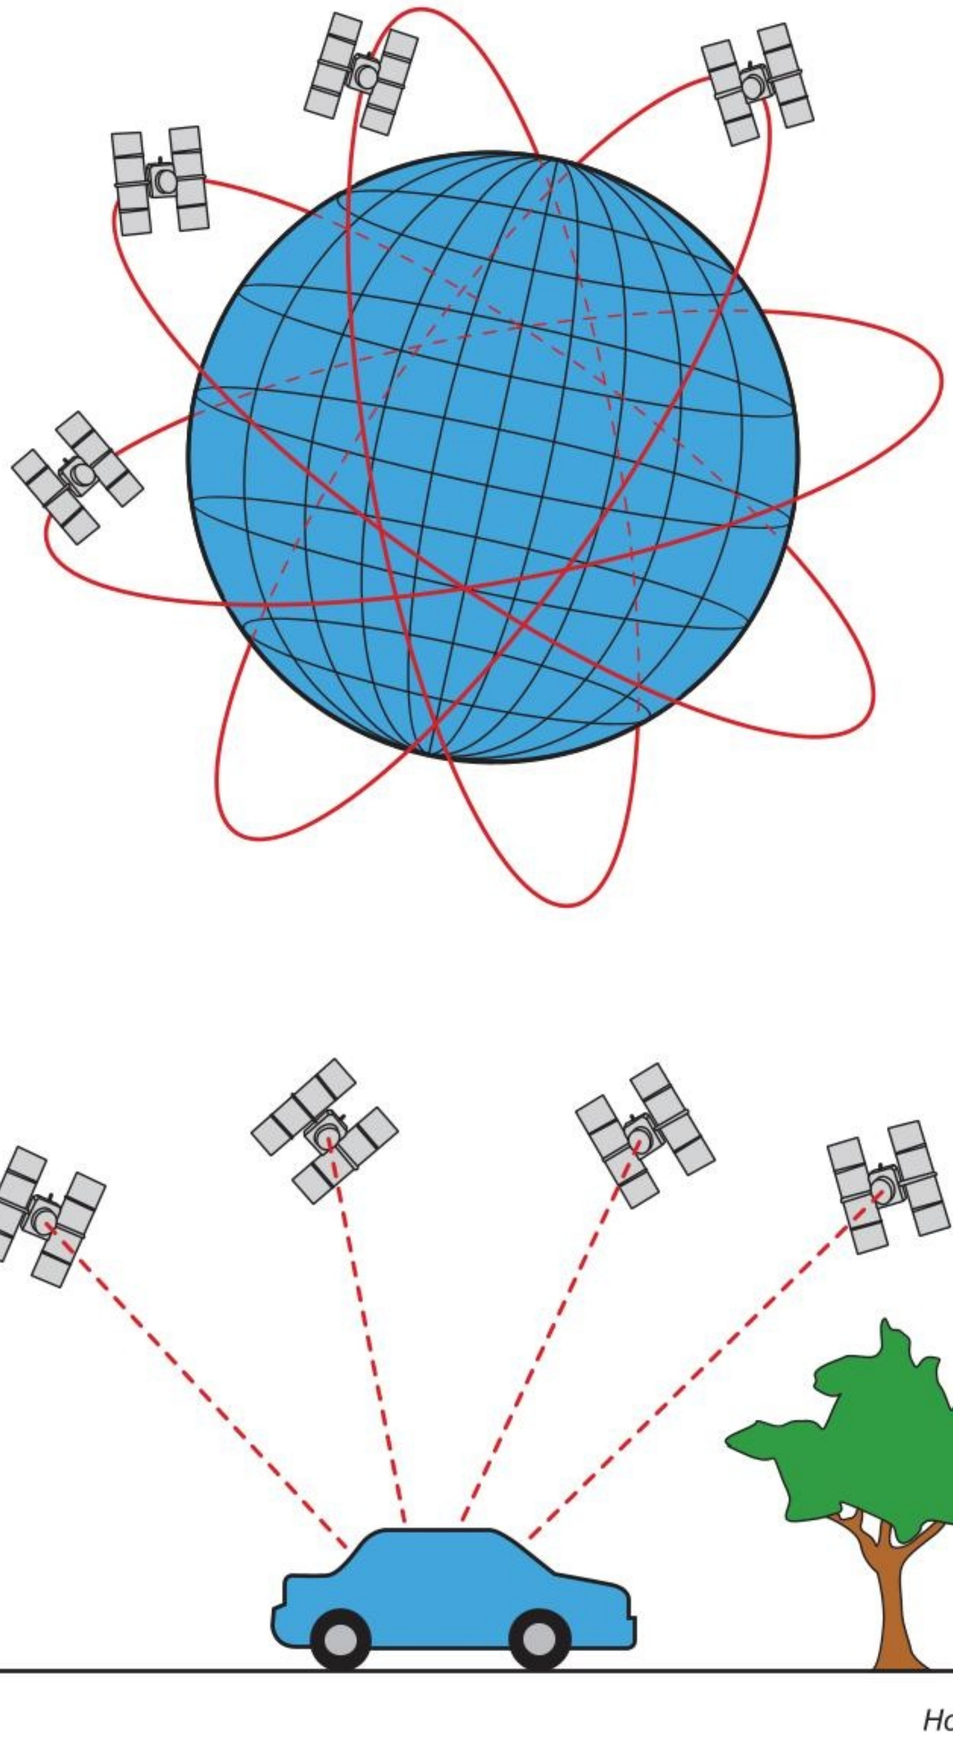
Some tracking systems also provide added security for the driver during a carjacking or kidnapping. The driver can press an emergency call button on his or her key ring. This allows the people at the response center to listen to conversation in the vehicle and to take action as needed. They can call the police and tell them the exact location and description of the vehicle. Other systems enable the vehicle to be remotely disabled.

Driver Information Center

The ***driver information center*** is a dash-mounted keyboard display for inputting and reading data about the vehicle. It allows you to send data to the instrumentation computer to find miles-to-empty, average fuel consumption, estimated time of arrival, and other information. The information center uses signals from many sensors to calculate this information. See **Figure 38-11**.

Driver information centers are very complex and vary with the vehicle's make and model. Always refer to the service manual for testing and repair directions.

Copyright Goodheart-Willcox Co., Inc.

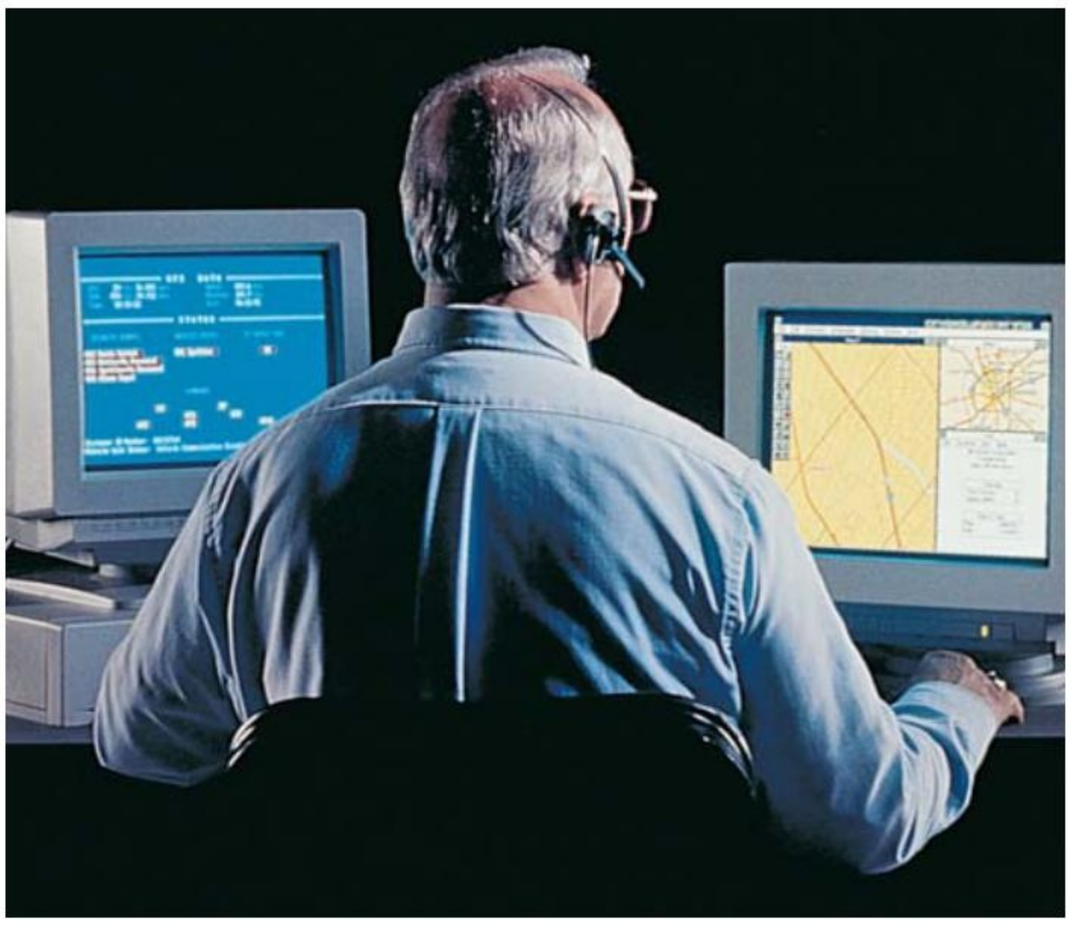


Honda

Figure 38-9. A global positioning system, or GPS, allows the navigation system to track a vehicle's location and show the location on a map on the display screen. Satellites orbiting above the earth send signals to the vehicle's GPS antenna so the on-board computer can calculate the vehicle's direction and location on surface of the earth.

Night Vision Systems

A ***night vision system*** uses an infrared camera and monitor system to help the driver view through fog, snow, rain, and other vision-impairing atmospheric conditions. The camera could be mounted in the front grille. When activated in bad weather or at night, the camera could produce an image on the dash-mounted monitor or on a heads-up display on the windshield. This would let the driver see longer distances through fog to detect oncoming vehicles,



ATX Research

Figure 38-10. A vehicle tracking system has trained operators at computer workstations 24 hours a day. If a vehicle is stolen or hijacked, an operator can phone police and give the exact location of the vehicle.

people, curves in the road, or other dangers. See **Figure 38-12**.

Video Camera Display

A ***video camera display*** is often used to show the view from the rear of the vehicle when the vehicle is in reverse. A tiny, low-resolution camera is mounted inside the rear body or bumper. The camera aims straight behind the rear center to show the road or driveway right behind the vehicle. The display screen gives a better view of what is behind the car than the side-view mirror and the windshield-mounted rear-view mirror, whose views are blocked by the rear body structure. Look at **Figure 38-13**.

Voice-Activated Systems

A voice-activated system uses a microphone and computer data to perform functions by reacting to spoken words. This is an optional feature on many modern phone and navigation systems. For example, if the driver says "call home," the recognition system will output a signal to the car phone to dial the home phone number. Other voice commands might include "change the radio station, mute the radio, and lock the doors."

A voice-activated system can be programmed to react to words such as "dial," followed by a phone

number or by the name of the person or place to call. The driver can also program new word commands into the voice-activated system. See **Figure 38-14**.

Collision Avoidance System

A ***collision avoidance system*** measures the distance between the front of a vehicle and any object in its path and automatically controls the braking and engine speed control systems to prevent an accident. Refer to **Figure 38-15**.

Most collision avoidance systems will first make an audible warning so the driver can slow down on his or her own. If the driver fails to take corrective action, the collision avoidance system might reduce engine (and vehicle) speed or even apply the brakes if a collision is probable.

There are two common types of distance sensors used in collision avoidance systems: radar sensors and infrared sensors. ***Radar sensors*** transmit electromagnetic energy waves from the front of the vehicle. These energy waves bounce off any objects in front of the vehicle and then return to the sensor. The system's computer monitors the amount of time it takes for the waves to return to the sensor and then uses this information, as well as data from the vehicle speed sensor, to calculate the distance between the object and the vehicle.

An ***infrared sensor*** sends out an invisible light beam from the front of the vehicle. This light beam bounces off objects in front of the vehicle and returns to the sensor. The amount of time it takes for the light beam to return to the sensor is monitored by the computer system and used to determine a safe driving distance for the exact road speed.

Adaptive Cruise Control

An ***adaptive cruise control system*** can alter vehicle speed automatically when coming up on another vehicle too quickly. Front-mounted radar works with the vehicle's on-board computer to reduce cruising speeds to prevent following too closely behind another vehicle.

Automatic Parking System

An ***automatic parking system*** uses computer control to back up, steer, and brake a car into a parking space. The driver simply pulls up next to a parking space, activates auto park, and the car drives itself into the parking space between two cars. See **Figure 38-16**.

Proximity sensors (usually sonar or sound sensors) around the perimeter of the vehicle measure the distance from the auto body to anything around the car. Some sonar sensors make a faint clicking sound. This allows a built-in sensor microphone to measure the amount of time it takes for the sound wave to return to the sensor. The proximity sensor can take very accurate assessment of distances of any object around the car to avoid a collision.

Bosch and Subaru

Figure 38-13. Various types of cameras and even radar can be OEM equipment on today's vehicles. A—Radar is for long-range sensing of objects in front of the vehicle. Infrared cameras can provide night vision in front of the vehicle. Video cameras can be used in the front and rear of the vehicle for operating the video screen in the passenger compartment. Rear camera is convenient to avoid hitting objects when backing up. B—A video image from a rear-mounted camera aids in backing up the vehicle. C—A vehicle-mounted video camera is very small. The stepped shroud prevents lens glare for clearer image.

Siemens

Figure 38-14. A voice recognition system can react to the spoken word. The driver speaks commands into a microphone in the dash. The microphone signal is processed by the instrumentation computer to perform the desired function given audibly by the driver.

Connectivity

Many new cars come equipped with advanced connectivity for the ability to communicate with other electronic products (laptop computers, smart phones, tablets, memory chips, etc.). Since vehicle wiring and components vary, you must refer to the factory service literature to understand these new and ever-changing local area networks. Refer to **Figure 38-17**.

Security and Navigation System Service

Servicing vehicle security and navigation systems usually involves part replacement. However, sometimes the problem can be a bad antenna or power feed problem to the unit.

Copyright Goodheart-Willcox Co., Inc.

A

B

Siemens

Figure 38-15. Devices using infrared radiation are used to avoid collisions. A—Collision avoidance sensors use either radar or infrared light to bounce a signal off any object in front of the vehicle. B—The computer calculates the time it takes the signal to bounce off the object and warns the driver or applies the brakes to avoid a collision.

Siemens

Figure 38-16. This auto-park system measures distance to objects all around the vehicle. It can then operate the engine throttle, brakes, and steering to park the car with minimum human intervention. Let go of the steering wheel and remove your feet from the brake and gas pedals. Activate automatic parking and the vehicle will back into its parking place by itself.

Goodheart-Willcox Publisher

Figure 38-17. Many new vehicles come with complete connectivity to many external sources of data. Devices can communicate wirelessly.

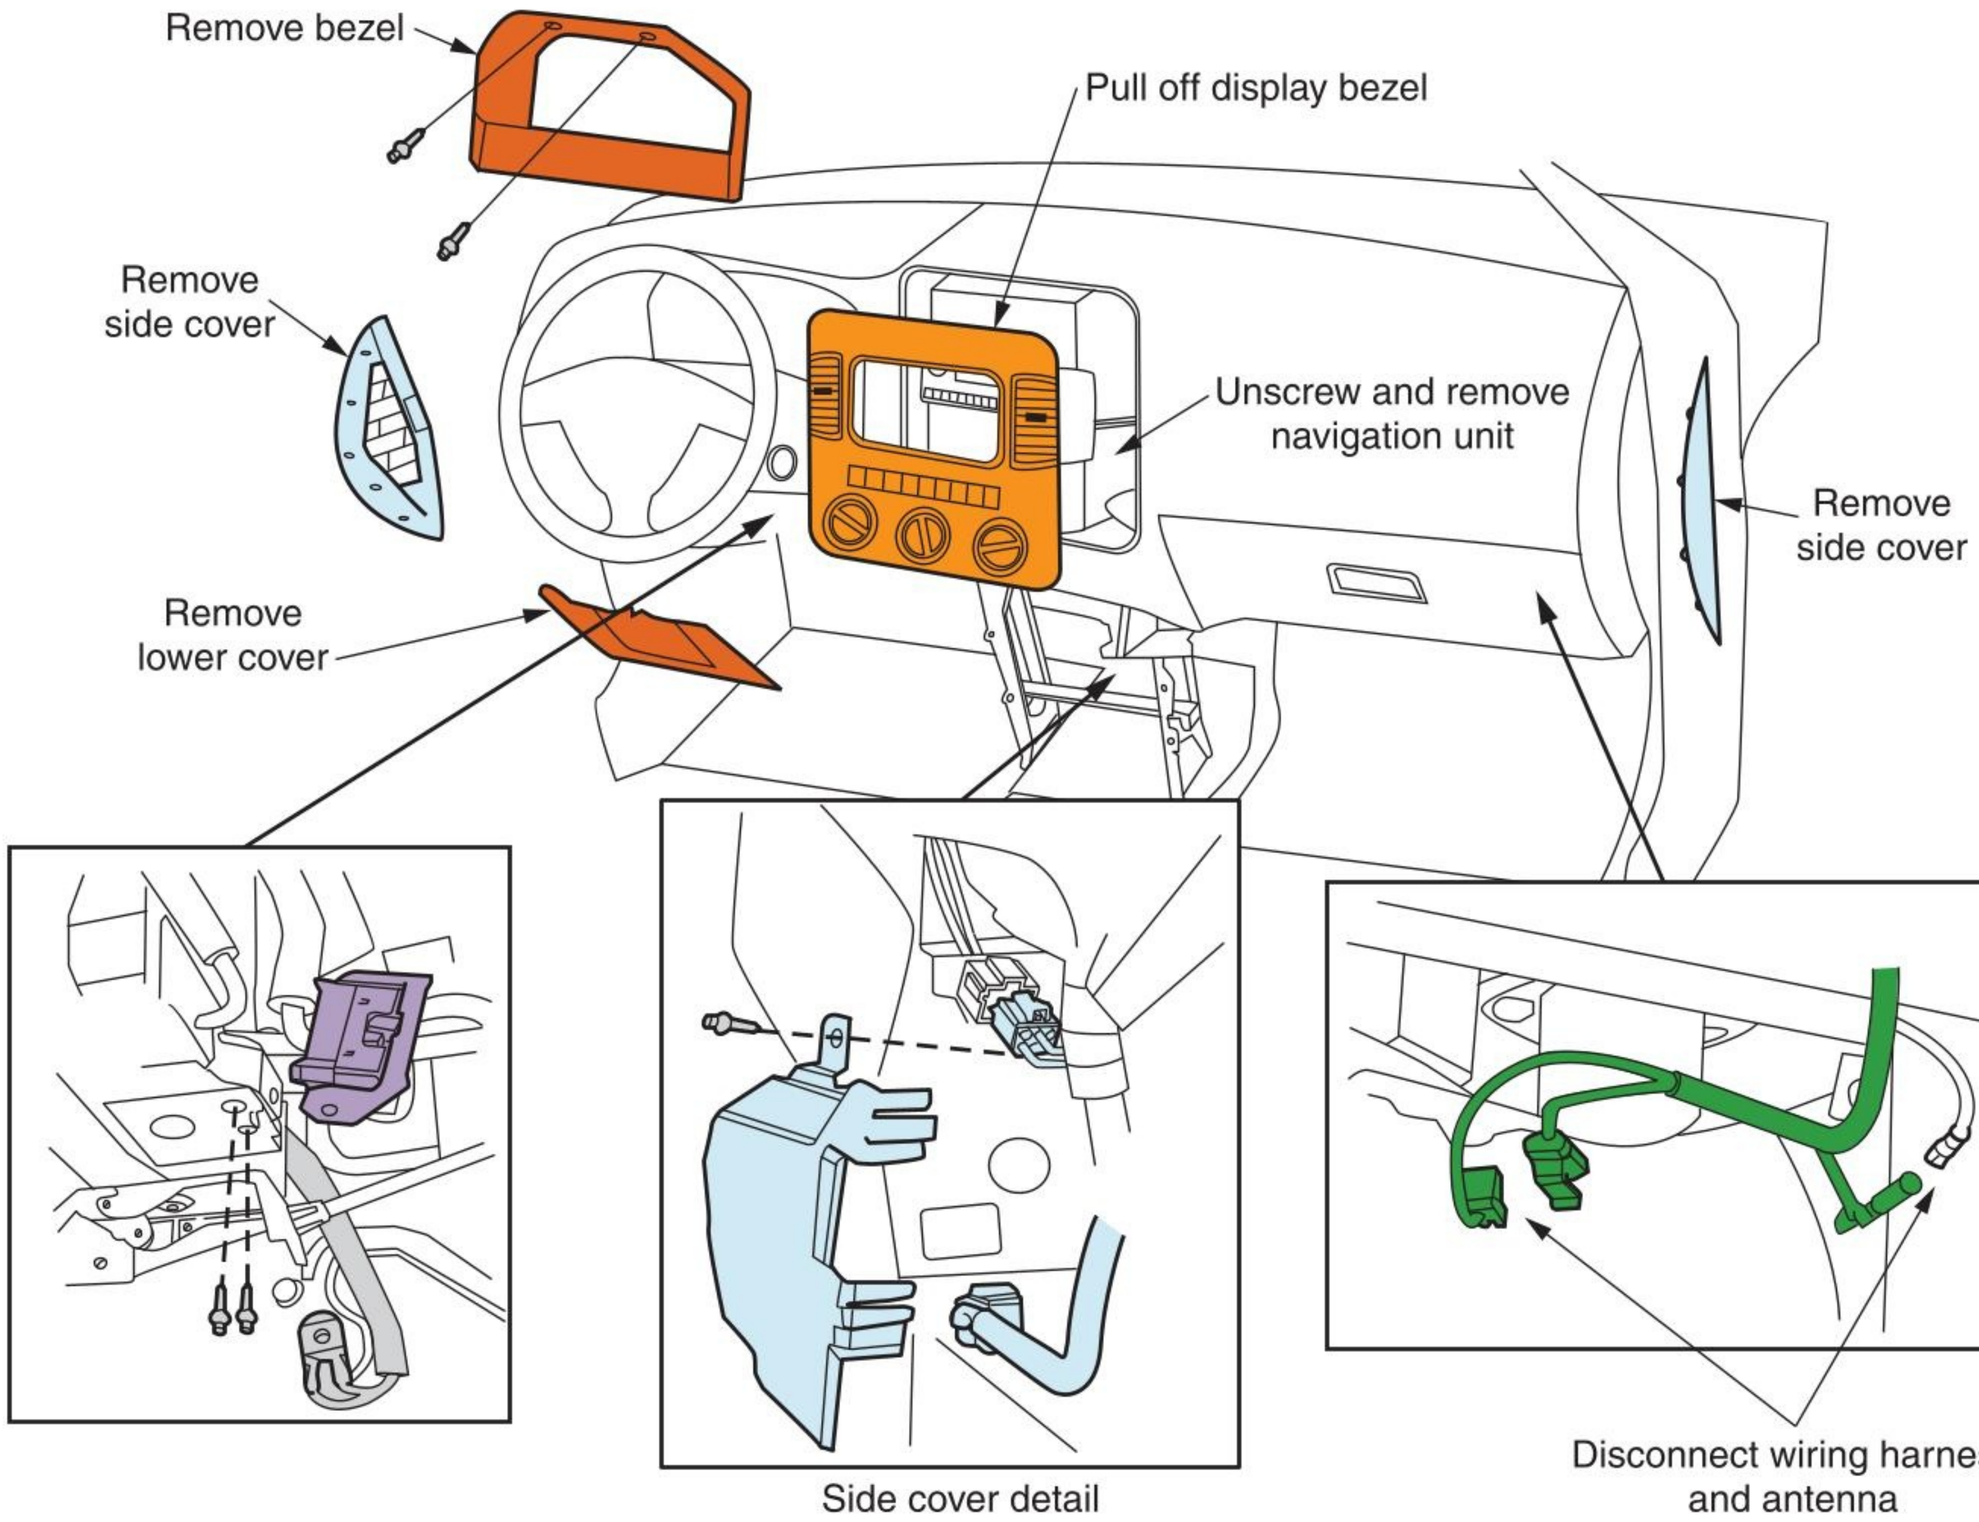
Service Procedure

To find the source of the problem:

1. Try to operate the failed system to verify the customer complaint.
2. Try to pinpoint any external problem that could keep the unit from operating (bad antenna, dead ECM, no display, etc.).
3. Check for blown fuses and for power going to the unit if the unit does not turn on.
4. If the power supply circuit has a relay in it, make sure the relay is working. Plug-in relay testers are available.
5. Make sure the unit has a good ground wire attached properly.
6. Review stored trouble codes, which may indicate the source of the problem.

Normally, if a unit is getting power and is grounded but fails to work normally, the unit must be removed for replacement or repair. Look at **Figure 38-18**.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 38-18. Note how front bezels come out of this vehicle dash. You must remove a few screws and then pull lightly on the part to free it from rubber mounted clips and dash.

Dropping Resistor Signals

Did you ever wonder what really happens when you press a button on a car's dash to change volume or look at a new display screen?

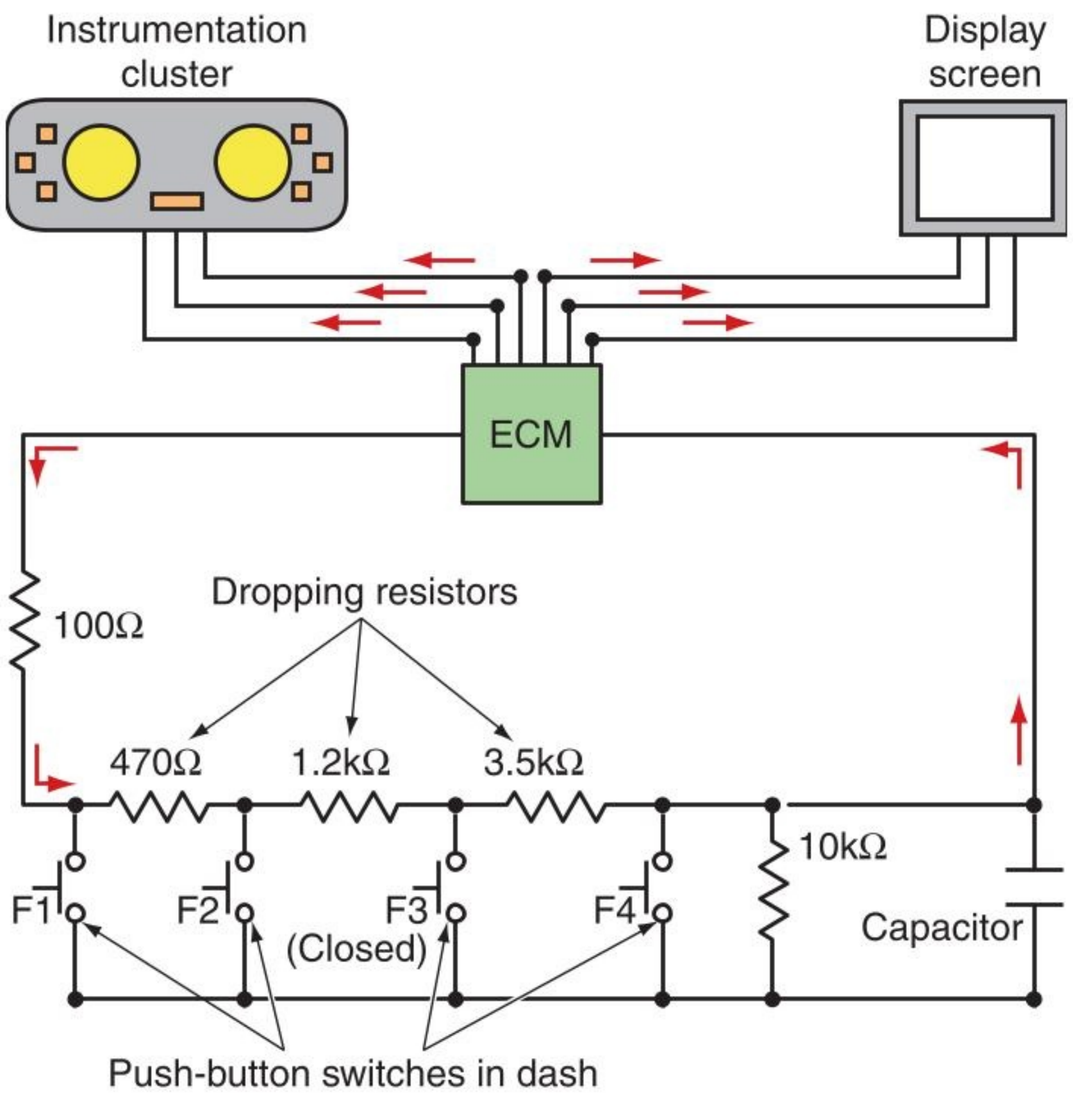
Dropping resistor signals are used to provide input signals to the body or instrumentation ECM as varying dc voltage and current signals. For example, by pressing a button on the vehicle dash, you are connecting a circuit with a specific amount of resistance to the ECM. The analog-to-digital converter chip in the ECM will output preprogrammed functions for each voltage and current level. Each switch and knob in the vehicle dash places a unique set of resistors in series to produce its own voltage/current signal. This allows many control buttons and knobs to be wired together in a circuit to one wire returning to the ECM. Study **Figure 38-19**.

Green Tech

Mercury Pollution

The mercury contained in fluorescent lights is considered to be toxic. Because of this, fluorescent lights should not be discarded as regular waste. Instead, they should be collected and recycled. It is important that fluorescent lights are not broken. Broken fluorescent lights can leak mercury, creating a hazardous area.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 38-19. Note how dash buttons or switches are often wired to an ECM. Dropping resistors allow each button switch to send a unique voltage/current signal back to the ECM. Different size resistors are placed across each switch to provide a unique signal from each switch. ECM can use these signals to operate a digital gauge cluster or LCD display screen.

Summary

- A security system is designed to help prevent theft of the vehicle and its contents.
- Security systems designs vary tremendously so thieves are not able to learn about the operation of any one system too well.
- A transponder key contains an electronic chip that sends a coded signal to a module. If the module recognizes the signal, it allows the engine to be started.
- Some theft deterrent systems use a resistance key which places a small electrical resistor in the side of the ignition key.
- Navigation systems use our nation's satellite global positioning system to display the geographic location of the vehicle.
- A vehicle tracking system is a security system that can track, or follow, the location of a car or truck if it is stolen.
- A night vision system uses an infrared camera and monitor system to help the driver view through vision-impairing atmospheric conditions.
- A voice-activated system uses a microphone and computer data to perform functions by reacting to spoken words.
- A collision avoidance system uses radar to detect a vehicle or other object in front of the vehicle.
- An automatic parking system uses computer control to back up, steer, and brake a car into a parking space.
- Servicing vehicle security and navigation systems usually involves part replacement; however, the trouble may be a bad antenna or power feed problem to the unit.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

adaptive cruise control system
automatic parking system
collision avoidance system
driver information center
dropping resistor signals
global navigation satellite system
global positioning system (GPS)
infrared sensor
keyless entry system
navigation systems
night vision system
proximity sensors
radar sensors
resistance key
security system
smart key system
transponder key
vehicle tracking system
video camera display

Activities

1. Pick any make and model car with a navigation system. Look up how to troubleshoot the vehicle's navigation system in factory service information. Write a short report of anything you learned about testing vehicle navigation systems.
2. Write another report on how to remove the navigation system for service.

Review Questions

Answer the following questions using the information provided in this chapter.

1. Describe the basic operation of a typical security system.
2. How is a security system activated or deactivated?

Copyright Goodheart-Willcox Co., Inc.

3. Why are security system designs so varied?
4. What is a transponder key?
5. How does a resistance key work in a security system?
6. What is the benefit of a smart key system?
7. What type of information can a navigation system provide?
8. Explain the operation of GPS.
9. A video camera display is often used to show the view from the rear of the vehicle when the vehicle is in _____.
10. How does a collision avoidance system operate?

ASE-Type Questions

1. Technician A says a security system uses motion sensors and switches to send signals to an electronic control module. Technician B says security systems are identical in all cars. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. When a resistance key's _____ is not correct, the control module opens the starter relay circuit so the engine will not crank.
   (A) current
   (B) voltage
   (C) resistance
   (D) All of the above.
3. Keypad-type keyless entry systems are being discussed. Technician A says these systems use a key fob that contains a small transmitter to lock and unlock the vehicle's doors. Technician B says the five numbers on the keypad must be pressed in the correct sequence for the doors to unlock. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Technician A says navigation systems use a satellite global positioning system to display the geographic location of the vehicle. Technician B says the vehicle's on-board computer compares satellite data with a large database of roads and highways. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Technician A says the driver information center is usually mounted on the vehicle dashboard. Technician B says the driver information center uses an infrared camera to help the driver see through fog, snow, and rain. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says a vehicle's video camera display gives drivers an obstructed view of objects located behind the vehicle. Technician B says a voice-activated system can be programmed to react to certain words. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says most collision avoidance systems use radar to measure the distance and speed of objects in front of the vehicle. Technician B says the ECM may also use signals from the vehicle speed sensor to detect a possible collision. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Technician A says many automatic parking systems use sonic proximity sensors. Technician B says that no one makes a car with an automatic parking feature. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. When you press a button on the dash, what happens?
   (A) The voltage to the ECM is changed.
   (B) The circuit resistance is changed.
   (C) The current to the ECM is changed.
   (D) All of the above.
10. Technician A says that dropping resistors are used to allow many dash buttons to be wired together into a control circuit. Technician B says that pushing each dash button produces a unique voltage/current signal that can be read and understood by ECM. Who is correct?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Chapter 46
Turbochargers and Superchargers—Construction, Operation, and Repair

Today's fuel systems must meter a precise amount of fuel into the engine under a wide range of constantly changing operating conditions. The fuel system has the important job of optimizing engine performance while keeping fuel consumption and emissions to a minimum. This is no easy task!

This section will explain modern fuel systems in detail. Chapter 39 describes the properties of various fuels and discusses normal and abnormal combustion. Chapter 40 covers fuel tanks, fuel pumps, and fuel filters. Chapters 41 and 42 describe the operation and service of electronic fuel injection, the most common type of fuel system. Chapters 43–46 explain the operation and repair of diesel injection, exhaust systems, turbochargers, and superchargers.

The information in this section will help you pass ASE Test A6, Electrical/Electronic Systems; Test A8, Engine Performance; and Test A9, Light Vehicle Diesel Engines.

Chapter 39
Automotive Fuels, Combustion Efficiency

After studying this chapter, you will be able to:

- Summarize how crude oil is converted into gasoline, diesel fuel, liquefied petroleum gas, and other products.
- Describe properties of gasoline and diesel fuel.
- Explain octane and octane ratings.
- Describe normal and abnormal combustion of gasoline and diesel fuel.
- Summarize the properties of alternative fuels.
- Correctly answer ASE certification test questions on automotive fuels and combustion.

An automotive ***fuel*** is any substance (liquid, gas, or solid) that can be easily burned to produce heat. Most passenger vehicle engines burn liquid gasoline, while a few consume diesel fuel, gasohol, alcohol, and alternative fuels.

Combustion is the chemical reaction that occurs when a fuel is burned with an oxidant (oxygen). ***Normal combustion*** is a primary factor controlling good fuel economy, maximum engine power, low exhaust emissions, and long engine service life. ***Abnormal combustion*** occurs when combustion happens too quickly (explosion) or too slowly (incomplete burn). ***Combustion efficiency*** is a measure of how well combustion consumes all the fuel's heat energy for maximum cylinder pressure (propulsion) and minimum exhaust by-products (pollution).

To quickly isolate numerous vehicle problems, you must understand the factors that affect proper fuel combustion. This knowledge will help you diagnose engine performance and mechanical problems more quickly.

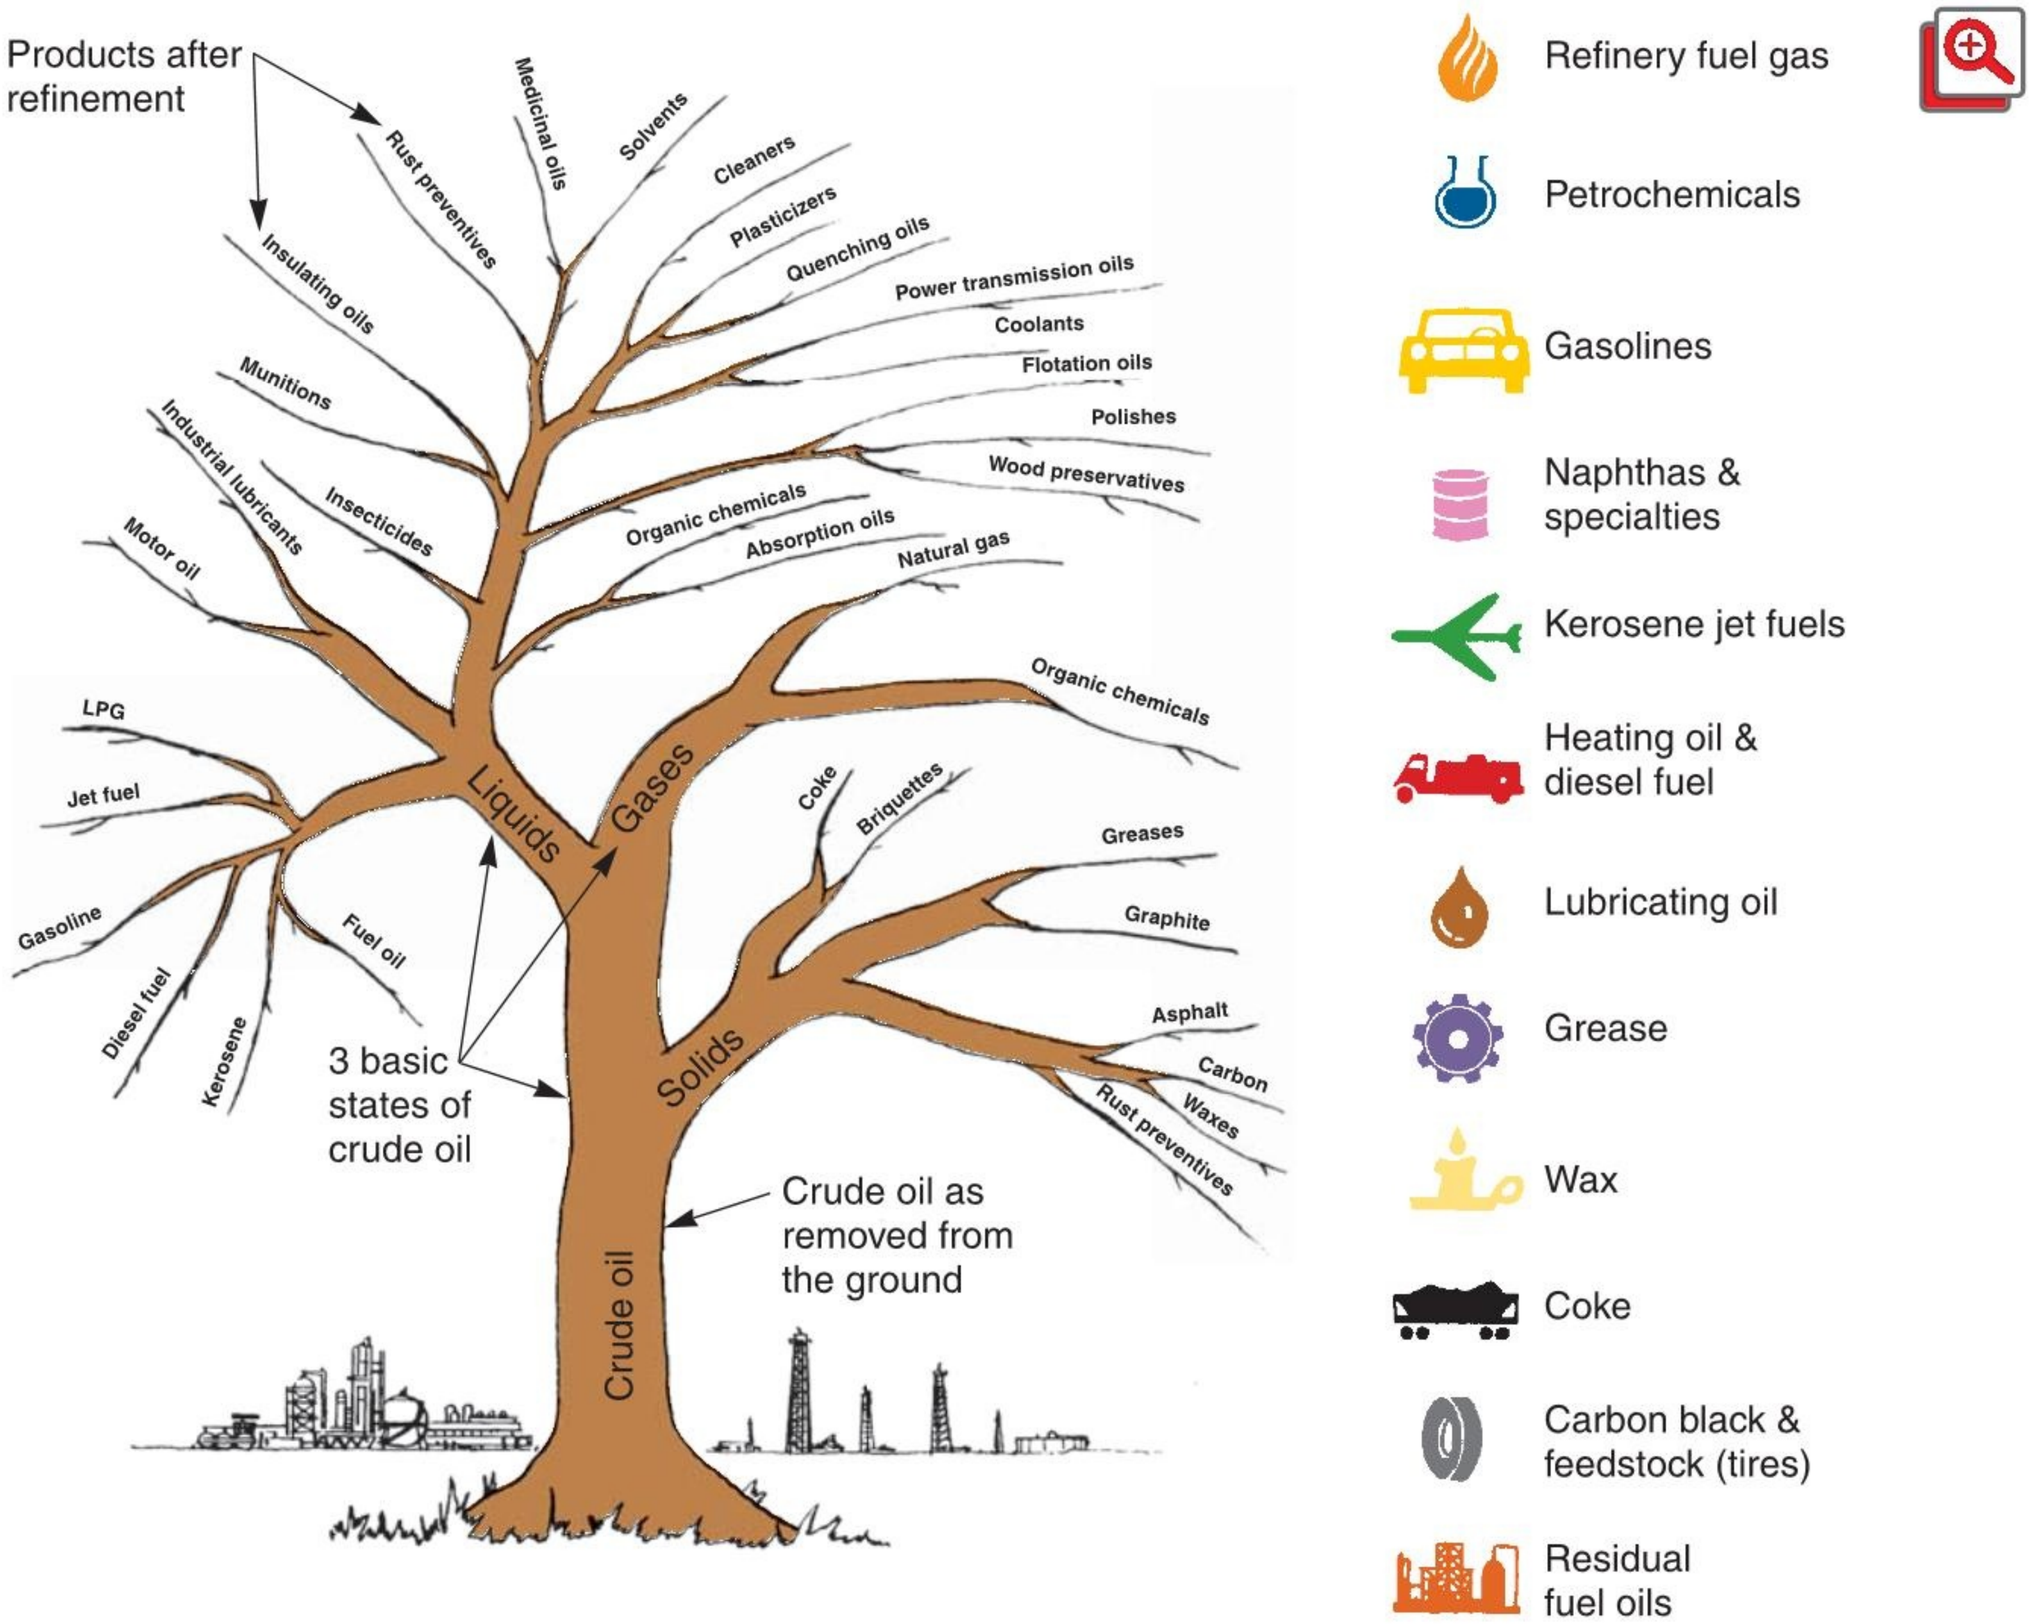
Petroleum (Crude Oil)

Crude oil, or ***petroleum***, is oil taken directly out of the ground. It is used to make gasoline, diesel fuel, liquefied petroleum gas, and many nonfuel materials (asphalt, motor oil, etc.). **Figure 39-1** shows some of the products made from crude oil.

Natural crude oil is a mixture of semisolids (neither solid nor liquid), liquids, and gases. Chemically, crude oil consists of highly flammable hydrocarbons.

Hydrocarbons are chemical mixtures of about 12% hydrogen (flammable gas vapor) and 82% carbon (heavy, black solid). Crude oil also contains sulfur, nitrogen, metals, and saltwater. These elements must be removed.

Copyright Goodheart-Willcox Co., Inc.



Gulf Oil Corp.

Figure 39-1. Crude oil is used to make many products besides gasoline and diesel fuel.

Processing Crude Oil

Crude oil deposits are contained inside the earth. Oil companies perform ***exploration tests*** (seismic studies, surface mapping, and test drilling) to find oil. After determining where oil might be located, a drill crew bores a hole thousands of feet into the ground. A huge steel derrick is used for the deep earth drilling operation. The derrick has a cutting bit capable of passing through dirt, sand, and rock.

Once the oil deposit has been reached, the oil is pumped to the surface and sent to a refinery. The ***refinery*** converts the crude oil into more useful substances, such as motor oil, gasoline, and diesel fuel. See **Figure 39-2**.

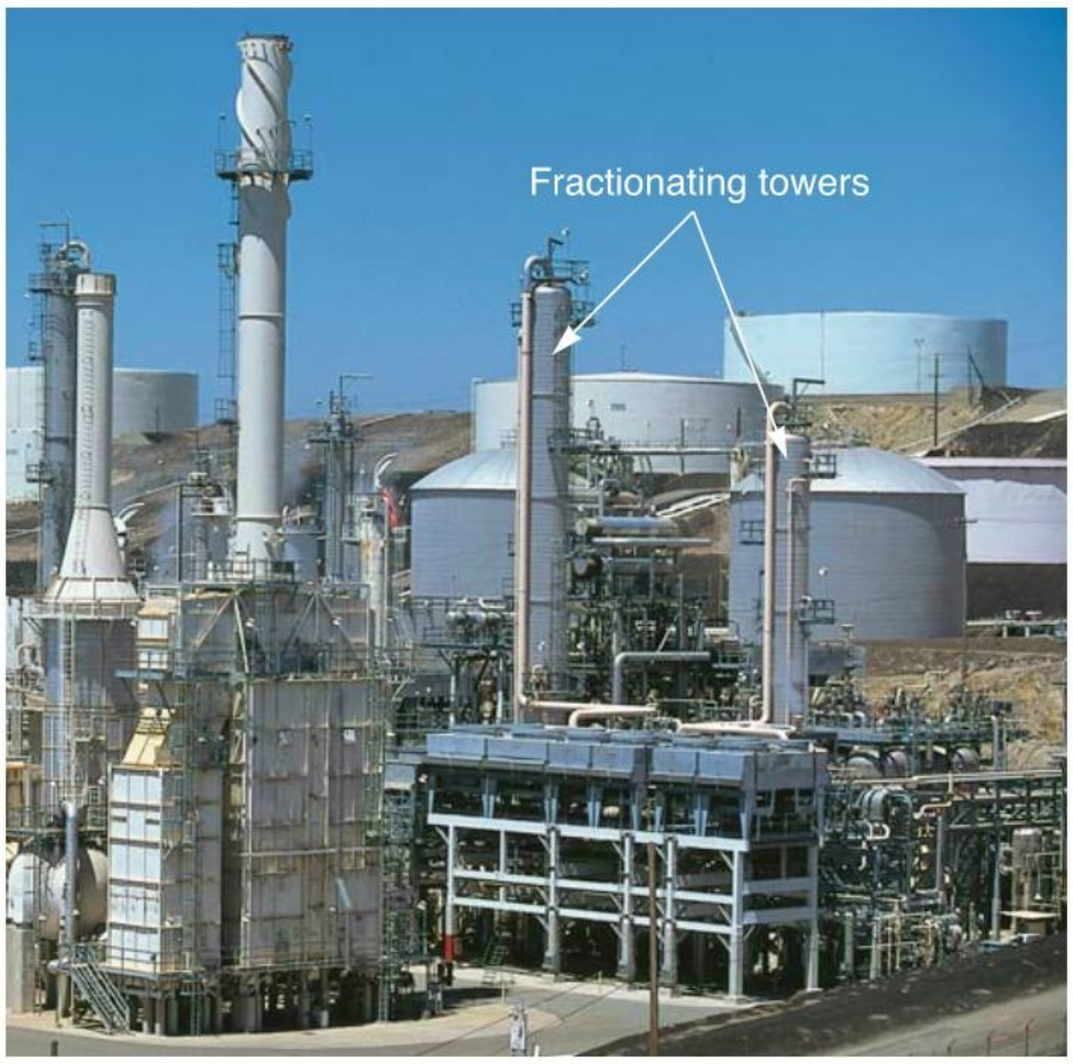
Distillation is the first conversion process. During distillation, a ***fractionating tower*** breaks the crude oil down into different parts, or fractions (LPG, gasoline, kerosene, fuel oil, and lubricating oils). Refer to **Figure 39-3**. After distillation, other processes purify and alter the content of each crude oil fraction.

Gasoline

Gasoline is the most common type of automotive fuel. It is an abundant and highly flammable part of crude oil. Extra chemicals, called additives (detergents, antioxidants, etc.), are mixed into gasoline to improve its operating characteristics.

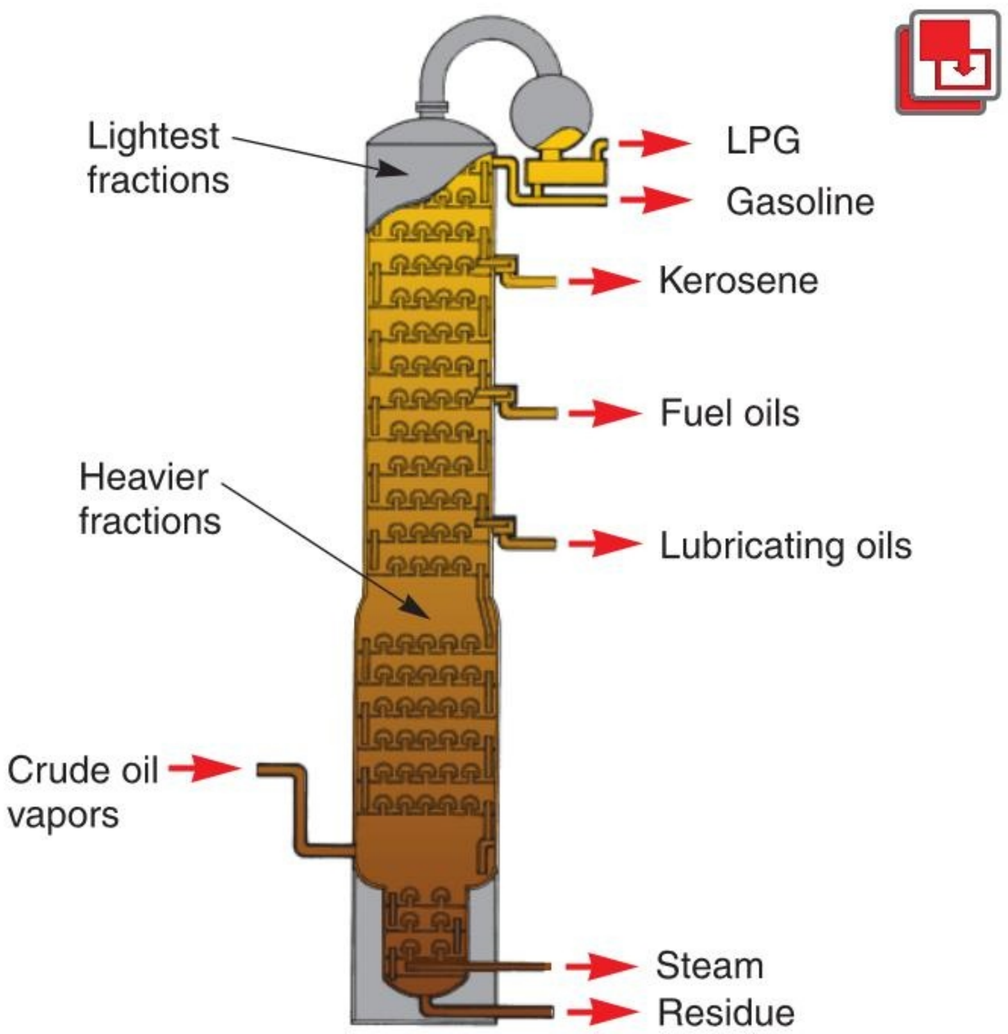
Antiknock additives slow down the burning of gasoline. This helps prevent engine ping, or knock (knocking sound produced by abnormal, rapid combustion).

Copyright Goodheart-Willcox Co., Inc.



Mercedes Benz

Figure 39-2. During the refining process, oil companies use large fractionating towers to separate the crude oil vapors into useful parts or fractions.



Ford

Figure 39-3. A fractionating tower allows crude oil vapors to condense and separate into trays. Each weight of vapor flows off its tray and into storage containers.

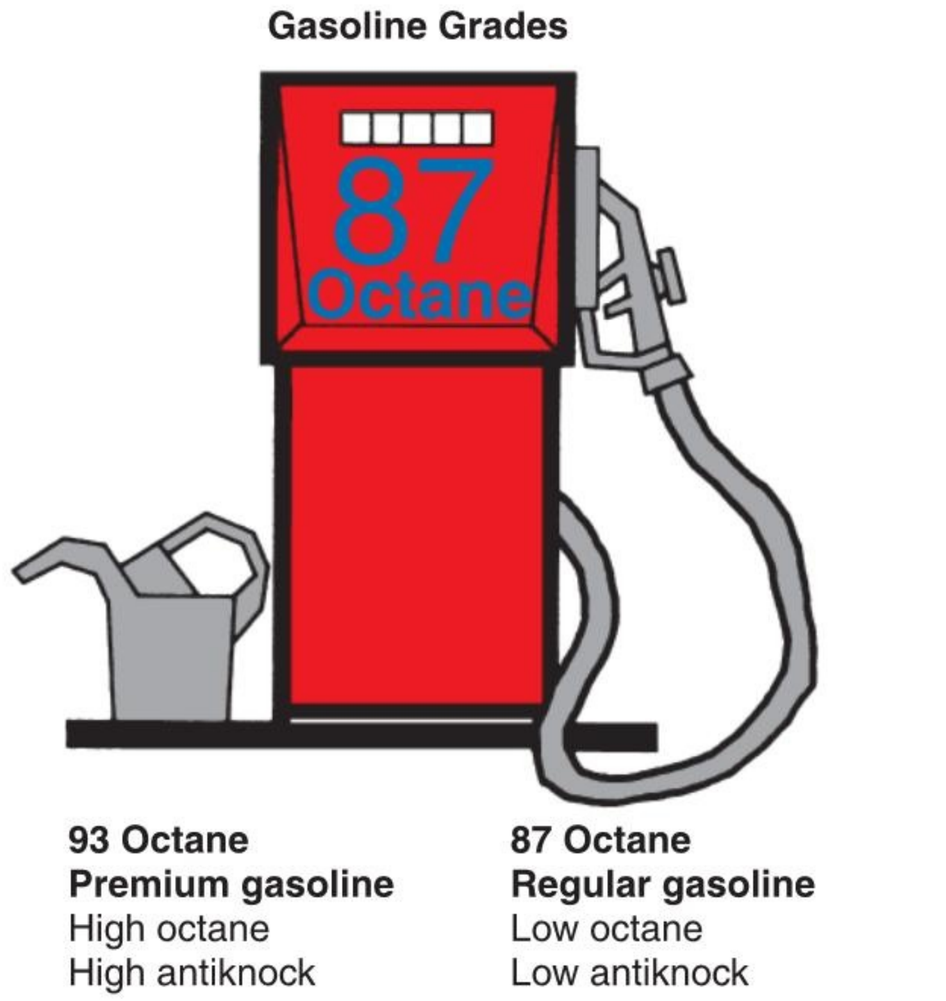
Tech Tip

Tetraethyl lead, or lead, is a naturally occurring heavy metal. For many years, lead was added to gasoline as an octane booster to prevent detonation and engine wear. After scientists learned that lead was a common cause of birth defects and other serious illness, all fuel and oil additives containing lead were banned from the market.

Gasoline Octane Ratings

The ***octane rating*** of gasoline is a measurement of the fuel's ability to resist knock or ping. Gasoline with a high octane number (91, for example) will resist knock and ping better than gasoline with a low octane number (87, for example). High-octane gasoline should be used in high-compression or turbocharged/supercharged engines. Low-octane gasoline is more suitable for normal compression, high efficiency engines.

Octane ratings are given as numbers on the gas station pump, **Figure 39-4**. Automakers recommend octane ratings of fuel for their engines. The owner's manual



Goodheart-Willcox Publisher

Figure 39-4. The gasoline grade indicates the antiknock value of gasoline blend.

Copyright Goodheart-Willcox Co., Inc.

will give the octane rating recommended for the car's engine. Use a fuel with an octane rating as high as the automaker's recommendations. **Figure 39-5** summarizes several factors that control engine octane requirements.

Octane enhancers, or ***oxygenates***, are now used as blending components in gasoline to increase octane levels and reduce engine knock. Octane enhancers are alcohols made up of hydrogen, carbon, and oxygen. Examples of octane enhancers include toluene, ethanol, and MTBE.

Tech Tip

Avoid using high octane fuel in an engine designed to burn low octane fuel. There is no benefit to engine power or fuel economy by purchasing the higher priced fuel. Contrary to what many people believe, a high octane fuel actually is less volatile and burns more slowly than low grade fuel. High octane fuel may not burn properly in a low compression, naturally-aspirated engine. Its improper use can actually decrease engine power and gas mileage. Use the cheaper, low octane fuel in engines with lower compression ratios.

Gasoline Combustion

For gasoline (or any other fuel) to burn properly, it must be mixed with the right amount of air. The volatile (flammable) air-fuel mixture must then be compressed, pressurized, and ignited. The resulting combustion, or rapid oxidation, produces heat, expansion of gases, and engine cylinder pressure. The cylinder and combustion chamber pressure pushes down on the pistons to rotate the crankshaft. Refer to **Figure 39-6**.

Normal Gasoline Combustion

Normal gasoline combustion occurs when the spark plug ignites the fuel and burning progresses quickly and smoothly through the air-fuel mixture. Maximum cylinder pressure should be produced a few degrees of crank rotation after piston TDC on the power stroke. Normal gasoline combustion is illustrated in **Figure 39-7**.

Normal combustion takes only about 3/1000 of a second. This is much slower than an explosion. Dynamite explodes in about 1/50,000 of a second. Under some undesirable conditions, however, gasoline can burn too quickly, making part of combustion like an explosion. This is detailed later.

Air-Fuel Mixture

For proper combustion and engine performance, the correct amounts of air and fuel must be mixed. If too much fuel or too much air is used, engine power, fuel economy, and efficiency will suffer.

A ***stoichiometric fuel mixture*** is a chemically correct air-fuel mixture. For gasoline, it is a mixture ratio of 14.7:1 (14.7 parts air to 1 part fuel, by weight).

Octane Requirement Factors

Octane number requirement tends to go *up* when:

1. Ignition timing is advanced.
2. Air density rises due to supercharging, a larger throttle opening, or higher barometric pressures.
3. Humidity or moisture content of air decreases.
4. Inlet air temperature goes up.
5. Lean fuel-air ratios.
6. Compression ratio is increased.
7. Coolant temperature is raised.
8. Antifreeze (glycol) engine coolant is used.
9. Combustion chamber design provides little or no quench area.
10. Vehicle weight is increased.
11. Engine loading is increased, such as when climbing a grade, pulling a trailer, or increasing wind grade, or increasing wind resistance with a car-top carrier.

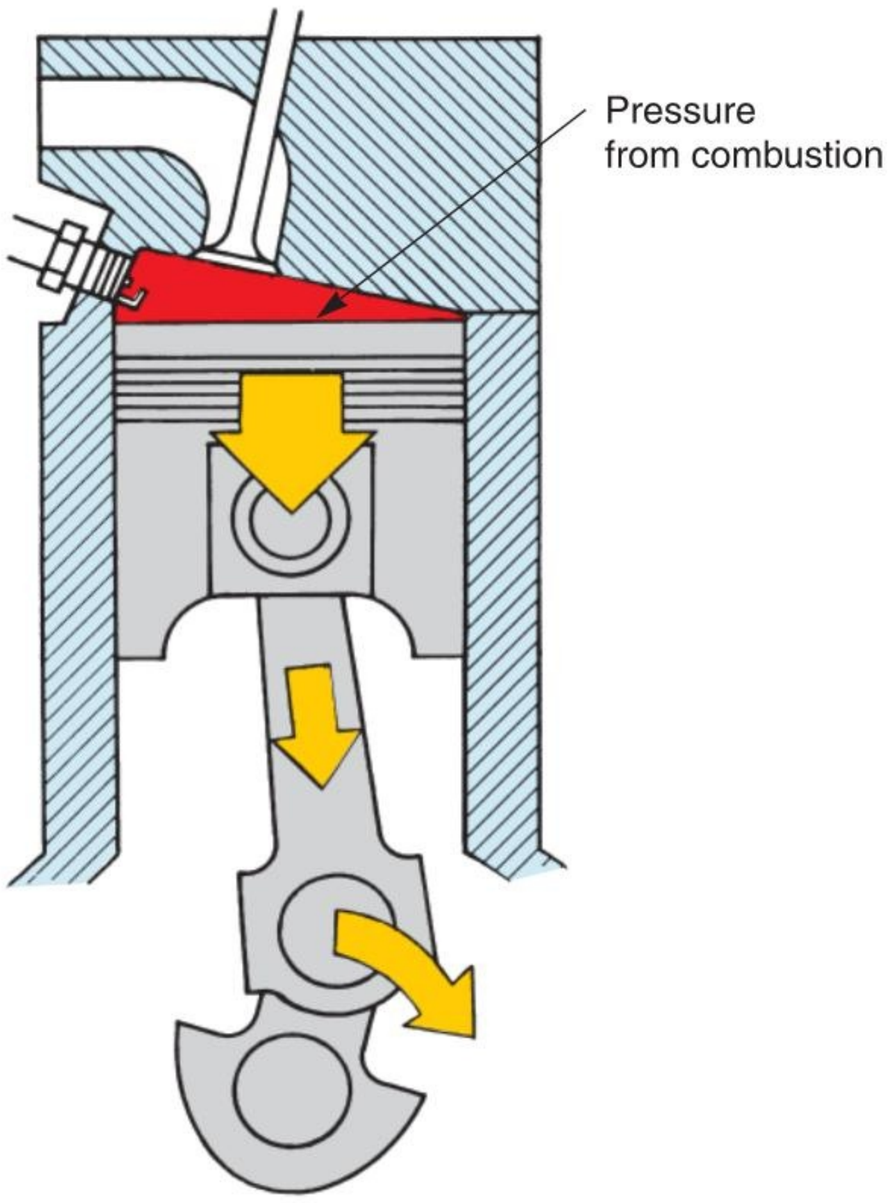
Octane number requirement tends to go *down* when:

1. Car is operated at higher altitudes (lower barometric pressure).
2. Fuel-air ratio is richer or leaner than that producing maximum knock.
3. Spark plug location in combustion chamber provides shortest path of flame travel.
4. Combustion chamber design gives maximum turbulence of fuel-air charge.
5. Compression ratio is lowered.
6. Exhaust gas recycle system operates at part-throttle.
7. Ignition timing retard devices are used.
8. Humidity of the air increases.
9. Ignition timing is retarded.
10. Inlet air temperature is decreased.
11. Reduced engine loads are employed.

Goodheart-Willcox Publisher

Figure 39-5. Various factors that control octane requirements.

Copyright Goodheart-Willcox Co., Inc.



Ford

Figure 39-6. Combustion flame produces heat. Heat causes gases to expand. Expansion causes pressure. Pressure pushes the piston down on power stroke.

Under constant engine conditions, this ratio helps ensure that all the fuel is burned as efficiently as possible during combustion.

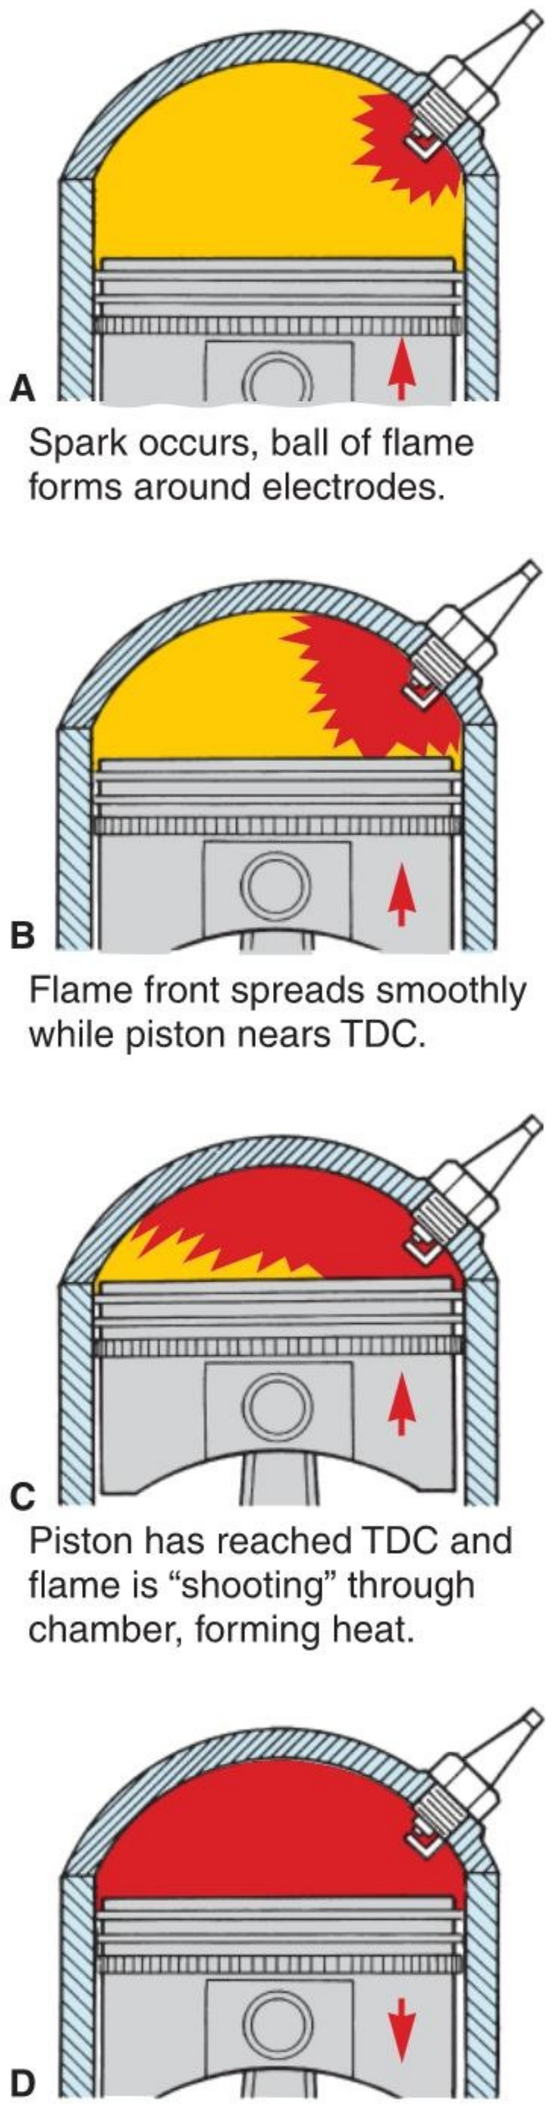
Lean and Rich Air-Fuel Mixture

A ***lean air-fuel mixture*** contains a large amount of air compared to fuel. Look at **Figure 39-8A**. For gasoline, 20:1 is a very lean mixture.

A ***rich air-fuel mixture*** is the opposite of a lean mixture; more fuel is mixed with a smaller portion of air. For gasoline, 8:1 (8 parts air to one part fuel) is a very rich fuel mixture. Refer to **Figure 39-8B**.

A slightly lean mixture is desirable for high gas mileage and low exhaust emissions. Extra air in the cylinder ensures that all the fuel is burned. Too lean a mixture, however, can cause poor engine performance (lack of power, missing, and even engine damage).

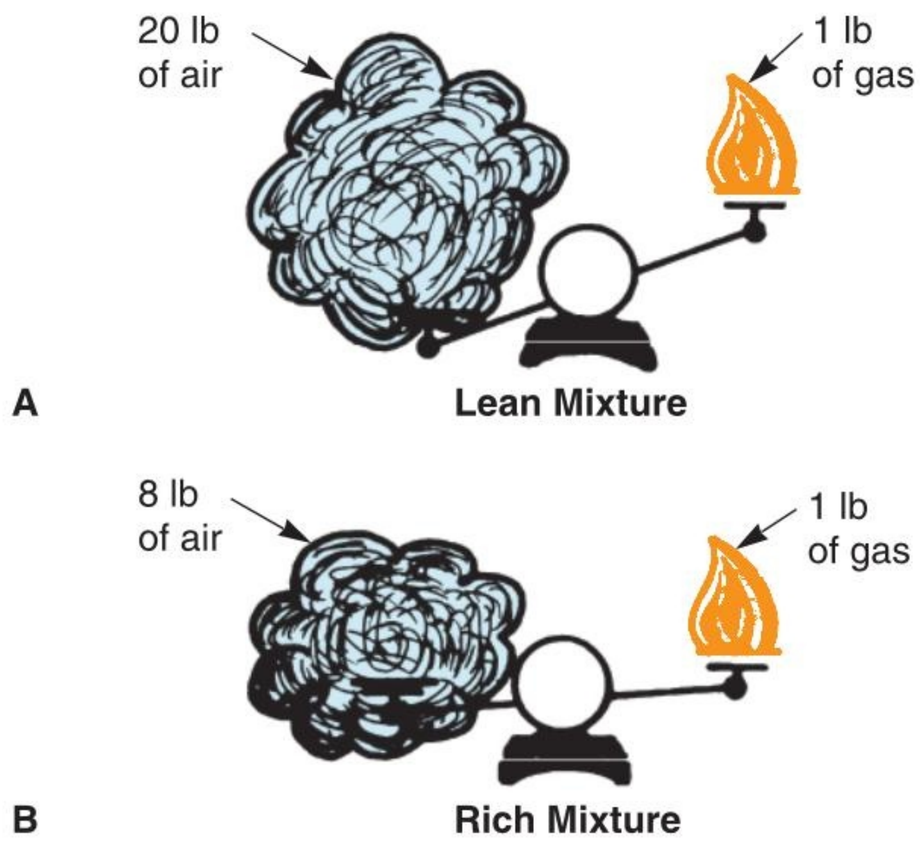
A slightly rich mixture tends to increase engine power. However, it also increases fuel consumption and exhaust emissions. An over-rich mixture will reduce engine power, foul spark plugs, and cause incomplete burning (black smoke at engine exhaust).



Goodheart-Willcox Publisher

Figure 39-7. The following is the process for normal gasoline combustion. A—A spark at the spark plug starts the fuel burning. A small ball of flame forms around the tip of the plug. The piston is moving up in the cylinder, compressing the fuel mixture. B—The flame spreads faster and moves about halfway through the mixture. Generally, the flame is moving evenly through the fuel mixture. The piston is nearing TDC, causing increased pressure. C—The piston reaches TDC. The flame picks up more speed. D—The flame shoots out to consume the rest of the fuel in the chamber. Combustion is complete with the piston only a short distance down in the cylinder.

Copyright Goodheart-Willcox Co., Inc.



Goodheart-Willcox Publisher

Figure 39-8. A—Lean fuel mixture has less fuel mixed with the air. B—Rich fuel mixture has more fuel mixed into the air.

Abnormal Combustion

Abnormal combustion occurs when the flame does not spread evenly and smoothly through the combustion chamber. The lean air-fuel mixtures, high operating temperatures, and low-octane fuels of today make abnormal combustion problems more common.

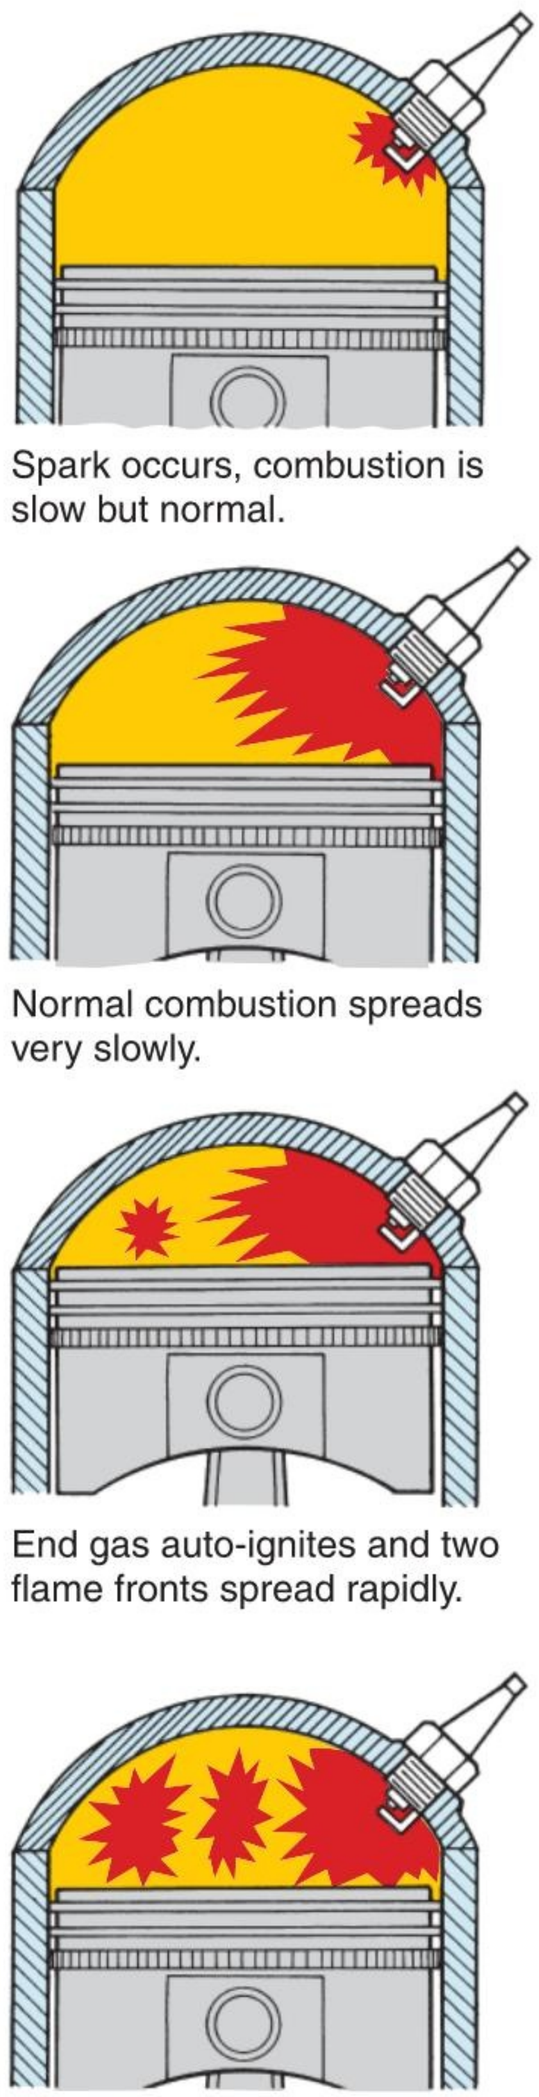
Detonation

Detonation results when part of the unburned air-fuel mixture explodes violently. This is the most severe and engine-damaging type of abnormal combustion.

Engine knock is a symptom of detonation. The combustion chamber pressure rises so quickly that parts of the engine vibrate. Detonation sounds like a hammer hitting the side of the engine. **Figure 39-9** shows the four phases of detonation.

As you can see, the ***end gas*** (unburned portion of mixture) is heated and pressurized for an extended period. Combustion is too slow because of an incorrect air-fuel mixture, a lack of turbulence, or a fuel distribution problem. This causes the end gas to explode with a "bang" (knock). Refer to **Figure 39-10**.

Detonation can greatly increase the pressure and heat in the engine combustion chamber. Detonation damage includes cracked cylinder heads, blown head gaskets, burned pistons, and shattered spark plugs. See **Figure 39-11**.



Goodheart-Willcox Publisher

Figure 39-9. Detonation is caused by combustion being too slow. End gas, or unburned air-fuel mixture, ignites and two flame fronts collide with a loud knock.

Goodheart-Willcox Publisher

Figure 39-10. Detonation can shatter the insulator on a spark plug.

Goodheart-Willcox Publisher

Figure 39-11. This piston was damaged from prolonged detonation. Heat melted the piston and pressure blew a hole along the side of the piston head.

Tech Tip

Racing fuels have additives to greatly increase their resistance to preignition and detonation. Racing fuels come in many blends, with ratings from 100 to 120 octane and higher. For example, if a small-displacement turbocharged engine is developing over 1000 horsepower at 50 pounds of boost pressure, the car better be running 118 octane or higher racing fuel. If a lower octane rating fuel is used, a split second of detonation will usually result in instant engine destruction. At these boost levels, even a split second of detonation can cause burned pistons, broken piston rings, badly bent connecting rods, and engine block damage.

Never recommend a racing fuel to customers driving their vehicles on city streets! This is against federal law and can result in expensive fines to you or your repair facility. Improper fuel can also void a vehicle's warranty and result in catalytic converter and engine damage. Always recommend fuel with an octane rating specified by the vehicle manufacturer. A fuel sticker displaying recommended octane rating for a specific engine is installed on the car. This sticker is usually located over the fuel filler opening. Recommended octane ratings will also be listed in the owner's manual.

Preignition

Preignition, or ***surface ignition***, results when an overheated surface in the combustion chamber ignites the air-fuel mixture. A "hot spot" (overheated bit of carbon, sharp metal edge, hot exhaust valve) causes the mixture to burn prematurely.

A ***ping***, or a mild knock, is a light tapping noise that can be heard during preignition. It is not as loud or as harmful as a detonation knock. Study **Figure 39-12**.

Preignition is similar to detonation, but the actions are reversed. Detonation begins after the start of normal combustion. Preignition begins before the start of normal combustion.

Caution

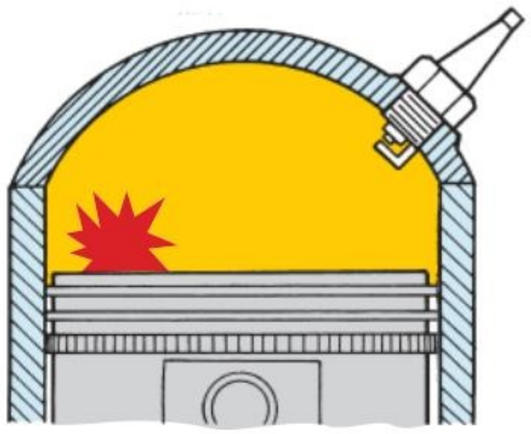
Prolonged preignition can produce harmful detonation. If an engine pings or knocks excessively, serious engine damage can result. Correct the problem right away.

Dieseling

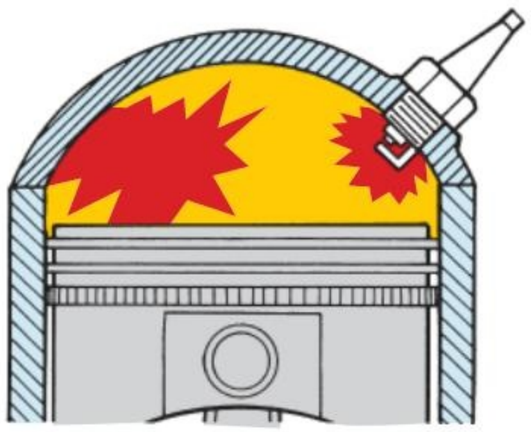
Dieseling, also called ***after-running*** or ***run-on***, is a problem in which the engine keeps running after the key is turned off. A knocking, coughing, or fluttering noise is heard as the fuel ignites and the crankshaft spins uncontrollably. When dieseling, the gasoline engine ignites the fuel from heat and pressure, somewhat like a diesel engine. With the ignition key off, the engine runs without voltage to the spark plugs.

The most common causes of dieseling are a high idle speed, leaking injectors, carbon deposits in the combustion chambers, low-octane fuel, an overheated engine, or spark plugs that have too high a heat range. This problem will be discussed later in the text.

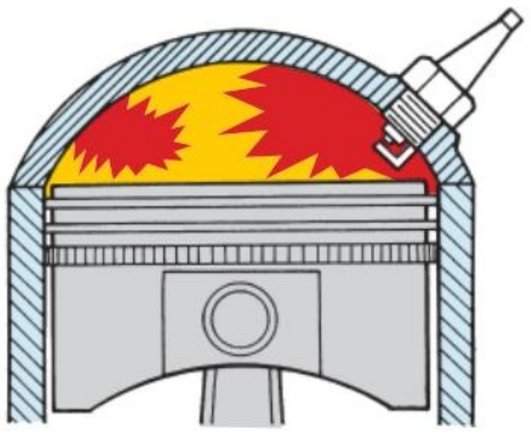
Copyright Goodheart-Willcox Co., Inc.



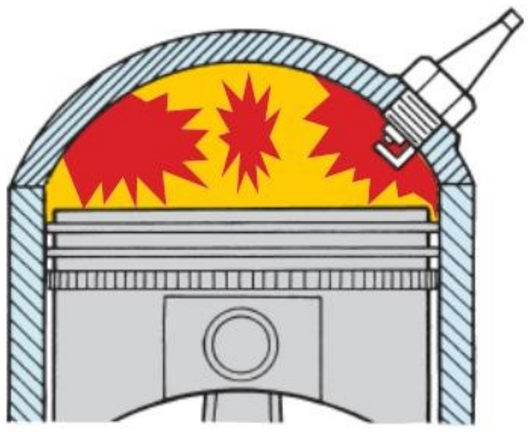
Hot carbon deposit ignites fuel mixture.



Spark plug "fires" and two flame fronts form.



Both flame fronts shoot toward each other at high speed.



Two flames collide causing pressure "spike" and a knock.

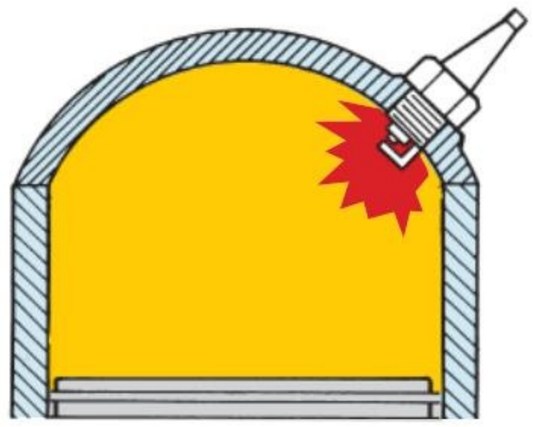
Goodheart-Willcox Publisher

Figure 39-12. Preignition is caused by early ignition of the fuel mixture. Abnormal and normal flames collide, producing a pinging noise.

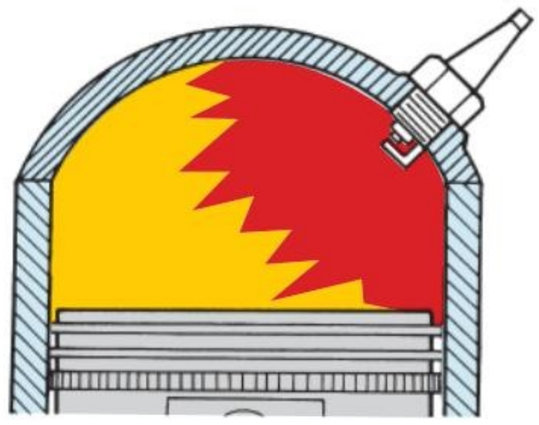
Spark Knock

Spark knock is an engine combustion problem caused by the spark plug firing too soon in relation to the position of the piston. Spark timing that is advanced too far causes combustion pressure to slam into the upward-moving piston. This causes maximum cylinder pressure before TDC, not just after TDC as it should. See **Figure 39-13**.

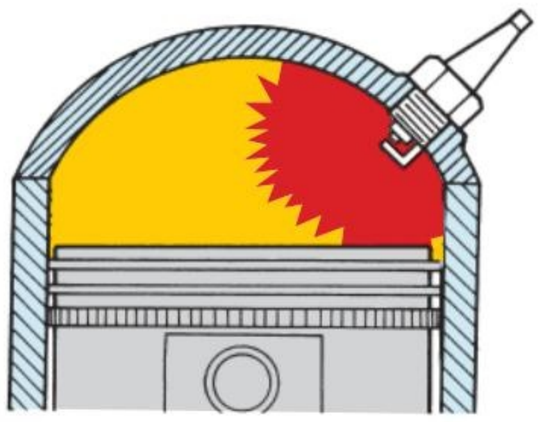
Spark knock and preignition produce about the same symptoms—pinging under load. To find the cause of pinging, first check the ignition timing. If timing is correct, check other possible causes.



Spark plug "fires" too soon.



Piston moves toward flame front.



Pressure builds as piston slams into combustion flame.

Spark knock occurs because of excessive pressure in cylinder.

Goodheart-Willcox Publisher

Figure 39-13. Spark knock is a ping or knock caused by an ignition timing problem.

Diesel Fuel

Diesel fuel is the second most popular type of automotive fuel. A gallon of diesel fuel contains more heat energy than a gallon of gasoline. It is a thicker fraction (part) of crude oil. Diesel fuel can produce more cylinder pressure and vehicle movement than an equal amount of gasoline.

Since diesel fuel is thicker and has different burning characteristics than gasoline, a high-pressure injection system must be used to spray the fuel directly into the combustion chambers. A low-pressure injection system or carburetor would not meter the thick diesel fuel properly. Look at **Figure 39-14**.

Diesel fuel will not ***vaporize*** (change from a liquid to a gas) as easily as gasoline. If diesel fuel were to enter the intake manifold of an engine, it would collect on the inner walls of the manifold. This would upset engine operation.

Combustion requires fuel to be in a vapor state. Diesel engines inject the diesel fuel directly into the combustion chamber. The compressed, hot air vaporizes and burns the fuel.

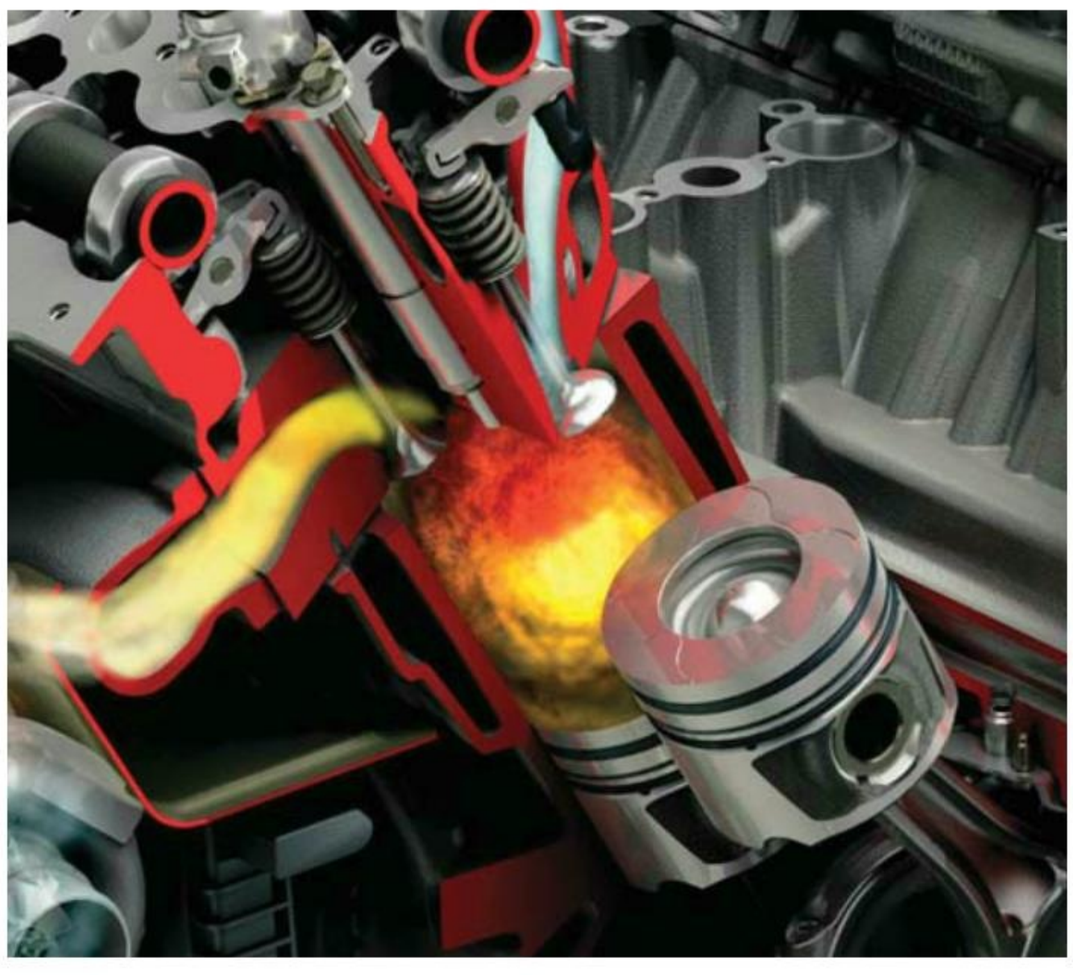
Diesel Fuel Grades

Diesel fuel grades ensure that diesel fuel sold all over the country has uniform standards. Diesel engine makers are then able to select a diesel fuel grade that meets the needs of their engines. There are three diesel fuel grades: No. 1 diesel, No. 2 diesel, and No. 4 diesel.

No. 2 diesel is normally recommended for use in diesel automotive engines. It is also the only grade of fuel available at many service stations. No. 2 diesel has a medium ***viscosity*** (thickness or weight), which provides proper operating traits for the widest range of conditions.

No. 1 diesel is thinner than No. 2 diesel and is sometimes recommended as a winter fuel. Low temperatures tend to thicken diesel fuel, causing performance problems (hard starting, poor fuel delivery).

Some auto manufacturers allow the use of only No. 2 diesel fuel, with special cold weather additives being used in the winter. In some engines, the thin No. 1 diesel fuel will not provide adequate lubrication. Metal-to-metal contact may occur, causing serious engine damage. When in doubt, refer to the vehicle's service manual.



Jaguar

Figure 39-14. A diesel engine is a compression-ignition engine. High pressure heats air in the cylinder. When fuel is sprayed into the hot air, combustion begins.

Caution

Diesel fuel should not be confused with fuel oil or home heating oil. Diesel fuel contains fewer impurities than fuel oil. Fuel oil should never be used in a diesel engine or damage will result.

Diesel Fuel Cloud Point

One of the substances in diesel fuel is ***paraffin*** (wax). At very cold temperatures, this wax can separate from the other parts of the diesel fuel. When this happens, the fuel will turn cloudy or milky. ***Cloud point*** is the temperature at which paraffin separates out of the fuel. At cloud point, the paraffin can clog the fuel filters and prevent diesel engine operation.

Diesel Fuel Water Contamination

Water contamination is a common problem with diesel engines. When mixed with diesel fuel, water can clog filters and corrode components. The parts in diesel injection pumps and nozzles are very precise. They can be easily damaged by water.

Many late-model diesel injection systems have ***water separators*** to prevent water damage. These will be covered in later chapters.

Diesel Fuel Cetane Rating

A ***cetane rating*** indicates the cold starting ability of diesel fuel. The higher the cetane number, the easier

Copyright Goodheart-Willcox Co., Inc.

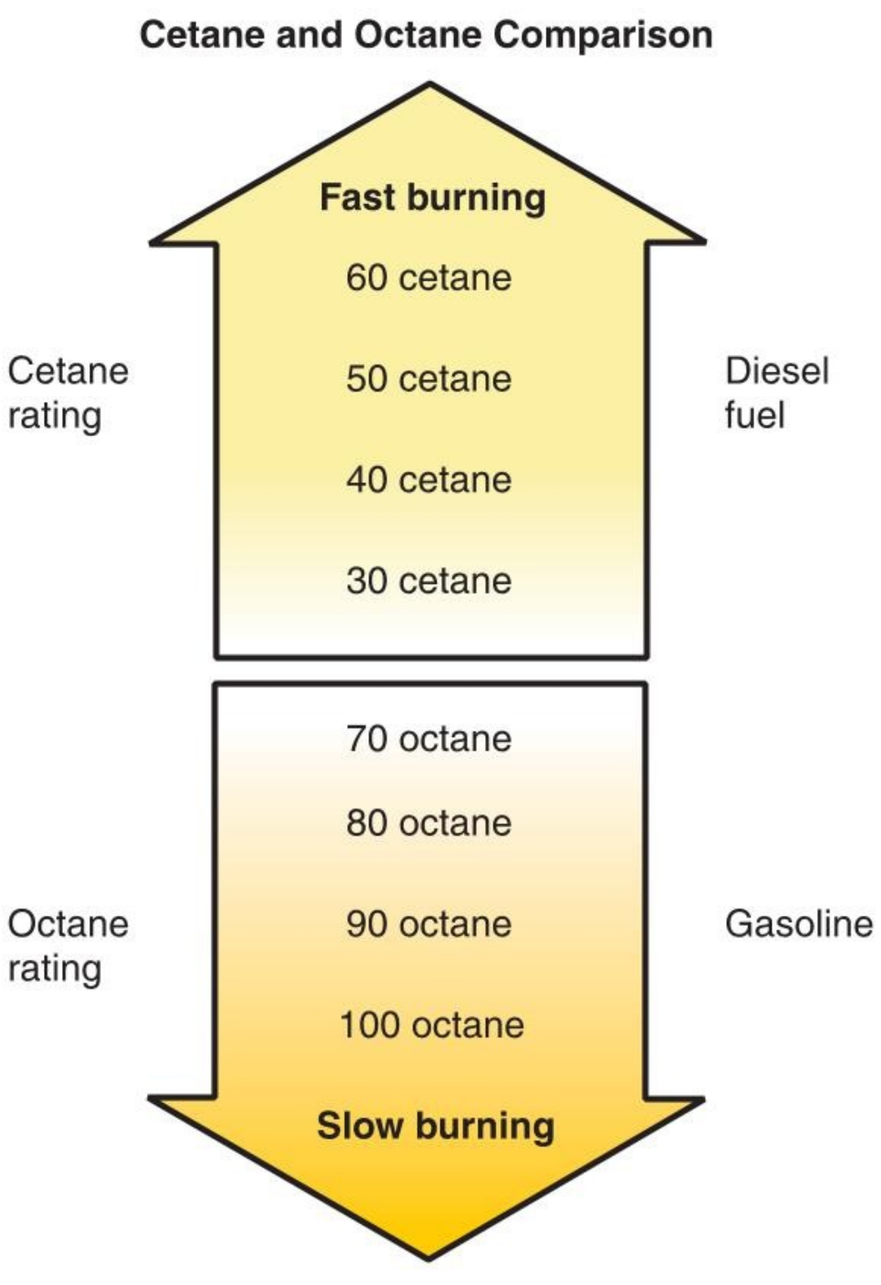
the engine will start and run in cold weather. Most automakers recommend a cetane rating of about 45. This is the average cetane value of No. 2 diesel fuel.

A cetane number, in some ways, is the opposite of a gasoline octane number. This is shown in **Figure 39-15**. A high cetane number means the fuel will ignite easily from heat and pressure. In a diesel, the fuel must ignite and burn as soon as it touches the hot air in the combustion chamber.

Diesel Combustion

A diesel engine is a ***compression-ignition engine***. This engine compresses air until it is hot enough to ignite the fuel. A spark plug would not ignite diesel fuel properly. If gasoline were used in a diesel engine, it would detonate on the compression stroke and not produce useful energy.

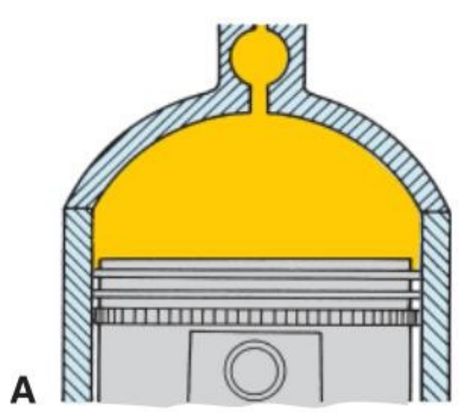
Diesel fuel is thick and hard to ignite. A high-pressure mechanical pump and nozzle force the fuel into the engine combustion chamber. An extremely high compression ratio heats the air in the cylinder. When fuel is sprayed into the hot air, it begins to burn. Normal diesel combustion is illustrated in **Figure 39-16**.

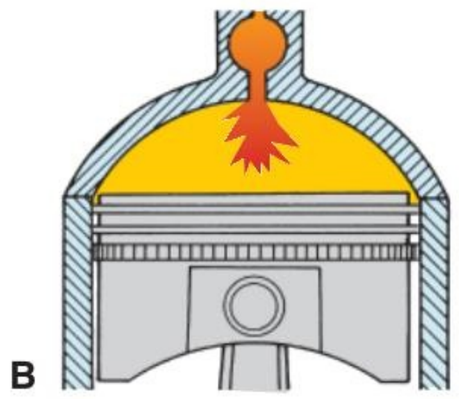


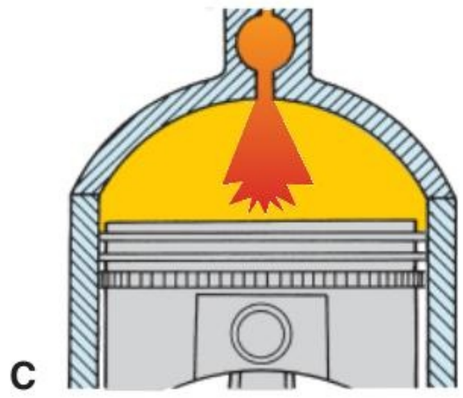
Goodheart-Willcox Publisher

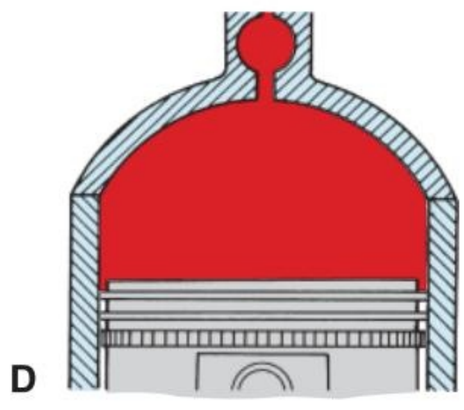
Figure 39-15. Diesel fuel cetane rating is the opposite of gasoline octane rating.

Note that fuel is injected into the engine for several degrees of crankshaft rotation. This causes a smooth, steady buildup of pressure for quiet diesel engine operation.









Goodheart-Willcox Publisher

Figure 39-16. Displayed here is normal diesel combustion. A—The piston moves up to compress and heat the air in the cylinder. Note that this is different than a gasoline engine, which compresses both fuel and air. B—Diesel fuel is injected directly into the combustion chamber. The hot air makes the fuel begin to burn and expand. C—More fuel is sprayed into the chamber. More pressure is developed and the piston begins to move down in the cylinder. D—The rest of the fuel is injected into the chamber. Pressure continues to form, pushing the piston down on the power stroke.

Copyright Goodheart-Willcox Co., Inc.

Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) systems can be found on some late-model diesel-powered vehicles. These systems automatically spray diesel exhaust fluid (DEF) into the vehicle's exhaust stream. A catalytic converter located downstream of the DEF spray nozzle breaks down toxic NO_x emissions into harmless water and nitrogen.

DEF is mixture of urea and de-ionized water. It is stored in a separate tank that typically has a blue filler cap and is located near the fuel tank. See **Figure 39-17**.

The rate of diesel exhaust fluid (DEF) consumption is termed the "dosing rate." Most diesel vehicles that use DEF have a dosing rate of 2% per gallon of diesel fuel burned. For every 100 gallons of fuel burned, 2 gallons of DEF would be injected into the exhaust system in front of the catalytic converter.

The EPA requires vehicle manufacturers to install safeguards that help prevent diesel engines from being operated without DEF. When DEF is low, a warning indicator on the instrument panel will illuminate. If the driver ignores the warning indicator and operates the diesel engine without DEF, the engine's ECU will greatly reduce engine power and limit driving speeds until the DEF container is refilled.

Alternative Fuels

Alternative fuels include any fuel other than gasoline and diesel fuel. Liquefied petroleum gas, alcohol, methane gas, and hydrogen are examples of alternative fuels.

Baloncici/Shutterstock

Figure 39-17. The DEF tank generally has a blue cap for easy identification.

Liquefied Petroleum Gas

Liquefied petroleum gas (LPG) is sometimes used as a fuel for automobiles and trucks. It is one of the lightest fractions of crude oil. Chemically, LPG is similar to gasoline. However, at room temperature and pressure, LPG is a vapor, not a liquid. Refer again to **Figure 39-3**.

A special fuel system is needed to meter the gaseous LPG into the engine. One is shown in **Figure 39-18**. Note the names and construction of the basic parts.

LPG is commonly used in industrial equipment, such as forklifts. It is also used in some fleet vehicles that always refuel at the same location. Being a gas, LPG burns cleanly, producing few exhaust emissions.

Alcohol

Alcohol has the potential to be an excellent alternative fuel for automotive engines. The two types of alcohol used in automobiles are ethyl alcohol and methyl alcohol.

Ethyl alcohol, also called ***grain alcohol*** or ***ethanol***, is made from farm crops. Grain, wheat, sugarcane, potatoes, fruit, oats, soy beans, and other crops rich in carbohydrates can be made into ethyl alcohol. This type alcohol is a colorless, harsh tasting, toxic, and highly flammable liquid.

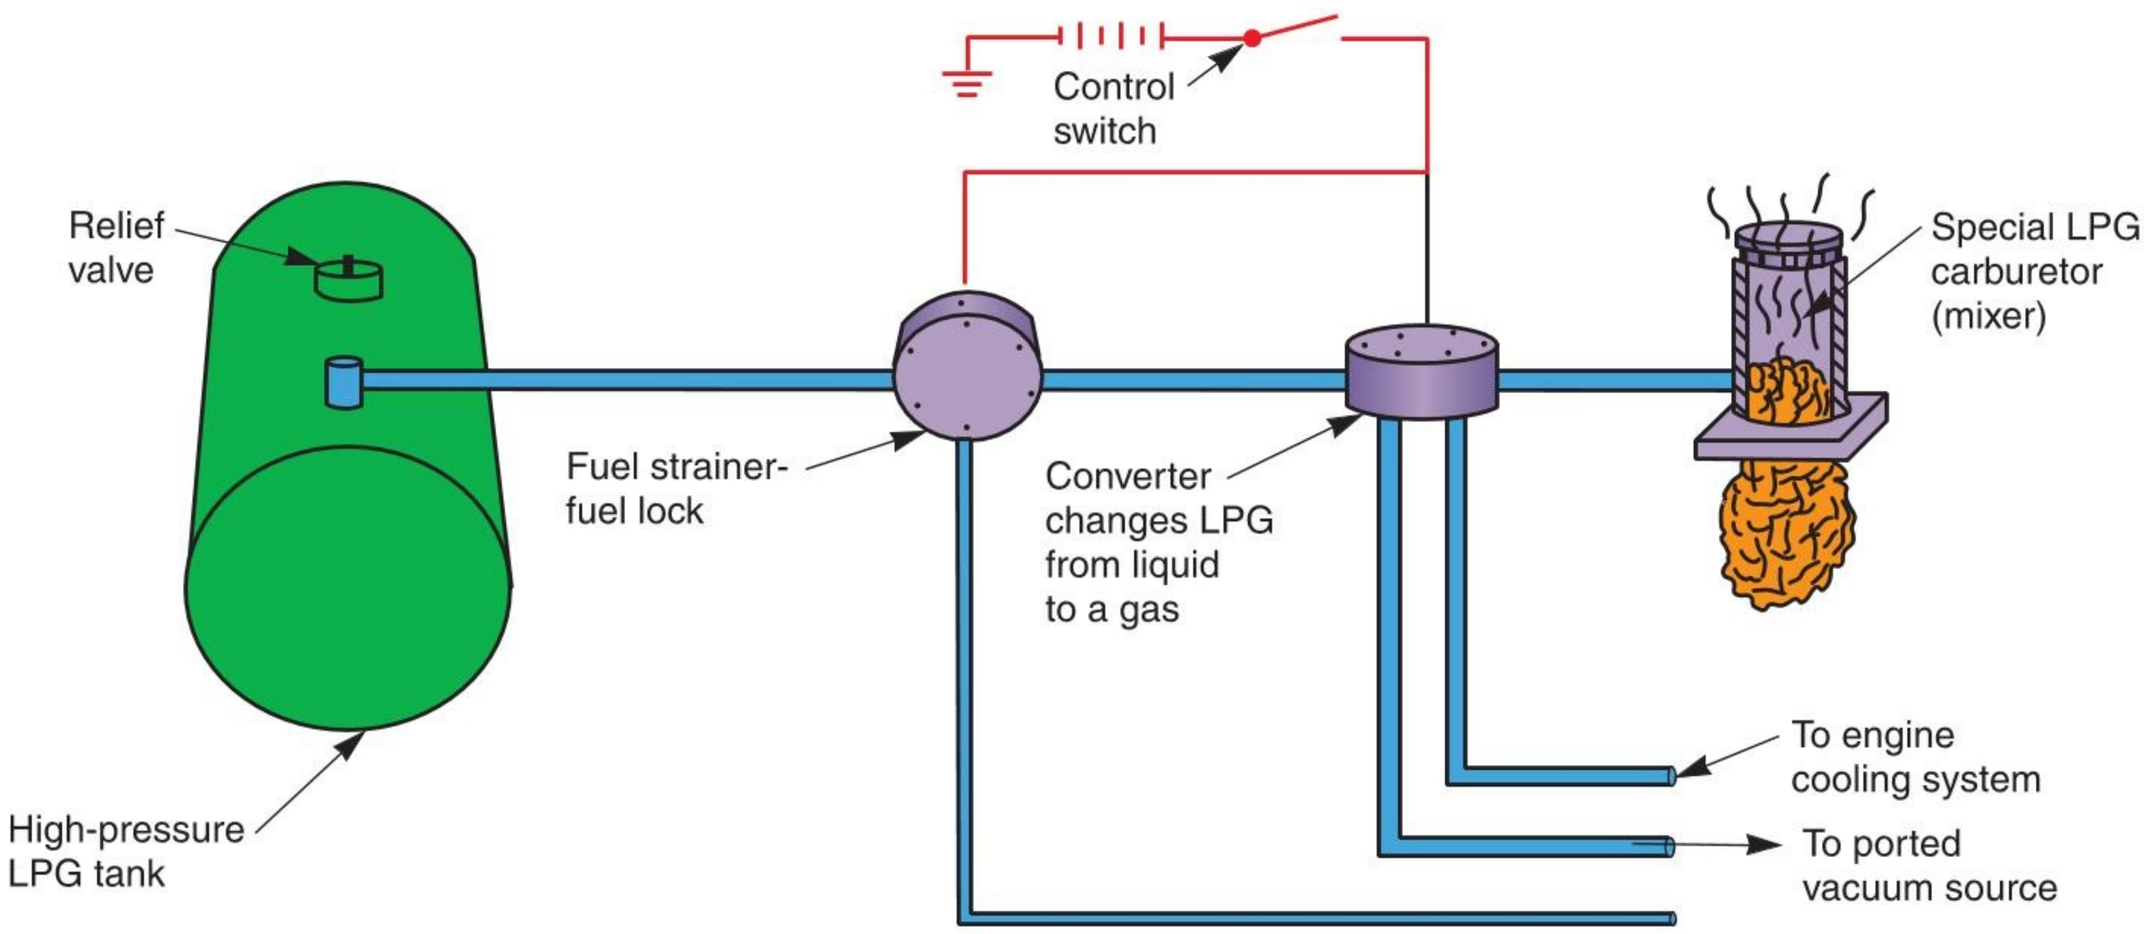
Methyl alcohol, also termed "***wood alcohol***" or ***methanol***, can be made out of wood chips, petroleum, garbage, and animal manure. It has a strong odor, is colorless, poisonous, and very flammable.

Alcohol is a clean-burning fuel for automobiles. It is not commonly used because it is expensive to use and produce. Also, the vehicle's fuel system requires modification before it can burn straight alcohol. Almost twice as much alcohol must be burned, compared to gasoline. This reduces fuel economy by 50%.

Tech Tip

Methanol is commonly used as a racing fuel. It burns cooler than gasoline and does not produce a visible flame. This can be very dangerous because you cannot see the flames if there is a fire. For increased safety, racing organizations have required the use of additives in methanol racing fuel to make its flame more visible.

Copyright Goodheart-Willcox Co., Inc.



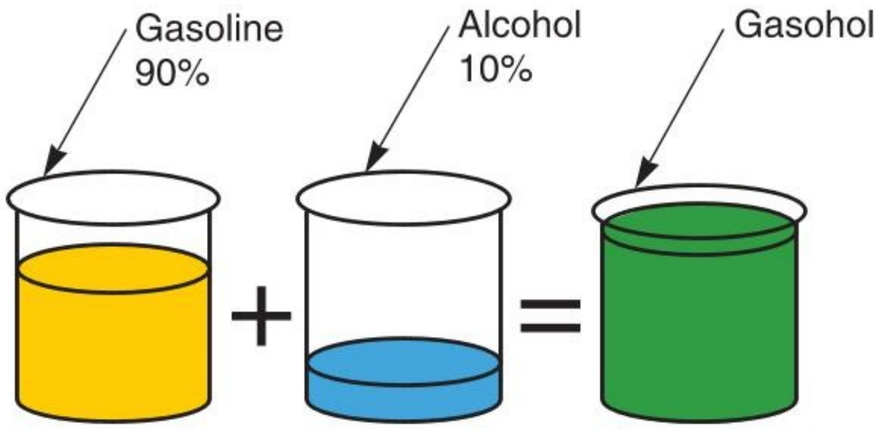
Goodheart-Willcox Publisher

Figure 39-18. An LPG fuel system uses a high-pressure storage tank. A fuel strainer-fuel lock cleans fuel and prevents leakage when the engine is not running. A converter uses heat from the engine coolant to change the liquid LPG into a gas. A special carburetor meters LPG into the engine.

Gasohol

Gasohol, as the name implies, is a mixture of gasoline (usually 87 octane gasoline) and alcohol (usually grain alcohol). The mixture can range from 2–20% alcohol. In most cases, gasohol is a blend of 10% alcohol and 90% gasoline. See **Figure 39-19**.

Gasohol is commonly used as an alternative fuel in motor vehicles because fuel system and engine modifications are not needed. Many gas stations sell gasohol as a high-octane fuel. The alcohol tends to reduce the knocking tendencies of the gasoline. It acts like an antiknock additive. For example, 10% alcohol can increase 87 octane gasoline to 91 octane. Gasohol can be burned in a high-compression, high-horsepower engine without detonating and knocking.



Goodheart-Willcox Publisher

Figure 39-19. Gasohol is usually a mixture of 10% alcohol and 90% gasoline.

Tech Tip

Flex fuel vehicles are designed to operate on a mix of up to 85% ethanol (alcohol) and only 15% gasoline. Their fuel system can sense the alcohol/gasoline percentages and adjust fuel injection as needed to maintain the correct air-fuel ratio.

Synthetic Fuels

Synthetic fuels are fuels made from coal, shale oil rock (rock filled with petroleum), and tar sand (sand filled with petroleum). See **Figure 39-20**.

Synthetic fuels are synthesized (changed) from a solid hydrocarbon state to a liquid or gaseous state. Synthetic fuels are being experimented with as a means of supplementing crude oil. As crude oil–based fuels become more expensive, synthetic fuels will become more practical.

Hydrogen

Hydrogen is a highly flammable gas that is a promising alternative fuel of the future. Hydrogen is one of the most abundant elements on our planet. It can be produced through the electrolysis of water (sending electric current through saltwater). This is illustrated in **Figure 39-21**.

Copyright Goodheart-Willcox Co., Inc.

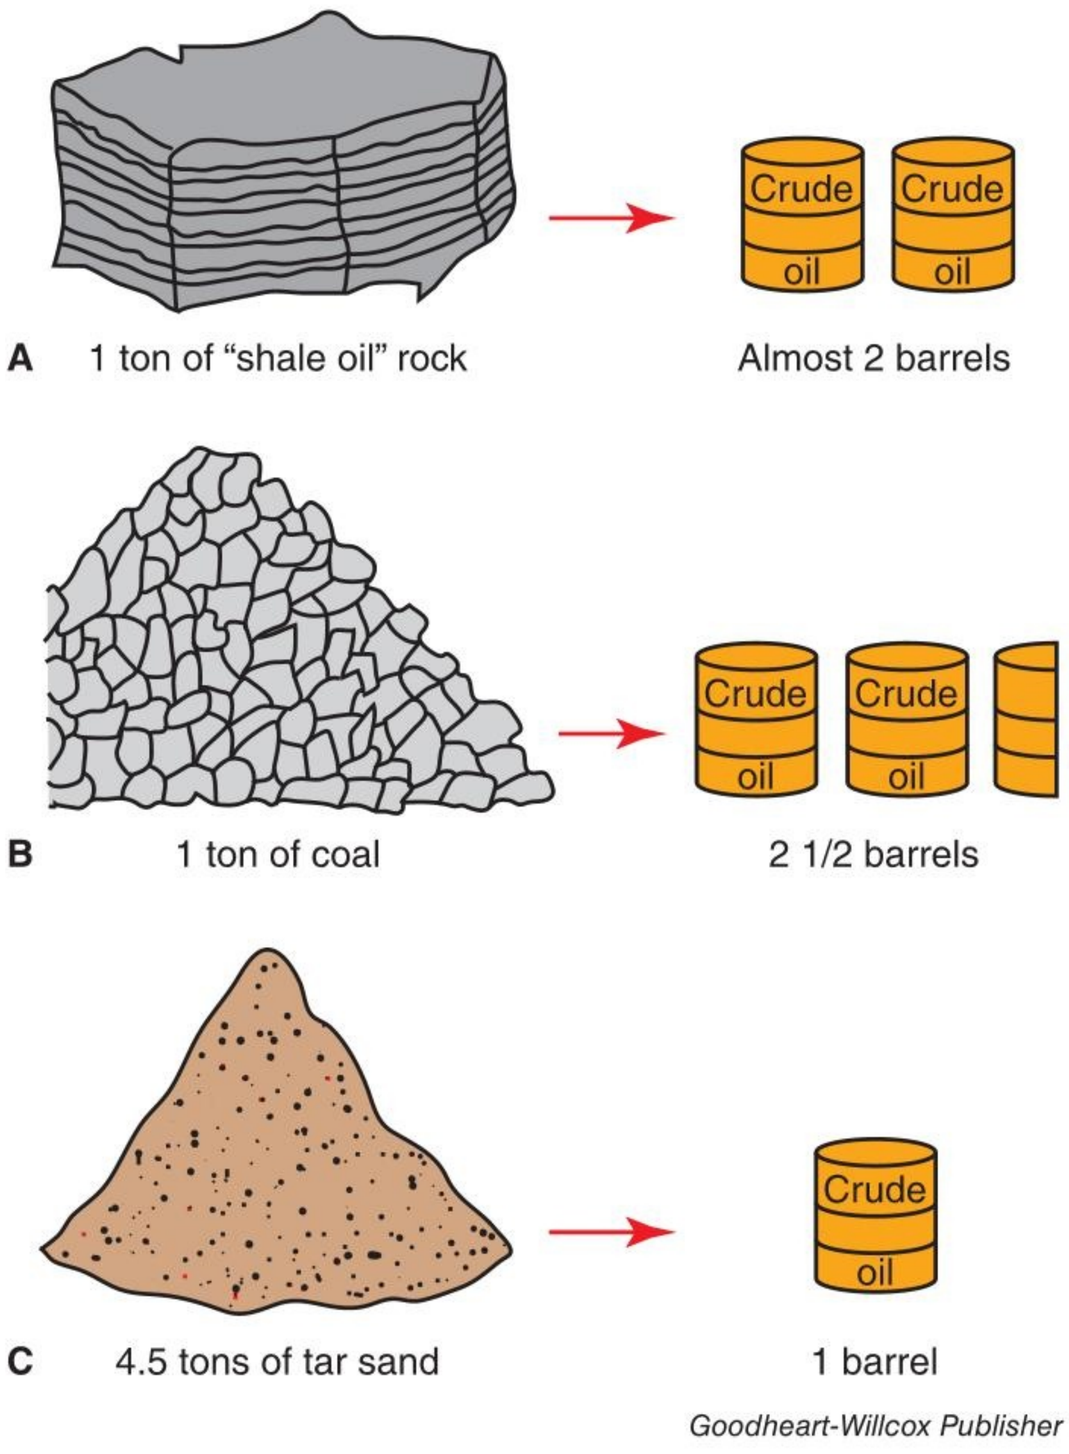


Figure 39-20. Synthetic sources of oil. A—Shale rock can be converted into oil. B—Coal can produce about two and one-half barrels of oil per ton. C—Four and one-half tons of tar can be changed into about one barrel of oil.

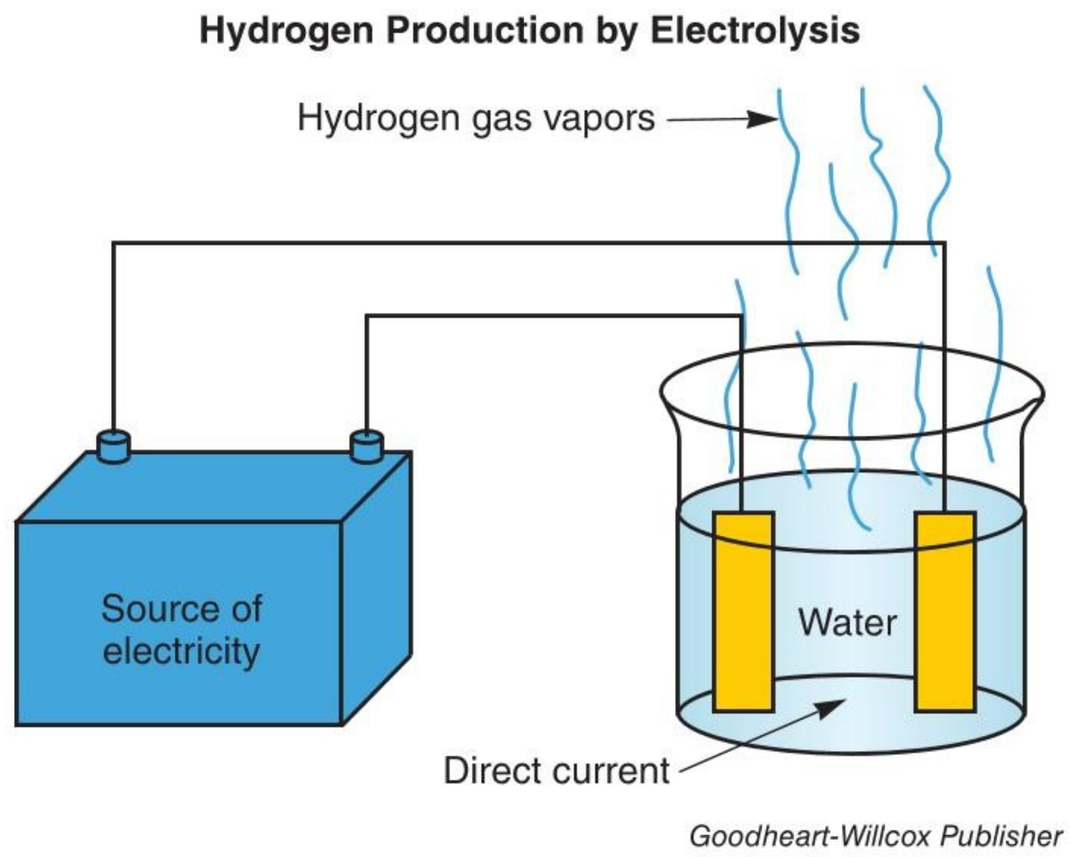

Figure 39-21. Hydrogen gas can be made through the electrolysis of water. Solar cells, wind energy, or ocean thermal energy may make production feasible someday.

Hydrogen is an ideal fuel. Hydrogen burns almost perfectly, leaving only water and harmless carbon dioxide as by-products.

Many manufacturers are now working to develop hydrogen-powered vehicles. Presently, hydrogen is expensive to make and store. However, as we use up our supply of crude oil, we may someday make hydrogen a major source of automotive fuel.

Diagnostic Case Study

Concern: Mrs. Shy drives her 2010 Cadillac into the shop for service. She says the car seems to be running fine, but it is making a noise that sounds like there is a woodpecker under the hood. A dash light is also glowing.

Cause: Duff drives the vehicle to verify the problem. He notices a light, erratic pinging sound coming from the engine compartment during acceleration. Duff suspects the sound is the result of using low-octane fuel in a high-compression engine. A scan tool reading also shows a trouble code for the knock sensor.

Duff questions Mrs. Shy about the type of gasoline she uses in the vehicle. She informs him that she uses regular gasoline because it is cheaper than the premium grades. She adds that she spent so much for the car that she has been trying to save a little money on gasoline. Duff checks the owner's manual, which specifies that fuel with an octane rating of 91 or higher should be used in the vehicle. Duff knows that prolonged engine ping can trip a code for the knock sensor circuit, which is hearing the pinging and reporting a problem to its ECM.

Correction: Duff assigns the repair to one of his apprentice technicians. He instructs the technician to drain the fuel tank and then refill it with "premium" gasoline.

The apprentice does as he is instructed. He then starts the car and allows it to run for a few minutes before performing a test drive. During the test drive, no pinging or knocking sounds are heard, and no further trouble codes are set. When the apprentice returns the car to Mrs. Shy, he shows her the fuel octane rating information in the owner's manual and explains the importance of using the correct grade of gasoline.

Summary

- Petroleum, also called crude oil, is oil taken directly out of the ground.
- Gasoline is the most common type of automotive fuel.
- The octane rating of gasoline is a measurement of the fuel's ability to resist knocking or pinging.
- Normal gasoline combustion occurs when the spark plug ignites the fuel and burning progresses smoothly through the air-fuel mixture.
- A stoichiometric fuel mixture is a chemically correct, or perfect, air-fuel mixture.
- Detonation results when part of the unburned air-fuel mixture explodes violently.
- Preignition results when an overheated surface in the combustion chamber ignites the fuel mixture prematurely.
- Dieseling, also called after-running or run-on, occurs when the engine keeps running after the key is turned off.
- Diesel fuel is the second most popular type of automotive fuel.
- No. 2 diesel fuel is normally recommended for use in car and truck diesel engines.
- A cetane rating indicates the cold starting ability of diesel fuel.
- Alternative fuels include any fuel other than gasoline and diesel fuel. LPG, alcohol, and hydrogen are examples of alternative fuels.

Technical Terms

Write the definitions for the following terms on a separate sheet of paper.

abnormal combustion
after-running
alcohol
alternative fuels
antiknock additives
cetane rating
cloud point
combustion
combustion efficiency
compression-ignition engine
crude oil
detonation
diesel fuel
diesel fuel grades
dieseling
distillation
end gas
engine knock
ethanol
ethyl alcohol
exploration tests
flex fuel vehicles
fractionating tower
fuel
gasohol
gasoline
grain alcohol
hydrocarbons
hydrogen
lean air-fuel mixture
liquefied petroleum gas (LPG)
methanol
methyl alcohol
normal combustion
octane enhancers
octane rating
oxygenates
paraffin
petroleum
ping
preignition
refinery
rich air-fuel mixture
run-on
spark knock
stoichiometric fuel mixture
surface ignition
vaporize
viscosity
water contamination
water separators
wood alcohol

Activities

1. Research automotive fuels on the Internet and prepare a written report on additives and their properties.
2. Research magazines and newspapers for information about the manufacture of alcohol for use as an automotive fuel.
3. Research and discuss modifications of engines for use of LPG as a fuel.

Copyright Goodheart-Willcox Co., Inc.

Review Questions

Answer the following questions using the information provided in this chapter.

1. _____, also called _____, is oil taken directly out of the ground.
2. What are hydrocarbons?
3. Crude oil is converted into more useful substances at a(n) _____.
4. _____ are extra chemicals added to gasoline to improve its operating characteristics.
5. The _____ of gasoline is a measurement of the fuel's ability to resist knock or ping.
6. If an automaker recommends gasoline with an octane number of 91, 87 octane gasoline is also acceptable. True or False?
7. Which of the following is *not* needed for proper combustion?
   (A) Air.
   (B) Compression.
   (C) Condensation.
   (D) Ignition.
8. Describe normal gasoline combustion.
9. Define the term *stoichiometric fuel mixture*.
10. A(n) _____ air-fuel mixture ratio contains a large amount of air.
11. A(n) _____ air-fuel mixture ratio contains a large amount of fuel.
12. What are the results of lean and rich air-fuel mixtures?
13. Explain detonation, preignition, spark knock, and dieseling in a gasoline engine.
14. How does diesel fuel differ from gasoline?
15. What does diesel fuel cetane rating indicate?
16. _____ is made from farm crops and _____ can be made out of wood chips, petroleum, garbage, and animal manure.
17. What is gasohol?
18. Gasohol can normally be used without major engine or fuel system modifications. True or False?
19. A certain gasohol mixture contains 5% alcohol. What is the approximate percentage of gasoline in this mixture?
   (A) 85%.
   (B) 92%.
   (C) 90%.
   (D) 95%.
20. Which of the following does *not* pertain to hydrogen as an alternative fuel?
   (A) Made from most abundant element.
   (B) Produced through electrolysis.
   (C) Burns without toxic emissions.
   (D) Economical or inexpensive to make.

ASE-Type Questions

1. Crude oil is used to make each of these *except:*
   (A) LPG.
   (B) gasoline.
   (C) hydrocarbons.
   (D) hydrogen.
2. Crude oil is a mixture of:
   (A) liquids.
   (B) semisolids.
   (C) hydrocarbons.
   (D) All of the above.
3. Which of these is a commonly used antiknock additive?
   (A) Naphthas.
   (B) Oxygenates.
   (C) Petrochemicals.
   (D) None of the above.
4. Which of the following is the measurement of a fuel's ability to resist knock?
   (A) Octane rating.
   (B) Cetane rating.
   (C) Cloud point.
   (D) All of the above.
5. Normal combustion takes about:
   (A) 1/100 of a second.
   (B) 3/1000 of a second.
   (C) 3/10,000 of a second.
   (D) 1/50,000 of a second.
6. A chemically correct air-fuel ratio is called a:
   (A) rich air-fuel mixture.
   (B) lean air-fuel mixture.
   (C) combustible fuel mixture.
   (D) stoichiometric fuel mixture.

Copyright Goodheart-Willcox Co., Inc.

7. Each of these is a form or result of abnormal combustion *except*:
   (A) detonation.
   (B) ignition lag.
   (C) engine knock.
   (D) after-running.
8. A diesel fuel substance that can separate from other fuel parts and clog fuel filters is:
   (A) lead.
   (B) water.
   (C) carbon.
   (D) paraffin.
9. Automakers recommend a cetane rating of about:
   (A) 45.
   (B) 50.
   (C) 55.
   (D) 60.
10. When looking at cetane ratings, Technician A says that the higher a cetane number is, the easier an engine starts and runs in cold weather. Technician B says that the higher a cetane number is, the easier a fuel ignites from heat and pressure. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Chapter 40
Fuel Tanks, Pumps, Lines, and Filters

After studying this chapter, you will be able to:

- Define the major parts of a fuel supply system.
- Describe the operation of mechanical and electric fuel pumps.
- Explain the tests used to diagnose problems with fuel pumps, fuel filters, and fuel lines.
- Repair a fuel line or replace a fuel hose.
- Locate and replace fuel filters in both gasoline and diesel fuel systems.
- State safety rules for working on fuel supply systems.
- Describe the construction and action of air filters.
- Correctly answer ASE certification test questions on fuel tanks, fuel pumps, fuel lines, fuel filters, and air filters.

A ***fuel system*** must provide a combustible air-fuel mixture to power the engine. See **Figure 40-1**. Today's cars commonly use gasoline injection and sometimes diesel injection systems. Older vehicles use carburetors.

This chapter explains the construction, operation, and service of fuel tanks, fuel lines, fuel filters, air filters, and fuel pumps. These parts make up the fuel and air supply systems. The information in this chapter will prepare you for later chapters on fuel metering systems. Study carefully!

The type of fuel system found on a passenger vehicle depends primarily on the vehicle's date of manufacture or model year. See **Figure 40-2**.

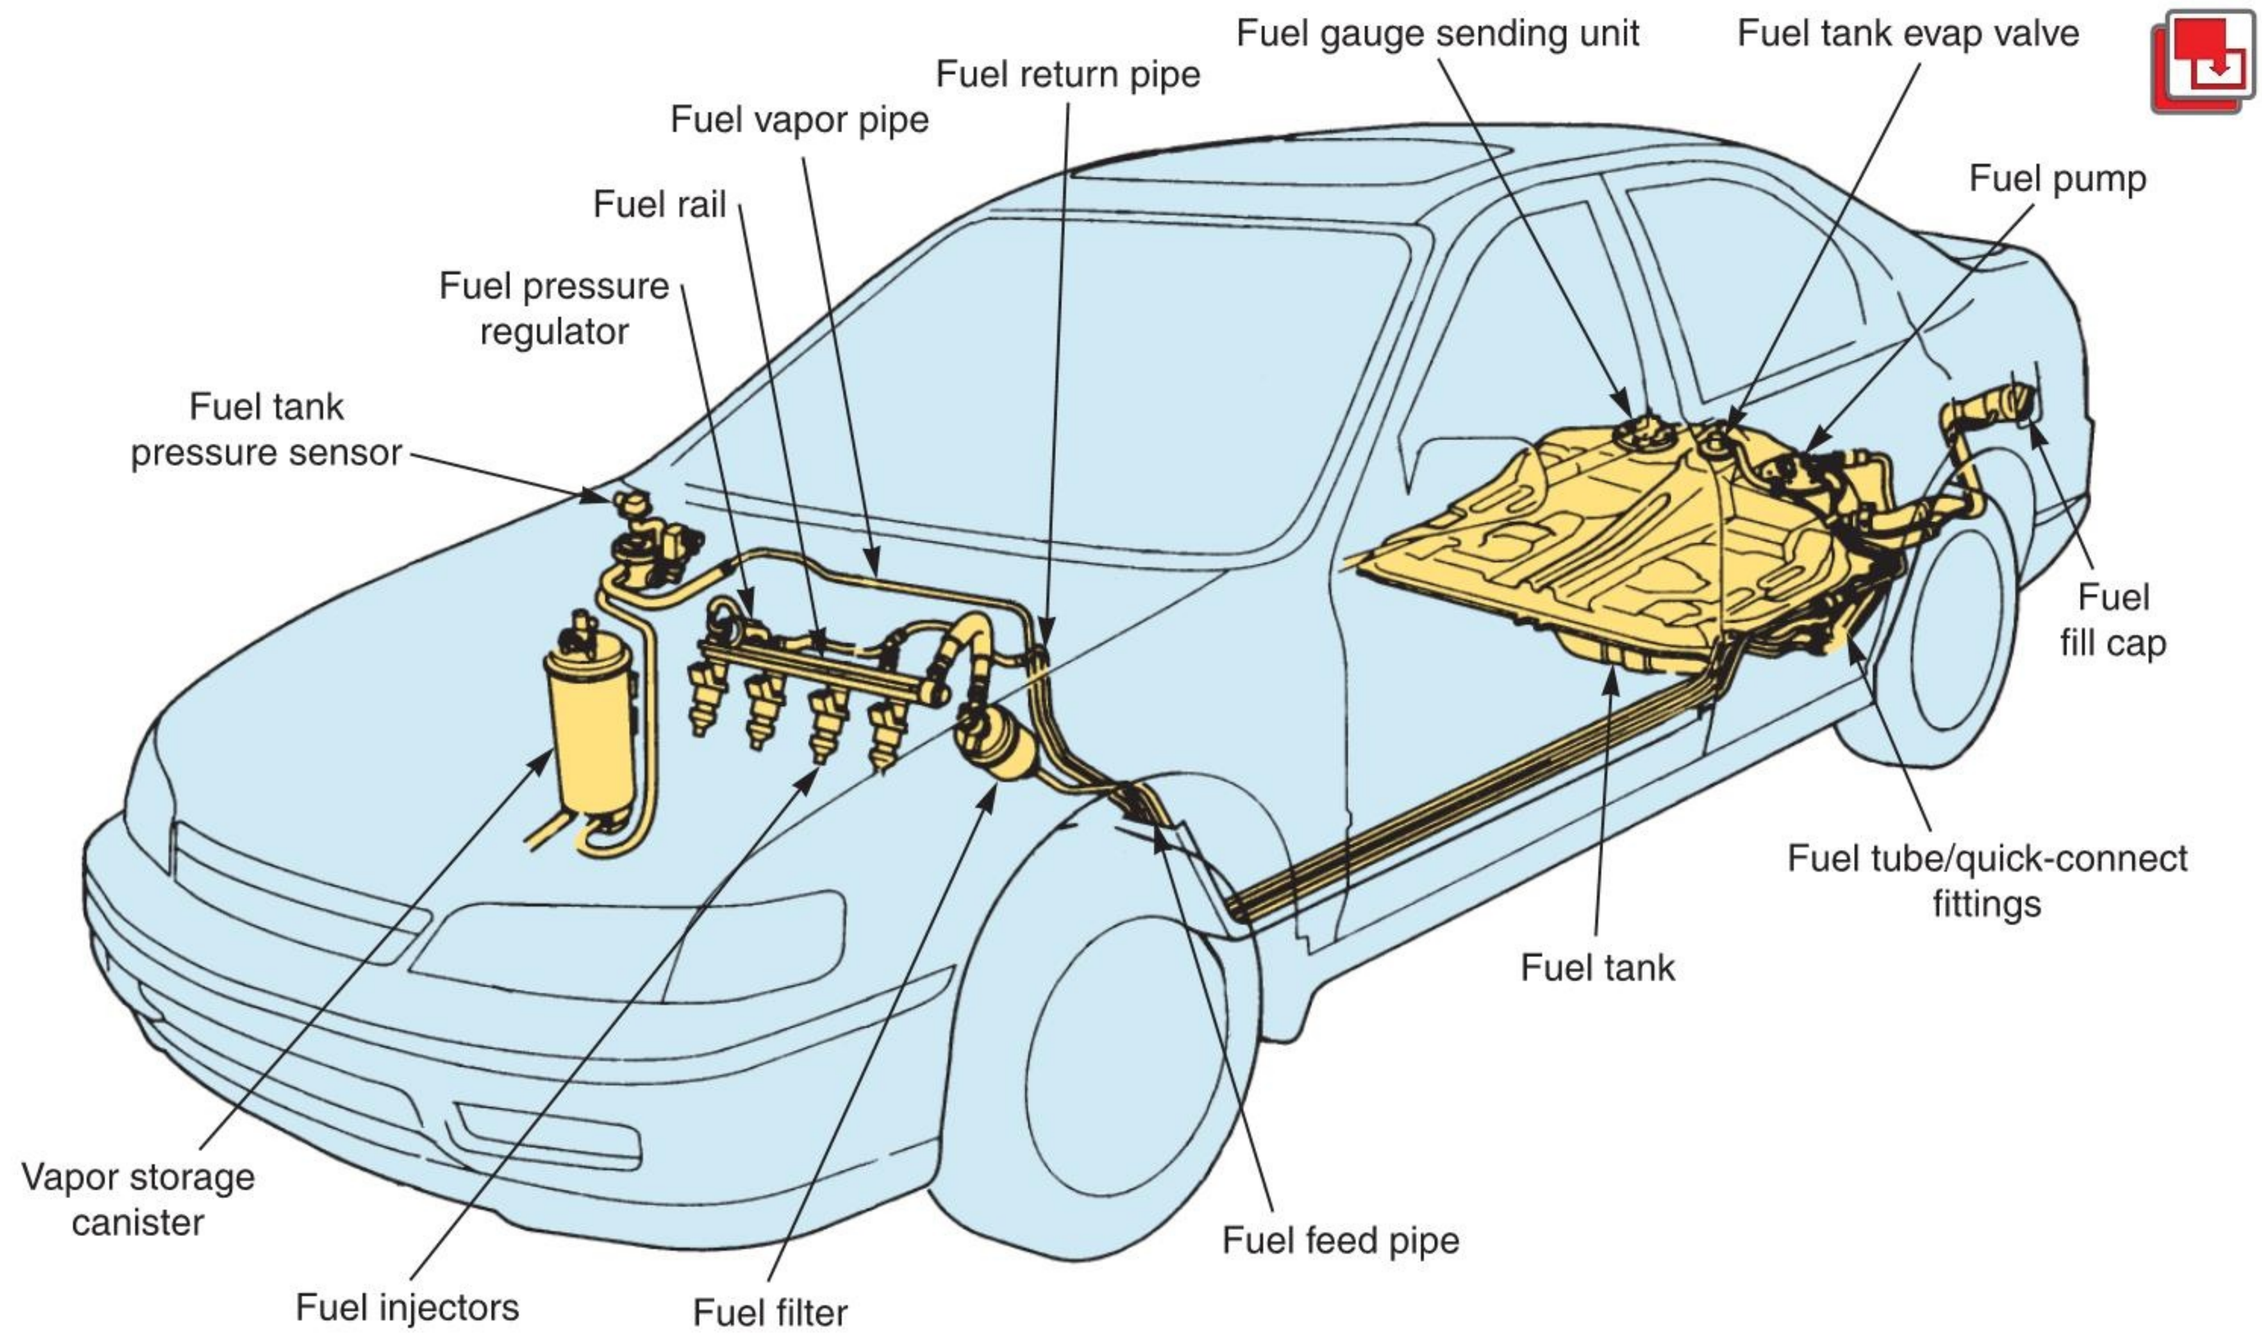
From the early 1900s to the late 1970s, passenger vehicles used carburetors and engine vacuum to meter fuel into the engine. A single, low-pressure, mechanical fuel pump was mounted on the engine to pull fuel from the tank and force it to the carburetor. Vacuum, or suction, pulled the fuel out of the carburetor and into the airstream entering the engine's intake manifold.

In the 1980s, cars and light trucks were equipped with throttle body fuel injection (single-point injection) and electronically-controlled carburetors. These early engineering attempts at electronic fuel control were not very dependable or efficient.

Most vehicles built since the 1990s use multiport, or multi-point, fuel injection to better meter gasoline into each engine cylinder. In a multiport injection system, each cylinder's fuel injector nozzle aims right at its intake valves. When the intake valves are pushed open, the air and fuel charge are pulled into the cylinder.

Many late-model gasoline engines are equipped with direct injection systems (DIS) to improve engine power and efficiency. In these systems, gasoline is sprayed into the air already inside the engine's combustion chambers for more complete burning of the fuel.

Copyright Goodheart-Willcox Co., Inc.



Honda

Figure 40-1. Note the location of typical fuel supply system components.

Direct fuel injection has always been used on diesel engines. Early-model diesels used a mechanical injection pump and mechanically actuated fuel injectors. Late-model diesels still use a mechanical fuel pump, but they use electronic fuel injectors instead of cam-operated mechanical injectors.

Tech Tip

A few late-model engines are equipped with both direct and port fuel injection systems to improve throttle response for higher performance.

Fuel System Technology

A modern fuel system has three subsystems:

- Fuel supply system—A ***fuel supply system*** provides clean, filtered gasoline, diesel oil, or alternate fuel to the fuel injectors.
- Air supply system—An ***air supply system*** allows clean, filtered, air to flow into the engine's combustion chambers.
- Fuel metering system—A ***fuel metering system*** meters the correct amount of fuel into the engine cylinders depending on engine speed, temperature, load, throttle position, and other factors.

Fuel Supply System

A fuel supply system draws fuel from the fuel tank and forces it into the fuel metering device (usually gasoline injectors). Modern vehicles use mechanical and electric fuel pumps in tandem.

A fuel supply system includes the following basic parts:

- Fuel tank—A ***fuel tank*** stores gasoline, diesel fuel, gasohol, alcohol, LPG, or other combustible material safely.
- Fuel lines—***Fuel lines*** safely carry fuel between the fuel tank, fuel pumps, fuel hoses, fuel filters, pressure regulator, and other parts of the system.

Goodheart-Willcox Publisher

Figure 40-2. Study the basic types of fuel supply systems. Note the differences between direct gas or diesel injection; port fuel injection; throttle body injection; and old carburetor systems.

Copyright Goodheart-Willcox Co., Inc.

- Fuel pumps—***Fuel pumps*** draw fuel from the tank and force it to the engine and fuel-injectors.
- Fuel filters—***Fuel filters*** remove contaminants such as water, rust, and other debris in the fuel.

Fuel Tanks

An automotive fuel tank must safely hold an adequate supply of fuel so the vehicle can be driven a reasonable distance without refueling. With front-engine vehicles, it is mounted in the rear of the car, under the trunk or the rear seat.

The size of a fuel tank determines, in part, a car's ***driving range*** (distance a vehicle can be driven without stopping for fuel). ***Fuel tank capacity*** is the volume of fuel (in gallons or liters) a fuel tank can hold. Average fuel tank capacity is 12–25 gallons (45–95 liters).

Fuel Tank Construction

Fuel tanks can be made of sheet steel, aluminum, or injection molded plastic, with adhesive bonding forming a chemical weld between mating surfaces. Sheet metal stampings may also be welded together robotically to form a leakproof seam all the way around the mating surfaces. Other parts (filler neck, baffles, vent tubes, expansion chamber) are added to form the complete fuel tank assembly, **Figure 40-3**. A zinc alloy is normally plated to the sheet metal to keep the tank from rusting.

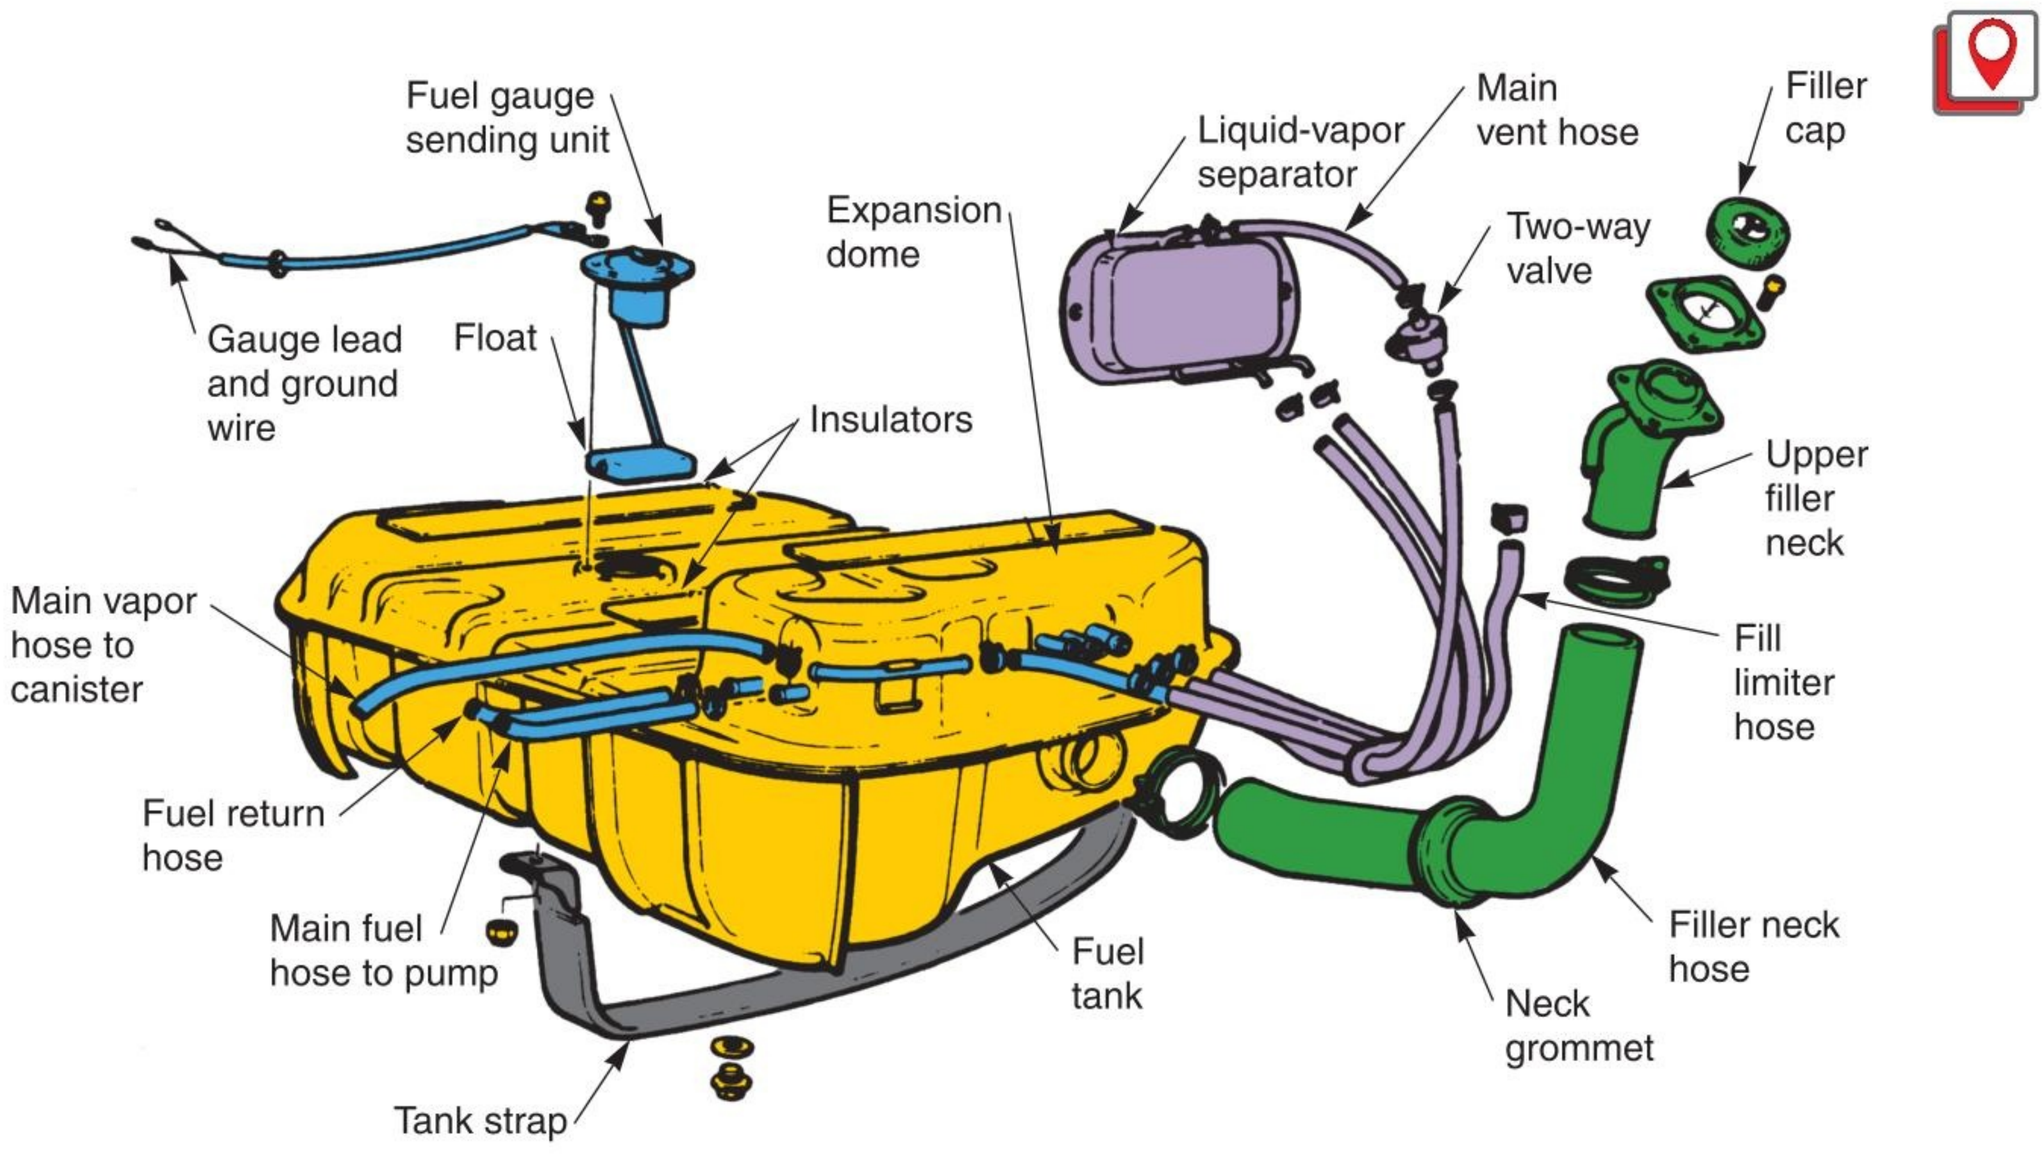
The ***filler neck*** is the extension tube that allows the gas pump nozzle to be used to fill the tank with fuel. The ***filler cap*** fits on the end of the filler neck. The neck extends from the tank through the body of the car. A flexible hose is normally used as part of the filler neck. It allows tank vibration without part breakage.

A ***spillback ball*** is a large "ping pong–type" ball in the filler neck to prevent fuel from leaking out of the vehicle during fill-ups.

Modern filler caps are sealed to prevent the escape of fuel and fuel vapors (emissions) from the tank. Normally, fuel vapors are not vented to the atmosphere.

Fuel tank baffles are located inside the fuel tank to keep fuel from sloshing, or splashing, around in the tank. The baffles are metal plates that restrict fuel movement when the car accelerates, decelerates, or turns.

Fuel tank straps are used to secure the tank to the vehicle. They are thick steel bands that bolt around the fuel tank to hold it in place. Some tanks are held in place with bolts that pass through the tank's flanges. A fuel tank cover is sometimes used to prevent damage from road debris.



Chrysler

Figure 40-3. The basic external parts of a typical fuel tank assembly are shown.

Copyright Goodheart-Willcox Co., Inc.

Fuel Tank Pickup-Sending Unit

A ***pickup-sending unit*** extends down into the tank to draw out fuel and operate the fuel gauge. A coarse filter is usually placed on the end of the pickup tube to strain out larger debris in the fuel tank.

The sending unit is a variable resistor. Its resistance changes with changes in the fuel level. See **Figure 40-4**. This allows the sending unit to control the amount of current reaching the fuel gauge in the instrument panel.

When the fuel level in the tank is low (float down), the sending unit has a high resistance. Only a small amount of current flows to the gauge. The gauge shows a low fuel level.

When the tank is full (float up), the sending unit has a low resistance. More current flows to the gauge, and the gauge needle moves to the full position.

Fuel Tank Pressure Sensors

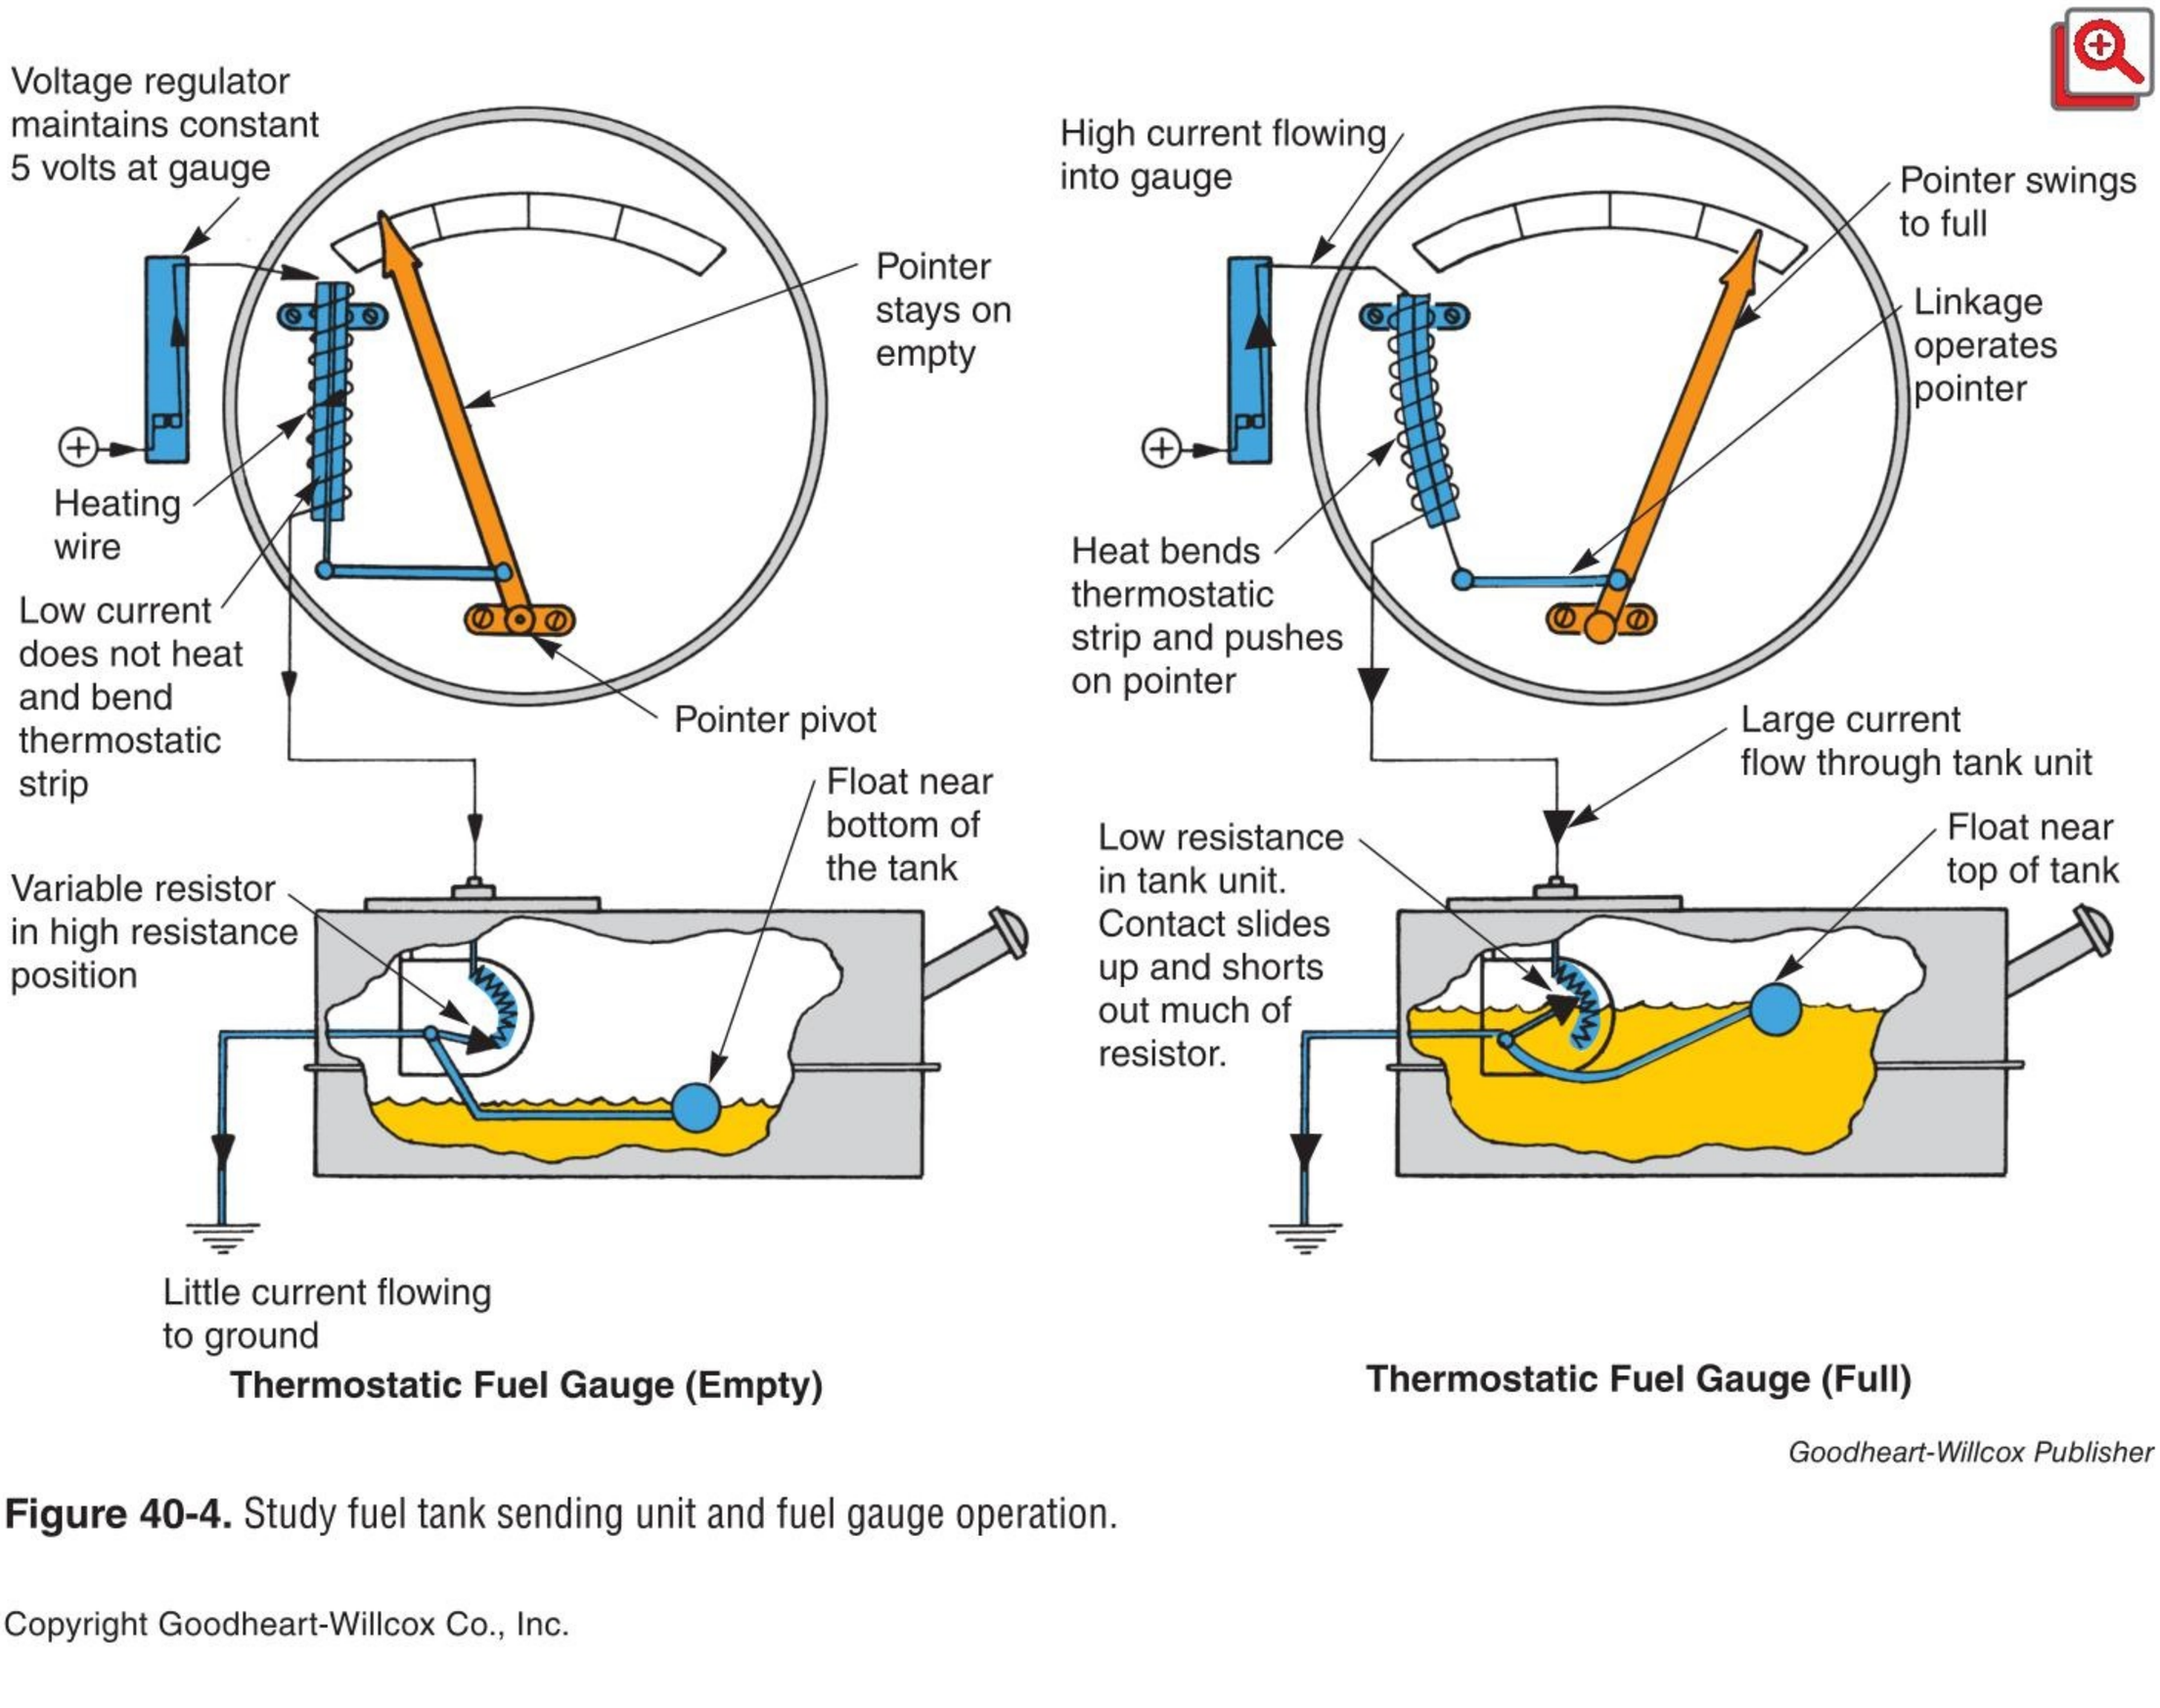
A ***fuel tank pressure sensor*** is used to monitor the buildup of fuel tank pressure in late-model vehicles equipped with OBD II systems. The sensor aids in the operation of the evaporative emissions and fuel return control circuits.

Fuel Lines and Hoses

Fuel lines and ***fuel hoses*** carry fuel from the tank to the engine. Refer to **Figure 40-5**. Fuel lines are normally made of strong, double-wall steel tubing. For fire safety reasons, a fuel line must be able to withstand the constant and severe vibration produced by the engine and road surface.

A ***fuel rail*** is a large-diameter fuel line that feeds fuel to the inlet openings of the fuel injectors. It serves the same purpose as the fuel line but provides a greater volume of fuel right before the injectors. The fuel rail prevents any injector from starving for fuel under high-demand conditions.

Fuel hoses, made of reinforced synthetic rubber, are needed where severe movement occurs between fuel system parts. For example, a fuel hose is used between the main fuel line and the engine. The engine



Goodheart-Willcox Publisher

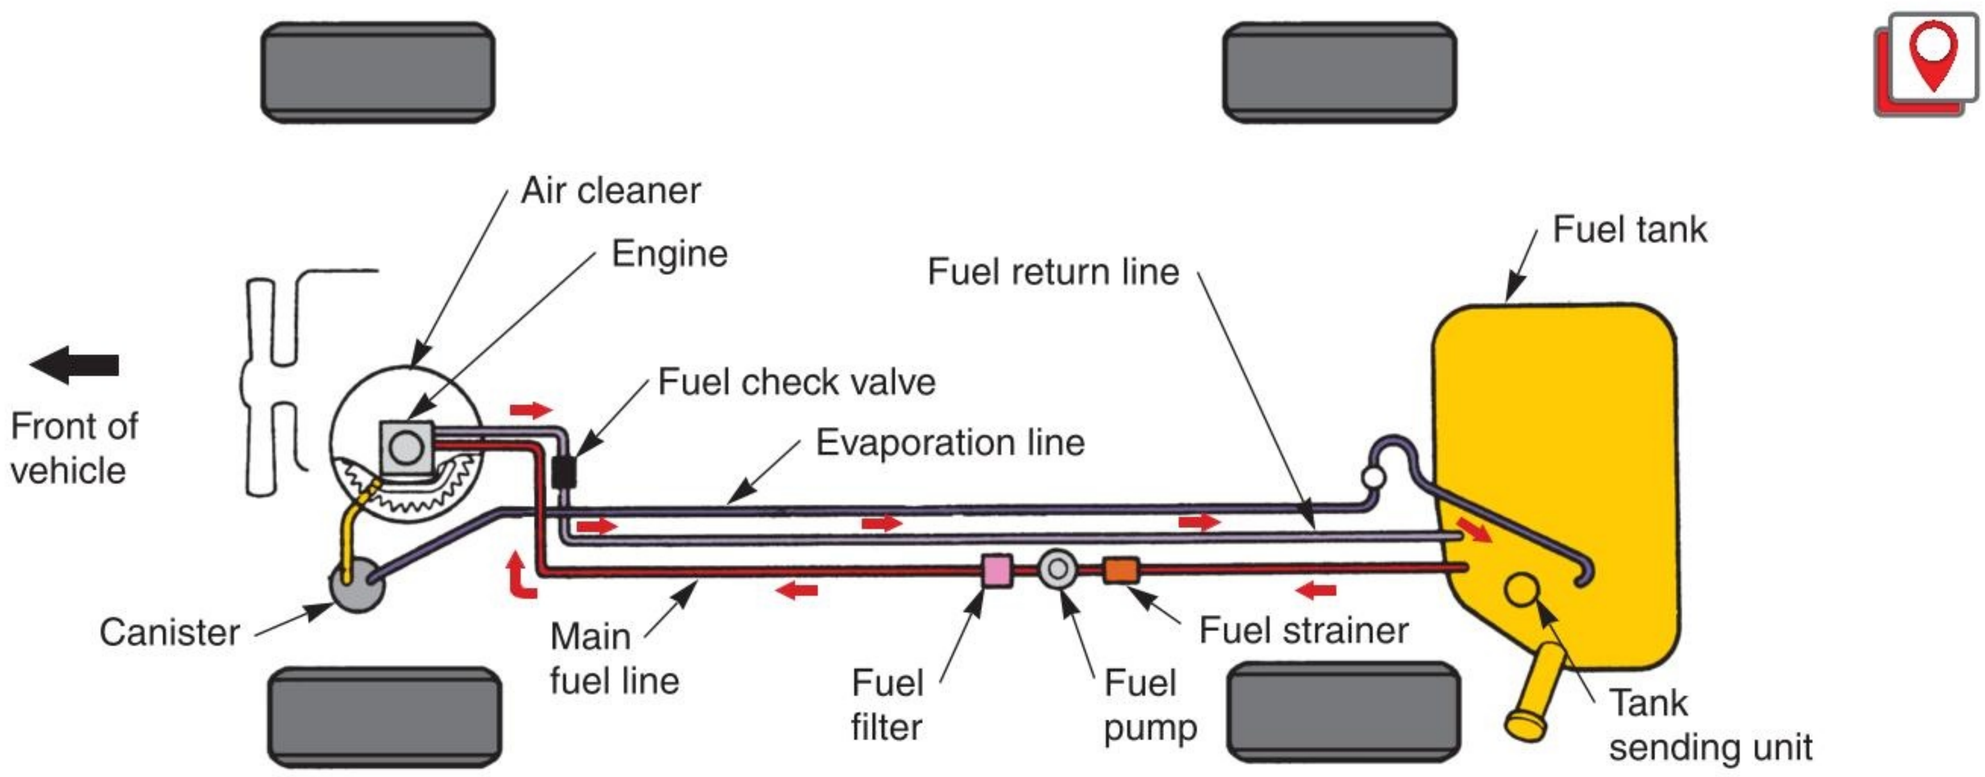
Copyright Goodheart-Willcox Co., Inc.



Mazda

Figure 40-5. Study fuel and emission control lines. Note the location of the fuel pump, filters, and other devices.

is mounted on rubber motor mounts. The soft mounts allow the engine some movement in the unibody or frame. A flexible hose can absorb this movement without breaking. ***Hose clamps*** secure fuel hoses to the fuel lines or metal fittings.

Plastic Fuel Lines

Plastic fuel lines, also called *fuel pipes*, are made of high-strength nylon tubing, which can withstand the chemical action, pressure, and heat encountered in fuel system applications. They can be used instead of metal lines in some low-pressure installations. Plastic lines are light and flexible, but they are not as strong as double-wall steel tubing.

Fuel feed, fuel return, and even injector feed lines can be made of plastic. The inside diameter of the plastic line determines its size when ordering. Rubber hose or heavy corrugated plastic conduit is often placed over the plastic line to protect it from chafing, vibration, and heat.

Quick-disconnect fittings are often used with plastic fuel lines. One end of the fitting is male, and the other end is female. An O-ring seal is compressed inside the fitting to prevent leaks.

Fuel Return System

Most vehicles use a ***fuel return system*** to cool the gasoline and prevent vapor lock (bubbles form in overheated fuel and stop fuel flow). In these systems, a fuel return line carries excess fuel back to the tank. This keeps engine heat from overheating the gasoline by constantly circulating unused fuel back to the fuel tank.

Returnless Fuel Injection Systems

Some late-model vehicles are equipped with ***returnless fuel injection systems***. As their name implies, these systems do not have fuel return lines. This design helps reduce evaporative emissions by minimizing fuel vaporization. In a conventional fuel return system, the fuel that returns to the tank is hot. The hot fuel warms the rest of the fuel in the tank. Warming the fuel in the tank causes it to vaporize more readily. Because hot fuel is not returned to the tank in a returnless system, the fuel in the tank remains relatively cool and fuel vaporization is minimized.

Returnless fuel injection systems control fuel system pressure by varying fuel pump output. When pressure in the fuel rail changes, this sensor signals the computer or ECM to increase or decrease current sent to the electric fuel pump motor, varying the output of the pump. The engine ECM can also vary the amount of time the fuel injectors are “on” to compensate for changes in system pressure.

Fuel Filters

Fuel filters stop contaminants (rust, water, corrosion, sand, dirt) from entering the fuel pump, fuel lines, pressure regulator, fuel rail, and injectors. A fuel filter inlet screen is normally located on the fuel tank pickup inside the fuel tank. A second fuel filter (main fuel filter) is commonly located in the main fuel line.

Fuel Filter Construction

A ***pleated fuel filter*** made of coated paper or plastic is the most common fuel filter element found in

Copyright Goodheart-Willcox Co., Inc.

gasoline fuel systems. Some fuel systems use a sintered bronze (porous metal) element or similar design. All types are capable of stopping very small particles that can easily damage precision fuel injectors and mechanical fuel pumps.

A ***bowl fuel filter*** can be found on modern diesel engines. These filters can easily trap water since water is heavier than fuel. The water settles to the bottom of the bowl while the light fraction gasoline floats on top of the water. When the element inside the bowl becomes dirty, the technician can remove the bowl for water removal, cleaning, and filter replacement.

A ***canister fuel filter*** is housed inside a metal container mounted in a fuel line. When the filter requires replacement, a new element can be installed inside its steel container.

A ***fuel strainer***, often called a *soft metal sock*, on the inlet of the in-tank fuel pump keeps debris from entering the system.

Fuel Filter Locations

Fuel filters may be found in the following locations:

- In the fuel tank on the end of the fuel pickup tube.
- In the fuel line before the fuel rail, fuel injectors, diesel injection pump, or carburetor.
- Inside the fuel pump.
- In the fuel line right after the electric fuel pump.
- Under the fuel line fitting in antique carburetors.

When in doubt about fuel filter locations, refer to a service manual. It will give information about service intervals, cleaning, and replacement of all system filters.

Tech Tip

If a fitting must be loosened when changing a fuel filter, use a flare nut wrench. Do not overtighten and strip the fitting when replacing the filter. Double-check that the fuel hose, if used, is fully installed over the fitting barbs.

Fuel Pumps

A fuel pump draws fuel out of the fuel tank and forces it to the engine under pressure. Many modern engines use two fuel pumps to push liquid gasoline or other fuel out of its storage tank, through the fuel lines, fuel filters, and pressure regulator, and to the electronic fuel injectors.

There are two basic types of automotive fuel pumps: electric and mechanical. The electric fuel pump is a low-pressure feed pump inside the fuel tank or in series with a fuel line. The mechanical fuel pump is a high-pressure fuel pump mounted on the engine. See **Figure 40-6**.

Most multiport injection systems use a single electric fuel pump. Some engines with multiport fuel injection often have two electric fuel pumps: one in the tank and one in a fuel line before the engine. The two fuel pumps are connected in series using fuel hoses and metal fuel lines.

Tech Tip

A spark or electric short will not ignite gasoline or diesel oil in its liquid state. In-tank fuel pumps are submerged in liquid fuel inside the fuel tank while being electrically energized. It is safe to send current through wires and fuel in the fuel tank. Only if the tank was empty and full of fumes could an in-tank fuel spark or pump short cause the tank to explode.

Never try to weld and repair a leaking gas tank! The heat can dissolve fuel varnish in the tank, generating flammable, explosive fumes.

Bosch

Figure 40-6. Study the parts of a high-pressure mechanical fuel pump.

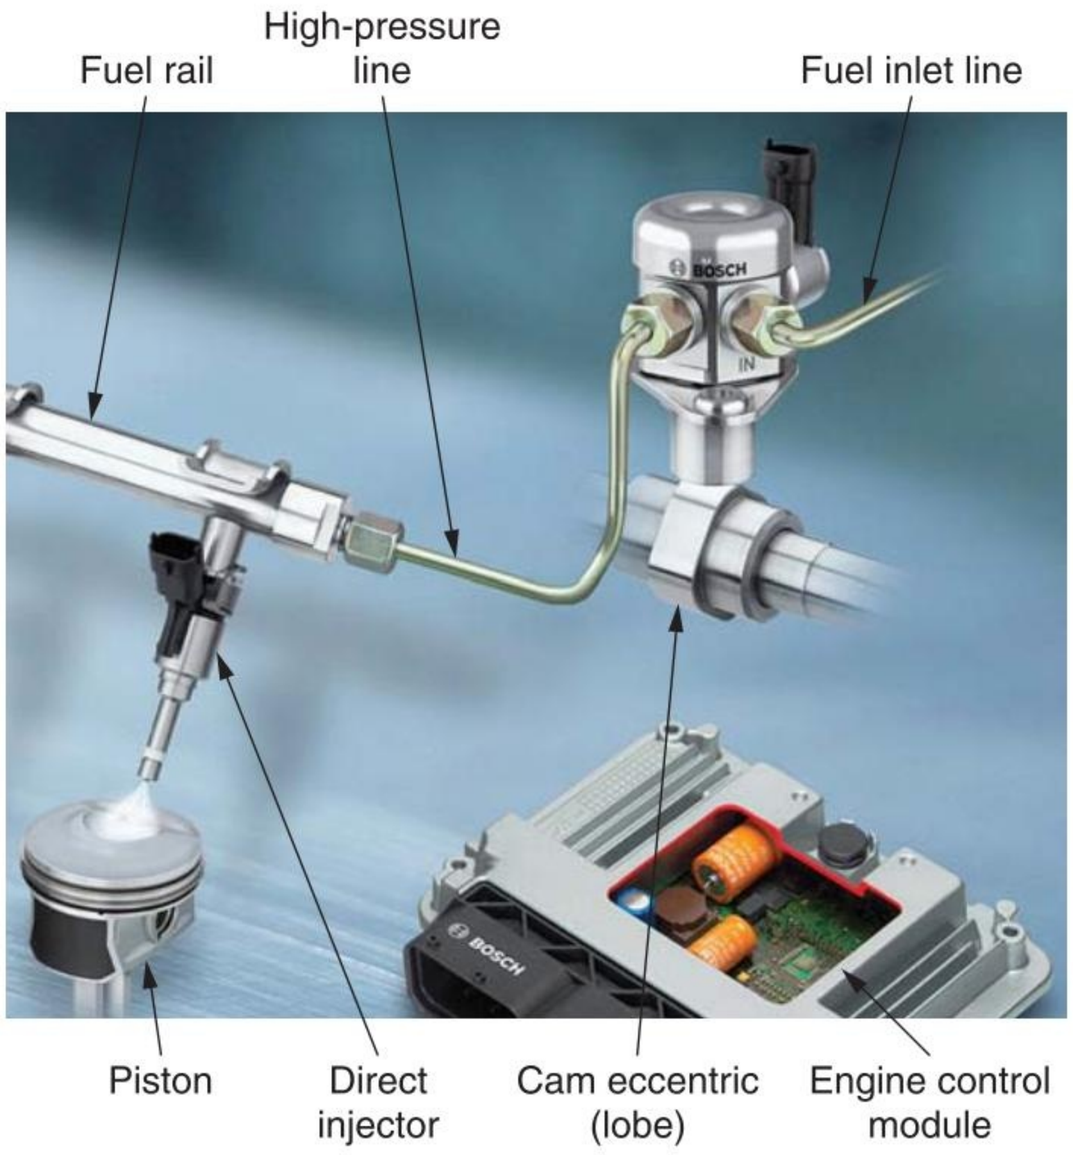
Copyright Goodheart-Willcox Co., Inc.

A direct fuel injection system has an electric feed pump and a mechanical high-pressure fuel pump in series to multiply pressure. The feed pump primes the high-pressure fuel pump with gasoline. The mechanical pump multiplies this fuel pressure to fill the fuel rail and injectors with gasoline or diesel oil.

Mechanical Fuel Pumps

A ***mechanical fuel pump*** is usually powered by an engine camshaft ***eccentric*** (egg-shaped lobe) to produce a reciprocating motion on a piston or plunger. The fuel pump eccentric can be inside the fuel pump or machined on the engine's OHC camshaft. As the eccentric rotates, its lobes push the pumping plunger into the pump to build pressure. Then, when the lobe rotates away from the fuel pump rod, spring tension pushes on the pump piston or plunger back down to fill the pressure chamber with another charge of fuel.

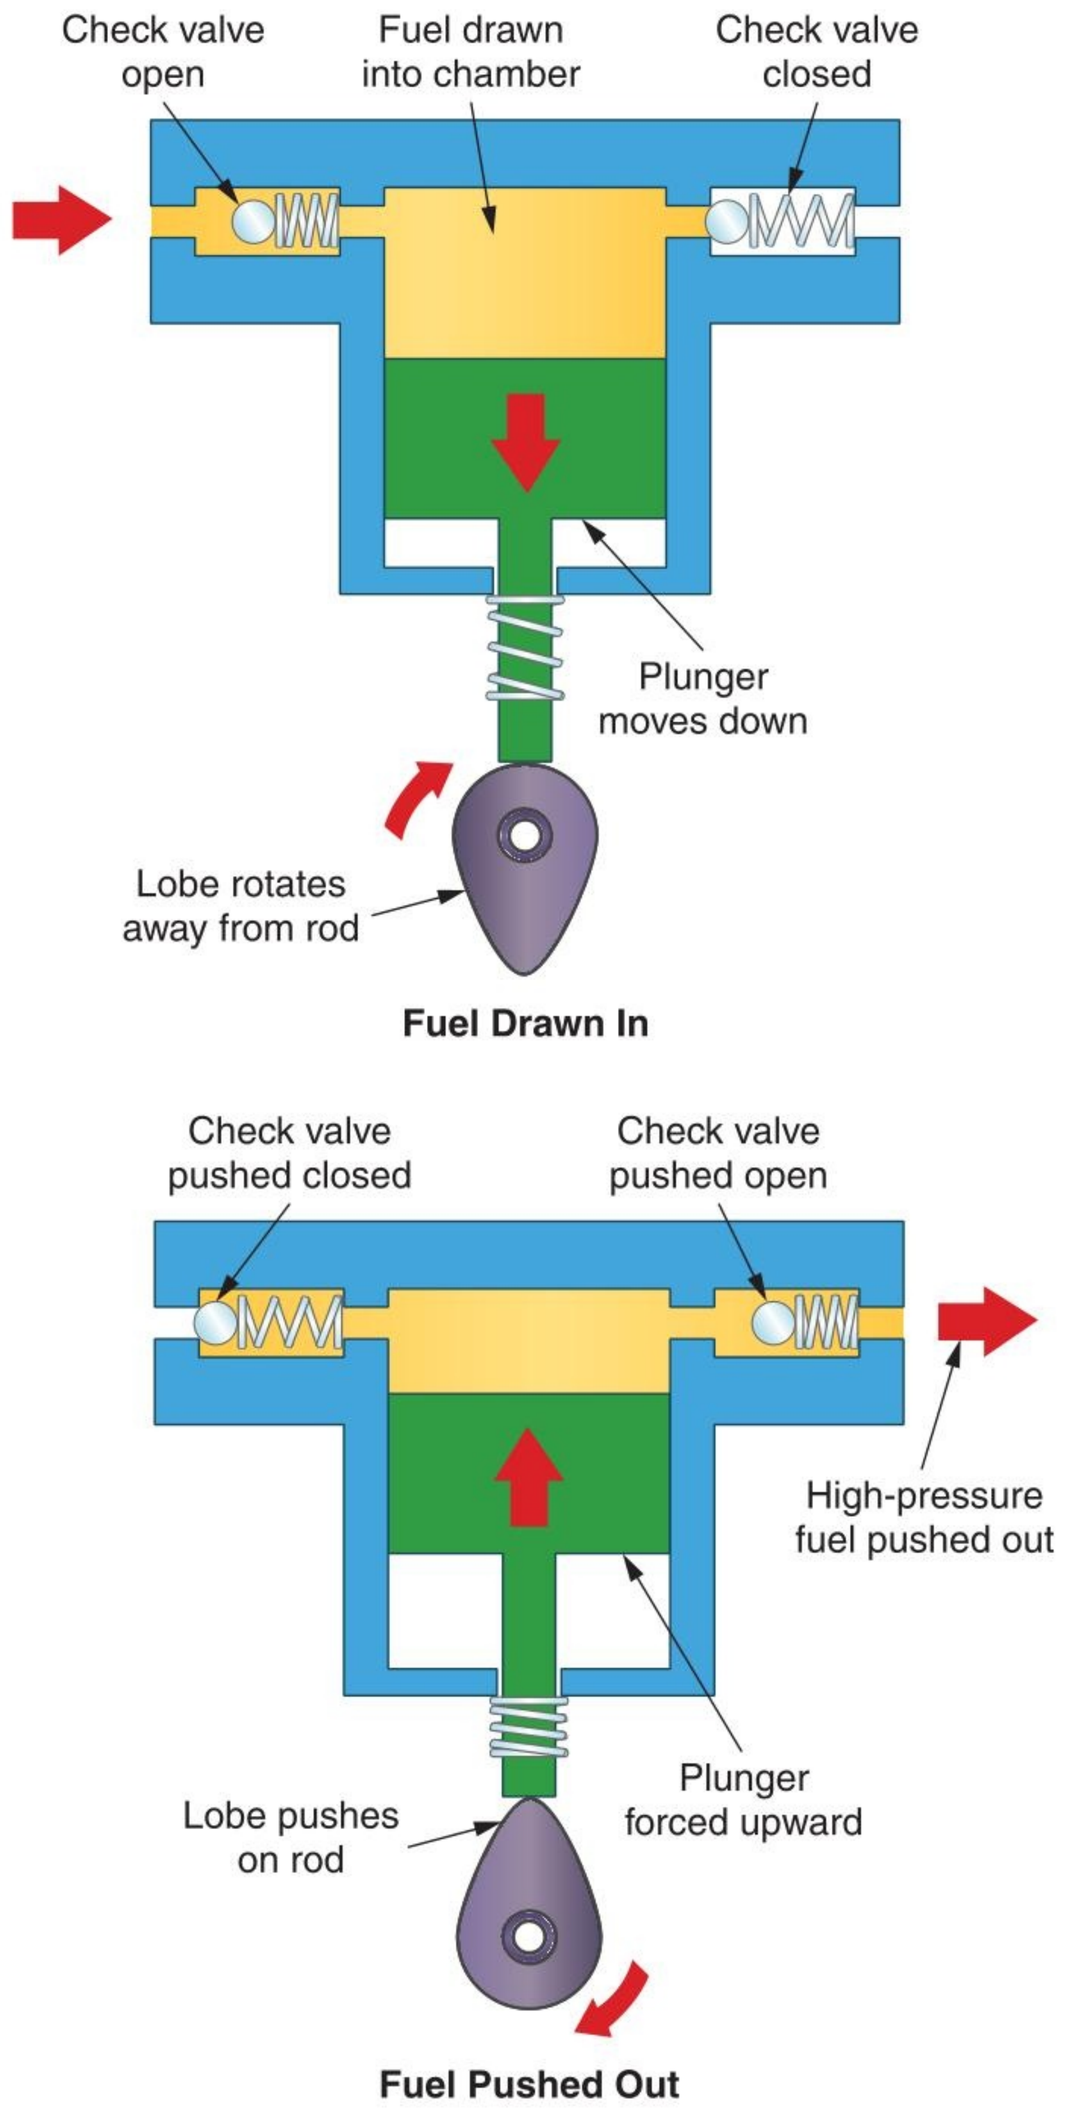
Mechanical fuel pumps are used on all engines with direct fuel injection and on older carburetor fuel systems. Since the mechanical pump uses a back-and-forth motion to create pressure, it is classified as a ***reciprocating*** pump. See **Figure 40-7**.



Goodheart-Willcox Publisher

Figure 40-7. The mechanical fuel pumps used in late-model direct ignition systems are often driven by a multi-lobe eccentric machined on the engine camshaft. This type of mechanical fuel pump can force 2000 psi of pressure into the injector body.

Two ***check valves*** are used in a mechanical fuel pump: the inlet check valve and the outlet check valve. Fuel flows easily through the valves in one direction but cannot flow through in the other direction. The two check valves are reversed to allow pump flow in only one direction. This causes the fuel to enter through one valve and exit through the other. Refer to **Figure 40-8**.



Goodheart-Willcox Publisher

Figure 40-8. Notice the direction of fuel flow through these check valves.

Copyright Goodheart-Willcox Co., Inc.

High-Pressure Mechanical Fuel Pump Operation

The operation of a high-pressure mechanical fuel pump used in DEFI systems is relatively simple. During the ***fuel pump pressure stroke***, the eccentric lobe pushes on the mechanical fuel pump rod and plunger. This compresses the fuel pump spring and pushes the plunger into the pumping chamber. The area in the pumping chamber is decreased. Since a liquid cannot be compressed, the resulting pressure pushes fuel past the outlet check valve. This forces fuel past the pressure regulator and into the fuel rail.

On the ***fuel pump charging stroke***, the eccentric lobe rotates away from the fuel pump. This releases the fuel pump spring so it can pull the pumping plunger and rod in the other direction. This snaps the outlet valve closed and pushes the inlet valve open so the pumping chamber can be refilled with fuel from the tank.

A fuel pump gasket prevents oil leakage between the mechanical fuel pump and the engine. Some late-model, high-pressure fuel pumps contain their own eccentric and are driven by the engine timing chain.

Fuel Pump Pressures

Pressures produced by the mechanical fuel pumps used in direct injection systems can range from 1500–2000 psi (10–14 MPa). A fuel leak at these pressures can be very dangerous. This is enough fuel pressure to cause serious injury even if the fuel does not ignite and burn. A high-pressure fuel leak can puncture your skin and inject gasoline into your bloodstream, which could be fatal.

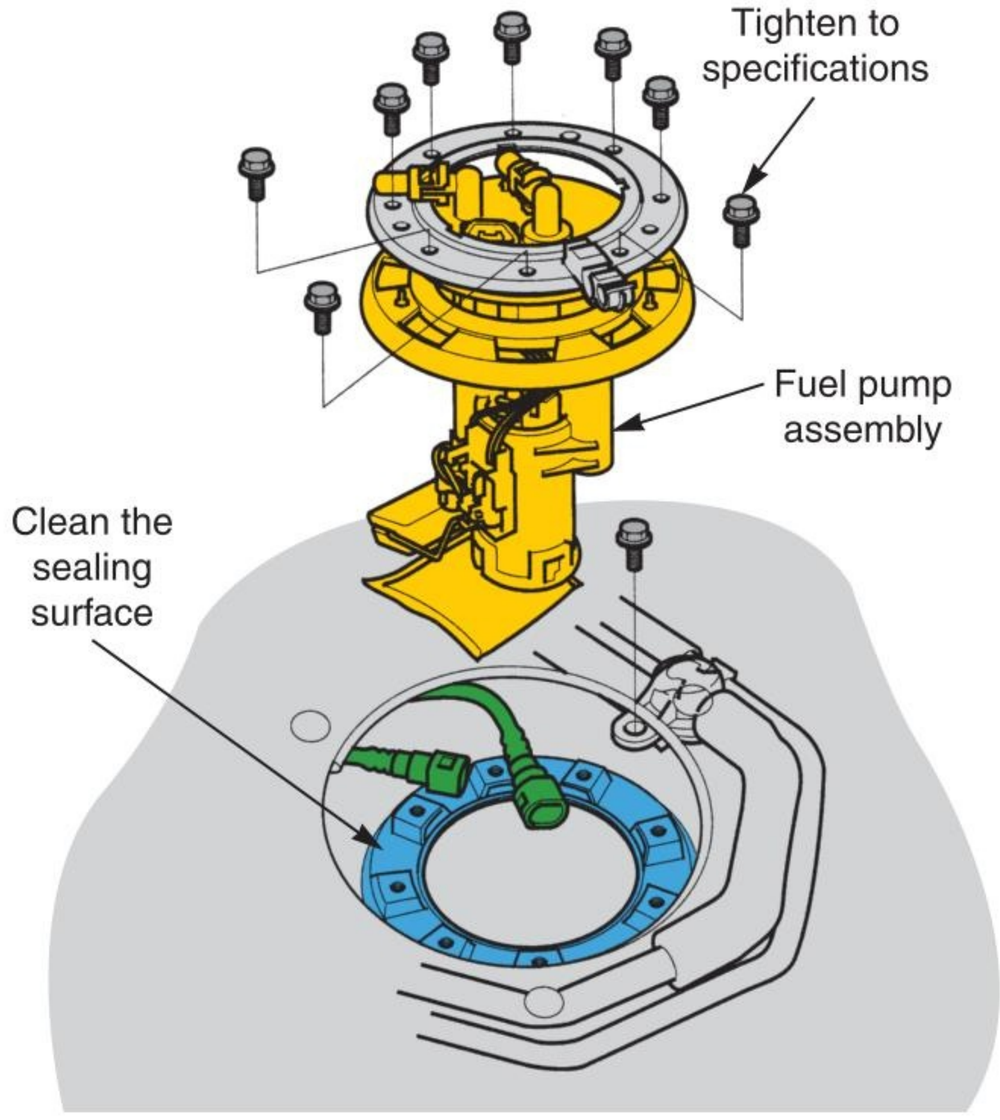
If a high-pressure fuel leak ignites, the fuel spraying out of the leak will look like a large blowtorch as hot flames shoot out of the engine compartment. High fuel pressures are only present after the engine-driven mechanical pump and inside the thick steel fuel line and fuel rail going to the fuel injectors.

Electric Fuel Pumps

An ***electric fuel pump***, like a mechanical pump, produces fuel pressure and flow for the fuel metering section of a fuel system. Electric fuel pumps are commonly used on all types of modern vehicles. They are usually located in the fuel tank or in series with a fuel line. Refer to **Figure 40-9**.

A few vehicles have one pump in the fuel tank and a second pump in the fuel line. In many late-model vehicles, the tank sending unit is an integral part of the in-tank fuel pump assembly. See **Figure 40-10**.

An electric fuel pump has advantages over a mechanical fuel pump. An electric pump can produce almost instant fuel pressure. A mechanical pump slowly builds pressure as the engine is cranked for starting. Also, most electric fuel pumps are rotary-type pumps. They produce a smoother flow of fuel (fewer pressure pulsations) than reciprocating, mechanical pumps.



Honda

Figure 40-9. When replacing an in-tank electric fuel pump, clean the sealing surface on the tank, install a new rubber seal (if needed), and torque the fasteners to specifications. Also, check that electrical connections and hoses are secure.

Electric fuel pump pressure ranges from 10–50 psi (68–344 kPa). All of the fuel supply system (hose, lines, filters and other parts) contains low fuel pressure to prime and pre-pressurize the engine-drive pump.

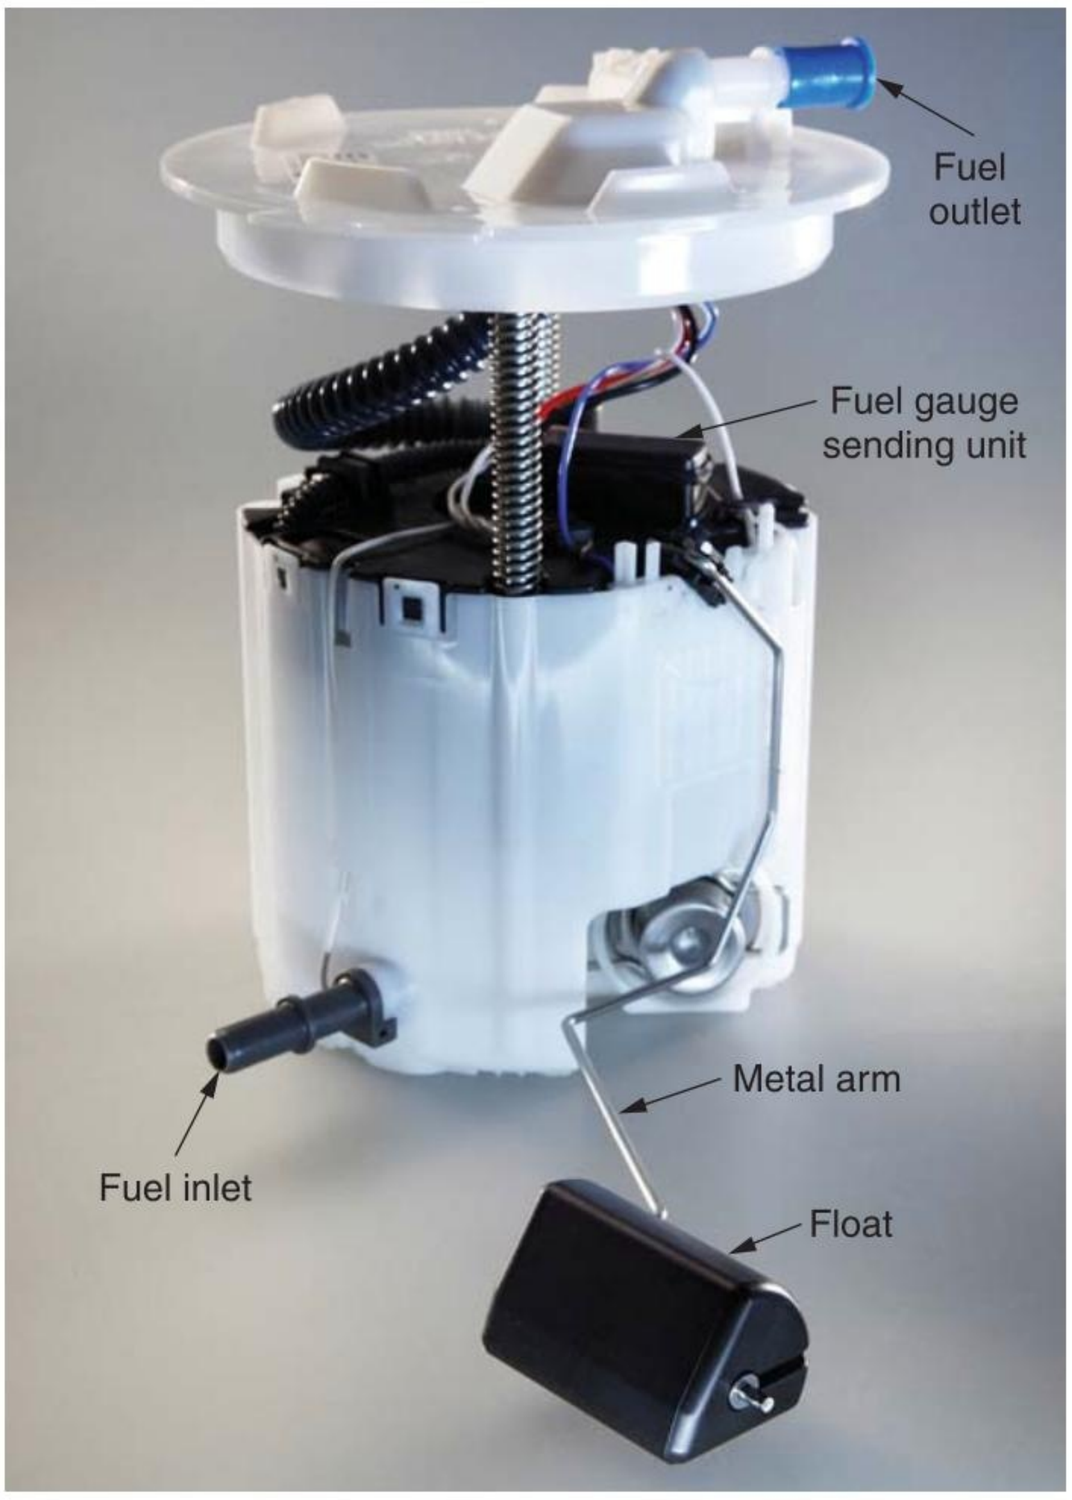
Rotary Fuel Pumps

Rotary fuel pumps include the impeller type, the roller vane type, and the sliding vane type. They all use a circular, or spinning, motion to produce pressure.

An ***impeller electric fuel pump*** is a centrifugal pump. Normally, it is located inside the fuel tank. This pump uses a small dc motor to spin the impeller (fan blade). The impeller blades cause the fuel to move outward due to centrifugal force (spinning matter is propelled outward). This produces enough pressure to move the fuel through the fuel lines. See **Figure 40-11**.

A ***roller vane electric fuel pump*** is a positive-displacement pump (each pump rotation moves a specific amount of fuel). It is normally located in the main fuel line. Small rollers and an offset-mounted rotor disc produce fuel pressure.

Copyright Goodheart-Willcox Co., Inc.



Bosch

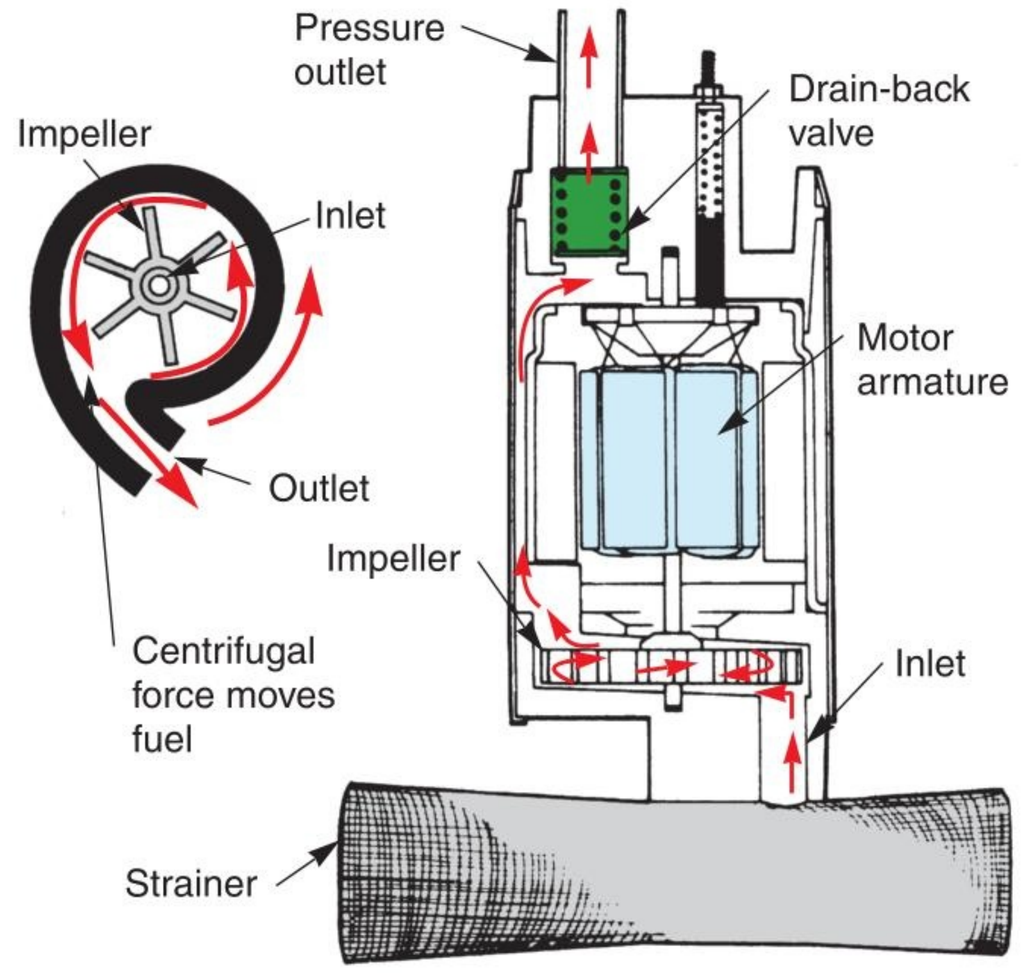
Figure 40-10. Study this in-tank fuel pump assembly. Note the location of the sending unit, which operates the instrument panel fuel gauge.

When the rotor disc and rollers spin, they pull fuel in on one side of the pump. Then, the fuel is trapped and pushed to a smaller area on the opposite side of the pump housing. This squeezes the fuel between the rollers, and the fuel flows out under pressure.

A ***sliding vane electric fuel pump*** is similar to a roller vane pump. However, it uses square vanes instead of round rollers.

Most rotary electric fuel pumps have check valves and relief valves. The check valves keep fuel from draining out of the fuel line when the pump is not running. A ***relief valve*** limits the maximum output pressure of the pump.

A ***reciprocating electric fuel pump*** has the same basic action as a mechanical fuel pump. However, it uses a solenoid instead of a ***rocker arm*** to produce a pumping motion. This is not a common type of original equipment pump.



Volvo, Ford

Figure 40-11. An in-tank, impeller-type electric fuel pump is shown. The impeller produces a very smooth flow of fuel through the system. A check valve prevents fuel from draining out of lines and back into the tank when the pump is not running.

Electric Fuel Pump Circuits

An electric fuel pump circuit must send a controlled amount of current to the pump motor. The engine ECM normally sends current through the fuel pump circuit when the engine is started or is running. The circuit must be fused so that excess current flow is prevented. A circuit for an electric fuel pump is shown in **Figure 40-12**.

An ***inertia switch circuit*** cuts electric fuel pump power in the event of a serious auto collision or accident. It is a normally closed switch that opens after an impact or sudden change in inertia. Since the switch is wired into the fuel pump circuit, it can prevent the fuel pump from running after an accident. The inertia switch is wired between the fuel pump relay or ECU and the fuel pump. This is a safety feature that can prevent a fire. If a vehicle will not start after it is involved in an accident, check the inertia switch. See **Figure 40-13**.

The ***oil pressure switch*** is a safety feature that protects the engine from damage by shutting off the fuel pump if the oil pressure is low. The engine will stop running a few seconds after the fuel pump is shut off. The oil pressure switch also acts as a bypass to the fuel pump relay, allowing the vehicle to start when the relay is faulty. This normally results in an extended crank time.

Figure 40-12. A typical electric fuel pump circuit with an oil pressure switch. If the engine oil pressure drops too low, the switch shuts off the fuel pump. Note other connections and parts of the circuit.

Fuel Supply System Service

Now that you have a basic understanding of how a fuel supply system functions, you are ready to learn about problems, tests, and repairs common to the system.

Warning

Always keep a fire extinguisher handy when working on a vehicle's fuel system. During a fire, a few seconds wasted looking for an extinguisher can be a lifetime!

Never weld or solder a fuel tank. A leaking tank should be sent to a well-trained specialist. Even an empty tank can explode. The heat produced during soldering or welding operations can cause fuel gum to melt, vaporize, and ignite.

Fuel Supply System Scanning

Depending on the symptoms, you will often want to scan for diagnostic trouble codes before starting fuel supply system repairs. Vehicles equipped with OBD II systems may monitor fuel tank pressure, fuel line pressure, fuel level, and other conditions. A scan tool will quickly let you find any stored codes. Modern scanners also display operating values (voltage, current, resistance) for the electrical circuit, which can speed troubleshooting.

Vapor Lock

Vapor lock is a problem created when bubbles in overheated fuel reduce or stop fuel flow. During vapor lock, engine heat transfers through the metal parts of the pump and into the fuel. The fuel "boils," forming bubbles that displace fuel. This can reduce fuel pump output and cause engine performance problems. In very hot weather, a clogged fuel filter, a fuel pump problem, or restricted fuel return system can cause fuel overheating and vapor lock.

Fuel Tank Service

Typical fuel tank problems include fuel leakage, physical damage (dents, holes, etc.), and contamination (rust, dirt, and water). Vibration or rusting can cause a fuel tank to develop pinhole leaks. Rocks can puncture the tank. Internal deterioration of the tank or foreign matter in the fuel can cause contamination problems.

Fuel Tank Removal and Replacement

A fuel tank can be located under the trunk floor, in a body panel, or under the rear seat. It can be held in the vehicle by large metal straps or by bolts passing through the tank flange. With rear-engine vehicles, the fuel tank can be located in the front.

Before servicing a fuel tank, make sure you empty the tank. A full tank is very heavy and can rupture if dropped.

To remove fuel from the tank, unscrew the tank's drain plug and allow the fuel to flow into an approved safety can. If necessary, use a funnel to direct the fuel into the safety can without spillage. If a drain is not provided, use an approved pumping method to draw the fuel out of the tank.

With modern vehicles, you can normally use the in-tank or inline electric fuel pump to empty the tank. Disconnect the fuel hose at the main fuel line and route it into an approved gas can. Turn the ignition key on and allow the fuel pump to force the fuel from the tank into the can. Refer to **Figure 40-14**.

Warning

When working on vehicles with direct injection systems, never attempt to use the high-pressure mechanical pump to drain the fuel tank.

Tech Tip

If the control module shuts the pump off after a few seconds, use a jumper wire to connect voltage directly to the pump terminal to allow for complete draining.

Goodheart-Willcox Publisher

Figure 40-14. With electric fuel pumps, you can use the in-tank or inline pump to drain gasoline from the tank. Connect a long hose from the pump outlet to an approved fuel can. Energize the pump and make sure fuel does not spill out.

After draining the tank, disconnect the wires and fuel lines going to the fuel tank sending/pickup unit. Then disconnect and pull off the filler neck on the side of the tank. Support the tank with a floor jack, remove the metal straps or fasteners that secure the tank to the vehicle, and slowly lower the tank to the ground.

Remove the old electric fuel pump and sending unit assembly from the bad fuel tank. Install the fuel pump into the new tank. Use a rubber O-ring to make sure the new fuel tank does not leak.

If you are working alone, secure the fuel tank on a transmission jack and raise it up under the vehicle. Make sure you replace the rubber insulators. Check that all fuel lines are properly secured. Replace the fuel in the tank and check for leaks. If needed, a service manual for the vehicle will detail tank installation procedures.

Warning

Wipe up fuel spills immediately with a shop rag. Do not spread oil absorbent on fuel spills, because the oil absorbent will become extremely flammable. Oil absorbent can burst into flames if saturated with gasoline.

Fuel Tank Sending Unit Service

A faulty fuel tank sending unit can make the fuel gauge reading inaccurate. Usually, the variable resistor in the sending unit fails. However, you should remember that the fuel gauge or the gauge circuit may be at fault.

First, test the fuel gauge. Connect a factory fuel gauge tester to the fuel gauge feed wire. When the tester is set on *full*, for example, the fuel gauge should read *full*.

If the gauge does not function, either the gauge or the gauge circuit is faulty. If the fuel gauge begins to work with the tester in place, the fuel tank sending unit is bad.

If your tests indicate an inoperative fuel tank sending unit, remove the unit after draining the tank. Unscrew the cam lock or screws holding the sending unit in the fuel tank. If you do not have a special cam tool, use a drift punch and light hammer blows to rotate the lock tabs. Lift the unit out of the tank, **Figure 40-15**.

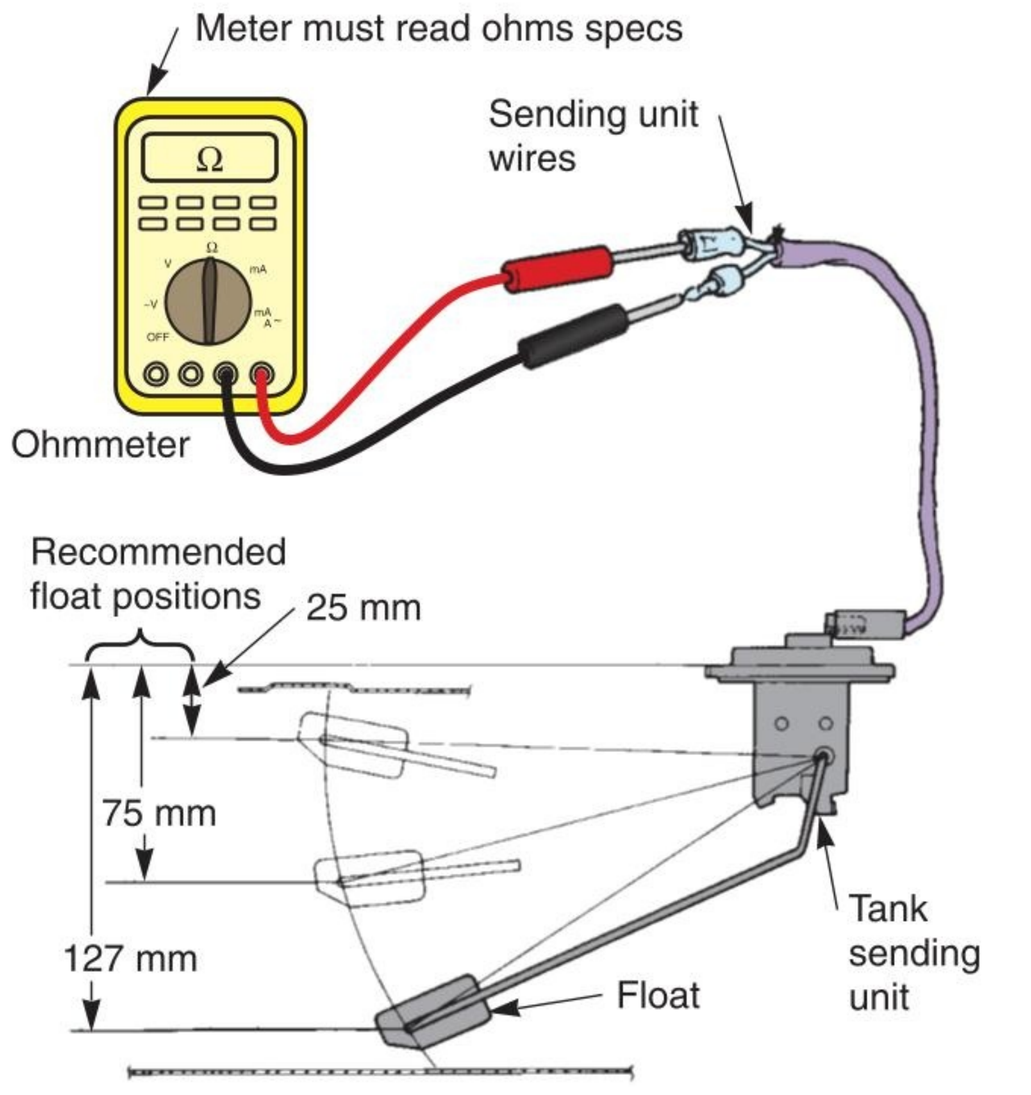
Figure 40-15. A long drift punch and light hammer blows will rotate and free the lock ring on a sending unit or fuel pump.



Honda

Figure 40-16. An ohmmeter can be used to check the condition of the tank sending unit. The reading should be within specifications with the float in prescribed positions.

Tech Tip

Some vehicles have a fuel pump access door in the trunk, so you do not have to remove the fuel tank to service the pump. By removing the small screws that hold the access door in place, you can service the in-tank pump more easily.

With the sending unit removed, measure its resistance with an ohmmeter, **Figure 40-16**. If the resistance is not within the factory specifications, or does not change when you move the float arm up and down, install a new sending unit.

Also, check the float for leakage. Shake the float next to your ear. If you can hear liquid splashing, replace the float. If the tank unit resistance is correct, check the tank ground. A poor ground could prevent gauge operation.

Fuel Line and Hose Service

Faulty fuel lines and hoses are common sources of fuel leaks. Fuel hoses can become hard and brittle after being exposed to engine heat and the environment. Engine oil softens and swells hoses. Always inspect fuel lines and hoses closely and replace any that are in poor condition. See **Figure 40-17**.

Caution

Some late-model fuel lines have snap-type fittings. Do not try to pry the fittings apart or they will be damaged. Use a fuel line fitting tool to release the fittings for service. This tool can be purchased at most auto part stores.

Metal fuel lines seldom cause problems. However, they should be replaced when smashed, kinked, rusted, or leaking. If available, install a new factory fuel line section to ease installation. Most metal fuel lines are bent and curved to fit the installation. Only if a replacement factory fuel line is not available should you make a fuel line using bending and flaring tools, **Figure 40-18**.

Fuel Line and Hose Service Rules

Remember these rules when working with fuel lines and hoses:

- Wear proper apparel, including work gloves and eye protection.
- Release any residual fuel pressure before working on fuel lines and hoses.
- Place a shop rag around the fuel line fitting during removal. This will keep fuel from spraying on you or on the hot engine. Use a flare nut or tubing wrench on fuel system fittings.
- Only use approved double-wall steel tubing for fuel lines. Never use copper or plastic tubing unless it is OEM equipment.
- Make smooth bends when forming a new fuel line. Use a bending spring or bending tool.

Honda and Chrysler

Figure 40-17. A—Always inspect fuel lines, hoses, and fittings for leakage and damage. Pay special attention to plastic lines. B—To disconnect this fuel line fitting, press down on the locking tab while pulling apart. C—To reconnect the fitting, simply push the two halves of the fitting together. D—When installing fuel hoses, make sure they are completely over raised areas on the fuel line. Clamps should be on the pressure side of flanges.

- Form double-lap flares on the ends of the fuel line. A single-lap flare is not approved for fuel lines.
- Reinstall fuel line hold-down clamps and brackets. If not properly supported, the fuel line can vibrate and fail.
- Route all fuel lines and hoses away from hot or moving parts. Double-check clearance after installation.
- Route plastic fuel lines in their original locations. They are more prone to damage from engine heat and abrasion than metal lines.
- A plastic line will kink if bent too sharply. This will restrict fuel flow and may cause the line to fail in service.
- Use a factory-recommended tool to release snap-type fittings used to secure plastic fuel lines.
- If a plastic line or fitting is damaged, replace it with a new one. Do not attempt repairs, such as inline splices.
- Do not use non-OEM plastic tubing to repair fuel systems. The line pressure rating and the composition of the plastic may be different. The incorrect plastic line can rupture.
- Plastic lines tend to stiffen in service. Avoid bending or rerouting used plastic lines.
- Always cover plastic fuel lines with a wet towel when welding, torch cutting, or grinding near them. A hot piece of metal can melt a plastic line.
- Never allow battery acid to contact a metal or plastic fuel line. Lines can be weakened or eaten away by acid.
- Use only approved synthetic rubber hoses in a fuel system. If vacuum-type rubber hose is accidentally used, the fuel can chemically attack and rapidly ruin the hose. A dangerous leak could result.

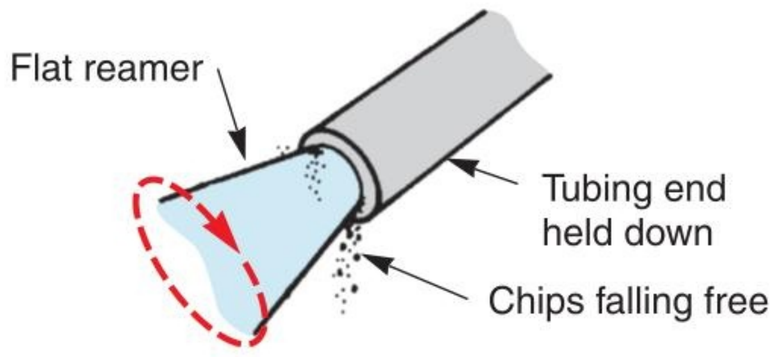
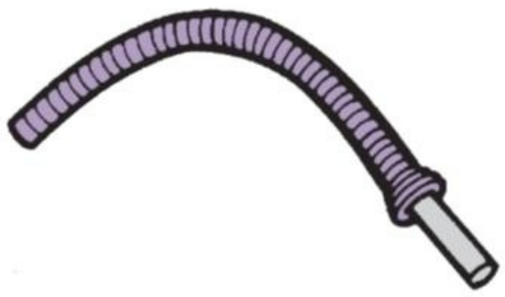
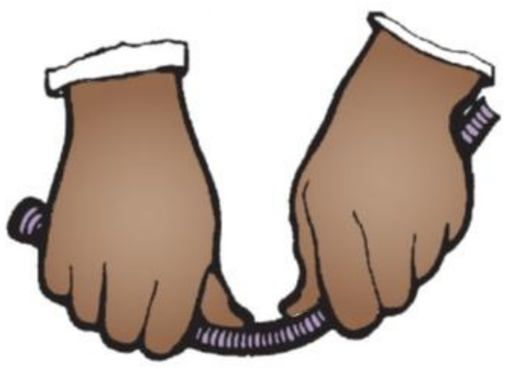
Step 1. Cut tubing with tube cutter.



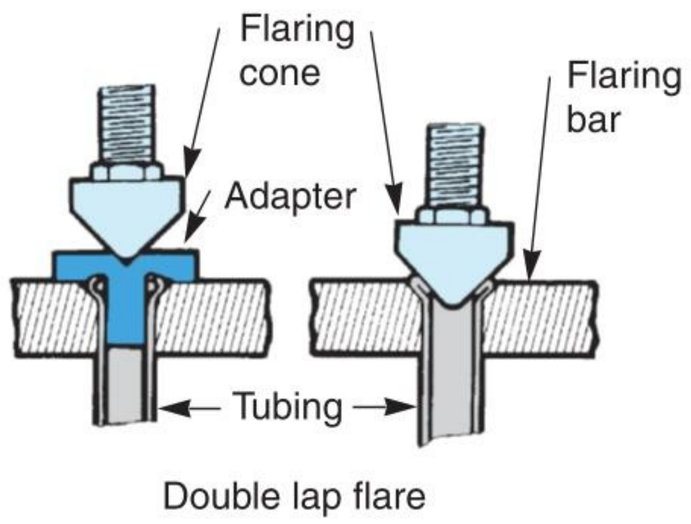
Step 2. Remove burrs.



Step 3. Slip bender over tubing.

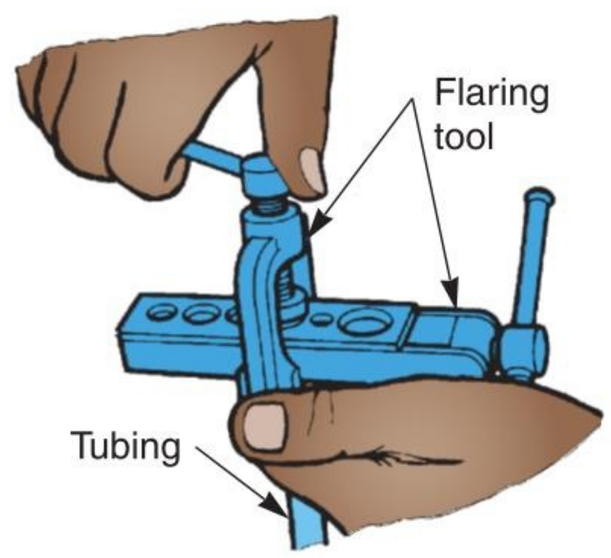


Step 4. Bend tubing to shape of old fuel line.



Double lap flare

Step 5. Use a flaring tool adapter to fold the tube end inward.



Step 6. Tighten flaring tool into tubing.

Florida Dept. of Voc. Ed. and Chrysler

Figure 40-18. Fuel lines need double-lap flares. Study the basic steps for making a new fuel line. This procedure also applies to other lines (brake lines, steel vacuum lines, etc.).

- Make sure a fuel hose fully covers its fitting or line before installing the clamps. Pressure in the fuel system could force the hose off the fitting if it is not installed properly.
- When servicing press-fit fuel line fittings, you may need to replace the O-ring seal to prevent fuel leakage. Make sure you purchase the correct seal.
- Double-check all fittings for leaks. Start the engine and inspect the connections closely.

Warning

Direct fuel injection systems produce very high fuel pressure, above 2000 psi for late-model vehicles. Many systems maintain this pressure even after the engine is shut off. Follow recommended procedures for releasing pressure before disconnecting a fuel line or fitting. This will prevent fuel from spraying from the line or fitting and possibly causing injury or a fire!

Fuel Filter Service

Fuel filter service involves periodic replacement or cleaning of system filters. It may also include locating clogged fuel filters that are upsetting fuel system operation.

A clogged fuel filter can restrict the flow of fuel to the pressure regulator, gasoline injectors, diesel injection pump, or carburetor. Engine performance problems will usually show up at higher speeds.

A partially clogged fuel filter may cause the engine to temporarily lose power or stall when a specific engine speed is reached. This is due to the flow restriction caused by a partially clogged filter. A partially clogged filter may pass enough fuel at low engine speeds. However, when engine speed and fuel requirements increase, the engine may "starve" for fuel.

On modern vehicles, a clogged in-tank strainer is a common and difficult-to-diagnose problem. When clogged, the in-tank filter can collapse and stop all fuel flow. Then, after the engine stalls, the strainer can open again, leaving no trace of a restriction.

Some fuel filters have a check valve that opens when the filter becomes clogged. This allows unfiltered fuel, which may contain contaminants, to flow into

Copyright Goodheart-Willcox Co., Inc.

the system. If a filter is clogged and contaminants are found in the fuel system, the tank, pump, and lines should be flushed with clean fuel.

Fuel Pump Service

Fuel pump problems include low fuel pressure, inadequate fuel flow, abnormal pump noise, or fuel leakage from the pump.

Low fuel pump pressure can be caused by worn pump bearings, high resistance in electric pump circuit, leaking check valves, or physical wear of moving parts. Low fuel pump pressure can make the engine starve for fuel at high engine speeds.

High fuel pump pressure is commonly caused by an inoperative pressure relief valve. If the pressure relief valve fails to open, both pressure and volume can be above normal. A faulty fuel pressure regulator can also cause high fuel pressure. This can produce a rich fuel mixture or even flood the engine, and will trip several trouble codes. On vehicles with fuel pressure sensors, a signal from the fuel pressure sensor may cause the ECM to shut down the engine.

Mechanical fuel pump noise (clacking sound from inside pump) is commonly caused by a weak or broken return spring or other part failure in the pump. Mechanical fuel pump noise can be easily confused with valve or tappet clatter. They sound very similar. To verify mechanical fuel pump noise, place a stethoscope on the pump body. The point of the loudest noise is the source of the problem.

Most electric fuel pumps make some noise (buzz or whirl sound) when running. Only when the pump noise is abnormally loud should an electric fuel pump be considered faulty. A clogged tank strainer can also cause excessive pump noise. Pump speed can increase because fuel is not entering the pump properly.

Fuel pump leaks are caused by physical damage to the pump body or deterioration of the gaskets. Inline electric pump leaks are usually from the inlet and outlet hoses.

Some mechanical fuel pumps have a small vent hole in the pump body. When the seal is ruptured, fuel will leak out of this vent hole.

It is possible for mechanical fuel pump with an internal leak to contaminate the engine oil with gasoline. Fuel can leak through the pump, into the cylinder head, and down into the oil pan. When a gasoline smell is noticed in the oil, replace the high-pressure pump. Then change the engine's motor oil and oil filter.

Fuel Pump Tests

Fuel pump testing commonly involves measuring fuel pump pressure and volume. Exact procedures vary, depending on fuel system type. Refer to a manual for exact testing methods. Sometimes, fuel pump vacuum is measured as another means of finding air leaks in fuel supply lines.

Always remember there are several other problems that can produce symptoms like those caused by a faulty fuel pump. Before testing a fuel pump, use a scan tool to check for:

- Restricted fuel filters (low fuel pressure live reading).
- Smashed or kinked fuel lines or hoses (low fuel pressure or lean codes).
- Air leak into vacuum side of pump or line (low fuel pressure code).
- Injection system troubles (injector codes, oxygen sensor codes, or engine misfire codes).
- Ignition system problems (engine misfire or other ignition related codes).
- Low engine compression (misfire code).

Tech Tip

Use a stethoscope to listen and learn the sound of normally operating high-pressure mechanical pumps. They will make a distinctive light churning sound as the pump rod rides up and down on its cam lobe and fuel moves through the system.

A bad mechanical fuel pump will usually be worn and make a louder, metal-on-metal tapping sound. A failed fuel pump may have a broken return spring, a worn or damaged pump plunger, leaking check valves, or a bad pressure regulating valve.
